Plantations are expanding globally and dominate landscapes in many parts of the world. Older plantations can provide habitat for some native trees and associated biota, and the amount of native trees may be a simple indicator of conservation value of plantations. We modeled basal area (BA) of native broad-leaved trees in Japan's conifer plantations. We quantified relationships between rates of increase in BA of broad-leaved trees and plantation tree species, density of planted trees, climatic, topographic and landscape covariates using the extensive plot data from the National Forest Inventory. Identity of plantation species had a strong effect on the BA of native trees. Japanese cedar *Cryptomeria japonica* and hinoki cypress *Chamaecyparis obtuse*, which are two primary plantation species in Japan (both from the cypress family), had low rates of increase in BA of broad-leaved trees with increasing stand age. In plantations of other species (pine, larch, fir and spruce from the pine family), broad-leaved trees started to increase in BA at 20 years old. Planted tree density also had important, but nonlinear effects on the BA of broad-leaved trees in plantations. Stands with fewer planted trees had higher rates of increase in the BA of broad-leaved trees. Management practices such as selection of plantation tree species, intensive thinning and long rotation time would greatly contribute to the conservation value of plantations. Native trees can also regenerate in plantations depending on environments, and their retention during silvicultural practices can have a positive benefit for conservation.

Retention forestry to balance biodiversity and timber production in planted forests

Kenichi Ozaki¹, Yuichi Yamaura¹, Nobuhiro Akashi², Akira Unno³, Toshiyuki Tsushima³, Katsuhiko Sayama⁴, Shigeho Sato⁵, Satoshi Yamanaka⁴
¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Hokkaido Research Organization, Forestry Research Institute, Hokkaido, Japan;
³Hokkaido Research Organization, Forestry Research Institute, Bibai, Japan; ⁴Forestry and Forest Products Research Institute, Sapporo, Japan; ⁵Forestry and Forest Products Research Institute, Kouchi, Japan
 (ozaki@affrc.go.jp; yamaura@ffpri.affrc.go.jp; akashi-nobuhiro@hro.or.jp; unno-akira@hro.or.jp; tsushima-toshiyuki@hro.or.jp; sayama@ffpri.affrc.go.jp; shigeho@affrc.go.jp; yamanakas@affrc.go.jp)

Ongoing global expansion of planted forests increases the need to develop silvicultural practices that conserve biodiversity in planted forests. Retention forestry, the practice of intentionally leaving important forest structure and organisms within logged areas, is increasingly implemented globally as an alternative to clearcut harvesting. However, there is little empirical information available for applying retention forestry in planted forests. We initiated a large-scale experiment (REFRESH) in 2013 in native fir plantations in Hokkaido, northern Japan to establish a forest management system that balances the ecological and economic values of planted forests. The REFRESH study involves eight treatments including aggregated and dispersed retention. In dispersed retention, naturally regenerated broad-leaved trees are retained in three levels to restore structures and elements of original natural forests in the region. We conducted field surveys to test the initial response of biodiversity (birds, plants and insects) and forestry efficiency. For birds, decline in the abundance of forest species were smaller with higher degree of tree retention. For understory plants, species composition changed largely due to heavy soil disturbance caused by harvest practices and preparation before tree planting, although forest aggregates serve as refugia for forest species. For insects, abundance of saproxylic beetles such as cerambycids increased after harvest but did not respond to retention level. For forestry efficiency, increase in the cost of harvesting operations was only 5% in the highest retention level. Overall, retention forestry is a promising method to balance timber production and biodiversity conservation in planted forests.

Retention harvesting mitigates harvesting impact on ground beetles in planted forests in Hokkaido, Northern Japan

Satoshi Yamanaka¹, Yuichi Yamaura², Katsuhiko Sayama¹, Shigeho Sato³, Kenichi Ozaki²
¹Forestry and Forest Products Research Institute (FFPRI) Hokkaido, Sapporo, Japan; ²Forestry and Forest Products Research Institute, Tsukuba, Japan;
³Forestry and Forest Products Research Institute Shikoku, Kochi, Japan (yamanakas@ffpri.affrc.go.jp; yamaura@ffpri.affrc.go.jp; sayama@ffpri.affrc.go.jp; shigeho@ffpri.affrc.go.jp; ozaki@affrc.go.jp)

Retention harvesting is a silvicultural method in which important forest structures and organisms are retained at the time of harvesting. Although retention harvesting can potentially contribute to balance biodiversity conservation and timber production in managed forests, its effects on biodiversity and ecosystem services have been investigated in limited regions and forest types. We launched a large-scale retention forestry experiment in fir-plantation forests in Hokkaido, Northern Japan. Our experiment has five treatments (clear-cutting, three levels of dispersed retention, and aggregated retention with a 0.36 ha intact forest patch) and two controls (unharvested natural forest and unharvested plantation). We compared ground beetle assemblages before and after harvesting and found that the abundance of most forest species decreased while non-forest species increased after harvesting in the clear-cut sites. We also found that the decrease in the abundance of some forest species was mitigated increasingly with the levels of dispersed retention and that the abundance of most forest species also increased inside the intact forest patches in aggregated retention sites. Our findings indicate that dispersed retention can mitigate the impact of harvesting on some forest species and that aggregated retention can provide a refuge for forest species after harvest.

Trade-offs between ecosystem services in response to tree species diversity and values

Austin Himes^{1,2}, Klaus Puettmann³
¹Oregon State University, Corvallis, USA; ²GreenWood Resources Inc., Portland, Oregon, USA; ³Oregon State University, Corvallis, Oregon, USA
 (austin.himes@oregonstate.edu; klaus.puettmann@oregonstate.edu)

Trade-offs between incommensurate services are a core challenge to the implementation of the ecosystem services (ES) framework. Integral to the challenge of ES trade-offs is how to incorporate multiple types of value in ES assessments. The International Platform of Biodiversity and Ecosystem Services (IPBES) recommends pluralistic valuations of ES that include intrinsic, instrumental, and relational values to better communicate to decision makers the different ways people value ES. In order to understand how value pluralism may effect trade-offs between ES, we conducted a study quantifying ecosystem ES proxies along a tree species diversity gradient in similarly aged intensively managed plantation forests of coastal Pacific Northwest, USA. Our objective was to determine what tree species composition and diversity minimize trade-offs between nine ES. Further, we developed four management frameworks emphasizing different bundles of the nine ES based on how ES clumped within a matrix of value types and level of social organization at which benefits are likely to accrue. We then determined tree species compositions that optimize priority ES under the four frameworks. Some ES responded in sync, but we found trade-offs between provisioning ES with primarily instrumental value and cultural ES with eudemonic relational values. Most individual ES were optimized by monocultures. We also found that high levels of tree species diversity supported the largest plurality of value types and hypothesize that biodiversity may be important not just for increasing ecosystem functions and services, but also increasing the types of values supported by ecosystem services.

Economic value of the mau forest complex, Cherangany Hills, and Mount Elgon Water Towers in Kenya

Joshua Cheboiwo¹, Jonah Kiprop¹, David Langat¹
¹Kenya Forestry Research Institute, Nairobi, Kenya (jkchemangare@yahoo.com; jonahkiprat@gmail.com; dkikipriurlangat@gmail.com)

Water Towers play a critical role in supplying provisioning and regulating ecosystem services. In Kenya there are five main Water Towers (Mt Elgon, Mau, Cherangany Hills, Aberdares and Mt. Kenya). Despite their importance, there has been widespread degradation and deforestation in the Water Towers. This Ecosystem Services Valuation (ESV) study was undertaken by Kenya Forestry Research Institute with funding and technical support from US Forest Service and USAID Kenya. The aim of the study was to highlight the significance of the Kenya Water Towers ecosystems through quantitative assessment. The ESV study focused on three of the five main Water Towers—Mau, Cherangany Hills, and Mt. Elgon—and used internationally recognized methodologies, such as the total economic value approach, and assessments, such as those used in the Economics of Ecosystems and Biodiversity (TEEB) study. From this assessment, the total economic value (TEV) of the three ecosystems is about KES 357 billion (USD 3.5 billion) per year. Disaggregated data show that the Mau, Cherangany, and Mt. Elgon ecosystems contribute an estimated KES 197 billion (USD 1.97 billion), KES 46 billion (USD 461 million) and KES 114 billion (USD 1.15 billion) respectively. Aggregated data show the dominance of regulating services from the three Water Tower ecosystems with 82 percent, 66 percent, and 95 percent (of TEV) respectively in the Mau, Cherangany, and Mt. Elgon ecosystems, underscoring the importance of indirect-use values in forest ecosystems. The provisioning services contributed 16 percent, 30 percent, and 4 percent of TEV for the three water towers

Experiences in monetizing forest ecosystem service values related to biodiversity and climate change

Lauri Valsta¹, Brent Matthies²

¹Department of Forest Sciences, University of Helsinki, Helsinki, Finland; ²Helsinki Institute of Sustainability Science, University of Helsinki, Helsinki, Finland (lauri.valsta@helsinki.fi; brent.matthies@helsinki.fi)

Boreal forests provide significant ecosystem services locally and globally. We analyzed the importance of forest species composition for provisioning, regulating and supporting services. In our case studies, forest mixtures of conifers and broadleaved trees were considered. The ecosystem service approach entails important questions concerning valuation of services, additionality, leakage, and policy options. We used the Finnish policy environment as the basis of analysis. We reviewed case studies that target forest management alternatives both at single stand level and at forest region level. Ecosystem services were assessed in terms of tree species composition, PES scheme, climate change mitigation values and commercial wood values. In general, our results indicate that the sum of ecosystem service values from mixed species forests often exceed those from pure, single stand forests. There are significant trade-offs among ecosystem service values, but a balanced management between providing for multiple objectives seems to provide a highest total value of services.

Economic contributions of non-timber forest products in the United States: frameworks, analytical approaches, and key findings

Non-timber forest products (NTFPs) are one of many economic benefits that forests provide to society, and understanding their value helps us understand the broad range of economic contributions of forests. NTFPs contribute to national, state, local and household economies through monetary and nonmonetary benefits. These resources serve a number of economic and social functions such as recreation, seasonal income, and subsistence. Market channels, level of market formality, and production methods are widely diverse. Impacts may be spread over a wide geographic range or be relatively local. Uses may be largely commercial to mostly personal. A consistent understanding of how NTFPs benefit individuals, communities, and regions across the U.S. has been hampered due to the informal and even secretive nature of many parts of NTFP business and trade, and to the diversity of products and data on the many products and markets in this broad industry. A recent assessment of non-timber forest products in the United States under changing climate examined the economic dynamics relative to these products. The synthesis of knowledge considered micro and macro, as well as market and nonmarket issues, and provides the foundation for this presentation. It explores valuation of broad benefits of NTFPs, as well as financial returns from production of NTFPs. This presentation will discuss applicable economic theories, what we know and don't know about the economics of NTFPs in the U.S., and some priorities for future research and policy.

Economic analysis of Brazil's main non-timber forest products / Análise econômica dos principais produtos florestais não madeireiros do Brasil

Anadálvo Santos¹, Aline Vaes¹, Thiago Paula¹

¹Universidade Federal do Paraná, Curitiba, Brasil (ajsantos.ufpr@gmail.com; alinevaes@gmail.com; uf_floresta@hotmail.com)

Esta pesquisa tem por objetivo analisar a evolução de mercado dos seis principais Produtos Florestais Não Madeireiros - PFNMs do Brasil. A metodologia consistiu em analisar o deslocamento das curvas de oferta e demanda em função das taxas de crescimento dos preços e das quantidades dos PFNMs, disponíveis na Pesquisa Produção da Extração Vegetal e da Silvicultura - PEVS disponibilizada pelo Instituto Brasileiro de Geografia e Estatística - IBGE durante o período de 2006 a 2016. A proxy do preço de cada produto foi obtida por meio da razão entre o valor bruto da produção e a quantidade produzida, seguido de deflacionamento pelo Índice de Preço ao Consumidor Amplo – IPCA. As taxas obtidas permitiram enquadrar os deslocamentos das curvas de oferta e demanda em cenários pré-definidos. Os resultados indicam que: a) os produtos açaí, castanha-do-brasil, erva-mate e piaçava apresentaram variação positiva na quantidade e no preço, que expressa um deslocamento dominante da demanda para direita, indicando que o mercado está em expansão; b) o babaçu apresentou variação negativa na quantidade e no preço, que expressa um deslocamento dominante da demanda para esquerda, por conta da concorrência com outras oleaginosas; c) a carnaúba apresentou variação negativa da quantidade e uma variação positiva no preço, que expressa um deslocamento dominante da oferta para esquerda, reflexo do desmatamento de carnaubais nativos para a implantação de outras atividades produtivas. A partir dos resultados, conclui-se há potencial de ampliação dos mercados, bem como a necessidade de novas estratégias para reverter as tendências negativas observadas.

Management scenarios and ecosystem service provision in Large German Forest landscapes. selected methods, results, and lessons learned

Peter Biber¹, Fabian Schwaiger¹, Werner Poschenrieder¹

¹Technical University of Munich, Chair for Forest Growth and Yield Science, Freising, Germany (peter.biber@lrz.tum.de; fabian.schwaiger@lrz.tum.de; werner.poschenrieder@lrz.tum.de)

The traditional perception that virtually all relevant forest ecosystem services would be provided to a sufficient extent just “in the wake” of sustainable wood production is long outdated by the actual requirements of modern societies. Consistent approaches for quantifying a broad range of ecosystem services as resulting from different forest management options are urgently required by decision makers from the political down to the operational level. Meanwhile, flexible management-oriented models for forest dynamics became standard tools, but the information they provide usually focuses on wood production. Helping to overcome this limitation based on ten case study landscapes in nine European countries is among the goals of the EU-project ALTERFOR (<https://www.alterfor-project.eu/>). The authors, being responsible for the modelling work in Germany, selected two landscapes (~ 100,000 ha) with very different forestal and socio-economic conditions. We implemented a set of contrasting management scenarios in our forest model SILVA, corresponding to the results of stakeholder studies by our partner social scientists. In addition, expected climate and frame socio-economic trends had to be taken into account. For assessing the provision

of ecosystem services like regulatory services, recreation, biodiversity, sustainable wood production, water related services, and carbon sequestration we developed evaluation methods partly based on fuzzy logic and systematic studies with an ecophysiological model. The results of 100-year simulations reveal how strongly the initial forest conditions influence dynamics and management options even on the long run, as well as partly unexpected but plausible tradeoffs between ecosystem services under different management.

Novel business models and mechanisms for the sustainable supply of and payment for forest ecosystem services

Harald Vacik¹, Anne Stenger-Letheux², Thomas Knoke³, Tomas Lämås⁴, Terje Gobakken⁵, Jordi Garcia-Gonzalo⁶, Jose Borges⁷
¹University of Natural Resources and Life Sciences, Vienna, Austria; ²French National Institute for Agricultural Research, Paris, France; ³Technische Universität München, Munich, Germany; ⁴Swedish University of Agricultural Sciences, Umea, Sweden; ⁵Norwegian University of Life Sciences, Oslo, Norway; ⁶Forest Sciences Centre of Catalonia, Solsona, Spain; ⁷School of Agriculture, Instituto Superior de Agronomia, Lisbon, Portugal
 (harald.vacik@boku.ac.at; anne.stenger-letheux@inra.fr; knoke@tum.de; tomas.lamas@slu.se; terje.gobakken@nmbu.no; j.garcia@ctfc.es; joseborges@isa.ulisboa.pt)

Research has identified Payments for Ecosystem Services (PES) as an important mechanism to close the gap between the demands of the society and the service providers (i.e., forest owners). Two main approaches can be identified: (i) payments to landowners to maintain or enhance services that an ecosystem provide and (ii) payments to mitigate and reduce pressures on ES, or prevent a change of land-use with potential negative impacts on service provisioning. In this contribution we will screen different business models and mechanisms to internalise the socio-economic value of forest ecosystems and combine public policy tools with business models for supporting the implementation of payments for forest ecosystem services (FES). Three types of business models will be considered a) private households or businesses companies directly pay providers for the provision of FES, b) Business companies pay providers for the FES and pass the costs to their clients, and c) government pays providers for the FES and pass the costs to consumers via taxes or fees. In implementing these business models, alternative mechanisms for the payments (e.g. voluntary payments, natural capital markets) will be explored. The demands for the provision of FES resulting from existing policies will be identified and the governance settings of successful business models will be discussed. This will help to facilitate the understanding of the importance of a target oriented sustainable management of forests.

D4p: FOREST ASSESSMENT AND ECOSYSTEM SERVICES

Local people's perceptions of forest and trees ecosystem services: case of managed Kalounaye classified forest

Antoine Sambou¹
¹Assane Seck University of Ziguinchor, Ziguinchor, Senegal (tonysambouegos@yahoo.fr)

Analysis of the relationships between communities at the peripheries of protected areas and their natural environments increasingly uses the notion of ecosystem services. Our study aims to identify the ecosystem services of the Kalounaye managed forest and woody species for the surrounding villages in the communes of Oouonck and Coubalan. To do that, surveys based on individual interviews and focus group discussions and field observations were carried out; ¹⁷⁹ individual interviews and ¹² focus group discussions were done. A semi-structured with free-listing approach was used to collect ethno botanical and ecosystem services data. The relative importance and the use of ecosystem services by rural people were assessed. The importance attributed to each category of ecosystem services and species was evaluated using use value (UV), informant consensus factor (ICF), citation frequency (CF) and fidelity level (FL). Local people considered Provisioning services characterized by a use value of 79% as the most important forest and trees function. Cultural services (13%) were the second most important ecosystem services provided by forest and trees followed by regulating/supporting services (8%). Among the provisioning ecosystem services, food, medicinal products, firewood and fodder were the most cited and used. A total of 27 species listed by the populations participated in the provision of three types of ecosystem services (provisioning, regulating/supporting and cultural services). However, the informant consensus factor for ecosystem services was greater than 80%. The Kalounaye managed forest is rich in very important species that provided provisioning, regulating/supporting and cultural services for the surrounding populations.

Improved model for semideciduous seasonal forest production of leaves and deciduousness

Thomaz Costa¹
¹Embrapa Milho e Sorgo, Sete Lagoas, Brasil (thomaz.costa@embrapa.br)

The climate, mainly the water availability and temperature, drive the renewal of biomass in the seasonal forest ecosystem, and the greenness and leaf area of its canopy are responsive by climate variations. This study verified models to explain the phenomenon of leaf production and deciduousness, with LAI (Leaf Area Index), NDVI (Normalized Difference Vegetation Index) and climate variables, on the period 2011-2016. The data were obtained in satellite images and in plots installed at forest monitoring sites, visited monthly. The analysis incorporated the water balance. Three equations were compared, two already published and the equation that was adjusted in the last work. The model was improved and validated with new variables and data. It is possible to estimate the fall and renewal of leaves biomass in semideciduous forests with reasonable precision.

Decline of giant trees in Brazil, the state of the art in Santa Catarina and the future

Marcelo Scipioni¹, Rafael de Paiva Salomão², Alexander Christian Vibrans³
¹Universidade Federal de Santa Catarina, Curitiba, Brasil; ²Museu Paraense Emilio Goeldi, Belém, Brasil; ³Fundação Universidade Regional de Blumenau, Blumenau, Brasil (marcelo.scipioni@ufsc.br; rpsalomaol7@gmail.com; acvibrans@gmail.com)

The loss of large trees is a global problem due to the indiscriminate cutting of timber and the opening of new areas for various human uses. Brazil presents many tree species and extensive forest areas covering different biomes. The species nut brazil and kapok are the giant trees of the Amazon. The jequitiba tree and the brazilian pine are among the largest Brazilian trees in the Atlantic Forest. The decline scenario of the population of large trees can be compared with data from the National Forest Inventory (NFI) in comparison to specific surveys of each species in the regional and national scenario. Santa Catarina is the first state to finalize its forest inventory. Few large trees were sampled in the NFI by systematic sampling. Brazil has trees with diameters greater than 3 m and historical records of 5 m. Recognition of maximum tree growth is important for the ecological management and tourism potential of giant trees. New researches and public policies should be developed for the cataloging and management of these resources in order to avoid permanent loss.

Seasonal changes in flora diversity in native açai palm groves in the Amazon estuary / Modificações temporal na diversidade florística em açais nativos do estuário amazônico

Danielle Rodrigues¹, Silas Mochiutti², José Queiroz³

¹Universidade Federal do Amapá, Macapá, Brasil; ²Embrapa Amapá, Macapá, Brasil; ³Embrapa Amazônia Oriental, Belém, Brasil (dani_enflor23@yahoo.com.br; silas.mochiutti@embrapa.br; jose.queiroz@embrapa.br)

O fruto do açazeiro (*Euterpe oleracea* Mart.) vem ganhando destaque no mercado de polpas e com isso se intensificaram as intervenções nas florestas de várzeas com maciços desta espécie. Neste estudo avaliou-se alterações ocorridas, num intervalo de dezessete anos, na diversidade florística em açais nativos destinados para produção de frutos. O estudo foi desenvolvido em 32 açais localizados na região do braço norte do estuário amazônico. Foram realizados dois inventários florísticos no mesmo açai, um em 2001 e outro em 2018. Em cada inventário foram marcadas parcelas de 20m x 50m, onde foram identificados e mensurados todos os indivíduos com CAP \geq 15cm. Além do açazeiro, as quatro espécies com maior valor de importância foram: *Virola surinamensis*, *Pterocarpus amazonicus*, *Pentachletra maculosa* e *Spondias mombin*. Foram encontrados nas 35 parcelas avaliadas um total de 3311 indivíduos distribuídos em 110 espécies em 2001, sendo 1759 de açazeiros e 1552 de outras espécies. Em 2018, nestes mesmos açais, foram encontrados 2706 indivíduos distribuídos em 70 espécies, sendo 2137 de açazeiros e 569 de outras espécies. O número médio de estípes adultos de açazeiros por parcela foi de 39 em 2001 e de 79 em 2018. A riqueza de espécies diminuiu em 36,4% entre 2001 e 2018 e o índice de Shannon Wiener (H') foi de 2,41 em 2001 e de 1,26 em 2018, observando uma redução significativa ($t=21,4$ $p<0,001$) da diversidade florística nos açais estudados. Os resultados indicam uma homogeneização dos açais nativos devido ao favorecimento do açazeiro, palmeira de maior interesse econômico.

Modeling spatial dynamics to identify areas where land cover can be converted / Modelagem dinâmica espacial para identificação de áreas passíveis de conversão de cobertura da terra

Rodrigo Macedo¹, Claudia Mester², Cláudia Almeida³

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade Federal Rural do Rio De Janeiro, Seropédica, Brasil; ³Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil (rodrigo_c_macedo@yahoo.com.br; claudiamester@usp.br; almeida@dsr.inpe.br)

A detecção de mudanças de cobertura e uso da terra é extremamente relevante na gestão ambiental, nos processos de zoneamento e de avaliação de impactos ambientais. Simular estas mudanças é um desafio devido à incapacidade para prever ações que ainda ocorrerão. Porém, através de modelagem dinâmica espacial (MDE) é possível gerar cenários futuros, com critérios pré-definidos e rigor metodológico. Desta forma, os cenários gerados apoiam processos de tomadas de decisão no cenário político-administrativo. Tal ensaio é dedicado ao entendimento da lógica funcional da MDE e seu potencial em estudos de mudança no território. Há uma grande demanda para a utilização e/ou desenvolvimento de ferramentas computacionais aptas para lidar com a complexidade envolvida na caracterização das funções ecossistêmicas e, conseqüentemente, no monitoramento de seus serviços ambientais. A avaliação ambiental é parte integrante nas análises de mudança de cobertura e uso da terra, pois os serviços ambientais prestados pelos ecossistemas variam de acordo com a própria mudança da paisagem. O presente estudo expressou o quadro geral de um processo de simulação de cenário futuro na plataforma computacional de MDE intitulada Dinâmica EGO, que demonstrou ser apta para a análise das mudanças de cobertura e uso da terra e do monitoramento de seus respectivos serviços e bens ambientais, uma vez que possibilita a explicitação das variáveis espaciais e temporais, além de propiciar o acoplamento de fenômenos biofísicos e socioeconômicos.

Roadways and landscape changes in Canaã dos Carajás (Pará, Brazil): ongoing multi-temporal analysis / Vias de circulação e evolução da paisagem em Canaã dos Carajás (Pará, Brasil): análise multitemporal contínua

Anderson Amaral¹

¹Universidade de São Paulo, São Paulo, Brasil (geoandersonanderson@gmail.com)

Com o objetivo de relacionar os padrões de vias de circulação e a evolução da paisagem em um município de fronteira agropecuária e mineral amazônico, a pronta disponibilidade dos produtos do Projeto Mapbiomas em sua terceira coleção com ampla cobertura temporal (1985-2017) ofertou subsídios diretos e indiretos para alcançar avanço da pesquisa em andamento (nível mestrado). Como produto direto, seus dados qualitativos e relacionais de classes de uso e cobertura da terra de forma gráfica e de fácil visualização dos períodos em sua plataforma *online*, incluindo-se os primordiais dados sobre desmatamento, asseguraram caminho metodológico para seleção temporal de imagens a serem investigadas em outras técnicas empregadas em nossa pesquisa, como a SVD (*Subtract, Vegetation, Dark*) que utiliza análise de imagens Landsat para aplicar o Modelo Linear de Mistura Espectral. A classificação de uso e cobertura da terra do Projeto Mapbiomas auxiliou fornecendo dados primários que utilizamos para produzir uma série de mapas multitemporais com esse tema, auxiliando no entendimento da evolução do território e paisagem da área de estudo ampliando a gama de variáveis a serem relacionadas. Como produto indireto, as vias de circulação que reconstituímos, por classificação não automatizada e com o suporte de outros produtos cartográficos ou dados oficiais do Governo, só foram possíveis devido ao acesso as imagens-mosaico anuais de qualidade, que por serem sem interferência de nuvens ou com melhor pixel disponível para cada ano e seleção de datas escolhidas em nosso estudo, foram fundamentais na reconstituição da evolução histórica da infraestrutura.

The research of state-owned forestry regions contribution of eco-civilization in Heilongjiang province based on gross ecosystem production

Xiangyue Liu¹, Zhifang Wan¹, Yukun Cao¹

¹Northeast Forestry University, Harbin, China (1335759586@qq.com; 1911686519@qq.com; cykkl@163.com)

Forestry ecological civilization is to protect and create a pleasant ecological environment, which is different from the industrial civilization. The value of ecological service and gross domestic product (GDP) belong to two different value systems. Externalities determine ecological civilization cannot measure by the traditional economic system GDP. Thus, the progress of the construction of ecological civilization needs a new scientific accounting system and more ecological indicators to verify the development of ecological civilization. As a result, the world conservation union IUCN proposed the ecosystem GEP (Gross Ecosystem Production) concept, GEP refers to the total ecological system of production and service, which reflects production and service function of ecosystem products and calculates the total of the ecological system's existing natural assets. This paper analyses the related research and summarizes them on ecological civilization with GEP status in China stated-owned forest regions. Also, it concludes the total cost of GEP stated-owned forest regions in Heilongjiang Province, particularly the current problems in ecological civilization development which restrict development of Heilongjiang province. Furthermore, this paper has changed the way of measuring forest industry from GDP to GEP, and calculate Heilongjiang stated-owned forest ecosystem gross production.

Ecosystem services provided by *Bertholletia excelsa* in the Brazilian Amazon

Lucieta Martorano^{1,2}, Marcelino Guedes³, Lúcia Helena de Oliveira Wadt⁴, Fátima Reale⁵, Daiana Tourne⁶, Pedro Martorano⁷, Kátia Silva⁸
¹Embrapa Amazônia Oriental, NAPT-MA, Santarém, Brazil; ²PPG, Rede Bionorte, Santarém, Brazil; ³Embrapa Amapá, Macapá, Brazil; ⁴Embrapa Rondônia, Porto Velho, Brazil; ⁵Secretaria de Educação do Estado do Pará, Oriximiná, Brazil; ⁶Universidade Estadual de Campinas, Pós-doc em Ambiente e Sociedade, Campinas, Brazil; ⁷Universidade Federal de Rural da Amazônia, Belém, Brazil; ⁸Embrapa Amazônia Ocidental, Manaus, Brazil
 (lucieta.martorano@embrapa.br; marcelino.guedes@embrapa.br; lucia.wadt@embrapa.br; fc.reale64@gmail.com; monteiro.dca@gmail.com; pmartorano60@gmail.com; katia.emidio@embrapa.br)

The development of regions such as the Amazon must not consider forest removal as a part of a purely mechanistic strategy because this will compromise the provision of ecosystem services to current and future populations. The objective of this work was to evaluate basic ecosystem services provided by *Bertholletia excelsa* (Brazil nut tree) as a conservation strategy for this important Amazon species. The RADAM Brazil Project conducted an inventory of individual stems and quantified human-modified areas as quantified by TerraClass by 2008. Ecosystem services provided by this species were categorized and analyzed in the MAPCAST project. Approximately 46% of the inventoried stems were located in human-modified areas in 2008. In native *Bertholletia excelsa* stands the ecosystem services provided, among others, were a natural source of selenium, fruit production, a food and economic resource for extractivist populations and wildlife, and attraction of pollinators (bees), which indicates a process of perpetuation of this species. With respect to climate regulation, using concepts from the “flying river” studies as a base, the total daily volume of water vapor pumped to the atmosphere (300 L) by evapotranspiration from a mature stem of *Bertholletia excelsa* contributes to thermal regulation and above- and below-ground carbon stocks, among others. Furthermore, socialization among extractivists during the fruit harvest period is an important cultural service provided by this species. Payment for environmental services (PES) is an important conservationist strategy, and in this sense the Brazil nut tree should a species included in agroforestry systems in the region.

D4q: FOREST BIOMASS ESTIMATION

Ratio and regression estimate applied to biomass modeling

Sylvio Péllico Netto¹, Alexandre Behling¹

¹Universidade Federal do Paraná, Curitiba, Brasil (sylviopelliconetto@gmail.com; alexandre.behling@yahoo.com.br)

Biomass in native and planted forests has been increasingly estimated for several purposes in Brazil. The idea was to make two assumption before defining the model, using regression or ratio to estimate biomass: *i*) the metric units of independent variables in a model should be composed to keep the same metric unit of the dependent variable, *ii*) the additivity of the components. The objective was to introduce a simple and consistent biological model using ratio estimate and compare its performance with regression modeling WNSUR (weighted-nonlinear seemingly unrelated regressions). The biomass estimation model was applied on stands of *Acacia mearnsii* in the state of Rio Grande do Sul, Brazil, using a sample of 670 trees in an age range of 1 to 10.75 years. The modeling of the biomass components was performed using: *i*) ratio estimate applied to the general model: $Y_{ij} = R_j * X_{ij}$, where Y_{ij} = biomass of a given component: stem, crown or total, in kg; R_j = Scalar Coefficients Proxy of Density, kg.m⁻³; X_{ij} = cylinder volume in m³, which is based in quadratic diameter of the stem, in m; *ii*) Spurr and Shumacher-Hall' models fitted by WNSUR. The results obtained by ratio estimates and WNSUR were similar. The fitted model by ratio estimate, for total biomass or its components, proved to be of great interest for biomass estimation and consistent when compared to the results obtained by WNSUR estimates (traditional method). The proposed model, using ratio estimates, is appropriate and promising for modeling of tree biomass.

Estimated biomass in the accumulated leaf litter in the Cerrado region of Niquelândia, Goiás, Brazil / Estimativa da biomassa de serrapilheira no Cerrado em Niquelândia, Goiás

Amanda Portela Pereira¹, Camilla Nascimento Brito¹, Rafael Tassinari Resende¹, Fábio Venturoli¹

¹Universidade Federal de Goiás, Goiânia, Brasil (portelaamanda0@gmail.com; canascimento@gmail.com; rafael.tassinari@gmail.com; fabioventuroli@gmail.com)

Este trabalho objetivou aplicar equações alométricas para estimar a biomassa seca (serrapilheira) em quatro fitofisionomias no Bioma Cerrado. A data dos ajustes vem da região de Niquelândia, em Goiás, em uma Reserva Particular para o Desenvolvimento Sustentável no Legado Verde do Cerrado. O modelo utilizado foi a regressão simples, para estimar a biomassa da serrapilheira seca (variável independente) em função da profundidade da serrapilheira (variável dependente). A biomassa estimada (kg.ha⁻¹) no Cerrado típico, Cerradão, Mata Seca e Mata Ciliar foram, respectivamente, 403,2; 1,329,6; 1,441,4; 1,761,4, respectivamente. Foram utilizadas duas estimativas para estimar a biomassa, sendo a primeira todas as subparcelas das 20 parcelas e a segunda considerando apenas a parcela central das 20 parcelas, para cada fitofisionomia. Os coeficientes de determinação das equações considerando todas as subparcelas foram insatisfatórios e na subparcela central apenas a fitofisionomia Mata Seca ($R^2 = 0,72$) e Típica Fechada ($R^2 = 0,66$). β_0 e β_1 foram testados entre as fitofisionomias foram estatisticamente significantes para um modelo único ($p < 0,05$). No entanto, para as duas análises, um modelo com diferentes β para cada fitofisionomia é mostrado, e β é comum para todas as subparcelas. O modelo ajustado na subparcela central apresentou $R^2 = 0,82$ e o modelo considerando todas as subparcelas em $R^2 = 0,85$. Embora o coeficiente de determinação tenha sido alto, o CV% (coeficiente de variação) foi considerado alto, sendo 51,3% e 48,2%, respectivamente. O trabalho foi apoiado e apoiado pelo Serviço Florestal Brasileiro, Universidade Federal de Goiás e Legado Verdes do Cerrado.

Biomass from natural regeneration of different plant physiognomies in the Cerrado Biome / Biomassa da regeneração natural de diferentes fitofisionomias no Bioma Cerrado

Camilla Brito¹, Amanda Portela Pereira¹, Fábio Venturoli¹

¹Universidade Federal de Goiás, Goiânia, Brazil (canascimentobrito@gmail.com; portelaamanda0@gmail.com; fabioventuroli@gmail.com)

A regeneração natural representa a atividade de renovação das árvores de uma floresta. Este trabalho teve por objetivo quantificar a biomassa da regeneração natural em diferentes fisionomias vegetais dentro da reserva particular de desenvolvimento sustentável Legado Verdes do Cerrado, localizada no Município de Niquelândia, Goiás. A área experimental consistiu-se de 80 parcelas de 10m x 10m, sendo cada parcela constituída de cinco subparcelas de 1m x 1m. Considerou-se indivíduos regenerantes aqueles que apresentavam altura total menor que 1,5m e diâmetro a altura do peito menor do que 5 cm, que foram abatidos e pesados em campo, e as amostras foram enviadas ao laboratório de Inventário Florestal da UFG para a determinação do peso seco. Quantificou-se 31,61 kg de biomassa úmida que correspondeu a 13,26 kg de biomassa seca em toda a área amostrada. A partir da análise de variância observou-se diferença significativa na quantidade de biomassa presente em cada fisionomia vegetal amostrada, e para a estimativa da biomassa seca foram construídos modelos. A

biomassa seca apresentou relação linear à biomassa úmida e as equações apresentaram bom ajuste com altos valores de coeficiente de determinação, $R^2=0,96$ para Mata Seca, $R^2=0,90$ Cerrado típico, $R^2=0,97$ Cerradão, $R^2=0,96$ Mata Ciliar, e boa distribuição entre os valores observados e ajustados. O trabalho recebeu apoio e suporte do Serviço Florestal Brasileiro, Universidade Federal de Goiás e Legado Verdes do Cerrado.

Compatible taper and stem outside-bark volume equations for five pine species in Mexico

Geronimo Quiñonez Barraza¹ Dehai Zhao² Héctor Manuel De los Santos Posadas³

¹Campo Experimental Valle del Guadiana, Instituto Nacional de Investigaciones Forestales Agrícolas y Pecuarias (INIFAP), Durango, DGO, Mexico;

²Warnell School of Forestry and Natural Resources, University of Georgia, Athens, GA, USA; ³Postgrado en Ciencias Forestales, Colegio de Postgraduados, Campus Montecillo, Texcoco, Estado de Mexico, Mexico (quinonez.geronimo@inifap.gob.mx; dzhao@warnell.uga.edu; hmsantos@colpos.mx)

Taper and volume equations are essential components of forest inventory, growth and yield prediction, and forest management-planning in mixed-species forests. Ten taper and stem outside-bark equations system derived from upper-height-based volume ratio functions were compared with a segmented compatible taper-volume system. All compatible systems were simultaneously fit to taper and stem outside-bark volume data of 46, 51, 69, 26 and 30 trees of Arizona pine, Aztec pine, Durango pine, Mexican white pine, and Smooth-leaved pine, respectively in mixed-species forests in Durango, Mexico. Total stem outside-bark volume and cumulative volume from the butt to successive bolt heights were calculated using the overlapping bolts method. In general, the systems derived from volume ratio equations performed better than the segmented compatible taper-volume system for most species with good of fit statistics such as the average error, relative error, standard error of estimate, relative standard error of estimate, and Akaike's information criterion. The resultant top three systems might be easier to implement than the segmented compatible taper-volume system for predicting upper-stem height, upper-stem diameter, variable-top merchantable volume and total stem outside-bark volume for considered species.

Using regression models and artificial neural networks to estimate the height of *Eschweilera idatimon* (Aubl.) Nied. in the Amazon region / Uso de modelos de regressão e redes neurais artificiais para estimativa da altura de *Eschweilera idatimon*. (Aubl.) Nied. na Amazônia

Fernanda Raquel Lambrecht¹, Harliany de Brito Matias², Carlos Moreira Miquelino Eieto Torres¹, Perseu da Silva Aparicio³, Robson Borges de Lima³, Jadson Coelho de Abreu³

¹Universidade Federal de Viçosa, Viçosa, Brazil; ²DAP Engenharia Florestal Ltda, Jêronimo Monteiro, Brazil; ³Universidade do Estado do Amapá, Macapá, Brazil (fernanda.lambrecht@hotmail.com; harlianymatias@gmail.com; carlos.eieto@ufv.br; perseu_aparicio@ueap.edu.br; rbl_florestal@yahoo.com.br; jadson.abreu@ueap.edu.br)

As relações hipsométrica são amplamente estudadas por meio de modelos de regressão. Recentemente cresce a utilização de Redes Neurais Artificiais (RNAs) como ferramenta de estimativa desta e de outras variáveis usuais no setor florestal. Assim, objetivou-se neste trabalho testar duas propostas para estimativa de altura de *Eschweilera idatimon* (Aubl.) Nied. Os dados de altura e DAP são do módulo II da Floresta Estadual do Amapá (FLOTA/AP), Amapá, Amazônia, Brasil. Foram testados 8 modelos de relação hipsométrica (5 aritméticos, 2 logarítmicos e 1 não linear). A melhor equação foi selecionada com base nos seguintes critérios estatísticos: Coeficiente de determinação ajustado (R^2_{aj}), Erro padrão da estimativa ($Sy_x\%$), Coeficiente de variação e Distribuição dos resíduos. A estimativa de altura também foi realizada por Redes Neurais Artificiais (RNAs). Foram treinadas de forma supervisionada 100 redes do tipo *Multilayer Perceptron*, empregando o algoritmo de aprendizagem *Backpropagation* e utilizando como neurônio de entrada a variável DAP. A escolha do melhor ajuste pelas RNAs consistiu na correlação entre alturas observadas e estimadas, desvio padrão e distribuição residual. Os dados coletados para DAP variaram de 10,06 cm a 90,43 cm; e para a altura foi de 3 m a 26,8 m. O modelo com melhor resultado foi Stoffels, com R^2_{aj} de 57,76%, $Sy_x\%$ de 26,28%. A rede treinada que obteve menor RSME (4,71%) foi a RNA 2 com estrutura 1-2-1. A estimativa de altura pode ser feita pela equação de Stoffels, contudo em termos de validação a estimativa por RNA apresentou melhor precisão.

Leaf area index to estimate interception, litter layer and above ground biomass

Yusuf Serengil¹

¹Istanbul University Cerrahpasa, Istanbul, Turkey (serengil@istanbul.edu.tr)

Leaf Area Index (LAI) is an easy to measure parameter with indirect methods. It may however provide some good estimates related to the stand structure and ecosystem functioning. The LAI of a stand helps to identify forest canopy attributes like crown closure, illumination and stand density. It may also be used to estimate forest floor parameters that are controlled by light penetration to the forest floor. An abundant below canopy shrub or herbaceous vegetation may form and survive if enough amount of light and water passes through the canopy. The deposition and decomposition of litter layer is also affected from light and throughfall (precipitation-interception) that determine temperature and moisture conditions. In this study we present our findings of a 3 year study that has been performed around the deciduous, coniferous and mixed stands of Istanbul. The main objective of the study was to estimate and evaluate the hydrology, carbon, biodiversity and water related ecosystem services. To reach this objective, among several observations, we measured aboveground biomass, litter layer mass, and LAI. While we sampled 48 plots in deciduous, coniferous and mixed forest stands we also established 8 stationary plots to monitor temporal changes in LAI since it is quite variable especially in deciduous stands. Our results suggest that litter layer carbon stocks are positively correlated with LAI which means that as the amount of leaf area increase the carbon stock in litter layer increase. The relationship between LAI and above ground biomass was opposite.

Reduction of sample size of trees to calibrate biomass regression

Maria Lucia¹, David Affleck², Henrique Koehler¹, Sylvio Péllico Netto¹, Alexandre Behling¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²University of Montana, Montana, USA (maluh.siqueira@gmail.com; david.affleck@umontana.edu; koehler@ufpr.br; sylviopeillonetto@gmail.com; alexandre.behling@yahoo.com.br)

The objective was to test if the measurement of 3, 5, 7 and 10 trees is enough to calibrate biomass equations to the stand level, since the coefficients are different between stands. Two samplings were conducted in *Acacia mearnsii* stands in Rio Grande do Sul, Brazil. Variables measured: above ground biomass (BY), diameter (d) and height (h) of 745 trees, collected in stands which ages vary from 1 to 10 years. These steps were performed: *i*) The Schumacher-Hall model ($\ln BY = B_0 + B_1 \ln d + B_2 \ln h$) was fitted by means of mixed effects, the random effects structure was specified by age, at the stand level using the first sampling data. *ii*) For the second sampling data, the model $\ln BY = B_0 + B_1 \ln d + B_2 \ln h + b_0 + b_1 \ln d + b_2 \ln h$ was calibrated for each age. The fixed effects (B_i) were obtained in step *i* and random effects (b_i) were predicted from 3, 5, 7, and 10 randomly selected trees at each age. *iii*) A traditional regression was fitted for each age, using the same traditional model, using the second dataset. The estimates in *ii* and *iii* were compared with each other by means of a Chi-square test. The

differences of the values estimated by the two equations were less than 5% and the Chi-square tests were not significant. The specific equation is more accurate than the calibrated - however, the calibration allowed to reduce sampling to 3 trees. It is concluded that only a small number of trees (as few as 3) are needed to calibrate biomass equations in local conditions.

Biomass of *Hymenaea stigonocarpa*, a large tree species from the Brazilian savanna

Suzana Maris Salis¹, Patrícia Póvoa de Mattos²

¹Embrapa Pantanal, Corumbá, Brazil; ²Embrapa Florestas, Colombo, (suzana.salis@embrapa.br; patricia.mattos@embrapa.br)

Hymenaea stigonocarpa Mart. ex Hayne is a fruit tree frequently present in Brazil's central-western savannas and Pantanal wetland region. Trees may reach 20 m high, presenting architecture and size very different from most Brazilian savanna species, which are smaller and branched. Despite its large size and an important source of food and timber, there is little information available regarding biomass and carbon accumulation. Therefore, the objective was to develop an equation to estimate more accurately the biomass of *H. stigonocarpa* in savanna areas. Eight trees, with the diameter at ground level (DGL) from 8 to 55 cm, were cut and measured the weight in Pantanal. In average, the species invest 58%±12 in trunks, 38% ±11 in branches and 5%±4 in leaves, presenting total tree aerial biomass varying from 5 to 2.758 kg. The best equations (R^2 greater than 0.8) were obtained using DGL instead of DBH (diameter at breast height) for total aerial biomass (Biomass = 0.0111 DGL³.0743; $R^2 = 0.9937$), and for the components individually (trunk, branches, and leaves). Generation of consistent biomass equations should be prioritized for a larger number of savanna species, aiming a better estimation of biomass and carbon stocks for national and global carbon inventories.

D4r: FOREST ASSESSMENT - HEIGHT, VOLUME, BIOMASS AND CARBON ESTIMATION

Carbon storage in soils in forest plantations in the Amazon region / Estocagem de carbono nos solos de plantios florestais na Amazônia

Alexis Bastos^{1,2}, Carlos Sanquetta³, Vanderlei Maniesi², Ana Paula Dalla Corte³, Mateus Inoue Sanquetta³, Ueliton Pinheiro¹, Marcelo Ferronato⁴

¹Centro de Estudos Rioterra, Porto Velho, Brasil; ²Universidade Federal de Rondônia, Porto Velho, Brasil; ³Universidade Federal do Paraná, Curitiba, Brasil; ⁴Ação Ecológica Guaporé, Porto Velho, Brasil (alexis@rioterra.org.br; carlossanquetta@gmail.com; vanmaniesi@hotmail.com; anapauladalla@gmail.com; mateus.sanquetta@gmail.com; ueliton.pinheiro10@gmail.com; marcelo@ecopore.org.br)

Mudanças do uso da terra ocorrerão para ampliar a produção de alimentos necessária à crescente população mundial. Nos países em desenvolvimento situados nos trópicos essas mudanças implicam na emissão de gases de efeito estufa, tendo como principal vetor, a conversão de florestas nativas para áreas agricultáveis. Para Amazônia, área de expansão da fronteira agrícola, se estabelece uma ameaça sobre seus serviços ecossistêmicos, não apenas pelas emissões advindas da supressão vegetal, mas pelas perturbações causadas no solo, compartimento que abriga os maiores estoques de carbono no planeta. Foram realizados estudos em Rondônia, para quantificar carbono nos solos em áreas de restauração florestal (idades entre 5 e 7 anos). O material foi obtido através de amostras indeformadas, retiradas com anéis volumétricos (100 cm³), em 36 pontos, nas profundidades de 0-5, 5-10, 10-20 e 20-40 cm pela obtenção das densidades e teores de carbono por combustão. Os valores das médias dos teores de carbono (%) foram de 1,762; 1,327; 0,923 e 0,697 para as profundidades de 0-5, 5-10, 10-20 e 20-40 cm, respectivamente. A profundidade de 0-5 apresentou 11,791 Mg/ha em média. A faixa entre 5-10, média de 9,940 Mg/ha. As amostras retiradas dos horizontes entre 10-20 e 20-40 cm continham 13,653 e 20,013 Mg/ha, respectivamente. O carbono total estocado entre 0-40 cm variou de 36,932 a 89,647 Mg/ha, sendo a média de 54,897 Mg/ha. Conclui-se que o plantio de florestas ajuda a manter a estabilidade dos estoques de carbono nos solos, sendo importante no enfrentamento às mudanças climáticas.

Impact of rectangular plantation spacing on productivity of *Eucalyptus* clones / Influência da retangularidade do espaçamento de plantio sobre a produtividade de clones de *Eucalyptus*

Marco Aurélio Figura¹, Regiane Abjard Estopa¹, James Stahl¹

¹Klabin SA, Telêmaco Borba - PR, Brasil (mafigura@klabin.com.br; restopa@klabin.com.br; jstahl@klabin.com.br)

A densidade inicial de árvores plantadas por hectare é uma decisão silvicultural que impacta diretamente a produtividade de clones do gênero *Eucalyptus*. Entretanto, para uma mesma densidade inicial, o arranjo das mudas no momento do plantio altera a competição por luz, água e nutrientes, agindo também sobre a produtividade florestal. Este arranjo pode ser quantificado pela relação entre a maior distância de plantio (entre linhas e entre plantas) dividida pela menor, originando um indicador conhecido como retangularidade (R). Um experimento foi conduzido em ensaio fatorial com 4 clones (2 híbridos de *E. grandis* x *E. urophylla* e 2 híbridos de *E. urophylla* x *E. globulus*) e 2 espaçamentos (3,75m x 2,40m – R=1,56 e 6,00m x 1,50m – R=4,00), ambos com 9 m²/árvore (1.111 árvores/ha). O experimento contou com 6 repetições e foi avaliado na idade de 7 anos. A interação entre clone e espaçamento não foi significativa (p=0,6033). A diferença entre clones foi significativa (p<0,001), mostrando a superioridade dos híbridos de *E. grandis* x *E. urophylla* (média de incremento médio anual em volume (IMA) de 58,6 e 56,4 m³/ha/ano) frente aos híbridos de *E. urophylla* x *E. globulus* (média de IMA de 32,9 e 25,1 m³/ha/ano). Os espaçamentos diferiram estatisticamente (p<0,001), com IMA médio para os 4 clones de 45,6 e 40,4 m³/ha/ano, respectivamente para os espaçamentos de 3,75m x 2,40m (R=1,56) e 6,00m x 1,50m (R=4,00), confirmando a importância de um correto arranjo de plantio sobre a produtividade do gênero *Eucalyptus*.

Qualitative variables and the selection of volume equation models in forest inventory

Vinicius Pizzo Ferreira¹, João Luís Ferreira Batista¹

¹University of São Paulo, Piracicaba, Brasil (vinicius.pizzo.ferreira@usp.br; joaoluiz.fbatista@gmail.com)

Individual tree volume equations are essential tools for forest inventories, since wood content of individual trees can not be measured precisely, except by means of destructive methods. In eucalyptus forests, the prediction of tree volumes is seldom done by the application of a single volume equations for the entire forest. Volume equations are usually specific for genetic material (clones), properties and project/age of the forest. In this study, we consider the influence of including the qualitative variables related to the spacial scale (municipalities, properties, projects and stands) in volume equation models and its impact in model selection. A total of 11 linear models were fitted, including both standard volume equation models (DBH and height as predictors) and local volume equation models (only DBH as predictor). Models were fitted by least squares and were compared using the coefficient of determination, residual standard error and several indexes based on model residuals. The qualitative variables were fitted as dummy variables changing only the intercept regression coefficient and changing both the intercept and the slope coefficients of all predictors in the model. The performance of all models was improved by adding the qualitative variables. As

expected, the improvement increased as the qualitative variable increased in spacial resolution from municipalities to properties, to project and to stands, but the difference in performance among the models decreased with spacial resolution. The selection of the appropriate spatial resolution (qualitative variable) was more important to determine volume equation performance than the selection of the actual model.

Machine learning and the fixed and mixed effect models in predicting total tree height / *Aprendizado de máquina e modelo de efeito fixo e misto na predição da altura total de árvores*

Ivaldo da Silva Tavares Júnior¹, Carlos Moreira Miquelino Eieto Torres¹, Jadson Coelho de Abreu², Samuel José Silva Soares da Rocha¹
¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Universidade Estadual do Amapá, Macapá, Brasil (ivaldojr8@hotmail.com; carlos.eieto@ufv.br; jadson.abreu@ueap.edu.br; samueljoserocha@gmail.com)

A altura total das árvores é essencial para entender a dinâmica da floresta e estimar a biomassa e estoque de carbono. Contudo, a mensuração dessa variável em florestas nativas é difícil devido à complexidade da estrutura. Objetivou-se comparar a acurácia do modelo de Gompertz com efeito fixo (GEF), modelo misto de Gompertz com efeitos fixo e aleatório (GEM), máquina de vetor de suporte (MVS) e rede neural artificial (RNA) na predição da altura total (Ht) de árvores na Mata Atlântica. O estudo foi realizado em um fragmento de 17 ha. Dez parcelas com 0,1 ha cada foram instaladas. Os dados: CAP (cm), Ht (m) e nomes científicos das árvores com CAP > 15 cm foram utilizados. A avaliação de todos os modelos foi realizada por meio da validação cruzada com 10 folds, repetida 50 vezes. Para cada repetição, médias da raiz do erro quadrático médio (RMSE) e erro absoluto médio (EAM) foram calculadas. As médias de RMSE e EAM das repetições de todos os modelos foram comparadas pelos testes de Friedman e Nemenyi. A MVS apresentou as menores médias de RMSE (2,79) e EAM (2,02) e o modelo GEF as maiores, RMSE (2,99) e EAM (2,18). No teste de Friedman, as predições de Ht entre os modelos diferiram ($p < 0,05$). No teste de Nemenyi, as distâncias entre os modelos de MVS e RNA para os modelos de GEF e GEM foram maiores que a distância crítica (0,66). Portanto, a MVS e a RNA foram mais eficientes na predição da altura total de árvores.

Multi-3D-window dead tree detection of dead standing *Eucalyptus camaldulensis* from voxelised full-waveform LiDAR data for tackling high differences in native forests

Milto Miltiadou¹, Maria Prodromou¹, Susana Gonzalez Aracil², Diofantos G Hadjimitsis¹
¹Cyprus University of Technology, Limassol, Cyprus; ²Interpine Group Ltd, Rotorua, New Zealand (milto_miltiadou@hotmail.com; ml.prodromou@gmail.com; susana.gonzalez@interpine.nz; d.hadjimitsis@cut.ac.cy)

Detection of dead trees is an important for managing biodiversity in native Australian forests. Most of the previous work on dead standing trees detection performs single tree crown delineation before health assessment. Nevertheless, classifications at tree level, while working with native forest is a challenge for multiple reasons: big spatial resolution, variance density of trees, different tree heights and sizes. Tree crown delineation is usually done by detecting local maxima from the canopy height model (CHM) and then segmenting trees using the watershed algorithm, but Eucalypt trees has multiple trunk splits making tree delineation difficult. Shendryk et al, 2016, published an interesting Eucalyptus delineation algorithm that performs segmentation from bottom to top, but pulse density was 36 points/m² around forested areas (expensive to acquire for big spatial resolution). Miltiadou et al, 2018, attempted detection of dead Eucalypt trees without tree delineation using 3D-windows and showed that it is possible, but the methodology can be improved. The presented work, takes that research a step forward and uses multiple 3D windows characterizing dead trees. A random forest classifier, a weighted-distance KNN algorithm are used to create a 2D probabilistic field for each 3D-window size. Then the results are merged, and the locations of the dead trees are predicted. It is shown that the multi-3D-window approach improved the results of the original research published work in 2018.

Reducing the bias effect in tree height estimation in black wattle stands

Mateus Sanquetta^{1,2}, Henrique Scolforo^{3,2}, Cristian Montes⁴, Luciane Schmidt⁵, Alexandre Behling¹, Carlos Sanquetta¹
¹Universidade Federal do Paraná, Curitiba, Brasil; ²Suzano, Limeira, Brazil; ³North Carolina State University, Raleigh, USA; ⁴University of Georgia, Athens, USA; ⁵Universidade Federal de Lavras, Lavras, Brasil (mateus.sanquetta@gmail.com; hscolforo@suzano.com.br; crmontes@uga.edu; lunaimekeschmidt@gmail.com; alexandre.behling@yahoo.com.br; carlossanquetta@gmail.com)

Censored data implies that a certain inventory variable was somehow not fully measured for all the trees. Assuming truncated values for the taller trees as it is typically observed in forest experiments result in volume under-estimation. Consequently, any inference about the forest pattern may be compromised by using these biased tree height values (truncated values). To overcome this problem, we present a methodology that treats the truncated tree height values differently. Different models were fitted to height-diameter data from black wattle stands. A total of 12 plots were fully inventoried with diameter at 1.30 meters aboveground and total height always being measured. To provide a framework of how dealing with censored data in field experiment analysis, we created a second dataset in which tree heights above 17 m were set to the constant value of 17 m. Hence, it is possible to compare the true regression line to the censored regression. The use of censored regression in the presence of censored data proved to be very powerful, since the tree height values can be substantially improved through estimation instead of being assumed as truncated, which naturally reflects in less biased volume estimation as well.

Influence of sample unit types on quantitative attributes analysis in tropical forests

Renata Aparecida Serio Abranches Junqueira¹, Rafaela Pereira Naves¹, João Luís Ferreira Batista¹
¹Universidade de São Paulo, Piracicaba, Brasil (renatabranches@yahoo.com.br; rafaelapnaves@gmail.com; joaoluiz.fbatista@gmail.com)

Sampling procedures allow a more precisely knowledge of the parameter of interest and can define better the plant communities and its potential for wood production and guidelines for conservation or environmental preservation, whether in native or planted forests. Considering different types of sample units, it's necessary to know whether the choice of a unit can influence on quantitative parameters to be analyzed. The objective of this work was to evaluate the influence of three different types of sample units such as circular, rectangular and Bitterlich points analyzing quantitative attributes such as density, basal area, mean diameter and mean squared diameter. These analyzes were carried out in three tropical phytophysiognomies, dense ombrophylous forest, semidecidual forest and cerrado. In general, the Bitterlich method differed from circular and rectangular units when analyzing structures of size and diversity. Phytophysiognomy also influenced the analyzes due to the structure of differentiated size and aggregate patterns of the species. Therefore, caution is required when choosing a sample unit, because depending on the physiognomy the quantitative attributes can show different behaviors and responses.

Mangrove condition and carbon stocks in African deltas and estuaries

Carl Trettin¹, Temilola Fatoyinbo², Wenwu Tang³, Mwita Mangora⁴, Zhaohua Dai⁵, David Lagomasino⁶, Seung Kuk Lee⁶, Marc Simard⁷, Salomao Bandiera⁸
¹US Forest Service, Cordesville, USA; ²NASA, Greenbelt, USA; ³Univ. North Carolina Charlotte, Charlotte, USA; ⁴Univ. Dar es Salaam, Zanzibar, Tanzania, United Republic of; ⁵Michigan Tech. Univ., Houghtont, USA; ⁶Univ. Maryland, Greenbelt, USA; ⁷NASA/JPL, Pasadena, USA; ⁸Univ. Eduardo Mondlane, Maputo, Mozambique (carl.c.trettin@usda.gov; lola.fatoyinbo@nasa.gov; wtang4@uncc.edu; mmangora@yahoo.com; zdai@fs.fed.us; david.lagomasino@nasa.gov; seungkuk.lee@nasa.gov; marc.simard@jpl.nasa.gov; salomao.bandiera4@gmail.com)

While mangroves have been shown to contain significant carbon (C) pools, there have been few objective inventories which characterize the distribution across large areas. We conducted objective field inventories using remote sensing data and a spatial decision support system to estimate above- and below-ground C stocks of mangroves within the Rufiji and Zambezi River Deltas, and the Gabon estuary. Carbon content in biomass in the deltas ranged from 89.6 to 224.9 Mg C ha⁻¹ in Rufiji and 99.2 to 341.3 Mg ha⁻¹ in Zambezi and 2.9 Mg C ha⁻¹ to 591.7 Mg C ha⁻¹ in the Gabon Estuary. Live tree biomass contained more than 80% of the biomass C pool. Soils were the dominant ecosystem C pool. In the deltas, soils C ranged from 213.7 to 359.5 Mg C ha⁻¹ accounting for 61.5-70.9% of the ecosystem C stock in the Rufiji and 354.7 to 644.9 Mg ha⁻¹ that comprises 47% to 72% of the ecosystem C stock in Zambezi. In the Gabon estuary the range in soil carbon was ranged from 393.7 Mg C ha⁻¹ to 899.5 Mg C ha⁻¹, accounting for 57.8% – 99.6% of the ecosystem carbon stock. Both soil and biomass C pools in the mangroves in Rufiji and Zambezi deltas were lower than in the Gabon estuary. The variation in carbon stocks are due to differences in species composition, disturbance regimes, and inherent site conditions.

D4s: FOREST ASSESSMENT AND PLANT COMMUNITIES

Interconnection among species of dominant tree populations of *Castanopsis* community in Three Gorges Reservoir region, China

Ruimei Cheng¹, Wenfa Xiao²

¹Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing 100091, China; ²Chinese Academy of Forestry, Beijing 100091, China (chengrm9533@sina.com; chengrm9533@sina.com)

Interconnection among the 19 dominant species, 171 species pairs in tree layer of *Castanopsis* community in Three Gorges Reservoir region in China was studied by using variance analysis, together with χ^2 test, percentage co-occurrence (PC) and association coefficient (AC). The results indicated that *Castanopsis carlesii* var. *spinulosa* was the constructive species of *Castanopsis* community in Three Gorges Reservoir region, China. The overall associations between dominant species in the community were not significantly negative, suggesting that the *Castanopsis* community was not mature and in the phase of active succession. The χ^2 test showed that among these 19 dominant species, 12 species pairs exhibited significantly positive association and 7 species pairs showed that significant negative association. However, most of the total 171 species pairs did not show significant interconnection, reflecting that the plant communities tended to distribute independently and still were in the unstable succession.

Assessment of implementation pathways for Sustainable Development Goal 15 based on spatio-temporal information

Sugyeong Park¹, Sea Jin Kim¹, Soo Jeong Lee¹, Mina Hong¹, Woo-Kyun Lee¹

¹Korea University, Seoul, Republic of Korea (ss2432@naver.com; bluegulcy@gmail.com; cuarzolee@gmail.com; alsdk920902@naver.com; leewk@korea.ac.kr)

The United Nations established the 17 Sustainable Development Goals (SDGs) in 2015 and encourages states to achieve global agenda. For life on land, UN set the independent goal for protecting restoring and promoting the sustainable use of terrestrial ecosystems. This study aims to assess the implementation pathways for SDG15 in Republic of Korea (ROK). To figure out the pathways, the study firstly explores the possibility to develop new indicators, while analysing the existing indicators and assessment by United Nations organization. On the basis of the reviewing indicators, the study represents the value of indicators in the district level of ROK. Along with this, the synergy and trade-off can be examined between other goals to identify the multiple role in terrestrial Ecosystem. As a result, existing UN indicators are not enough to represent the circumstance in ROK, while the proxy indicators from national statistics are more likely to represent it. Also Goal 15 has closely link with agriculture, water, consumption and production, providing socio-economic environmental benefits to life. The study found that it is necessary to have integrated polices for achieving the SDG 15 rather than the separate approach of local government. In the future study, it needs to develop the nexus evaluation with synergy and trade-off as well as spatial implementation pathways in order to assess the implementation pathway for SDG15.

Establishment of resident participatory governance type for management of Mongolian Green Belt

Chang-Jun Lee¹, Sebin Kim, Bohwi Lee¹

¹Department of Environment and Forest Resources, Chungnam National University, Daejeon, Republic of Korea (lcj3529@naver.com; sbkim@cnu.ac.kr; bohwi00@gmail.com)

This study aims to develop a model for sustainable use and management of afforested areas through resident participatory governance. Korea Forest Service carried out the afforestation project in Mongolia for 10 years (2007-2016) in order to reduce desertification, reduce yellow sand dust and increase in forest area. Manpower and costs to manage the afforestation area occur annually, but Mongolia's local government is burdened with direct management. In order to overcome these problems, this study conducted literature and case studies. After that, we surveyed the status of afforested areas, available human resources and infrastructure, and interviewed stakeholders to build a resident participatory governance model. The core members for forming regional governance are retired teachers with guidance experience and existing afforestation area managers with management competencies. Other members are made up of residents, external institutions are local government forestry officials, NGO, and environmental agencies. Resident participatory governance can gain new revenue streams by leveraging regional afforested area. Agroforestry is an exemplary way to utilize empty space within the plantation area. In this space, agroforestry can be applied because of the advantages of windproofing of trees, water supply using irrigation pipes, and blocking of animal access through fence installation. Residents can produce crops such as cucumbers, pumpkin, corn, potato, tomato, chili pepper, and zucchini. In addition, the empty spaces can be utilized as silvopasture forms for livestock. In order for this type of governance to spread, not only income but also awareness of agroforestry and education about the community should be done together.

Plant community structure of the floating meadows of a hypereutrophic wetland in the Indo-Burma Biodiversity Hotspot

Syed Ainul Hussain¹, Chongpi Tuboi, Ruchi Badola¹

¹Wildlife Institute of India, Dehradun, India (hussain@wii.gov.in; chongpituboi@gmail.com; ruchi@wii.gov.in)

Floating meadows are widespread globally, but ecological information on their vegetation structure and functions is lacking which hinders their conservation. We examined the vegetation composition of the floating meadows of Loktak Lake located in the Indo-Burma Biodiversity Hotspot. The floating meadows in the park are crucial for the survival of the globally threatened Eld's deer (*Rucervus eldii eldii*) and the hog deer (*Axis porcinus anamiticus*). Vegetation data were collected from 936 plots of size 0.5 m×0.5 m during winter and summer. The vegetation data were analyzed using two-way indicator species analysis (TWINSPAN) with PC-ORD version 4.20. Nine plant communities were observed in summer and eight in winter, with two communities being common to both seasons. The overall Shannon and Simpson diversity indices, species richness and evenness of the communities varied significantly between summer and winter. The evenness (0.713) and diversity (H' , 1.335) indices in summer indicate high species diversity, due to homogenous distribution of the species. The Ivlev Electivity Index (IVI) indicates that plant communities have a specific preference for meadow thickness, *i.e.*, communities that prefer thick meadows avoid thin meadows. Competition among plant communities in terms of moisture and nutrient availability was low due to hypereutrophic condition of the lake and floating nature of meadows. But *Capillipedium* spp., *Phragmites karka*, *Leersia hexandra* and *Zizania latifolia* exhibit monodominance indicated by their frequency and abundance in most of the communities. Protection of areas with thick meadow is crucial for long-term conservation of the Eld's deer and associated wild ungulates.

Brazil's national forest inventory: quality data / Inventário florestal nacional do Brasil: dados com qualidade

David Fagner de Souza e Lira¹, Raquel Leao¹, Doádi Antônio Brena¹, Claudia Maria Mello Rosa¹, Joberto Veloso de Freitas¹

¹Serviço Florestal Brasileiro, Brasília, Brasil (liradfs@gmail.com; raquel.leao@florestal.gov.br; dabrena@gmail.com; claudia.rosa@florestal.gov.br; joberto.freitas@florestal.gov.br)

O Inventário Florestal Nacional do Brasil (IFN-BR) dispõe de um programa de avaliação e controle da qualidade, desenvolvido pelo Serviço Florestal Brasileiro, que serve de referência para avaliação dos trabalhos das equipes de campo. Os principais objetivos do controle de qualidade são: assegurar que os procedimentos metodológicos previstos sejam rigorosamente seguidos em campo, dar transparência ao processo de gestão do Inventário Florestal e promover a melhoria contínua da metodologia. O Controle de Qualidade (CQ) é baseado na checagem de componentes, itens e verificadores relacionados aos produtos entregues, ao sistema de amostragem, informações sobre uso e cobertura da terra, às medições biofísicas, à composição das equipes, ao rendimento dos trabalhos, às condições de acesso, à qualidade dos dados coletados, à logística e aos demais procedimentos previstos em sua metodologia. São analisados 42 verificadores distribuídos em 6 indicadores da qualidade. Até o início de 2019 foram realizados levantamentos de dados do IFN-BR em 24 estados, todos os biomas e 9.931 Unidades Amostrais. O Programa de Avaliação e Controle da Qualidade realizou a análise em todos os estados com levantamento de dados e o resultado conjunto dos Indicadores da Qualidade revelou alto nível de confiabilidade dos dados (87%). O indicador 1 – Recursos humanos e materiais, obteve o maior nível de confiabilidade (94%) e o menor foi o 5 – Características qualitativas (81%). A análise do Programa de Avaliação e Controle da Qualidade é um processo evolutivo e contínuo com intuito de aumentar a precisão e confiabilidade dos dados.

D5a: IMPROVING FOREST MANAGEMENT CERTIFICATION: INTEGRATING ECOSYSTEM SERVICES WITH FOREST ASSESSMENTS

Certifying forest-based ecosystem services: results from the world-first application of the FSC ecosystem service procedure in Italy

Alex Pra^{1,2}, Federico Pinato¹, Lucio Brotto¹, Mauro Masiero², Paola Gatto², Davide Pettenella²

¹ETIFOR, Padova, Italy; ²University of Padova, Padova, Italy (alex.pra@etifor.com; federico.pinato@etifor.com; lucio.brotto@etifor.com; mauro.masiero@unipd.it; paola.gatto@unipd.it; davide.pettenella@unipd.it)

In recent years, several mechanisms have been put in practice to value forest-based ecosystem services in order to maintain or enhance their provision. Mechanisms range from more traditional - e.g. regulation of land use, taxes and subsidies - to more innovative market-based ones such as Payments for Ecosystem Services (PES). More recently, the use of voluntary third-party forest certification schemes based on standards and procedures specifically aimed at considering the provision of ecosystem services has gained interests. Certification schemes have already been established for specific ecosystem services, in particular focusing on carbon, in some cases including biodiversity conservation as a co-benefit. The Forest Stewardship Council® (FSC) is currently the only scheme promoting the certification of multiple ecosystem services by demonstrating the positive impacts of FSC-certified forest management practices on five regulating and cultural services. A dedicated procedure has been developed, that allows the assessment of the impact of forest management on carbon sequestration and storage, biodiversity conservation, watershed services, soil conservation and recreational services, by means of specific methodologies and indicators. We critically analyzed the world-first application of the FSC ecosystem services certification procedure with reference to the forest certification group Waldplus and Associazione Forestale di Pianura (Lowland Forest Association) in northern Italy. The case study includes 1,043 hectares of different forest types, from semi-natural productive forests to conservation forests, traditionally managed to deliver multiple benefits. Our objective is to give insights that could inform and improve future developments in the field of certification, promotion and marketing of ecosystem services.

Open access/source, calibratable tool for planning and assessments makes sustainable forestry more assured and valuable for commodity and non-commodity values

Chadwick D. Oliver¹, Gediz Metin Kocaeli², Kagan Ozkal², Davut Atar², Luke Rogers³, Andrew Cooke³, Jeffrey Connick³, Jason Cross³, Anna Schuerkman¹, Bahtiyar Kurt⁴, Nuri Ozbagdattli⁴

¹Yale University, School of Forestry and Environmental Studies, New Haven, USA; ²General Directorate of Forestry of Turkey, Ankara, Turkey; ³University of Washington, College of the Environment, Washington, USA; ⁴UN Development Programme, Ankara, Turkey (chad.oliver@yale.edu; gmkocaeli@ogm.gov.tr; mustafakaganozkal@ogm.gov.tr; davutatar@ogm.gov.tr; lwrogers@uw.edu; chad.oliver@yale.edu; chad.oliver@yale.edu; chad.oliver@yale.edu; chad.oliver@yale.edu; chad.oliver@yale.edu)

Ensuring forests are sustainably managed presents many opportunities but also different ways of thinking. Certifying sustainability is to ensure that values are neither depleted nor unnecessarily hoarded. Some forest values are sustained by actions that maintain a dynamic forest where different stands provide different

subsets of values at different times, but altogether dynamically providing the values at all times. Other values are sustained by actions that preserve some areas. Sustaining many forest values requires complex analyses to determine, coordinate, and assess the impact of various actions. The analyses require much data, calibration to each forest, and calculations. These can now be done with computers and satellite technologies. A transparent, on-line open-source planning/ coordinating/impact assessment tool will soon be available online cooperatively by the United Nations Development Programme, the General Directorate of Forestry of Turkey, Yale University, and the University of Washington. It is based on the University of Washington LMS (Landscape Management System) and the U.S. Forest Service "Suppose." It allows many values to be simultaneously sustained and can be calibrated throughout the world. Online posting of long-term management plans will enable anyone to assess adherence and impact of a plan from the ground or satellites. The transparency both reduces management costs and increases prices and diversity of values provided. The transparency will allow forest operations/equipment to be efficiently planned for expected terrain and species; and more people can plan and target diverse values by knowing beforehand when and where the operations will/will not be done.

Water conservation of the rivers of the amazon forest fragment based on economic valuation mechanisms

Mônica de Souza Barbosa¹, Rogério Fonseca¹

¹Universidade Federal do Amazonas Manaus, Brasil (barbosamonica11@gmail.com; rogeriofonseca@ufam.edu.br)

Considering the scarcity of information related to studies on the forest fragment of UFAM and on payment for environmental services, research initiatives on economic valuation are essential for the preservation and conservation of the ecosystem. The present study aimed to suggest a methodology for economic valuation of UFAM water resources and identify the demand for payments for environmental services among residents who use the university's water resources. It's difficult to attribute monetary value to forest products and services, so to determine the values of the willingness to pay given to the interviews, four specialists were consulted. A stratified sampling with a 10% safety margin was applied and 440 questionnaires, both physical and online, were applied in Manaus during one week of September 2018 using the contingent valuation method, where a hypothetical scenario was presented in which one institution would be responsible for UFAM's water resources. The results were submitted to logistic regression and a socioeconomic profile of the population was made. The methodology was satisfactory, since it minimized the economic cost of the research and allowed the reach of a larger number of people in a short period of time. Through logistic regression it was noted that younger people are more willing to pay; 55.91% were willing to pay for the conservation of the water resources of UFAM, being one of the most cited limiting factors in relation to those who were not willing was the economic one. Thus, there is a possible market for the university's water resources.

Using the ecosystem services approach to inform sustainable forest management and forest certification in New Zealand

Richard Yao¹, Tim Payn^{1,2}, Sally Strang³, Colin Maunder⁴

¹Scion (New Zealand Forest Research Institute), Rotorua, New Zealand; ²Toi Ohomai Institute of Technology, Rotorua, New Zealand; ³Hancock Forest Management (NZ) Ltd, Tokoroa, New Zealand; ⁴Timberlands Limited, Rotorua, New Zealand (richard.yao@scionresearch.com; tim.payn@scionresearch.com; sstrang@hnrg.com; colin.maunder@itll.co.nz)

The importance of incorporating non-market ecosystem service values of planted forests in decision making gained increasing attention over the last decade. A tool that helped facilitate discussions between researchers, industries and governments on this issue is the ecosystem services (ES) framework. The framework has been widely used to assess and demonstrate forestry's economic, environmental and social values. Key non-market ecosystem services have been incorporated into major certification initiatives. The Forest Stewardship Council has recently considered including water, carbon, biodiversity, soil and recreational services. This study demonstrates how to assess relevant non-market ES values of selected forests to support sustainable management and certification. At least four New Zealand forestry companies have either commissioned or supported the ES assessment of their respective forest estates. The objectives of the ES assessment included renewal of certification and demonstration of the environmental and social values of forests to inform sustainable forest management. These assessment objectives were achieved. Forest managers were also satisfied that the quantified non-market monetary values, using the appropriate protocols, can help inform management decisions. The study also found that the ES values estimated (e.g. carbon sequestration, avoided erosion) can contribute to the further development of forest certification systems to sustain and enhance the provision of non-market ecosystem services in planted forests. Recommendations were provided by forest managers to improve future ES assessment projects such as assessing other relevant ecosystem services (e.g. water regulation, carbon storage) and to identify the appropriate metrics for each non-market ecosystem service.

The effectiveness of standards in driving adoption of sustainability practices: a State of Knowledge evidence review

Gillian Petrokofsky¹, Steve Jennings²

¹University of Oxford, Oxford, United Kingdom; ²Keel LLP, Oxford, United Kingdom (gillian.petrokofsky@zoo.ox.ac.uk; steve.jennings@3keel.com)

Voluntary sustainability standards are an important means of providing assurance that products and materials traded in complex, global supply chains have been produced in an ethical and environmentally benign way. Understanding what these standards deliver on the ground is an important part of the debate about their ongoing relevance. An evidence evaluation was undertaken to understand the effectiveness of sustainability standards and certification tools in driving the adoption of more sustainable practices in certified entities, thereby contributing to the achievement of key sustainability outcomes. The report focuses on the changes of practices by organisations or individuals – such as the use of chemical inputs, retention of wildlife habitat, and providing better conditions for hired workers – as a necessary step towards the final impacts of standards systems. A total of 116 controlled studies (before-and-after, controlled intervention, or a combination) which reported relevant outcomes from entities certified with a sustainability standard, were filtered from an original body of over 13,000 studies from the peer-reviewed and 'grey' literature. We report results of the systematic mapping of the studies in six thematic areas: Conservation and Biodiversity; Input Use, Community Benefits and Development; Occupational Health and Safety; Good Production Practices, and Management Systems. There is a focus on research in developing countries in the tropics and sub-tropics, with comparatively little on developed and temperate countries. Most of the research was on coffee and forestry, and on Rainforest Alliance, Organic, Fairtrade and FSC standards. We demonstrate an interactive visualisation of our review findings.

Bundling ecosystem services to increase forestland value and enhance sustainable forest management in the USA

Robert Deal¹, Vitalie Gulca², Nikola Smith³

¹USDA Forest Service, PNW Research Station, Portland, USA; ²Ethno-Cultural Center-VATRA, Chisinau, Moldova, Republic of; ³USDA Forest Service, Portland, USA (rdeal@fs.fed.us; vitalie.gulca@gmail.com; nmsmith@fs.fed.us)

The ecosystem services concept has emerged as a way of framing and describing the broad suite of benefits that people receive from ecosystems. These services include commonly recognized goods like timber, forest products and fresh water, as well as climate regulation, and cultural assets. There has been interest in

the use of incentives and market-based strategies to increase forestland value and to help accomplish conservation goals. These can be in the form of direct payments to landowners, through trading credits or other market-based approaches. Ecosystem services including carbon credits, water quality and quantity, and conservation values can add substantial economic return from forests. One promising option is to allow landowners to bundle or stack payments for ecosystem services. We use an integrated approach to bundle values of different ecosystem services including carbon, water, and fish and wildlife conservation. We outline some of the policy and regulatory frameworks for some of the emerging markets for ecosystem services in the United States, and discuss the role that different regulatory agencies play for each of these services. We then assess the potential benefits for bundling different ecosystem services including carbon credits, water quality trading, and wetland and species mitigation banking. Our purpose is to establish a framework for assessing the potential value for different ecosystem services, understand the process for combining these services, and develop an integrated approach for bundling these services. This process can be used to restructure public incentive programs so that multiple resource benefits can be captured.

Ecosystem services certification in China

Lu Wenming¹

¹Chinese Academy of Forestry, Beijing, China (luwenmingcafa@126.com)

Independent third-party forest certification emerged in the 1990s as a tool for assessing and communicating the environmental and social performance of forest management operations. Today, forest certification is mainstream, supported worldwide by major producers and buyers, and elements of certification are directly or indirectly required in a number of national forestry or government/public procurement policies. There are 2 international forest certification schemes and dozens of national ones. All these schemes have promoted environmental, social and economic sustainability for forest management, and ecosystem services play a very important role in the whole forest certification process, but all international and national forest certification schemes, except in China, do not have any scope of ecosystem service certification or special and independent ecosystem service certification standard(s) assessing the special requirements of ecosystem service. The paper will discuss the design, development, operation and management of ecosystem service certification in China as 2 kinds of other special scopes of forest certification apart from certification of forest management and chain of custody (COC). China, through the China Forest Certification Scheme (CFCS) which is managed by the China Forest Certification Council (CFCC) has identified 2 scopes of ecosystem service certification covering forest parks and nature reserves, and 2 independent certification standards for assessing them. China also developed audit directives and operational guidelines for certification of forest parks and nature reserves in corresponding certification standards. The paper also analyzes 2 case studies of CFCC certified forest parks and nature reserves with its impact of ecosystem service management.

Development of voluntary forest certification schemes in Russia and their impact on forest management

Andrey Ptichnikov¹

¹Institute of Geography Russian academy of sciences, Moscow, Russian Federation (aptichnikov@igras.ru)

Recently at public hearings in the Russian Parliament (State Duma) of the Russian Federation, at the media the issues of voluntary forest certification were actively discussed. Some politicians would like to see forest certification that is fully consistent with the current state strategies and existing interests in the forest sector. There are fears that international certification organizations may somehow “disconnect” Russia from certification and thereby deprive the forest business of the international market. Some statements were done that “The national certification scheme will be driven by national interest and will defend Russia’s position on global markets”. The article explores all policy and trade implications of the potential national forest certification scheme, which is fully in line with existing national legislation and government interests. The following aspects are analyzed: - Fundamental difference between stakeholder based international forest management standards and expert based national legislation; -The concept of risks from the point of view of international stakeholders and national governments; - Independence and credibility of certification in relation to market demand for certified forest products; -The possibility of acceptance of national forest certification schemes by buyers through intergovernmental agreements; -The possibility of suspension of countries from international forest certification schemes in case national legislation will create a significant barrier for international certification scheme; - Harmonization of certification requirements and regulatory framework of forest management. The study is the first of its kind to describe the limits of national regulations in international forest certification and forest product trade. Supported by Institute of Geography RAS assignment 0148-2019-0006.

Environmental Impact Assessments for rural properties: case studies from producing eucalyptus energy wood in Goiás, Brazil / Avaliação de impacto socioambiental de propriedades rurais: estudos de caso da produção de lenha de eucalipto em Goiás

Claudio Cesar de Almeida Buschinelli¹, Flávio José Simioni², José Mauro Magalhaes Ávila Paz Moreira³

¹Embrapa Meio Ambiente, Jaguariúna, Brasil; ² Universidade do Estado de Santa Catarina, Lages, Brasil; ³Embrapa Florestas, Colombo, Brasil (claudio.buschinelli@embrapa.br; flavio.simioni@udesc.br; jose-mauro.moreira@embrapa.br)

A avaliação de impacto de atividades produtivas rurais é apontada como importante ferramenta de apoio aos produtores para atingir patamares de produtividade com a adequada conservação dos recursos naturais, além de possibilitar ajustes para a obtenção de certificações de produção sustentável. A demanda por biomassa para geração de energia vem aumentando e o cultivo de eucalipto é a opção mais lucrativa para o setor, expandindo-se para novas fronteiras de produção. O trabalho avaliou duas propriedades de referência em 2018 no cultivo de eucalipto para produção de lenha nos Municípios de Rio Verde e Cristalina, em Goiás. Para tanto, foi utilizado o Sistema Ambitec-Agro (Sistema de Avaliação de Impacto Ambiental de Inovações Tecnológicas Agropecuárias), desenvolvido pela Embrapa e que integra 125 indicadores quantitativos de 24 critérios de avaliação de desempenho socioeconômico e ambiental da atividade produtiva, sempre comparando o uso atual da terra frente ao anterior. A atividade contou com apoio financeiro do Sebrae/Goiás. Os resultados apontaram para a adequação dos sistemas de produção adotados, já que as duas propriedades apresentaram índices de impacto final positivos de 3,1 em Rio Verde e 5,8 em Cristalina. O Sistema Ambitec-Agro não visa comparar propriedades rurais, já que cada uma possui um contexto próprio de produção ajustado à sua localização geográfica e histórico do produtor; mas sim, avaliar o sistema de produção adotado no contexto geral da propriedade. Ao apontar impactos positivos e negativos, os resultados auxiliam na gestão ambiental da propriedade com critérios de qualidade e sustentabilidade produtiva.

Workplace health and safety, an approach according to Social Life Cycle Assessment (LCA-S) / Saúde e Segurança do Trabalho, uma abordagem segundo a Avaliação Social do Ciclo de Vida (ACV-S)

Vitor Gomes Bevilacqua Junior¹, Marcelo Langer¹, Sandro Andrioli Bittencourt¹, Dimas Agostinho da Silva¹

¹Universidade Federal do Paraná, Curitiba, Brasil (vitorgbjr_uff@yahoo.com.br; marcelolanger@ufpr.br; sandro.bittencourt@ufpr.br; dimass@ufpr.br)

O setor florestal é enquadrado na alíquota máxima do GIIIL-RAT – Grau de Incidência de Incapacidade Laborativa dos Riscos Ambientais do Trabalho, que acarreta um aumento dos custos previdenciários e tributários das empresas. Também é um dos setores *hot spots* em acidentes e questões relacionadas a Saúde e Segurança do Trabalho (SST). A média anual de acidentes laborais neste setor, entre os anos de 2006 a 2016 foi de 3% do total de ocorrências laborais registradas em todos os setores do Brasil. Neste período, o setor florestal apresentou redução do número de acidentes em 37%, entretanto, essa quantidade representa 22.748 pessoas acidentadas em média por ano. Algumas ferramentas de gestão de desempenho dos programas de SST, como a ACV, têm apoiado nas decisões dos tomadores de decisão para o monitoramento de impactos e resultados gerenciais da Organização. A ACV-S é uma técnica mundial para mensurar impactos sociais incluindo os acidentes do trabalho e identificar os principais fatores contribuintes na melhora dos sistemas de gestão de produtos. O objetivo deste trabalho foi parametrizar os padrões da ACV-S aos princípios das certificações florestais utilizando a ACV e a pesquisa em bases de dados. Os resultados prévios apontaram que os fatores prováveis para a redução de acidentes observados no Brasil foram: avanço da legislação trabalhistas, principalmente a NR31 de segurança e saúde para o setor florestal; aumento em 51% das notificações trabalhistas no período de 2006 a 2015 e o crescimento das certificações voluntárias como FSC em 23,58% de 2012 a 2016.

D5c: PRODUCTIVE CONSERVATION: MORE SUSTAINABLE SYSTEMS

Social and economic impacts of gem harvesting in resinous silviculture

Henri Husson¹, Javier Calvo²

¹Centre régional de la Propriété forestière de Nouvelle-Aquitaine, Bordeaux, France; ²CESFOR, madrid, Spain (h.husson@cnpf.fr; javier.calvo@cesefor.com)

The natural resin harvest is back in the spotlight in European countries. The natural resin extraction represents an asset for the local economy and an enhancement of the ecosystem forest services. Some of the main sectoral European stakeholders have joined their efforts in SustForest Plus, a cooperation project supported by the European Interreg Sudoe Program, aimed to improving resin harvesting techniques, supporting the resin tappers workers activity and reinforcing the status of resinous local forests as natural resin source for the European industry. One of the goals is to make compatible the resin harvesting activity with wood quality production. The impact of this additional harvest is being studied to qualify the mechanical qualities of the wood. The use of the local crude pine oleoresin will make it possible to rediscover very varied and ecological uses of this natural raw material that fits perfectly in the new bioeconomy, compared to synthetic and petrochemical products. The aim of the project is to satisfy the demand for natural resins of the industry in south-west Europe, generating at the same time stable and quality employment in the rural areas of the south-west European region.

An assessment of clonal forest nurseries in Paraguay / Diagnostico de viveros forestales clonales en el Paraguay

Julia Maria Tileria Ferreira¹, Maria Laura Quevedo Fernandez¹, William Tomaz Folmann²

¹Universidad Nacional de Asuncion, Asuncion, Paraguay; ²Investigador, Asuncion, Paraguay (julia.tileria@gmail.com; marialauraquevedo@gmail.com; wfolmann@gmail.com)

En Paraguay se dio un aumento en la superficie plantada principalmente con Eucalipto producido mediante miniestaquia, por lo cual el trabajo busco realizar una caracterización de los viveros forestales clonales en el país, ella fue realizada utilizando un cuestionario para coleccionar datos. En el año 2007 se inició la producción clonal y actualmente existen 12 viveros clonales de comercialización, todos correspondientes al sector privado con origen del capital nacional. La capacidad productiva anual es de 45.180.000 mudas de las cuales se producen aproximadamente actualmente 29.730.000. El 100 % de las empresas venden a particulares y 75 % a empresas privadas. Las empresas consideran categorías de precios diferenciados siendo entre 0,23 a 0,33US\$ minoristas y los mayoristas entre 0,17 a 0,25US\$, el rubro genera mano de obra de 145 personas fijas, principalmente femenino. Con relación a los materiales, se comercializan 32 de los cuales el 60 % proviene de Brasil, siendo más utilizados el VM01, I144, A08 y H13. Se han identificado materiales que se han descartado, en su mayoría por ser susceptibles a *Leptocybe invasa*, entre los materiales que serán introducidos se destaca el *C. torrelidora*. En canaletones, 10 x 10cm es el espaciamiento más utilizado, ahí el fertiriego es realizado por goteo y 100 % utiliza tubetes plásticos. En casa de vegetación la temperatura varía de 30 a 38°C con humedad entre 60 a 80%, considerándose alrededor de 90 días para expedición manteniendo altura promedio de 25cm. El factor más crítico identificado por las empresas fue la competencia desleal.

Integrated forest management: a European approach?

Jakob Derks¹, Agata Konczal¹, Joost de Koning¹

¹European Forest Institute, Bonn, Germany (jakob.derks@efi.int; agata.konczal@efi.int; joost.dekoning@efi.int)

Integrated forest management (IFM) is a topical issue, but the definition varies quite a bit. Even within a continent so small as Europe, different local cultures, climatic and geographic conditions and forestry traditions have led to very different applications of this concept. The project “Integrated Forest Management Learning Architecture” (INFORMAR) of the European Forest Institute (EFI) analyses existing knowledge relating to the implementation of IFM in order to address and fill potential knowledge gaps. Thirty-six selected cases in twelve European countries are explored to find answers to research questions that have been jointly developed together with the project stakeholders (foresters, researchers, policymakers, forest owners, NGOs). The selected case studies will cover different ownerships structures, sizes and geographical regions. Doing this, we hope to understand and map out the current and future ecological, socio-political and economic driving forces of IFM we hope to establish a comprehensive overview of how nature conservation and wood production can be integrated in the same stand under very different conditions. Doing this, we hope to establish a comprehensive overview of how nature conservation and wood production can be integrated in the same stand under very different conditions.

Procitropicos: american network for sustainable systemsJamil Macedo¹¹IICA Brasil / IICA - Instituto Interamericano de Cooperación para Agricultura (jamil.macedo@iica.int)

The first Cooperation Agreement between the agricultural research institutions of the tropical countries and IICA for the execution of the activities of the Cooperative Program for Research, Development and Agricultural Innovation for the South American Tropics (PROCITROPICOS), entered into force on June 20, 1991 and, since then, new agreements were signed. In December 2014, the directors decided to carry out an External Evaluation, which involved diversified and representative interest groups, including members, allies, the public and private sectors, universities, embassies, regional consortiums and international organizations around an agenda structured, which verified the strategic importance of PROCITROPICOS as a geopolitical instrument to share the advances of science, technology and agricultural innovation for the tropics. In summary, the evaluators concluded that the Program has managed to implement a large part of its objectives, with significant results, operational efficiency and good capacity for mobilizing competencies and indicated the corrections of the route for the full exercise of its mission.

Conservation production: network for sustainable management of forest seed and seedlings¹Dan Érico Lobão¹Fundação Pau Brasil, Bahia, Brasil (ericolobao@hotmail.com)

The project proposes to economically make possible the exploitation of forest by the rural property in the Cacao Region of Bahia, through the creation of a network of seeds and forest seedlings, guaranteeing the conservation of associated natural resources the continuity of harmony between production and conservation, that is, man and nature, provided by the traditional system of cocoa cultivation, cacao-cabruca.

Revisiting the changing role of forest beekeeping in Ethiopia: when does honey production assist conservation?Tefera Belay Endalamaw¹, Dietrich Darr²¹Hawassa university, Wondo Genet, Ethiopia; ²Rhine-waal university of applied sciences, Kleve, Germany (teferabelay@gmail.com; dietrich.darr@hochschule-rhein-waal.de)

Beekeeping has been accepted as a tool for improving the livelihoods of forest communities, while simultaneously contributing to forest ecosystem conservation attaching additional economic value to keeping forests intact. However, while this relationship was the case for traditional beekeeping, which largely takes place inside forests, it is less clear how technological advances in beekeeping and its transfer to domesticated environments affect the farmers' incentives to conserve the forests. Based on a case study on 91 beekeepers in southwest Ethiopia where modern beekeeping had been promoted, we find evidence for a gradual detachment of beekeepers from their forests. For example, farmers do no longer need trees to hang their hives. Moreover, forests are no more a non-substitutable source of pollen and hive construction material. Hence, the strategic role of trees and forests for beekeepers is decreasing, reducing the additional incentives for beekeepers to conserve forests. However, we also found that income from modern beekeeping was significantly larger, which may help reduce the excessive extraction of forest products for subsistence purposes. In conclusion, while beekeeping is still an important source of sustainable forest-based income, technological development and domestication in beekeeping fundamentally altered the role of forests in modern apiculture.

Qualitative and quantitative characteristics of mixed scotch pine and norway spruce in the North-West of RussiaDmitriy Danilov^{1,2}, Natalia Beliaeva¹¹St. Petersburg State Forest Engineering University named after S. M. Kirov, St. Petersburg, Russian Federation; ²Leningrad Research Institute for Applied Agricultural Science (Belogorka), Leningrad region, Gatchina district, Russian Federation (stown200@mail.ru; galbel06@mail.ru)

Growth and the formation of pine and spruce in a mixed tree stand due to the composition of the stand, which affects the entire life cycle of its development. In mixed stands of pine and spruce, by age, the pine part of the forest is older than the spruce part of the stand for 15-20 years. Mixed stands of pine and spruce in the boreal zone are notable for their high productivity. In the most productive forest conditions, their stock by the age of 80-100 years exceeds the stock of pure plantations of pine and spruce by 1.5 times. An analysis of the mutual influence between conifers showed that the composition of the plantation has a significant effect on the average diameter and height of the tiers in the mixed coniferous stand of spruce and pine. The quantitative characteristics of mixed stands of pine and spruce are reflected in the quality indicator, which is the density of the wood. In coniferous stands mixed in composition, higher rates of pine wood density are noted compared to pure pine forests. The density of spruce wood in mixed stands increases with its predominance in the composition of plantings to a greater extent than that of pine. In mixed stands of spruce and pine, the dependence of the basic density of wood from the distribution of trees by diameter classes is more pronounced when the share of pine in the composition of tree stands is smaller.

D6a: ETHICS AND VALUES IN RELATION TO FOREST, RECREATION AND WILDLIFE MANAGEMENT**Relational values: the key to pluralistic valuation of ecosystem services.**Austin Himes^{1,2}, Barbara Muraca^{1,3}¹Oregon State University, Corvallis, Oregon, USA; ²GreenWood Resources Inc., Portland, Oregon, USA; ³University of Oregon, Eugene, Oregon, USA (austin.himes@oregonstate.edu; barbara.muraca@oregonstate.edu)

Multiple frameworks have recently been proposed adopting relational values as a new domain of value articulation distinct from the dichotomy of intrinsic and instrumental values that has dominated environmental ethics for decades. In this article, we distinguish between the innate relationality of all evaluative processes and relational values as the content of valuation which is a new and fruitful category for expressing the importance of specific relationships people hold with non-human nature. We examine the concept of relational values used in recent frameworks and propose a simple conceptualization with clear distinctions between relational, instrumental, and intrinsic (inherent moral) values. We argue that as a new category of value articulation, relational values provide conceptual and empirical insights that the intrinsic/instrumental value dichotomy fails to deliver. Finally, we draw on theoretical and empirical research to show why a clear distinction between instrumental and non-instrumental relational values is important for environmental conservation, sustainability, and

social justice. From the perspective of conflict associated with forest management, relational values provide a mode of articulating what diverse stakeholders deem important in their own context specific language. When considered alongside instrumental and inherent moral values, relational values provide more fulsome articulation of the impacts of forest management on services and disservices that diverse people derive from forests.

The stability of public preferences for novel forest management: the case of assisted migration

Findlater Kieran¹, Guillaume Peterson St-Laurent¹, Shannon Hagerman¹, Robert Kozak¹

¹*University of British Columbia, Vancouver, Canada (kmf@mail.ubc.ca; guillaume.peterson@ubc.ca; shannon.hagerman@ubc.ca; rob.kozak@ubc.ca)*

A major policy challenge created by emerging technologies is that public preferences tend to be unstable. Typically, surveys are used to measure such preferences, but survey questions tend to evoke quick decisions, rather than allowing for deeper, deliberative thinking to emerge. Within the realm of forest management, technical solutions to climate change adaptation may be particularly fraught as survey respondents could be unfamiliar with the issues at hand, but nonetheless, must make challenging trade-offs between novel technological risks and uncertain climate change impacts within dynamic and complex socioecological systems. This is further complicated by the fact that public preferences of risk, support, or opposition for novel technologies are constructed and driven by a combination of ethical, values-based and social factors. Here, we use data from a survey of 1926 residents of British Columbia (BC), Canada to evaluate the stability of public preferences around climate change adaptation in commercial forestry, specifically genomics-based assisted migration (AM) of tree seedlings during reforestation following harvest. We show that preferences are highly unstable when people are given new information about AM's potential implementation and impacts. The magnitude of this instability varies with the degree of the proposed intervention (within or outside of species' historic natural range), the type of information being provided (e.g., data on climate change vs. forest resilience), and individuals' demographic and attitudinal characteristics. More broadly, the labile nature of public preferences among diverse publics and stakeholders points to the crucial need to study novel risk contexts using robust, mixed-methods approaches.

Environmental violations observed by the environmental police in the Northern region of Santa Catarina State, Brazil

Jessica Silva Costa¹, Raquel Valério Sousa¹, Veraldo Liesenberg¹

¹*Universidade do Estado de Santa Catarina, Lages, Brasil (jessica.dsilvacosta@gmail.com; raquel.sousa@udesc.br; veraldo.liesenberg@udesc.br)*

The performance of the Environmental Military Police (PMA) in monitoring and applying the environmental legislation includes the prevention, combat and control of practices that cause environmental damage. This study aimed to diagnose the environmental infractions that occurred in the northern region of the state of Santa Catarina from 2014 to 2016. It was possible to show that the PMA's efforts should be directed to fight the environmental violations regarding the damage caused in native vegetation without authorization from the competent environmental authority, in the activity of maintaining birds in captivity and in the functioning of potentially pollutant activities or establishments that do not have a license of the competent environmental agencies, to ensure the protection and preservation of the fauna and flora in the northern region of the State of Santa Catarina (Brazil).

A tale of two squirrels: exploring the conflict arising from efforts to conserve and control

Mike Dunn¹, Mariella Marzano¹, Jack Forster²

¹*Forest Research, Roslin, United Kingdom; ²Forest Research, Farnham, United Kingdom (michael.dunn@forestry.gov.uk; mariella.marzano@forestry.gsi.gov.uk; jack.forster@forestry.gsi.gov.uk)*

Impacts of the non-native, invasive grey squirrel (*Sciurus carolinensis*) on broadleaf woodlands and red squirrel (*Sciurus vulgaris*) populations are well recognised among the UK's foresters and conservationists. In response, wildlife managers, landowners and volunteers dedicate substantial time and resources to controlling the species across its expanding range. However, attempting to eradicate one species in order to conserve another is controversial, particularly when the targeted species has been prevalent in gardens, parks and the countryside for decades, as is the case for the UK's grey squirrels. Drawing on survey responses from the general public and interviews with those participating in red and grey squirrel management, we seek to understand the underlying factors which give rise to the controversy surrounding grey squirrel control. Specifically, we contrast the orthodoxy of the grey squirrel as a pest species with the perceptions of the wider public, many of whom neither recognise nor experience the species' negative impacts. Additionally, we assess the relative acceptability of management methods, and examine how their attributes and application can lead to certain approaches being regarded as more (or less) contentious than others. Finally, we highlight how conflicts around squirrel management manifest and propose a number of actions that can help to reduce tensions among those with starkly different values. We contend that these findings are pertinent to other wildlife management conflicts, particularly when dealing with charismatic species or contested notions of so-called pests.

Moose or spruce: Systems analysis for managing conflicts between wildlife, forestry, and society in Sweden

Oskar Franklin¹, Andrey Krasovskii¹, Dmitry Schepaschenko¹, Sylvain Leduc¹, Anton Platov¹, Florian Kraxner¹

¹*IIASA, Laxenburg, Austria (franklin@iiasa.ac.at; krasov@iiasa.ac.at; schepd@iiasa.ac.at; leduc@iiasa.ac.at; platov@iiasa.ac.at; kraxner@iiasa.ac.at)*

Sweden has the world's highest density of moose. Moose is not only a valuable game species, it also causes forest damages and traffic accidents. To avoid moose browsing, foresters respond by planting spruce to an extent that reshapes the forest landscape with impact on both production and biodiversity. To address this problem and maintain a healthy moose population in balance with the other interests, an adaptive management based on the knowledge and experiences of local hunters and landowners is advocated. However, the different stakeholders do not agree on what is an appropriate moose population, which leads to conflicts that are hard to resolve. A key problem is that it is very difficult to encompass and foresee long term consequences of different options for moose hunting and forest management. This makes it challenging to form coherent strategies that integrate different sectorial interests at a national level. To address this issue we have developed a systems analysis framework for integrated modeling of the moose population, forestry, and their interactions and consequences for biodiversity and traffic accidents. We analyze the short and long term consequences for multiple scenarios of moose hunting and forest management. Based on the results we elucidate and quantify the trade-offs and possible synergies between moose hunting, forest production, biodiversity and the risk of traffic accidents. This analysis will be used to support better informed and more constructive discussions among the stakeholders in the Swedish forest sectors, and to support policies for long term sustainable forest and moose management.

Deer and forest management in Hokkaido, Japan: roles of recreational hunting and culling by forest managers to reduce forest damage

Nobuhiro Akashi¹

¹Hokkaido Research Organization, Forestry Research Institute, Hokkaido, Japan (akashi-nobuhiro@hro.or.jp)

The sika deer population in Hokkaido, Northern Japan, increased during the second half of the 20th century and caused various problems, such as damage to forests and agriculture, degradation of natural vegetation, and collisions with vehicles. Hunting regulations have been changed since the 1990s to increase the number of deer culled by hunters. Since 2004, there has been no limit on the number of female deer a hunter can take each day during hunting season, but the deer population continued to increase until around 2010. In 2013, a new subsidy from the national government to local hunters was introduced, and the deer population began to decrease. I evaluated the current impact of deer on forest regeneration and estimated deer density using a distance sampling method in a forest managed by Hokkaido government in two neighboring municipalities, and also interviewed representatives of local hunting associations in each municipality. The estimated deer density in November was 8 deer/km². This is still too high for hardwood species. One of the two representatives of the local hunting associations stated that hunting is a recreational endeavor for hunters, while the other emphasized that hunters should play a role in controlling local problems. Recently, hunters have been shooting deer around farmland for almost the entire year to get the subsidy, and this has led to a decrease in recreational hunting in forests. Culling by forest managers is necessary to maintain hardwood trees, but it costs more than the income obtained from forest management.

Managing conflict through shared values in the New Forest, England

Helen Dancer¹

¹University of Sussex, Brighton, United Kingdom (h.e.dancer@sussex.ac.uk)

This paper explores local forest values and governance in England's most extensive ancient forest landscape – the New Forest. The New Forest's international and national importance lies in its natural and cultural heritage – a mosaic of habitats, high biodiversity and ancient commoning practices. The legal origins of commoners' rights predate the Forest's establishment as a Royal Forest by William the Conqueror in c.1079. Conflicts between the interests of the Crown and commoners spanned centuries. In recent decades, the importance of conservation and recreation has generated new challenges and tensions between Forest stakeholders and shifted governance priorities and values, most recently with the Forest's designation as a National Park in 2005. The New Forest now has the most complex legal frameworks and governance structures of any forest in the UK. This paper draws upon extensive fieldwork conducted by the author in the New Forest between 2018 and 2019, exploring the legal and cultural dimensions of human-forest relationships in practice. The paper takes as its focus the priorities and approaches of the Forest's key governance bodies - the Court of Verderers, Forestry England, Natural England and the National Park - the values they embody, and their management of conflict and disputes in the Forest. The paper explores the relationships and significance of shared values between the statutory bodies, the local community and wider public, towards ensuring effective forest governance and conflict management.

Value orientations of prospective forest, nature and wildlife management professionals

Christian Gamborg¹, Sofia Stamati¹, Frank Søndergaard Jensen¹

¹University of Copenhagen, Copenhagen, Denmark (chg@ifro.ku.dk; cq859@alumni.ku.dk; fsj@ign.ku.dk)

Values underlie our attitudes, and attitudes in turn might predict our behavior. While values cannot be observed directly, value orientations are more numerous and may be seen as an expression of values. This study examined value orientations among prospective forest, nature and wildlife management professionals in Denmark – that is students at five MSc study programs at the University of Copenhagen enabling them to a professional career. We focused on value orientations towards wildlife and used a US developed survey instrument on Wildlife Value Orientation types ('utilitarian', 'mutualist', 'pluralist', 'distanced') delivered via an Internet-based questionnaire in 2018 ($n = 180$). The majority of prospective management (and policy) professionals were mutualists as general orientation. However, Forest and Nature Management respondents were more utilitarian than other study programs, and females among the five study programs were more mutualist oriented than males. As a whole, prospective professionals were more mutualist oriented than stakeholders such as hunters and landowners (found to be notably utilitarian) and more mutualist oriented compared to members of the general public (found to be especially distanced). Information about forest, nature and wildlife management professionals' value orientations can be used to check on, or anticipate potential differences in value orientation *viz a viz* stakeholders and the public in general. Whether professionals or the public should adjust their values is an open question. Nevertheless, knowledge about value orientations can be helpful in improving communication and limit potential conflicts. Future studies should explore value orientations of accomplished forest, nature and wildlife management professionals.

D6b: FOREST AND ECOSYSTEM SERVICES IN CITIES: ACHIEVEMENTS AND EXPECTATIONS

Providing environmental, economic and health benefits through nature-based solutions across cities: the case of the proGREG project

Giuseppina Spano¹, Vincenzo Giannico¹, Mario Elia¹, Giuseppe Colangelo¹, Raffaele Laforteza^{1,2}, Giovanni Sanesi^{1,3}

¹Department of Agricultural and Environmental Sciences, University of Bari, Bari, Italy; ²Department of Geography, University of Hong Kong, Hong Kong, China; ³SISEF - Società Italiana di Selvicoltura ed Ecologia Forestale, Viterbo, Italy (giuseppina.spano@uniba.it; vincenzo.giannico@uniba.it; mario.elia@uniba.it; giuseppe.colangelo@uniba.it; raffaele.laforteza@uniba.it; giovanni.sanesi@uniba.it)

ProGREG (productive Green Infrastructure for post-industrial urban regeneration) is an EU-funded H2020 project that seeks to implement eight nature-based solutions (NBS) in four "front runner cities" in Europe and China for their replication in five "follower cities" in Europe. The overarching goal is to embed business models stemming from the project outcomes into urban planning through the assessment of social, economic, environmental and health benefits resulting from each NBS at city, district and "Living Lab" level where the NBS will be realized. Examples of NBS to be implemented are: renaturing landfill sites; regenerated soil for urban farming; community-based urban gardening; and accessible river corridors. A preliminary baseline evaluation has been conducted on indicators of socio-cultural inclusiveness, human health and wellbeing, ecological and environmental restoration as well as economic and labor market benefits. At present, the implementation and monitoring of specific NBS are under way. The second phase of proGREG will involve the assessment of short-term NBS benefits; the following results are expected: a) positive impact on physical health and wellbeing, local identity and community cohesion; b)

reduction of inequality, social exclusion and criminality; c) accountability and stewardship of the environment by the local community; and d) eradication of marginalization and poverty for residents and immigrants in deprived urban neighborhoods. The effectiveness of active collaboration among citizens, NGOs, political authorities, research institutions and the private sector to address the social, economic and environmental challenges in today's post-industrial urban society will be investigated.

The hidden benefits of urban trees enjoyed by local communities

Alan Simson¹

¹*Leeds Beckett University, Leeds, United Kingdom (a.simson@leedsbeckett.ac.uk)*

The benefits that trees can bring to urban areas have been known for a long time, but it was only with the advent of the concept of urban forestry in the latter years of the 20th century, and the resulting research into the potential benefits of urban forestry that has subsequently taken place, that the very broad spectrum of these benefits has been established and quantified. Without a doubt, trees and woodlands have the potential to play a significant role in the viability and experiential quality of our urban environments, and thus urban forestry has increasingly gained political traction in many towns and cities around the world, improving the health and well-being of their citizens as a result. It could be argued however that Urban Forestry Strategies have all too often centred upon promoting a fairly narrow spectrum of scientific benefits, which have not always convinced local communities. This presentation will suggest that a broader perspective is required when promoting urban forestry and engaging with local communities, a perspective that takes into consideration the deep psychological and emotional ties that people have with their urban forests. It will cite a case study from the City of Sheffield in the UK, where the City Council started to fell thousands of streets trees, falsely claiming that they were 'dangerous, dying, diseased, dead or damaging', which resulted in a violent community uprising. As a result, the UK Government has recently announced plans to give communities a greater say in protecting their local trees.

Nature-based solutions for restoration of urban ecosystems in Portugal

Thomas Panagopoulos¹, Dulce Antunes¹, Ana Paula Barreira¹, Luis Loures²

¹*University of Algarve, Faro, Portugal; ²IPP, Elvas, Portugal (tpanago@ualg.pt; mantunes@ualg.pt; aprodrigues@ualg.pt; luisloures@gmail.com)*

Unsustainable, non-resilient urbanisation and neglect of urban areas have caused the fragmentation, depletion and destruction of habitats, biodiversity loss and the degradation of urban ecosystems and their services. Restoring urban ecosystems through nature-based solutions (NBS), is necessary to enhance ecosystem resilience and adaptive capacity to cope with the effects of climate change and to enable ecosystems to deliver their services for more liveable, healthier and resilient cities. The main objective of the study is to co-create with stakeholders and informed citizens the development and implementation in demonstration areas as "living laboratories", of innovative, replicable, and locally adapted NBS for inclusive urban regeneration. The study aim to develop smarter, environmentally just, inclusive, resilient and increasingly sustainable societies through nature-based innovation jointly created by and for people. The project's ambition is to reassess the role and responsibility of local government to facilitate co-design and co-creation within an innovative socially engaged, citizen-driven paradigm. A range of local actors were engaged, including local authorities, planners, designers, landscape architects, private business (the tourism sector), the voluntary sector (associations representing deprived communities and particular social groups), to design and take responsibility for sustainable future cities emphasizing NBS. The approach will be demonstrated in Faro and Elvas, Portugal and upscaled to the city Masterplan representing a variety of urban regeneration contexts and issues. Specific objectives were to design NBS for restoration and rehabilitation of urban ecosystems at a derelict industrial site of Faro and to develop a sustainable city Masterplan that systemically embeds and integrates NBS.

Legislation for urban green space management in Democratic People's Republic of Korea

Mi Sun Park¹

¹*Seoul National University, Pyeongchang, Republic of Korea (mpark@snu.ac.kr)*

Democratic People's Republic of Korea (DPRK) faces a problem of deforestation and forest degradation. DPRK has established and implemented greening policies in rural and urban areas. In particular urban greening policies have been emphasized for two decades. Urban greening policies include management of ecosystem services including provisioning, regulating, supporting and cultural services. This study focuses on legislation for urban green space management in DPRK. In this research, the relevant legal texts about urban green space management were collected and analyzed including, the Forest Act, the Act of Urban Green Space, the Act of Urban Planning, the Act of Urban Management. The legislation includes the principles of building and protecting urban green spaces, management of urban greening projects and the plan of urban greening. The contents were analyzed focusing on ecosystem services. The results were compared with Vietnamese legislation for urban green space management including the Urban Planning Law and the Decree of Urban Plant Management. Both DPRK and Vietnam emphasize green space management in urban planning. Their approach reveals integrated approach between forestry and urban sector. In conclusion, the research findings do contribute to a better understanding of legal systems for urban green space management in DPRK. It can be expected that the research findings contribute to modifying legislation for urban green space management towards urban sustainability in DPRK.

Ecosystem services of urban forest: development of a forest education strategy for students of secondary level in Colombia

Diana Patricia Morales Epinosa¹, Liz Villarraga¹

¹*Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (dpmorales@gmail.com; lizv@udistrital.edu.co)*

Educational institutions should find strategies that serve to promote and accomplish the Sustainable Development Goals (SDG); among all of the aspect to consider, citizens of urban areas need to be awarded all of the conflicts that may cause urbanization and all the benefits that urban green areas provided. This is a longitudinal study aims to assess secondary level students' changes in perception about the ecosystems services of urban forest after receiving a 6-month module of forestry classes. The experimental sample population consists of 126 students of grades eighth and ninth of a private secondary school in Bogotá Colombia, and the control group consists of 126 students of same grades and of the same institution. An instrument of 38 statements is applied in three times, before the classes, after the classes, and six months later. The module or intervention is composed of three sections: 1) general concepts about urban forest ecosystem services and their relation to the SDGs, 2) applied projects where students will relate those concepts with their surroundings, 3) visual representation (infographic) of their learning. This is a work in progress, the first application of the instrument is completed and classes will be finished by July 2019. We will use non-parametric statistical test Mann Whitney and Wilcoxon sign rank tests, along with Cronbach alpha. The final goal of this study is twofold, to sensitize young students about the importance of green areas in the cities, and to develop a forest education program that can be applied in other schools.

Governing for urban forest resilience: the Canadian experience

Cecil Konijnendijk¹, Lorien Nesbitt, Zach Wirtz¹

¹University of British Columbia, Vancouver, Canada (cecil.konijnendijk@ubc.ca; lorien.nesbitt@ubc.ca; wirtzz@mail.ubc.ca)

Knowledge about urban forest governance is still limited in many countries, especially in the case of medium-sized, lower-profile cities. This research analyses urban forest governance in selected medium-sized cities in Canada in order to identify success factors and promising governance arrangements that foster resilience in the context of climate change and urbanization. Policy analysis, semi-structured interviews with key governance actors, and focus group discussions were carried out in four case study cities. Surrey (BC) and Oakville (ON) are both recognised for their successful urban forestry programs. Both cities are situated in a larger metropolitan area with dominant 'first cities' (Vancouver and Toronto, respectively), which leads to both challenges and opportunities. Fort McMurray (AB) and Prince George (BC) are 'stand alone' cities in rural areas that have both faced recent major urban forest loss due to devastating wildfire and mountain pine beetle infestation, respectively. Initial findings show that urban forest governance in the cities has changed over time in terms of governance arrangements, leading discourses, actors and alliances involved, the 'rules of the game' set for governance, and the power and resources mobilised by actors. Where Surrey and Oakville developed comprehensive governance in the face of rapid urban development, governance in Fort McMurray and Prince George was challenged due to climate change calamities and related changed discourses, but also saw new opportunities due to involvement of a wider range of actors and interests. Study findings can be used to inform urban forest governance and resilience planning in Canada and internationally.

The national strategy for urban green space: Italy as case study

Marco Marchetti¹, Lorenzo Sallustio², Giovanni Santopoli¹

¹Università degli Studi del Molise, Campobasso, Italy; ²Università degli Studi del Molise, Pesche, Italy (marchettimarco@unimol.it; lorenzo.sallustio@unimol.it; giovanni.santopoli@unimol.it)

Recently the Italian Ministry for the Environment, Land and Sea Protection, adopted the National Strategy for Urban Green Space. The Strategy assigns to urban forests a central role as providers of goods and ecosystem services that are essential for human welfare and the climate change mitigation. The strategy aims to promote the conservation of biodiversity and the provision of ecosystem services, to mitigate climate change and to improve the quality of life through communication programmes, planning activities and monitoring. In this study we present a clustering approach that classify the municipalities, according to territorial homogeneity and population density, in order to support decision makers in planning activities for reaching the aims of strategy. Six clusters were defined considering urban forms (monocentric versus sprawl), primary infrastructures, population density and the ecoregions. Results show that more than 50% of municipalities present a good condition and only actions aimed to improve the ecological connectivity between urban forests and other green spaces are necessary. Significant interventions, such as the implementation of green belt, are necessary in 43% of municipalities in order to improve not only the ecological connectivity but also to promote the provision of ecosystem services. Finally, for the cities with high population density (3% of total), it is strongly necessary to introduce green belt or other green spaces in order to accomplish the strategy aims. In this case it is strongly important to consider also the surrounding little municipalities which can play an important role to support the human wellbeing.

The ages of ecosystem services: an historical dialogue between cities and forests

Fabio Salbitano¹

¹University of Florence, Firenze, Italy (fabio.salbitano@unifi.it)

Ecosystem services refer to a relatively new concept, popularized after 2000 and very often associated to urban societies. No doubts that trees and forests are a key provider of ecosystem services in Anthropocene. But can we associate the concept of ecosystem services along the history of human societies particularly focusing on the urban adventure? Which kind of relationships cities in different cultural/environmental contexts had with forest and trees? Is it useful to apply the Ecosystem services framework to understand the significance of this relationship and what can we learn from the past for the future? Since the dawn of permanent proto-urban settlements forest and trees accompanied cities in their trajectory of development as favourite living places for human communities. A controversial but often reciprocal relationship. Nevertheless, by adopting the ecosystem services concept as key factor of interpretation, we could try to trace back and highlight the changing role of forest and trees during cities development process. By using primary sources, historical and archeological evidences, narratives, iconography, and oral history approaches, the research focuses on qualifying and quantifying the changing interactions between forests/trees and urban communities. From the Age of Dependence to the Age of Otherness, we tried to stress a periodization of behaviours and associated benefits (identified as ecosystem services ante litteram) that city dwellers felt and attributed to forest and trees. The periodization was filtered through the prepositional declination of forest/city relationships, i.e. forest in/around/of/for/with/without/versus the cities.

Preliminary assessment of green areas of Politecnico Campus, to develop an urban forestry plan for the UFPR campi / Avaliação preliminar de áreas verdes do campus centro politécnico, para a elaboração do plano de arborização dos campi da UFPR

Carla Maria Camargo Corrêa¹, José Elias Emellek², Rodrigo Dall'agnol Trompczynski¹, Leonardo Rogal¹, Vitória Maria Bisewski¹, Priscila Caldas¹

¹Universidade Federal do Paraná, NIMAD, Curitiba, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (cmcamargocorrea@gmail.com; eemellek@yahoo.com.br; rtrompczynski@gmail.com; leonardorogal98@gmail.com; vibisewski@gmail.com; priscilacaldass@gmail.com)

A falta de planejamento e de manejo das áreas verde dos campi da UFPR vem causando diversos problemas em edificações, nos sistemas de infraestrutura, nas pavimentações do sistema viário, causadas por raízes de árvores, além da interferência de galhos nas redes de energia elétrica, entupimento de calhas e danos às coberturas, causados por quedas de folhas e grimpas nas edificações próprias e de terceiros e principalmente a disseminação descontrolada de espécies exóticas invasoras nos campi. Os problemas acima relacionados tem trazido uma série de consequências à UFPR, seu patrimônio, seus usuários e a terceiros como: aumento significativo nos custos de manutenção das edificações e dos sistemas de infraestrutura e viário, risco de queda de energia e acidentes graves com as redes elétrica, infiltrações e vazamentos de grandes proporções nas edificações da instituição, restrição à implantação de novas edificações nos escassos terrenos livres da UFPR, devido ao plantio de árvores sem planejamento e redução da biodiversidade das comunidades vegetais nativas em áreas de preservação internas e vizinhas da UFPR, devido à proliferação de espécies exóticas invasoras além de senescência acelerada de árvores devido à falta de manejo. Visando reduzir os problemas apresentados, a UFPR vem elaborando um plano de arborização para seus campi, que deverá contemplar os campi: Centro Politécnico, Setor de Ciências Agrárias e Jardim Botânico. Os dados apresentados representam a fase de diagnóstico do plano, no Centro Politécnico, onde foram inventariadas 4335 árvores, sendo que 69 % das espécies amostradas são exóticas, em grande parte invasora ou com potencial.

D6c: FOREST HEALTH DEFENDERS: EMPOWERING CITIZENS TO PROTECT FORESTS THROUGH RESEARCH CONTRIBUTIONS

Eyes on the trees: forest health monitoring at a 'human' level

Michelle Cleary¹, Johanna Witzell¹

¹Swedish University of Agricultural Sciences, Alnarp, Sweden (michelle.cleary@slu.se; johanna.witzell@slu.se)

Citizen Science (CS) has taken a big leap forward from the traditional volunteer engagements in science. Some of the biggest global societal challenges like global warming and invasive species can only be resolved through a better recognition of the 'shared responsibility' in society, outside of the regular 'blamed' players (industries or sector trades). The power of CS allows for capacity building in society, foster learning, promote networking among public stakeholders and better exchange of information between the public and the scientific community. CS can play an important role in forest health monitoring allowing for better spatial and temporal resolution of data capture of new and emerging threats which can then alert a decision response for control actions to be taken. Many polices dealing with invasive alien species (IAS) stress the importance of raising public awareness and commitment to own part of the problem such that it will encourage private efforts and voluntary compliance, and influence behavioral changes in stakeholders, decision makers (politicians) and citizens (consumers) who often play a role in the movement of IAS. However there are many challenges to gathering information when it comes to e.g. data flow, ensuring effective engagement, and quality of the data that is received. Relevant EU COST Action networks in CS including "ALIEN CSI: Increasing understanding of alien species through citizen science" aim to explore possibilities to establish a European-wide CS IAS network that will among other things, help inform decision-making and implementation of requirement for compliance to the EU regulations on IAS.

Methods of public engagement in forest health research

Joseph Hulbert¹

¹Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa (joey.hulbert@fabi.up.ac.za)

Recognition of the value of non-scientist participation in research is increasing and stimulating the application of citizen science approaches in many fields of ecology. For example, the benefit of enhanced sampling capacity has led to the inclusion of many non-scientists in projects that monitor forest pest outbreaks and disease epidemics. However, each of these projects generally engage citizens through different methods. Many projects are collection based, inviting non-scientists to submit physical samples (e.g. soil, plant tissues, insects, etc.) and other projects invite citizens to share observations online, or some mixture of both. Projects also vary in their provisions of sampling equipment (sampling-kits or recycled household materials) and the platforms of their online environments (grassroots or pre-existing applications). Determining the appropriate methods also depends on the desired complexity of the experimental design and the target group of participants. In general, whether citizens are participating in a collection-based microbiome study or monitoring for a specific insect pest, there are many methods to consider. The objective of this presentation is to review the approaches used by many of the forest health based citizen science projects internationally and to provide recommendations for those interested in engaging the public in their research programs.

Observatree: the evolution of a citizen science programme as a contribution to a tree health early warning system for Britain

Chris Quine¹ , Peter Crow², Jake Morris³

¹Forest Research, Edinburgh, United Kingdom; ²Forest Research, Farnham, United Kingdom; ³Department for Environment, Food and Rural Affairs, Defra, London, United Kingdom (chris.quine@forestresearch.gov.uk; peter.crow@forestresearch.gov.uk; jake.morris@defra.gov.uk)

We describe the development and operation of Observatree, a citizen science programme which has mobilised and trained a network of volunteers to look out for pests and diseases and so contribute to a tree health early warning system. The programme was initiated in response to growing concern over the rise of new pests and diseases in British woodlands and was developed with support from EU LIFE funding by a consortium of seven partners spanning governmental and third sector organisations. The partnership has proved robust and a second phase of the programme, beyond the initial funding, has been progressed. We review the lessons of the first Phase, how observations were targeted on specific pests and diseases, the data collected and the evaluation of volunteer motivations and responses. We introduce the range of training materials developed, and the data collection processes that have evolved. Steps have been taken within the second phase to enhance both the volunteer experience and the quality of the data made available for early warning including through the use of sentinel trees and null reports. The programme design, and activities requested of the citizen scientists has evolved over time. In particular, it has to strike a balance between engagement and awareness raising, and the provision of scientifically robust data. We summarise the rationale for the current mix of volunteer activities and identify prospects for further improvement.

Dissecting a successful Citizen Science program and increasing buy-in from professionals

Matteo Garbelotto¹

¹University of California, Berkeley, USA (matteog@berkeley.edu)

The Sudden Oak Death (SOD) Blitz program enlists over 500 volunteers yearly to monitor the spread across California of the exotic forest disease SOD, and ranks as one of the oldest Citizen Science programs in the world focused on tree diseases. Here, we present results of questionnaires filled out by participants during the 12 year-long program, to compare answers across different regions, years, and professional background of participants. We also compare answers from SOD blitzes with answers provided in similar questionnaires handed out during informational non-citizen science programs. The main aims of this "exercise" were to: 1) Identify motivational drivers unique to volunteers participating in Citizen Science; 2) Compare and contrast answers between more and less successful SOD Blitzes, where success is determined by number of participants and number of trees surveyed, and; 3) Determine whether some participants contribute more than others, and "profile" them. Results highlight motivational drivers of citizen scientists, and identify participants significantly more committed to Citizen Science than the average volunteer. Often, this subset comprises skilled workers in the sector and professionals. Although we show that participation in *ad hoc* trainings results in equal proficiency across all SOD Blitz volunteers, scientific returns from skilled volunteers can be significantly higher. Based on this information, we launched a program dedicated to skilled professionals in the "art" and profession of tree care: we briefly describe the program and rename Citizen Science aimed at professionals wanting to elevate their "art" to a science, as "Artisan Science".

Validating maps of land cover and land degradation with citizen science and mobile gaming

Inian Moorthy¹, Neha Joshi¹, M Thoha Zulkarnain², Andree Ekadinata², Tobias Sturn¹, Fathir Mohamad³, Bunga Goib³, Ping Yowargana¹, Olha Danylo¹, Ian McCallum¹, Florian Kraxner¹, Linda See¹, Steffen Fritz¹

¹International Institute for Applied Systems Analysis (IIASA), Laxenburg, Austria; ²World Agroforestry Centre (ICRAF), Bogor, Indonesia; ³World Resources Institute (WRI), Jakarta, Indonesia (moorthy@iiasa.ac.at; joshin@iiasa.ac.at; m.zulkarnain@cgiar.org; a.ekadinata@cgiar.org; sturn@iiasa.ac.at; fathir.mohamad@wri.org; bunga.goib@wri.org; yowargan@iiasa.ac.at; danylo@iiasa.ac.at; mccallum@iiasa.ac.at; kraxner@iiasa.ac.at; see@iiasa.ac.at; fritz@iiasa.ac.at)

Peatland comprises around 24% of South Sumatra, a province on the island of Sumatra in Indonesia. Following catastrophic fires in 2015, peat restoration has become a priority for this area. To identify candidate areas for restoration, both land cover over time and land degradation have been mapped using optical and radar remote sensing. Limited field data have been used to help validate these maps but more validation data are still needed. One way to fill this gap is to tap into the power of citizen science, which has become an emerging area of interest. In citizen science, any member of the public can take part in scientific research, whether this is through data collection, analysis of the data or hypothesis generation. Here we present the results from a citizen science campaign using the Urundata mobile gaming application, which has been developed as part of the Restore+ project. Urundata has two main components: a rapid image assessment tool that allows users to classify satellite imagery by the type of land cover/land use visible or to examine pairs of images for detection of change over time (developed from an application called Picture Pile). The second component sends users to specific locations on the ground via a mobile device and asks for information related to land cover and evidence of land degradation (developed from an application called FotoQuest Go). Together these two components have been used to help validate land cover and land degradation maps of South Sumatra through citizen science.

P-FOR INIA: a smartphone app for pest management and reporting sanitary issues in commercial forestry

Sofía Simeto¹, Gonzalo Martínez¹, Demian F. Gómez², Gustavo Balmelli¹

¹INIA, Tacuarembó, Uruguay; ²University of Florida, Gainesville, USA (ssimeto@inia.org.uy; gmartinez@inia.org.uy; demiangomez@ufl.edu; gbalmelli@inia.org.uy)

TICs can be a great ally to deal with the global increase in pest and disease invasions in forestry, providing tools for early detection of health issues and allowing the deployment of management strategies. The pest and disease recognition smartphone app P-FOR INIA, has been available for 4 years for foresters, students and general public. Here we assess its potential as a tool for early alert of new sanitary issues in commercial plantations. The app contains a library, a symptom key, and a query module. The latter enables users to take georeferenced pictures and post a query about the observed signs, symptoms or organisms. The queries are sent to a central database and answered by a group of forest health experts. This tool allows incidental data collection on distribution and seasonality of key forest pests and diseases. In the last year, a new strategy for involving forester in data collection via directed requests was implemented. By using push messages via the app, we asked the users to look for particular signs or symptoms. This has proven useful to locate local pest resurgence for the release of biological control agents. We are also working on the integration of the data collected by P-FOR INIA into phytosanitary official databases.

Citizen science in a common garden: one pine at a time

Ethan Bucholz¹, Jared Swenson¹, Ehren Moler¹, Mike Chizhov², Ella Colella³, Lara Schmit³, Julia Hull¹, Emily Musta⁴, Amy Whipple¹, Kristen Waring¹

¹Northern Arizona University, Flagstaff, USA; ²Grand Canyon Trust, Flagstaff, USA; ³Northern Arizona University: Southwest Experimental Garden Array, Flagstaff, USA; ⁴Flagstaff High School, Flagstaff, USA (eb692@nau.edu; jks383@nau.edu; erm287@nau.edu; michael.chizhov@gmail.com; ella.colella@nau.edu; lara.schmit@nau.edu; julia.b.hull@gmail.com; emusta@fusd.org; amy.whipple@nau.edu; kristen.waring@nau.edu)

Climate change and pests threaten native conifer species globally. Our research group incorporated citizen science volunteers in a large-scale common garden experiment studying climate adaptation in southwestern white pine (*Pinus strobiformis*). Citizen scientists have gathered phenological and morphological data on over 20,000 *P. strobiformis* seedlings planted in three elevationally-varied common gardens on the north rim of Grand Canyon, Arizona. This large-scale ecological research enables a better understanding of climate adaptation in *P. strobiformis*, while also facilitating crucial networking opportunities between scientists and the general public. Through collaboration with researchers at Northern Arizona University (NAU), a local nonprofit called Grand Canyon Trust (GCT), Flagstaff High School, and infrastructure provided by the Southwestern Experimental Garden Array (SEGA), our team has generated detailed, meaningful data sets and created lasting community connections. Further involvement with undergraduate coursework at NAU provides undergraduates authentic experiences with field research and data analysis. NAU researchers assisted high school students in the development of their own common garden, serving as a study system for multiple senior research projects. Our partnership with the GCT has provided additional opportunities for high-school students, as well as interested citizen volunteers, to gain field experience while enabling researchers to develop effective strategies for communicating with broad audiences. Using preliminary data, we discuss the benefits and difficulties in creating meaningful partnerships, relying on citizen science volunteers, and incorporating educators and underrepresented youth in climate change research with emphasis placed on the value of collaborative science for the promotion of meaningful STEM opportunities.

Citizen science and tree health assessment: how useful are the data?

Richard Hallett¹

¹USDA Forest Service, NYC Urban Field Station, Bayside, NY 11359, USA (rhallett@fs.fed.us)

Emerald ash borer (*Agrilus planipennis*) has killed millions of trees in the United States. Community managers face treatment or removal decisions for all publicly owned ash (*Fraxinus* spp.) trees. These decisions are based on the overall condition of each tree. In this study, the U.S. Forest Service trained a Boy Scout troop in Oconomowoc, Wisconsin, U.S., in a tree health assessment protocol that used rubrics designed to measure physiological stress symptoms. The city provided tree inventory data, which included the location of 316 city-owned ash trees. After a two-hour training session, the Scouts and adult leaders assessed all ash trees in August 2015. A tree health expert re-assessed 20% of the trees. The protocol measured diameter at breast height and included a suite of tree stress assessment variables. Researchers used a five-class system for defoliation, leaf discoloration, and overall vigor. Fine-twig dieback was estimated in 5% classes. Digital photographs were taken and automatically processed so as to measure percent crown transparency. Expert/volunteer agreement for diameter at breast height was within 2.5 cm 92% of the time; defoliation, discoloration, and vigor were within two classes 100%, 93%, and 92% of the time, respectively. Crown dieback estimates were within 10% of each other 76% of the time, and transparency estimates were within 15% of each other 76% of the time. Researchers calculated an overall stress index value and ranked the trees from lowest to highest stress. The volunteer-generated data enabled Oconomowoc to make science-based management decisions for its infested ash trees.

Silvalert: reporting forest damages in South West Europe

Sarah Yoga¹, Christophe Orazio¹, Eduard Mauri¹

¹European Forest Institute, Cestas, France (sarah.yoga@efi.int; christophe.orazio@efi.int; eduard.mauri@efi.int)

Forest ecosystems occupy more than 30% of the land area in South West Europe. Forests in France, Portugal, and Spain are vulnerable to the increasing occurrence of biotic and abiotic hazards. Forest hazards can cause important and complex damages visible even beyond administrative borders. The risk of occurrence of multiple forest hazards has remained high for the past years requiring an on-going surveillance program by local forest authorities. Collecting field data on a regular basis is, however, cost-demanding. Participatory observations can help improve and diversify data collection. Silvalert is a mobile application that has been designed to report forest damages caused by diverse hazards. It is an open access application that can be downloaded after registration. The application has a simple user-friendly interface built to geolocate and capture photos of an encountered forest damage. Forest users can create offline reports and provide information on the type, extent, or severity of a forest damage. The information can later be uploaded to a server when internet coverage/signal is recovered. Reports are verified by the forest authorities who can use them as decision tools to determine for example, where to conduct extensive field surveillance. They are open access to the registered users who can visualize the type and extent of reported forest hazards which are currently prevailing at a European scale. Scientists can have an exhaustive access to all the reports and associated data.

Non-scientist contributions to plant disease research in South Africa

Joseph Hulbert^{1,2}, Francois Roets², Treena Burgess³, Michael J. Wingfield¹

¹Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa; ²Department of Conservation Ecology and Entomology, Stellenbosch University, Stellenbosch, South Africa; ³Centre for Phytophthora Science and Management, Environmental and Conservation Sciences, Murdoch University, Murdoch, Australia (joey.hulbert@fabi.up.ac.za; fr@sun.ac.za; t.burgess@murdoch.edu.au; mike.wingfield@fabi.up.ac.za)

Cape Citizen Science (<http://citsci.co.za>) is a program in South Africa that engages the public in plant health research. Many non-scientists were engaged in the pilot study about the diversity and distribution of *Phytophthora* species in the Greater Cape Floristic Region, a biodiversity hotspot. Citizens collected samples from private properties, plant productions, botanical gardens, nature reserves, and national parks. The project also provided a platform for citizens to report unhealthy plants online. Multiple species of *Phytophthora* that were previously undocumented in South Africa and at least one novel species were recovered from their contributions. Online reports also revealed multiple potential novel plant-microbe interactions. Non-scientist engagement therefore increased the breadth of the sampling distribution and facilitated discoveries that would still be unknown without their participation. The results of the pilot study demonstrate that non-scientist engagement can be valuable and that there are many methods to engage the public in plant health research.

D6e: FOREST AND ECOSYSTEM SERVICES IN CITIES: ACHIEVEMENTS AND EXPECTATIONS

Designing green public squares with suitable tree species for optimum ecosystem services

Mohammad A Rahman¹, Moser-Reischl Astrid¹, Thomas Rötzer, Stephan Pauleit¹

¹Technical University of Munich, Germany, Freising, Germany (ma.rahman@tum.de; astrid.moser@lrz.tum.de; thomas.roetzer@lrz.tu-muenchen.de; pauleit@tum.de)

Greenspaces can moderate the effects of climate change and urbanization through the provision of ecosystem services (ES). However, due to high heterogeneity at micro-scales, there are still uncertainty concerning the magnitude, pattern and the process of mitigation. Over the last four years we continuously measured eco-physiological, dendrochronological, meteorological and edaphic variables along with the heat fluxes below and above canopy of contrasting tree species at different street canyons in Munich, Germany. Species characteristics leading to different growth patterns influenced shading and transpirational cooling with an decrease in air temperature up to 2 °C at the centre of the crown and around 1 °C at 1.5 m height from the ground. Trees with higher above and below ground growth also linearly increased the soil infiltration potential. Largely, ES were also dependent on various meteorological variables and below-canopy surfaces. Trees grown over paved surfaces and within narrow-street canyons provided lower boundary layer cooling and also hinder the wind flow; where grass meadows were more efficient. Conversely, on wider street canyons, trees in combination with grasses were more efficient. Overall, trees with less water demand and lower canopy density showed higher potential of cooling and runoff reduction once they are planted over grass surface than over built surfaces through the grass evapotranspiration and extended fine rooting system. However, there were trade-offs between different indicators for ES such as carbon gain and transpiration; number of trees and wind flow. Thus the study provided new insights on designing public squares and choice of species.

Quantifying growth and ecosystem services of urban trees under present and future climate conditions

Thomas Rötzer¹, Mohammad Rahman², Hans Pretzsch¹, Stephan Pauleit²

¹Chair for Forest Growth and Yield Science, TU Münchenn, Freising, Germany; ²Chair of Strategic Landscape Planning and Management, TU München, Freising, Germany (thomas.roetzer@lrz.tum.de; ga95pas@mytum.de; hans.pretzsch@lrz.tu-muenchen.de; pauleit@wzw.tum.de)

UN forecasts predict that in the year 2030 the urban population will amount to more than 60 % of the global population and exceed six billion people in 2050. Because of the increasing urbanization and along with the global climate change the climate of a city will be modified substantially. The urban green and especially urban trees can mitigate the negative effects of climate change by providing ecosystem services. These are among others the reduction of rainwater runoff, pollutant filtering, carbon storage, shading, or cooling by transpiration. The amount of the individual ecosystem services are closely associated with the tree species as well as with a tree's age, size, structure and vitality. By using the newly developed process based tree growth model CityTree growth and ecosystem services of individual trees, of the green of a city's square or of an entire city can be estimated. In a recent study tree growth and ecosystem services of the main tree species were simulated and analyzed for Central European cities both under current climate conditions and for climate scenarios. The simulations reveal that the urban green and urban trees can significantly improve the urban climate and mitigate climate change effects. The quantity of the improvements depends on tree species and tree size as well as on the specific site conditions. This way, urban green can contribute significantly to adapt cities to climate change.

Natural regeneration in the city: comparing plant recruitment dynamics in urban and rural forested natural areas

Max Piana¹, Steven Handel², Myla Aronson¹, Richard Hallett³, Steward Pickett⁴, Peter Morin¹

¹Rutgers University, New Brunswick, USA; ²Rutgers, University, USA; ³USDA Forest Service, New York City, USA; ⁴Cary Institute of Ecosystem Studies, Millbrook, USA (max.r.l.piana@gmail.com; steven.handel@rutgers.edu; myla.aronson@rutgers.edu; rahallett@gmail.com; stapickett@caryinstitute.org; peter.morin@rutgers.edu)

Understanding the functional differences between urban and rural habitats is a critical focus for urban ecology theory and the basis for sustainable management of urban forested natural areas. While studies have observed suppressed recruitment of native woody species in urban forests, the ecological barriers to regeneration are not well understood and remain understudied. Here we present a conceptual framework for recruitment limitation in urban plant populations and the results from a three-year experiment comparing seed production, dispersal, seed predation, and early-establishment in urban and rural forests located in the greater New York City area. The findings from this experiment point towards functional shifts in ecological processes critical to natural regeneration, which may represent significant barriers to native plant recruitment. For example, we observed strong preference for seeds of native species and a deviation from the inter-annual patterns of seed predation that are commonly observed in rural forests dominated by masting tree species. Seed predation represents a significant, and overlooked, barrier to native species recruitment in urban forests with implications for future forest composition and structure, and as a result, forest function and associated ecosystem services. Advancing a mechanistic understanding of how these drivers alter plant population dynamics will improve the conservation, restoration, and management of urban forested natural areas.

Measuring the effects of governance on the demand for forest ecosystem services and disservices in Bogota, Colombia

Alexandra Pineda Guerrero¹, Francisco J. Escobedo², Fernando Carriazo²

¹Jardin Botánico de Bogota, Bogota, Colombia; ²Universidad del Rosario, Bogotá, Colombia (alepineda02@gmail.com; franciscoj.escobedo@urosario.edu.co; fernando.carriazo@urosario.edu.co)

Governance is frequently mentioned as a requirement for improved management of, and provision of benefits from urban and peri-urban forests. However the concept has many definitions and applications. In addition, there is little information on how people in Latin American cities perceive these benefits as well as costs or ecosystem services (ES) and disservice (ED), respectively. We used semi-structured surveys, econometrics, and spatial analyses to explore the effect of governance on the perceptions towards urban and peri-urban forests and their willingness to pay or not for their conservation. We focused on an urban sub-basin in the city of Bogota, Colombia and specific green areas and forests including wetlands, parks, and other socioeconomic contexts. We also correlated green space cover with responses from a city-level survey on community well-being. Results identified a suite of perceived ES-ED and the influence of governance on how people valued these. Our analyses shows that air quality and biodiversity were very important to respondents, while flood regulation was the least important despite the sub-basin's acute problems with stormwater. The ED of the feeling of insecurity due to crime was significantly related to poor levels of maintenance and infrastructure in the green areas. We also correlated the amount and size of green spaces with citizen well-being. Perceived transparency, corruption and poor government performance influenced people's unwillingness to pay for green space conservation. Results identified the socioeconomic backgrounds and government processes that most influenced the perception and willingness to pay for urban/peri-urban forest conservation.

The role of the Simón Bolívar Central Park (Bogotá, Colombia) in the provision of ecosystem services: analysis of synergies, trade-offs and service packages

Nicole Morales-Freese¹, Luz Piedad Romero-Duque¹ 

¹Universidad de Ciencias Aplicadas y Ambientales UDCA, Bogotá, Colombia (nishaoran210@gmail.com; luz.romero@udca.edu.co)

Knowing the interactions between ecosystem services (SE) makes possible to improve management strategies to meet the needs of adaptation to environmental changes in cities. Urban parks provide SE, whose type and supply varies with the elements and spaces that constitute these parks. From the context of the biophysical evaluation, we identify the interactions between 14 SEs provided by the 8 land covers of the Simón Bolívar Central Park (Bogotá, Colombia). We also apply 120 semi-structured surveys to users over 18 years of age to assess the same 14 SEs. Forests, sparsely wooded pastures and densely wooded pastures supply the most provision and regulation services. Unwooded pastures provide more recreation and recreation services. Forests and the lake provide more sense of well-being, scenic beauty and spiritual value. The Park is well perceived from the physical, mental and emotional well-being as well as from the environmental field, since most users recognize and value the diversity of services it provides. Results show that the variety of land covers in the parks allows the supply of multiple SEs that are identified, valued and used by the beneficiaries in different ways. This allows guiding decision-making on urban park planning based on the needs of the immediate context. The next step is to know these interactions between different parks in order to enhance synergies in the distribution of SE throughout the city.

Impact of built-environment on woody tree species diversity in a nigerian university: implications for enrichment planting and *in-situ* conservation strategies

Peter Oni¹

¹Federal University, Wukari, Nigeria (petidowu2000@yahoo.co.uk)

The impact of built-environment on woody tree species loss and biodiversity within Federal University Wukari, Taraba state, Nigeria was investigated. The built-environment of the campus was sub-divided into four compartments (I, II, III, and IV) based on buildings distribution and formed criteria for land areas determination (ha⁻¹). All wood tree species in each compartment were counted, identified and frequency of occurrence determined. All were classified into taxonomic families, relative abundance (RA) and their diversity index computed. Findings indicated that the surveyed area covered approximately 67.1 hectares. Compartment IV had the highest land area (32.57 ha, 48.54%) while compartment II was least (5.51 ha, 8.21%). A total of 28 individual wood tree species belonging to 17 taxonomic families were encountered. Fabaceae was most represented (5) RA 18.5% while seven other families had only 2 species. Verbanaceae was the least represented (1 individual). Compartment IV had the highest number of woody tree species (20 individuals), while compartments I and III had (18) individuals each and compartment II had the least (9 individuals). On individual species basis, *Eliaes guineensis* had the highest frequency of occurrence (11.60%) followed by *Danielia oliveri* (10.78 %) while *Eucalyptus camaldulensis* was least (0.16%). Species diversity index indicated highest value (2.495) in compartment IV and least (2.009) in compartment II. Relating the total land area assessed (67.1 hectares) with total species frequency (602) stems, it translated to approximately 8.97 trees h⁻¹. The number of species ha⁻¹ appears moderate within the built-environment, the need for enrichment planting and conservation efforts are implicated

A review on the roles of urban forests on different scales in atmospheric particulate matter

Donghui Han¹, Lixin Chen¹, Hailong Shen¹, Wenbiao Duan¹

¹Northeast Forestry University, Harbin, China (hdh_nefu@yeah.net; chenlixin@nefu.edu.cn; shenhl-cf@nefu.edu.cn; duanwenbiao@nefu.edu.cn)

Urban forests perform a vital function for atmospheric particles and an increasing number of relevant studies have been done during recent years as environmental quality issues induced by particulate matter are drawing more attention. On the basis of previous articles, this review discussed how urban forests influenced particles at three levels, including plant level, stand level and regional level; in addition, the physical characters of particles were analyzed in vertical and horizontal directions at stand level. As an individual tree, it captured particles through each organ like leaf, bark, branch or shoot, the existing results in this aspect were related to plant characteristics and experimental methods. At stand level, in vertical direction those studies focused on the models of dry deposition velocity which suggested the differences in plant species and weather condition. On regional scale, this review revealed that the removal of atmospheric particles by urban forest depended on particulates concentration, greening coverage area and leaf area index. Multi-scale analyses on effects of atmospheric particles could better understand the role of urban forest as a complex system and provide foundation for future research.

The importance of conserving natural forests in and around cities: analyzing ecosystem services for resilience along an urban-rural gradient

Tahia Devisscher¹, Matthew Mitchell¹

¹University of British Columbia, Vancouver, Canada (tahia.devisscher@ubc.ca; matthew.mitchell@ubc.ca)

Managing urban landscapes is one of the greatest challenges of this century. As cities continue to grow, they become increasingly vulnerable to multiple risks caused by urbanization and climate change interactions. The state of ecosystems and the wellbeing of urban dwellers will greatly depend on the way cities anticipate and prepare for rapid change in the next decade. Urban forests have an important role to play in this regard, yet little has been done to measure the effects of urbanization on the multiple, essential ecosystem services (ESs) these forests provide for urban resilience. Pressure on land in and around cities is increasing, and some cities are struggling to conserve their natural forest and biodiversity. In these cities, there is a growing demand to better understand the role of surrounding forests and natural forest fragments in terms of their potential contribution to urban resilience and human wellbeing. This study will show results of research conducted along an urban-rural gradient in the City of Maple Ridge, Canada, selected due to its very rapid urbanization rate and expansion into surrounding forests. Structure, composition, and ecosystem services deemed important for urban resilience were evaluated in forest plots along the gradient. Citizens were also engaged along the gradient to evaluate their interaction with the urban forest and perceptions of the benefits these forests provide. Findings will be used by Maple Ridge to inform future land policies, and the conservation of forest areas that play a key role in the resilience and sustainability of the city.

Urban pollution writes in tree rings the history of anthropic events, detectable through dendrochemistry

Claudia Cocozza¹, Roberto Tognetti², Paolo Cherubini³

¹University of Florence, Florence, Italy; ²University of Molise, Campobasso, Italy; ³WSL, Birmensdorf, Switzerland (claudia.cocozza@unifi.it; tognetti@unimol.it; paolo.cherubini@wsl.ch)

Tree rings record environmental events as they have changed in the past. Trees are affected by environmental pollution in relation to the level of pollutants and their exposure to them, tree species, environmental conditions, geographical context and the location of trees in relation to pollution sources. Tree-ring chemical analyses, i.e., dendrochemistry, provide a tool to reconstruct the temporal and spatial dynamics of pollutants in the environment. Different pollution levels and sources, exposure intervals, and industrial process intensities require increasingly investigation to validate and implement the approach to detect pollution signals. The chemical content of tree rings allows to characterize the peculiarity of different industrial urban areas. Different study cases reveal the potential of tree rings, e.g. *Quercus pubescens* and *Pinus sylvestris*, as sensitive indicators of changes in anthropized ecosystems, detecting specific signals of the considered pollutants to reconstruct past environmental conditions in urban areas. However, taking into account that trace elements can be deposited onto plant surfaces (e.g., stem, bark), absorbed from the atmosphere by foliage and up-taken from the soil by the roots (and accumulated in the xylem), physiological processes are involved in the definition of the pollution signal in tree rings. Copious study cases are necessary to increase the resolution of the dendrochemistry for its application in urban areas.

Managing cities green infrastructure to enhance the provision of ecosystem services to create more liveable and resilient cities

Pedro Pinho¹, Paula Matos¹, Ana Luz¹, Natália Koch², Filipa Grilo¹, Bernardo Rocha¹, Joana Vieira¹, Teresa Mexia³, Cristiana Aleixo¹, Cristina Branquinho¹

¹Centre for Ecology, Evolution and Environmental Changes, Faculdade de Ciências, Universidade de Lisboa, Portugal, Lisboa, Portugal; ²Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brasil, Porto Alegre, Brazil; ³Centro de Estudos Florestais, Instituto Superior de Agronomia, Universidade de Lisboa, Portugal, Lisboa, Portugal (ppinho@fc.ul.pt; psmatos@fc.ul.pt; acluz@fc.ul.pt; natimkoch@gmail.com; afgriolo@fc.ul.pt; brerocha@fc.ul.pt; jivieira@fc.ul.pt; mmexia@fc.ul.pt; caaleixo@fc.ul.pt; cmbranquinho@fc.ul.pt)

Urban areas are hubs for human development and will host an increasingly larger share of global human population. Yet, urbanization creates challenges to human life, such as atmospheric pollution and urban heat island effect. Cities' green infrastructure is suggested by UN New Urban Agenda to tackle such environmental problems. Wooded areas, such as parks and urban forests are critically important for this, as they provide important support & regulation ecosystem services, such as microclimate and air quality regulation. Its importance to human wellbeing was made evident by Lisbon citizens movements across the city to visit green areas. However, ecosystem services provision depends of ecosystem's biodiversity, but this biodiversity is in turn affected by the same problems that challenge human life, such as atmospheric pollution and the urban heat island effect, added to other factors that influence ecosystem functioning, such as habitat fragmentation. Because monitoring stations cannot measure impacts in ecosystems, we used ecological indicators in urban areas of Portugal and Brazil, to show how accumulation of metals, satellite and microclimate measures, and metrics of lichen diversity – more importantly trait-based metrics related to growth form and tolerance to disturbances, can be used as to quantify the impacts of urbanization. This effect was modelled at city, park and square spatial scales, allowing us to map, with high resolution the provision of multiple ecosystem services. This provided evidences of the trade-offs that occur between ecosystem services, and also how can management and city planning can influence the provision of ecosystem services.

D6p: FOREST AND ECOSYSTEM SERVICES IN CITIES: ACHIEVEMENTS AND EXPECTATIONS

A comparison of leaf litter decomposition intensity: peri-urban forests vs. urban green spaces

Lina Straigyte¹ , Tadas Vaidelys¹, Michael Manton¹ 

¹Vytautas Magnus University, LT53361, Lithuania (lina.straigyte@vdu.lt; tadas.vaidelys@vdu.lt; michael.manton@vdu.lt)

Urban green space environments are different from peri-urban forest environments. However, there are knowledge gaps on how urban environments and peri-urban forests affect tree leaf decomposition intensity. To fulfill these gaps, we measured biomass loss of the leaf litters of four dominant native deciduous tree species: *Tilia cordata*, *Acer platanoides*, *Betula pendula*, and *Quercus robur* collected from peri-urban forests (control) and four different types of urban green spaces in Kaunas, Lithuania. We collected leaf litter samples from 60 sites and used the modified litter bag technique. The results indicated that the decomposition of leaf litter among tree species as well as the five types of urban green spaces are different. We found the leaves of *B. pendula* and *A. platanoides* decayed faster in green street spaces. The composition rates of these species accelerated during summer. The leaf litter decomposition of *T. cordata* was not influenced by the types of green spaces, and the losses of leaf litter mass between green spaces were insignificant. *Q. robur* leaf litter decomposed faster in peri-urban forest than in urban green spaces but the leaf litter mass loss differences between green spaces were small but significant. In conclusion, environmental processes are different between green spaces and tree species, results showing that *T. cordata* and *Q. robur* were the least affected species in all types of green spaces and maybe the most suitable species to cope with the demands and change of urban green spaces. However, rapid decomposition of *B. pendula* and *A. platanoides* leaf litter from street greeneries indicates that these leaves can be left as fertilizer.

Diversity of the urban forest network along roads in the São Francisco Xavier district of Dois Vizinhos, Paraná, Brazil, using the Odum index / Diversidade da arborização urbana viária do Bairro São Francisco Xavier em Dois Vizinhos, Paraná usando o índice de Odum

Davidson da Silva Novaes¹, Flávia Gizele Konig Brun¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brazil (davidson.novaes@gmail.com; flaviagbrun@gmail.com)

Conhecer a diversidade da arborização urbana viária permite tomar várias decisões importantes quanto a sanidade das árvores que compõe a vegetação urbana. O Bairro São Francisco Xavier possui 1.479 habitantes e pertencente ao Município de Dois Vizinhos e foi usado como local de estudo para o presente trabalho. Foram percorridas as 13 ruas do bairro, onde foram levantados 910 indivíduos de 82 espécies distintas. Cada rua teve seu próprio índice calculado e com esses valores foi calculado a média, que foi considerada como a diversidade do bairro. A Índice de Odum do bairro São Francisco Xavier é de 3,97. O número de indivíduo médio por rua é igual a 71, com coeficiente de variação de 36,75%. A quantidade de espécies por rua é igual a 18, com coeficiente de variação de 29,79%. O coeficiente de variação para o índice de Odum foi igual a 24,63%. O índice de Odum deve variar entre 2,45 e 26,99, não sendo desejável valores extremos, mas sim os mais próximos da média. O bairro São Francisco Xavier possui um índice de diversidades de Odum considerável, mas não aceitável. O valor calculado mostra que a arborização do bairro está mais próxima da homogeneidade. Este é o reflexo de plantios não criteriosos. A baixa diversidade gera monotonia na paisagem e abre precedente para dizimar parte da arborização em caso de ataque da pragas e doenças. A Principal forma de melhorar a diversidade é substituir parte dos indivíduos pôr os de outras espécies, enriquecendo gradualmente a arborização do bairro.

Surveying exotic species used in urban forestry in Brazil / Levantamento de espécies exóticas na arborização urbana no Brasil

Ana Cláudia Nogueira da Silva¹, Hiohanes Moura Cardoso¹, Thamires de Souza Carvalho¹, Angeline Martini¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (anasilvanogueira@yahoo.com.br; hiohanes.cardoso@gmail.com; dsc.thamires@gmail.com; martini@ufv.br)

As espécies exóticas invasoras são a segunda maior causa de perda da biodiversidade no mundo, essas espécies quando introduzidas em novos ecossistemas, livres de predadores naturais, se adaptam e começam a reproduzir-se a ponto de ocupar o espaço de espécies nativas e provocar alterações nos processos ecológicos naturais, tornando-se dominantes após o período de tempo necessário para sua adaptação. Nesta premissa, foi realizado um levantamento de 21 inventários da arborização urbana brasileira, publicados em artigos científicos nos últimos 15 anos, visando avaliar a presença de espécies exóticas invasoras. Dentre os inventários, buscou-se aqueles que demonstraram de forma representativa a arborização em áreas consolidadas, tanto em capitais quanto cidades interioranas, nas cinco regiões geopolíticas do Brasil. Foram avaliados 4 inventários na região norte, 5 na região nordeste, 4 na região centro-oeste, 4 na região sudeste e 4 na região sul. Foram identificadas 190 espécies vegetais exóticas na arborização urbana, sendo que 67 (35%) das exóticas identificadas possuem potencial de invasão. Este estudo apontou 16 (8%) espécies presentes na lista de espécies invasoras no Brasil, as espécies exóticas com maior potencial de invasão utilizadas na arborização urbana foram *Ficus benjamina*, *Mangifera indica*, *Syzygium cumini*, *Leucaena leucocephala* e *Terminalia catappa*. Este estudo irá auxiliar em futuros planos diretores de arborização urbana e projetos de manejos, recomenda-se a substituição das espécies com grande potencial invasor. Esta pesquisa corrobora com a Estratégia Nacional para Espécies Exóticas Invasoras enfatizando a importância da utilização de plantas nativas, diminuindo a introdução, dispersão de exóticas invasoras.

Silviculture in the city: can traditional silvicultural practices inform urban forest management?

Richard Hallett^{1,2}, Max Piana³, Clara Pregitzer^{4,5}

¹USDA Forest Service, New York City, USA; ²New York Urban Field Station, New York City, USA; ³Rutgers University, New Brunswick, USA; ⁴Yale School of Forestry and Environmental Studies, New Haven, USA; ⁵Natural Areas Conservancy, New York City, USA (rahallett@gmail.com; max.r.l.piana@gmail.com; clara.pregitzer@yale.edu)

Cities around the world are focusing attention on trees and green space within city limits motivated by a wide range of documented economic, ecological and social benefits of urban forests. Urban forested natural areas are a subset of what is commonly thought of as the “urban forest”. These natural areas are more like rural forests than street, park, and yard trees. In addition, the urban forested natural areas are often overlooked and under-managed. Yet these areas may contain the majority of the trees within the city. In this talk we present a conceptual framework that borrows from traditional silvicultural and forest management practices typically applied to rural forests. While similar to rural forests, the impacts of urban conditions (e.g. heat island, heavy metals, altered soils) on forest ecosystem patterns and processes requires modified management practices. Also, forests in cities need to provide ecosystem services not lumber. For these reasons we suggest the need for an urban silvicultural framework. As we discuss this framework, we will synthesize emerging research in urban forest management and identify challenges and opportunities for advancing goal setting, assessments, and on-the ground management strategies for urban forested

natural areas. Adopting the urban silviculture concept will support innovative research and management strategies capable of addressing the impacts of urban stressors and climate change, and therefore sustain the benefits of urban forests over time.

Assessing the performance of least cost path modelling in defining ecological corridors for birds in urban landscapes

Gabriela Graviola¹, João Pena¹, Milton Ribeiro¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Rio Claro, Brasil (gabriela.rosa@unesp.br; joaoapena@gmail.com; mcr@rc.unesp.br)

Although connectivity is fundamental for species conservation, this topic in urban landscapes remains understudied. In order to fill this gap, this project aims to verify the accuracy of least-cost path (LCP) modeling in finding the best routes for birds between urban parks. We also intend to evaluate how different aspects of urban landscapes (such as tree density and exposure to noise) influence the taxonomic and functional characteristics of bird communities inhabiting streets and urban parks of a Neotropical city (Bauru, São Paulo, Brazil). First, we produced a land use/land cover map to characterize the urban landscape structure. The connectivity was assessed by simulating least-cost paths between 10 urban parks using the LSCorridors software. With the simulation results, we selected 10 streets considered as preferential routes and 10 streets not crossed by least cost paths. Currently we are performing bird surveys using the *point count* method in these three contexts (30 sampling points). We expect that streets nearby or considered as preferential routes will present higher species richness, number of individuals, functional richness and evenness. We also expect that urban parks and streets with higher tree density and lower exposure to noise will positively influence the taxonomic and functional characteristics of these urban bird communities. With these results, it will be possible to suggest guidelines for urban planning in order to create multifunctional urban ecological corridors and management strategies to assist in the conservation of bird species inhabiting Neotropical cities.

Conservation of natural ecosystems within urban ecosystems in Eastern Amazonia

Pedro Martorano¹, Francisco Oliveira¹, Lucieta Martorano²

¹Universidade Federal Rural da Amazônia, Belém, Brazil; ²Embrapa Amazônia Oriental, Santarém, Brazil (pmartorano60@gmail.com; fdeassis@gmail.com; lucieta.martorano@embrapa.br)

The Macrodrainage project in Belém, Capital of Pará, was a public policy strategy that aggregated value and quality of life to the urban population, principally in low-lying areas and peripheral neighborhoods at the end of the 1990's. Projects such as "Ação Metrópole" (Metropolitan Action) amplified the Trabalhadores Highway by removing vegetation from a nearby park. The objective of this work was to evaluate loss of tree cover in the area of the park called "Gunnar Vingren" due to these projects by quantifying the percentage of the natural ecosystem converted to urban area. A forestry inventory was done of trees with CAB_≥15cm in a 44.06 ha area, and geoprocessing and GIS methods were applied to evaluate vegetation removal. The results show that there are stands of pioneer species in large openings with a predominance of formations of macega, an open field transition area with aquatic macrophytes (17.94%). Secondary vegetation typical of shrubby secondary forest was present in low-statured (6.03%) and high-statured (2.95%) formations. High-statured forest was present in the várzea (river margin) (65.36%) and terra firme (upland) (2.89%) areas. Of the 3,160 stems inventoried there were 21 families, 42 genera and 48 species. The "Ação Metrópole" project caused significant disappearance of terra firme forest and exposed the flora and fauna of the northeastern portion of the park to human pressure. There is a great necessity to conserve this ecosystem and its water springs as a strategy of environmental compensation for ecosystem services for the population of Belém.

Developing and evaluating the Korean Green Gym for implementing citizen-participatory forest- management activities

Dawou Joung¹, Bum-Jin Park¹

¹Department of Environment and Forest Resources, Chungnam National University, Daejeon, Republic of Korea (dawo.jeong@gmail.com; bjpark@cnu.ac.kr)

The present study proposed an operational model for a citizen-participatory forest-management activity based on forest welfare to encourage active public participation in forest management. The Green Gym initiative introduced in England is a representative regional forest-improvement activity. This initiative is concerned not only with environmental conservation but also with individuals' health statuses. Therefore, the present study involved the development and evaluation of model citizen-participatory forest-management activities based on forest welfare by referring the Green Gym. In the field experiment, the model Green Gym program involved removing vines, pruning, stacking cut branches following pruning, planting containerized seedlings, and cleaning the forest (picking up trash). The Ovako Work Posture Analysis System was used to investigate any potential harm to the musculoskeletal system based on the forest management activity performed. Workload index was analyzed using the percentage of heart rate reserve to determine the work level associated with each activity. In addition, the psychological states of the participants before and after performing forest management activities were evaluated using the following tests: Positive and Negative Affect Schedule, Rosenberg Self-Esteem Scale, WHO Quality of Life, and Perceived Restorativeness Scale. Thus, we found that forest management activities were light work-level activities, which did not burden the musculoskeletal system and had positive physical and mental effects. The application of the proposed model can help in providing forest welfare service with personal and social benefits concerning the forests.

Studies on the relationship between primary production of *Pinus densiflora* forest and climate change factors in Mt. Namsan, Seoul Metropolitan City

Eunpill Lee¹, Sooin Lee², Seungyeon Lee¹, Euijoo Kim³, Yongsik Hong¹, Youngho Jung⁴, Jaehoon Park⁵, Sanghoon Lee⁶, Younghan You¹

¹Kongju National University/Life science, Gongju, Republic of Korea; ²Baekdudaegan National Arboreum/Forest Plant Industry, Bonghwagun, Republic of Korea; ³Kongju National University, Gongju, Republic of Korea; ⁴Baekdudaegan National Arboreum/Seed Vault Department, Bonghwagun, Republic of Korea; ⁵Kwater convergence institute, Daejeonsi, Republic of Korea; ⁶National Institute of Ecology/Division of basic Ecology, SeoCheongun, Republic of Korea (lyp2279@kongju.ac.kr; ecolove093@kongju.ac.kr; ecollee21@kongju.ac.kr; euijoo@kongju.ac.kr; hongjin@smail.kongju.ac.kr; jyh5250@kongju.ac.kr; kn5314@smail.kongju.ac.kr; sanghunlee@nie.re.kr; youeco21@kongju.ac.kr)

To find out the impact of climate change on the carbon budget and cycle, we monitored standing biomass, litter production, net primary production and soil respiration for 10 years in *Pinus densiflora* forest of Namsan Mountain, South Korea's representative urban forest ecosystem. Also regression analysis was performed to find correlation between its ecological change phase and climate change components (average annual temperature, average monthly amounts of precipitation, tree days, average monthly temperature from March to May (in the beginning period of growing season), average monthly amounts of precipitation from March to May (in the beginning period of growing season), number of typhoons). Standing biomass was related positively with average annual temperature and frequency of monsoon typhoons. Litter production was related negatively with frequency of monsoon typhoons. Net primary production was related positively with average monthly amounts of precipitation at the beginning period of growth season, but average annual temperature and number of monsoon

typhoons negatively. Soil respiration was related positively with average temperature at the beginning of growth, but average monthly amounts of precipitation were vice versa. These results mean that ecological functions of urban forest in Seoul Metropolitan City are affected by climate change in recent years. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (No. NRF-2018R1A2B5A01021358) and Research on Ecosystem Climate Change (NIE-Based Research-2018-21) funded by National Institute of Ecology.

D6q: FOREST AND ECOSYSTEM SERVICES IN CITIES: ACHIEVEMENTS AND EXPECTATIONS

Epitaph: the forest leaves the city?

Júlia Senra¹, Bernardo Gontijo¹

¹*Universidade Federal de Minas Gerais, Belo Horizonte, Brazil (juliabenficas@gmail.com; gontijobm@yahoo.com.br)*

Mata da Izidora (Izidora Woods) is a threatened urban forest located in Belo Horizonte, Brazil. It is the most extensive remnant of vegetation of this municipality that is not a protected area, covering an approximate area of 10,000,000 m², with a biodiversity relative to the Atlantic Forest and Brazilian Savanna Biomes. It is susceptible to complex interactions inside and outside its boundaries. In its interior, there are particular rural properties, one quilombola community and three urban occupations. In addition to the internal interactions that influence the local dynamics, the interests of the public power and the real estate sector should also be taken into account. This study's main aim was to "identify possibilities for the survival of urban forest fragments through social appropriations". In order to achieve this objective, we sought to extensively present the addressed issue through documents, reports, maps, figures, semi-structured interviews and poetry. In this scenario, a problematization of the reality of space were carried out with the data obtained, in order to analyze the motivations for social coexistence or not with Mata da Izidora. As a result of the possibilities identified, this work recommended the creation of a conservation unit as an alternative to reconcile some of the yearnings for the area, corresponding to category VI "Protected area with sustainable use of natural resources" of the IUCN Protected Area Categories System. This work intends to contribute to the discussions on urban forest fragments and with other possibilities for the coexistence between nature and city.

Tourist uses of urban green infrastructure in Europe: a cross-cultural study

Theano Terkenli¹, Simon Bell², Ivana Zivojinovic³, Jelena Tomicevic⁴, Thomas Panagopoulos⁵, Inga Straupe⁶, Oliver Toskovic⁷, Katarina Kristianova⁸, Lina Straigyte⁹, Liz O'Brien¹⁰

Urban landscapes are often determined by their green areas, which fulfil various needs of both inhabitants and visitors, hence urban green infrastructure (UGI) has a highly potential role in city branding. This research contributes to knowledge regarding trends of tourists' uses of UGI in Europe. In order to achieve a broader applicability of the study, a cross-cultural approach was adopted and carried out with the aid of face-to-face interviews with foreign tourists in the Czech Republic, Greece, Latvia, Lithuania, Portugal, Serbia, Slovakia and United Kingdom. The study research questions addressed tourists' perceptions, understanding and uses of UGI, and the ways that this understanding influences tourists' choice of visiting a certain city. The selection of case studies follows a roughly comparative logic, namely on-site questionnaire surveys administered in large and medium size cities in these Southern, Central and Northern European countries. In the context of a series of very interesting findings responding to our study's research questions, our results show that tourists visiting Northern and Central European cities show more interest in and intention to visit UGI, than tourists visiting Southern European cities. Such north-south differences emerged concerning more than one of our study variables, including willingness to pay for the use of UGI, thus opening up a broad field for data interpretation and discussion, which helps in understanding how tourists view, use, benefit from, and impact UGI. This may support future improvement of UGI planning and management, and strengthen the role of UGI in cities tourism development.

Urban residents' preferences of ecosystem services of urban forests: the case of Beijing

Zhi-Ying Han¹, YOUN Yeo-Chang¹, Mi Sun Park¹

¹*Seoul National University, Seoul, Korea, Republic of (335640510@qq.com; youn@snu.ac.kr; mpark@snu.ac.kr)*

This paper aims to investigate the Beijing citizens' preferences over various options of urban forest management strategies. The literature review and expert Delphi method were employed to rank the importance of 18 ecosystem services (ESs) and to classify the ecosystem services of urban forests into 6 categories: (1) fresh water, (2) noise reduction, (3) moderation of extreme events, (4) air quality regulation, (5) species diversity and wildlife habitat, and (6) recreation and spiritual experience. The main choice experiment survey was conducted by interviewing Beijing citizens who have visited any one of the urban forests located in Beijing. The results are as follows: Firstly, the air quality regulation ES was considered as the most influential service received from urban forest for citizens. They were willing to pay 85~264 RMB/year to invest in urban forest expansion for improving air quality. In addition, they regarded the fresh water as the second-most important ES. Secondly, citizens with high monthly household income were more willing to pay for urban forest ESs. Thirdly, apartment owners were willing to pay municipality tax more compared to non-apartment owners. Fourthly, citizens emotionally connected to Beijing tend to willing to pay more municipality tax. The results indicate that citizens are willing to pay a higher tax for supporting urban forestry for air quality improvement. This research suggests for urban environmental policy makers in Beijing to pay more attention to air quality regulation function of forests when designing and managing urban forests to satisfy its visitors' preferences and improve citizens' welfare.

Perception of ecosystem services in urban green areas of Curitiba, Brazil

Alessandro Panasolo¹, Franklin Galvão¹, Hermes Yukio Higachi², Edilson Batista de Oliveira³, Fernando Campos de Oliveira⁴, Carlos Augusto Wroblewski¹
¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade Estadual de Ponta Grossa, Ponta Grossa, Brasil; ³Embrapa Florestas, Curitiba, Brasil;
⁴Fundação Botânico, Curitiba, Brasil (apanasolo@gmail.com; fgalvao@ufpr.br; hhigachi@uepg.br; edilson.oliveira@embrapa.br; fercampos@gmail.com; carloswroblewski@ufpr.br)

This present research aims to identify the ecosystem services (SE) of urban green areas of Curitiba, capital city of Paraná, Brazil. Using an exploratory method, a qualitative research was carried out with specialists in the environment through the Ecosystem Services Review (ESR) tool, in order to identify the most important SEs related to the generation of socioeconomic well-being. The study sites are representative of the main geographic and phytophysiognomic contexts of the city, which together accumulate a total of 40 protected hectares, encompassing a fragment of Mixed Ombrophilous Forest, as well as the last remnants of Steppes of Curitiba. It is possible to conclude that the ecosystem services studied, especially those identified as more relevant, should be carefully observed and incorporated into the management of urban green areas. In addition, it was possible to identify which SEs are considered irreplaceable, in the case of suppression of green areas.

Urban high voltage power line right of way and urban forests: conflict or harmony?

Paulo Guilherme Molin¹, Frederico Tomas de Souza e Miranda², Nathalia Veloso Aguiar¹, Girlei Costa da Cunha², Luciana Cavalcante Pereira³, Luiz Eduardo R. C. Rielli⁴, Guilherme Bazan⁵, Giulio Bossi Santoro¹
¹Universidade Federal de São Carlos, CCN, Buri, Brasil; ²Biodendro, Piracicaba, Brasil; ³Nace Pteca, Piracicaba, Brasil; ⁴NOVi Soluções Socioambientais, São Paulo, Brasil; ⁵ISA CTEEP, São Paulo, Brasil (pgmolin@ufscar.br; fredtsmiranda@gmail.com; https://app.oxfordabstracts.com/dashboard; girlei.cunha@biodendro.com.br; lcavalpereira@gmail.com; luiz.rielli@noviconsult.com.br; gbazan@isactcep.com.br)

The irregular occupation of high voltage power line right of ways is a reality in multiple countries, especially in metropolitan areas. In Minas Gerais, Brazil, there are estimates of nearly 80.000 people living in these right of ways. Irregular occupation causes hazards not only for the population living in these areas, but are also a conflict for the concession companies that depend on these areas for access, repairs and maintenance. The occupation problem needs to be treated with multiple solutions, including prevention of new occurrences through sustainable land uses and practices. One of the sustainable management models proposed is implementing urban forests along the right of way, not only increasing ecological corridors and landscape connectivity in urban landscapes but also increasing quality of life for the population. The problem encountered in this solution is the conflict between power lines, vegetation height, legislations and standards. We present an overview of the conflicts, harmonies and synergies that exist in Brazil and other countries with similar cases. We also make a diagnostic of São Paulo metropolitan area and the concession lines of ISA CTEEP. Finally, we propose a regional zoning where urban forests could be implemented and the probable social and environmental gains.

Valuing green urban areas in the Polytechnical Campus to develop an urban forestry plan for the UFPR campi / Valoração de áreas verdes urbana no campus Centro Politécnico, para a elaboração do plano de arborização dos campi da UFPR

Vitória Maria Bisewski¹, Carla Maria Camargo Corrêa¹, Priscila Caldas¹, Rodrigo Dall'agnol Trompczynski¹, Leonardo Rogal¹
¹Universidade Federal do Paraná, NIMAD, Curitiba, Brasil (vibisewski@gmail.com; cmcamargocorrea@gmail.com; priscilacaldass@gmail.com; rtrompczynski@gmail.com; leonardorogal98@gmail.com)

Este trabalho avaliou a importância da arborização no campus Centro Politécnico, foi realizado uma revisão bibliográfica e um estudo de caso, com aplicação de um questionário de sensibilização com o propósito de conhecer o perfil da comunidade acadêmica e transeuntes que frequentam o *campus*. Foram avaliados os seguintes parâmetros: gênero, idade, estado civil, escolaridade, profissão, tipo de relacionamento com a instituição, forma de deslocamento até a instituição, tempo de permanência, assim como informações pertinentes a arborização urbana, como: qual a importância da arborização nos *campi*, qual a importância de um programa de educação ambiental nos *campi*, qual a importância da arborização na qualidade de vida, além de um espaço destinado a sugestões. Os resultados representam cerca de 1% da comunidade acadêmica (333 avaliações), onde foi constatada a predominância do gênero feminino, em comparação ao gênero masculino, a faixa de idade variou entre 20 e 30 anos representando cerca de 60%, o estado civil da população avaliada é predominantemente solteiro e cerca de 50% tem como grau de escolaridade a graduação, desse montante 72% são alunos, que utilizam automóvel particular ou coletivo como forma de deslocamento até a instituição, o tempo de permanência na instituição varia de 20 a 40 horas. Quanto às questões relacionadas à arborização urbana: cerca de 85% considera muito importante a arborização nos campi associado a implementação de programas de educação ambiental e 94% considera muito importante a arborização urbana para a qualidade de vida. Principais sugestões: substituição de espécies exóticas por nativas e por frutíferas.

Quality index for urban green spaces (IQAVU) / Índice de qualidade das áreas verdes urbanas-IQAVU

Silvia Méri Carvalho¹ , Dulcina Aquino Hernandez de Oliveira Queiroz¹
¹Universidade Estadual de Ponta Grossa, Ponta Grossa, Brasil (silviameri@brturbo.com.br; dulcinah@gmail.com)

Nos cenários urbanos dos dias atuais, um dos problemas que mais preocupam governos, empresas, meio acadêmico, instituições globais e a comunidade de forma geral é a escassez de elementos naturais nos ambientes urbanos. Uma maneira de combater esse problema consiste em considerar as áreas verdes como elemento integrante do processo de planejamento das cidades. A qualidade das áreas verdes em um determinado espaço urbano é diretamente influenciada pelos atributos incluídos em cada função, os quais são importantes provisões de bens e serviços (BOLUND; HUNHMMAR, 1999; YOUNG, 2010). A avaliação de áreas verdes urbanas é útil para a análise do nível de sustentabilidade das cidades, sendo que um dos desafios consiste em identificar as diferentes funções das áreas verdes a fim de avaliar de forma equitativa e integrada a qualidade desses elementos em ambientes urbanos. Nesse sentido, o presente trabalho apresenta o Índice da Qualidade das Áreas Verdes Urbanas (IQAVU), que avalia a qualidade das mesmas em ambientes urbanos por meio de uma média geométrica entre indicadores das funções Social, Ambiental e Estética. Portanto, uma área verde urbana com deficiência em ao menos uma de suas funções, não pode ser considerada uma área verde funcional. Pretende-se que a aplicação do índice seja possível a qualquer área urbana, independente da realidade demográfica, geográfica ou política. O cálculo do IQAVU, realiza-se mediante à aplicação de uma média geométrica, onde as três funções das áreas verdes tornaram-se subíndices, caracterizadas por um conjunto de indicadores a elas associadas.

Getting real: the costs and benefits of urban forests and flow of ecosystem services in dynamic environments: who should pay? Insights from a multidisciplinary dialogue

Sandra J. Velarde¹, Lisa Sharma-Wallace², Marie McCarthy¹, Andrea Stocchero¹, Karen Bayne³, Robert Radics³, Emily Telfer¹, Georgia Garrard⁴, Wendy Jackson⁵, Asenaca Nawaqalevu⁶, Alan Leckie³, Richard Yao¹

Our cities are rapidly changing. Urban planners need to adapt to the new demands posed by a constantly evolving social fabric. People living in cities increasingly have a transient and mobile lifestyle within the ‘gig economy’ creating disruption to sense of place and ‘ownership’ of the urban environment. In this context, integrating nature into cities brings up unique challenges that need to respond to these evolving needs. In 2018, we held a multidisciplinary dialogue to explore practical examples of the process of greening cities in the Oceania region and around the world. We brought together local government officials, urban planners, economists, architects, urban foresters, ecologists, biologists, conservationists, geneticists, policy experts and community engagement specialists to explore the costs and benefits of ‘urban green spaces’ including forests and their ecosystem services. We discussed the emerging issues of ‘biodiversity sensitive’ urban design, urban planning in space-constrained areas and urban green sacred spaces. Participants highlighted the need for reconnecting people with nature, and how urban green spaces could provide these opportunities so that people benefit from forests and their ecosystem services in cities. While successful examples of integration of nature into cities highlight measurable benefits such as increased environmental sustainability, lifestyle affordability and quality of life, including mental health, integrating nature into cities come at a cost as well. This paper also reports insights into who should pay to make forests and their ecosystem services available for people in a world of rapid change.

planejamento florestal de grande teor digital, são as aeronaves remotamente pilotadas (RPAs) ou mais conhecidas como *drones*. O manejo de precisão de florestais tropicais na Amazônia também acompanha a nova geração tecnológica, contemplando para isso: os inventários florestais semiautônomos a partir de RPAs, GNSS pós-processado e uso de algoritmos para segmentação e geolocalização automática de árvores. O objetivo do trabalho foi propor um calendário preliminar de inventário florestal com uso de RPAs (classe III), contemplando as árvores codominantes e dominantes, acima de 50 cm de DAP1,3m. O mapeamento da cobertura florestal a partir de ortofotos de alta resolução (< 7 cm) será uma etapa que deverá preceder a entrada da equipe de inventário em campo. Dessa maneira, a equipe de inventário florestal iniciará seus trabalhos com a geolocalização precisa de todas as árvores dominantes, facilitando significativamente a busca por espécies de interesse. O trabalho foi na reserva florestal da Embrapa Acre, na Amazônia Brasileira, com a RPA DJI P4Pro, por meio de voos semiautônomos. Para segmentação foram testados diversos parâmetros utilizando o algoritmo GEOBIA. O acompanhamento mensal da floresta a partir de ortofotos de alta resolução, possibilita traçar um perfil modal preliminar das fenofases de cada uma das 14 espécies estudadas, demonstrando assim a viabilidade do inventário automatizado com as RPAs.

D7b: BIODIVERSITY, BIOTIC INTERACTIONS AND THREATS TO FOREST ECOSYSTEM SERVICES ASSOCIATED WITH TREE REPRODUCTIVE STRUCTURE INSECTS AND PATHOGENS IN A CHANGING WORLD

Variation in cone crop, trap catch and density of larvae between orchards and years: a challenge for Integrated Pest Management

Olle Rosenberg¹

¹Skogforsk, Uppsala, Sweden (olle.rosenberg@skogforsk.se)

For some years, Integrated Pest Management (IPM) has been obligatory for controlling pests. This means that countermeasure decisions against pests should be based on e.g. monitoring in the field to avoid unnecessary treatments. In Sweden, synthetic sex pheromones are available for monitoring of male lepidopteran pest species in Norway spruce seed orchards. During a study period of four to five years, cone crop was estimated and trap catches and larvae in cones counted in two different seed orchards. The preliminary results demonstrated a great variation in both cone crop and insect density between years, and between seed orchards within a year. Low trap catches and a relatively high number of larvae found implies that trap catch may not be a reliable method for decision of pest management actions.

Pheromones for monitoring and control of insect pests in spruce seed orchards

Olle Anderbrant¹, Olle Rosenberg², Hong-Lei Wang¹, Erling V. Jirle¹, Ilme Liblikas³, J. Michael Chong⁴, Christer Löfstedt¹, Glenn P. Svensson¹

¹Department of Biology, Lund University, Lund, Sweden; ²The Forestry Research Institute of Sweden, Skogforsk, Uppsala, Sweden; ³Institute of Technology, University of Tartu, Tartu, Estonia; ⁴Department of Chemistry, University of Waterloo, Waterloo, Canada (olle.anderbrant@biol.lu.se; olle.rosenberg@skogforsk.se; hong-lei.wang@biol.lu.se; erling.jirle@biol.lu.se; ilme.liblikas@ut.ee; jmchong@uwaterloo.ca; christer.lofstedt@biol.lu.se; glenn.svensson@biol.lu.se)

The production of high quality trees, adapted to local environments, requires reliable access to seeds from selected clones. Seed production for some species, notably Norway spruce, *Picea abies*, is especially challenging due to irregular flowering and fungal and insect pests destroying or consuming the seed yield. Some of the insects spend much of their life inside the cones, well protected from chemical or biological pesticides. For these species the use of pheromones or possibly kairomones might contribute to reduced damage and higher seed yield. The female produced sex pheromones have been identified for three moth species, *Cydia strobilella*, *Dioryctria abietella* and *Eupithesia abietaria*. The two former pheromones are used commercially for monitoring and experimentally for mating disruption in spruce seed orchards in Sweden. Pheromone traps are useful for determining flight periods, but catches are not yet able to reliably mirror or predict the population size or future damage. However, improved methodology and longer data series might generate valuable results in the future. The sensitive traps can also be essential for locating pest-free areas for site selection of future seed orchards and for quarantine purposes. Mating disruption attempts have shown mixed results and a number of improvements related to formulation and application of the compounds will be suggested.

Genotypic diversity and reproductive biology of *Thekopsora areolata*, the causal agent of cherry spruce rust in Norway spruce seed orchards

Hernán Capador¹, Berit Samils¹, Juha Kaitera², Åke Olson¹

¹Swedish University of Agricultural Sciences, Uppsala, Sweden; ²Natural Resources Institute Finland, Oulu, Finland (hernan.capador@slu.se; berit.samils@slu.se; juha.kaitera@slu.se; ake.olson@slu.se)

Swedish forestry is sustained by planting about 200 million Norway spruce (*Picea abies*) seedlings every year. Most of these seedlings come from seeds orchards, which have been established to transfer the genetic gain in growth and yield achieved through plant breeding since the 1940s. However, today there is a deficit of seeds coming from Swedish seed orchards because of irregular flowering and cone set, but also due to pest and pathogen infections such as *Thekopsora areolata* - the causal agent of cherry spruce rust, a fungus that reduces significantly seed production in Fennoscandia. To investigate the reproduction mode and population structure of the pathogen, newly developed microsatellite markers and a hierarchical sampling strategy were used. From one location in Norway, one location in Finland and five locations in Sweden, one aecium per infected cone was analysed. In addition, multiple aecia per scale and cone were sampled at two locations in Sweden. The results show an over-all high genotypic diversity, at country and location levels no genetic structure was found which indicates high gene flow and random mating in *T. areolata*. At the cone/scale level multiple identical genotypes were found and non-random mating was observed. These results suggest that *T. areolata* has long distance spore dispersal in Fennoscandia with common recombination events and clonal or vegetative spread in cones and scales.

Disease problems in seed, seedling and plantation of *Dalbergia oliveri* Gamble ex Prain in Myanmar

Wah Wah Linn¹, Wai Wai Than¹

¹Forest Research Institute, Nay Pyi Taw, Myanmar (wahwahlinn48@gmail.com; waiwaiyaw2007@gmail.com)

The Rose Wood, *Dalbergia oliveri* Gamble ex Prain, is popular in the markets, very good price in furniture due to the good color and very hard. Nowadays, it is one of the CITES species as an endangered (IUCN Red List Nghia, 1998). Previously, the disease problems are not studied yet not only in Myanmar but also in the growing regions, therefore it was conducted in 2016. Objective was: preliminary study the disease problems in seed, seedling and plantation of *Dalbergia oliveri* Prain. Five study sites were surveyed and recorded of symptoms. In the laboratory, disease isolation, identification, and disease occurrence using the formula: disease occurrence % = $n / N \times 100$ (Mao, 1996). About dead trees 47.4% in Moe Nyin Tamalan Plantation, 18.86% in the Katha Tamalan Plantation, 6.2% in Katha Nursery; and 3.8% in Yezin Nursery were found. Symptoms necrosis, tar spot, dieback, yellowing, were observed. Pathogenicity were found *Rhizotonia solania* in Necrosis of leaf; *Cladosporium sp.* in tar spot of leaf; *R. solania*, *Cladosporium sp.* in dieback of shoot tip; *Perithecia sp.*, *Pythium sp.*, *Caldosporium sp.*, *R. solania* from leaf and, *Fusarium sp.* from root in yellowing of leaf. Dieback was the most occurrences and serious among the four common diseases and found larva of beetle borer insect infestation. This preliminary study is just information and probably to approach application treatments for future rose wood plantation.

Beekeeping: a source of income and sustainable development in the Ntacuja community in the Niassa National Reserve, Mozambique / Apicultura: fonte de renda e desenvolvimento sustentável na comunidade de Ntacuja - Reserva Nacional do Niassa

Felipe André Angst¹, Vitalina Temporário¹

¹UCM, Lichinga, Mozambique (fangst@ucm.ac.mz; vtemporario@ucm.ac.mz)

As comunidades que residem dentro e na zona-tampão da Reserva Nacional do Niassa (RNN) na busca de meios alternativos de fontes de rendimento tem efetuado práticas prejudiciais ao meio ambiente que influenciam na redução da biodiversidade condicionada pelo desflorestamento, caça furtiva, mineração ilegal (garimpo) e pelas queimadas descontroladas. Com isso a Universidade Católica de Moçambique – Faculdade de Gestão de Recursos Florestais e Faunísticos esta a implementar o Projeto “Apicultura Sustentável - Mel 100% Puro” na comunidade de Ntacuja dentro da RNN na tentativa de oferecer meios alternativos sustentáveis de fontes de rendimento visto que as abelhas, símbolo do desenvolvimento sustentável, são “parceiros estratégicos” na manutenção da biodiversidade devido a sua capacidade polinizadora e mantenedora de espécies naturais. A pesquisa tem como objetivo identificar e analisar os resultados alcançados pelo projeto a nível florístico e socioeconômico em Ntacuja-RNN. Será feito um levantamento fitossociológico da estrutura horizontal, vertical e da regeneração natural da espécie em 40 parcelas de 10 m x 10 m, distribuídas nos dez (10) apiários do projeto (quatro para cada) e serão analisados o índice de desenvolvimento humano e o índice de condições de vida dos beneficiários a fim de se obter-se mudanças da composição florística bem como das condições de vida dos beneficiários do projeto.

Simulating wind and bark beetle disturbances in Austrian Forests

Werner Rammer¹, David Leidinger², Herbert Formayer², Manfred J. Lexer²

¹University of Natural Resources and Life Sciences, Vienna, Austria; ²University of Natural Resources and Life Sciences, Vienna, Austria (werner.rammer@boku.ac.at; david.leidinger@boku.ac.at; herbert.formayer@boku.ac.at; mj.lexer@boku.ac.at)

In European forests disturbances cause substantial damage to timber stocks. In Austria between 20-50% of annual harvests are triggered by disturbances. By far the most important disturbance agents are wind and bark beetles. Under climate change disturbance regimes are expected to intensify. Emerging disturbance regimes not only will affect future forest composition and structure but also the provisioning of ecosystem services. In order to project impacts on forests and related ecosystem service provisioning forest ecosystem models are inevitable tools for simulation-based impact assessments and adaptation planning. So far, weak point of many climate change impact assessments in forestry has been the lack of consistent inclusion of disturbance regimes. In this study we present the simulation of timber damaged by wind and bark beetles in Austria in the period 2003-2015 by linking a state-of-the-art dynamic forest model, including interacting disturbance modules for wind and bark beetles, with weather data at 1x1 km spatial resolution. Simulated damages are compared with data from the Austrian Forest Damage Monitoring System which records damages by disturbance agent at the resolution of 70 Austrian administrative districts. We describe the simulation setup of 4 mill ha forest land paying particular attention to (i) the interacting disturbance modules for wind and bark beetles, (ii) providing the initial forest state in 2003 based on data of the Austrian National Forest Inventory, and (iii) the use of weather data including wind gust speed to drive the simulations. Pattern of deviances between simulations and observations are explained by ecological and socio-economic attributes.

Improved forest insect outbreak modeling under climate variability

Steve McNulty¹, John Cobb III¹, Ge Sun¹

¹USDA Forest Service, Research Triangle Park, USA (smcnulty@fs.fed.us; jgcobb@fs.fed.us; gesun@fs.fed.us)

The Southern pine beetle (*Dendroctonus frontalis*, SPB) is a major commercial pest across the southeastern United States (US). The insects target highly valuable southern pine species including loblolly pine (*Pinus taeda*). Beetle Outbreaks are episodic with many years between major population increases. A rapid response of cutting and burning infected trees is the best control measure for reducing the outbreak severity, and a model to predict outbreaks would assist in the budgeting and personal planning for beetle control. Therefore, this study used combination of southern pine beetle survey data, US Forest Service Forest Inventory and Assessment Data, gridded historical climate data, National Oceanographic and Atmospheric Administration (NOAA) short term climate prediction forecasts, Coupled Model Intercomparison Project Phase 5 (CMIP 5) long-term climate change scenarios, and the WASSI Hydrologic Model to develop a southern pine Beetle Outbreak Model (BOM). Using previous years beetle location, stand density, adjacency to other counties with beetle outbreaks, maximum monthly air temperature and estimated stand evapotranspiration, BOM predicted 67% of interannual variability in SPB outbreaks when model predictions were compared to reserved outbreak data not used in model development. The validated model was then used with short- and long-term climate forecasts to predict annual outbreak locations and to examine the impact of long-term climate change on SPB populations across the southeastern US. This paper will discuss the model and implications for its use.

D7c: BIOLOGICAL INVASIONS, BIODIVERSITY AND ECOSYSTEM SERVICES - 1

Regional impacts of forest insect and disease invasions on forest carbon loss

Andrew Liebhold^{1,2}, Songlin Fei³, Randall Morin⁴, Christopher Oswalt⁵

¹USDA Forest Service Northern Research Station, Morgantown, USA; ²Czech University of Life Sciences, Prague, Czech Republic; ³Purdue University, West Lafayette, USA; ⁴USDA Forest Service Northern Research Station, Newtown Square, USA; ⁵USDA Forest Service Southern Research Station, Knoxville, USA (aliebhold@gmail.com; sfei@purdue.edu; rsmorin@fs.fed.us; coswalt@fs.fed.us)

Worldwide, forests are increasingly affected by non-native insects and diseases, some of which cause substantial tree mortality. Forests in the USA have been invaded by a particularly large number (>450) of tree-feeding pest species. While information exists about ecological impacts of certain pests, a region-wide assessment of the composite ecosystem impacts of all species is lacking. Here we analyze 92,978 forest plots distributed across the USA to estimate carbon loss associated with elevated mortality rates caused by the 15 most damaging non-native forest pests. We find that these species caused an additional (above background levels) annual tree mortality rate of 7.48 TgC/yr, which is comparable to annual carbon emissions from 5.9 million automobiles or 25.2% of all wildfires in the USA. In addition, 41.1% of total live forest biomass in the USA are at risk to loss from these 15 pests. These results indicate that forest pest invasions, driven primarily by globalization, are casting a huge risk to forests in the USA and have significant impacts on carbon dynamics.

Eucalypt insect pests in Africa: spread, threats and opportunities for management

Brett Hurley¹, Mesfin Wondafra^{1,2}, Michelle Schröder¹, Gudrun Dittrich-Schröder¹, Caitlin Gevers¹, Samantha Bush¹, Bernard Slippers³

¹Department of Zoology and Entomology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²School of Plant Sciences, Haramaya University, Dire Dawa, Ethiopia; ³Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa (brett.hurley@fabi.up.ac.za; mesfin.gossa@fabi.up.ac.za; michelle.schroder@fabi.up.ac.za; gudrun.dittrich@fabi.up.ac.za; caitlin.gevers@fabi.up.ac.za; samantha.bush@fabi.up.ac.za; bernard.slippers@fabi.up.ac.za)

Native to Australasia, Eucalyptus is one of the most planted genera of trees in the world. These trees provide an important socio-economic role in many countries of sub-Saharan Africa, providing fuel and fibre and supporting a diverse range of stakeholders. However, the sustainability of Eucalyptus as a plantation species is challenged by the introduction of Eucalyptus-feeding insects from Australia that have become serious pests in their invasive range. We provide a summary of current and ongoing studies to better understand this threat and investigate suitable management responses. A recent survey across 14 countries in sub-Saharan Africa showed a broad distribution of many of the major insect pests. Analysis of genetic diversity indicated a common origin of geographically distant populations for some of these insects, whereas high diversity and even distinct lineages were present for other species. Screening trials and field surveys have indicated high variation of susceptibility between host species for some of the insect pests. Survey data has also confirmed the establishment of released biological control agents. In addition, the occurrence of natural enemies unintentionally introduced and native parasitoids expanding their host range to these invasive insects have been reported. Ongoing research is continuing to increase our understanding on host resistance and biological control approaches for these pests, and to investigate other opportunities for their management. Efforts are also being made to facilitate exchange of information and collaboration between countries in the region on issues pertaining to invasive species.

Spatial patterns of discovery points and invasion hotspots of non-native forest pests

Samuel Ward¹, Songlin Fei¹, Andrew Liebhold²

¹Purdue University, West Lafayette, USA; ²USDA Forest Service, Morgantown, USA (ward225@purdue.edu; sfei@purdue.edu; aliebhold@gmail.com)

Establishments of non-native forest insects and pathogens continue to increase worldwide with intensification of invasion pathways. Quantifying spatiotemporal patterns in establishment locations and subsequent invasion dynamics may provide insight into the underlying mechanisms driving invasions and assist biosecurity agencies with prioritizing areas for proactive surveillance and management. Using locations of first discovery and county-level occurrence (presence/absence) data for 101 major non-native forest insects and pathogens across the contiguous USA, we (1) quantified spatial patterns in discovery points and county-level species richness and (2) identified environmental correlates of these observed spatial patterns. We found that discovery points were highly aggregated in space and located in areas with high densities of ports and roads. Though concentrated in the northeastern USA, discovery points occurred farther west and became less aggregated as time progressed. Invasion richness was statistically higher in several counties in the northeast. However, patterns of discovery points and invasion richness varied substantially among pest origins (i.e., world region of pests' native ranges) and pest feeding guilds. Significant variation in invasion richness was attributable to patterns of first discovery locations. Our results indicated that spatiotemporal variability in the intensity of invasion pathways has resulted in marked geographical patterns of establishment and contributed to current macroscale patterns in invasion richness in the USA.

Tracing the role of human civilization in the globalization of plant pathogens

Alberto Santini¹ , Andrew Liebhold², Duccio Migliorini¹, Stephen Woodward³

¹Institute for Sustainable Plant Protection – C.N.R., Sesto fiorentino, Italy; ²US Forest Service Northern Research Station, Morgantown, USA; ³University of Aberdeen, Department of Plant and Soil Science, Institute of Biological and Environmental Sciences, Aberdeen, United Kingdom (alberto.santini@cnr.it; aliebold@fs.fed.us; duccio.migliorini@ipspp.cnr.it; s.woodward@abdn.ac.uk)

The last three decades have witnessed a flood of invasive plant pathogens appearing around the world. It is accepted that 1500 CE is a starting date for anthropogenic biological invasions; however prehistoric findings and historical reports suggest an earlier connection between human migration and movement of invasive plant pathogens. Pathogens have several pathways of entry into new environments, the great majority of which are human mediated. The fossil record provides evidence that diseases commonly affected plants some 250 million years ago. In the last 200 years the incidence of diseases affecting plants has increased exponentially in terms of both numbers and severity. Most of newly emerging plant diseases arose following the introduction of exotic pathogens into a new environment. The introduction of alien pathogens can lead to novel host-pathogen associations or indeed novel pathogen-pathogen combinations, for which there is no previous co-evolutionary history. Technological developments have facilitated trade in goods, and a consequent transport of pathogens. Historical geopolitics and regulation of trade have influenced the establishment of pathogens in different world regions. Here we provide an analysis of this phenomenon focusing on the means of introduction of these organisms, which generally can be attributed to technological developments, human behaviour and government policies. Developing an in depth understanding of the historical context of these invasions could reduce the rate of future invasions leading to significant impacts on economics, ecology and on human health and wellbeing.

Using interception and establishment data to reconstruct invasions of bark and wood boring beetles

Eckehard Brockerhoff¹, Rebecca Turner², Andrew Liebhold^{3,4}

¹Swiss Federal Institute WSL, Birmensdorf, Switzerland; ²Scion (New Zealand Forest Research Institute), Christchurch, New Zealand; ³USDA Forest Service Northern Research Station, Morgantown, USA; ⁴Czech University of Life Sciences, Prague, Czech Republic (eckehard.brockerhoff@gmail.com; rebecca.turner@scionresearch.com; aliebold@gmail.com)

Invasions of forest insects can have severe environmental and economic consequences. Although actual invasion events of insects are very rarely observed, and most invasions are only detected years later when incipient populations are larger, analysis of border interception and establishment data can provide valuable information about insect invasion processes. Interception data can be used as a proxy of arrival rate, a key driver of invasions. We used interception and establishment data from New Zealand, the USA and other countries to illustrate their usefulness for documenting the role of propagule pressure in invasions, temporal and geographic patterns of interceptions and establishments, and bridgehead effects (i.e., invasions originating not from the native region of an invasive species but from other invaded regions). Our analyses focus mainly on bark and wood boring beetles (Scolytinae, Cerambycidae, and Buprestidae) as these taxa are comparatively well-known and interceptions are often documented at the species level which allows more conclusive analysis. We will also discuss the reasons why interception data may be less informative for some taxa to illustrate how future gathering of interception data could be improved to provide better data for future assessments of invasion risks and processes.

Impacts and management cost of pine invasions in Patagonia

Martin Nuñez¹, Romina Dimarco², Yamila Sasal³, Carolina Quintero³, M. Noelia Barrios Garcia³, Mauro Sarasola⁴, Juan Pablo Diez⁴, Andres S. Martinez Von Ellrichshausen², Mariano Rodriguez Cabal⁵, Juan Paritsis³

¹Universidad del Comahue/CONICET, Bariloche, Argentina; ²INTA/CONICET, Bariloche, Argentina; ³CONICET, Bariloche, Argentina; ⁴INTA, Bariloche, Argentina (nunezm@gmail.com; rominadimarco@gmail.com; shamilacony@gmail.com; quintero.carolina@gmail.com; x@eee.edu; sarasola.mauro@inta.gob.ar; diez.juan@inta.gob.ar; andmarv77@gmail.com; rodriguezcabal@gmail.com; j.paritsis@gmail.com)

Forestry plantations with nonnative species is an important economic resource in many parts of the world, but these plantations can generate environmental problems. One of these problems is the invasions in neighboring communities. Here we study the impacts of Lodgepole pine (*Pinus contorta*) invasion, probably the most invasive forest species in the southern hemisphere. We analyzed its impact on biodiversity, ecosystem services, and fuel load. We compared non-invaded zones with invaded zones of contrasting densities, and areas where invasive trees had been removed. We also evaluated the costs of pine invasion removal. We found that *Pinus contorta* has a high impact only when it reaches high densities. This gives some hope because it indicates that there is a relatively long period (10 years from the beginning of the invasion) during which appropriate management should be conducted. Removing pine invasions was very effective to reduce fire risk. However, after one year the removal of pines did not result in improvements in biodiversity indices or ecosystem services metrics. Post-removal sites in areas with previous high pine density were colonized by nonnative plants. Control costs grew with the increase in density of pines. Our results show that if managers focus on early interventions, numerous environmental impacts can be avoided and the costs of invasion management will be reduced. However, if forestry practices continue to ignore invasions, environmental impacts may reach an unprecedented level given the high probability of future pine invasion in the Southern hemisphere.

(Towards) a global strategy for invasive alien trees

Giuseppe Brundu¹, Anibal Pauchard², Petr Pyšek³, David M. Richardson⁴

¹Department of Agriculture, University of Sassari, Sassari, Italy; ²Laboratorio de Invasiones Biológicas, Facultad de Ciencias Forestales, Universidad de Concepción, Concepción, Chile; ³Institute of Botany, Department of Invasion Ecology, The Czech Academy of Sciences, Průhonice, Czech Republic; ⁴Centre for Invasion, Biology, Department of Botany & Zoology, Stellenbosch University, Stellenbosch, South Africa (gbrundu@iit.it; pauchard@udec.cl; petr.pysek@ibot.cas.cz; rich@sun.ac.za)

Forests, woodlands and plantations are among the world's most productive land-based ecosystems and are essential to life on earth and for providing a plethora of ecosystem services. We argue, however, that a significant number of alien tree species (apart from suffering from invasive alien pests) are invasive or might become invasive – i.e. they spread from planting sites into adjoining areas, sometimes causing substantial damage to biodiversity and ecosystem services. The challenge is to manage alien trees and existing and future planted forests of alien trees to maximize current benefits and opportunities, while minimising risks and negative impacts, without compromising future benefits and land uses. Besides their use in provenance trials and planted forests, alien trees have been and are introduced and used for multiple reasons, such as gardening and landscaping, protective functions, arboreta, erosion protection, soil phytoremediation and for increasing the forest area through afforestation of abandoned or derelict land. The notion that forested areas are of major conservation and societal value over treeless environments has halted efforts to control invasive tree species. However, evidence is mounting that invasive trees can have major impacts on

biodiversity, ecosystem services with relevant economic costs. We suggest that the European Code of Conduct for Invasive Alien Trees could be a suitable discussion and working basis to implement a more general Global Strategy for Invasive Alien Trees. Such a Strategy would not just recognise that there is a global problem, but also call for best practices, innovative solutions and a better-coordinated global approach.

The presence of exotic tree species may not necessarily limit natural regeneration in tropical forest restoration

Nino Amazonas¹, Tiago Barreto¹, Paulo Sérgio Sampaio de Oliveira²

¹Fundação Espaço ECO, São Bernardo do Campo, Brazil; ²REVERDE, Guaratinguetá, Brazil (namazonas@gmail.com; tiagoebarreto@yahoo.com.br; reverdeguara@gmail.com)

When forest restoration started spreading in Brazil, species diversity was not a serious concern, nor was the exclusive use of native species. In that context, *Syzygium jambolanum* (Lam.) DC. was widely planted. Nowadays, eliminating exotic trees is an important component of management plans as it is a common belief that natural regeneration is limited by allelopathic effects or by characteristics of the leaf litter of exotic species. However, this limitation must be evaluated case by case. We are evaluating natural regeneration in a restoration project located in Guaratinguetá, São Paulo, in the Atlantic Forest of Brazil to test the hypothesis that *S. jambolanum* is hindering natural regeneration. We measured sapling density under the canopy of *S. jambolanum* and under native trees and used a general linear model to test if density was related to the canopy species, leaf litter thickness or forest age (older, intermediate and younger patches). In this first assessment, we found that sapling density was not influenced significantly by canopy species nor litter thickness. However, forest age was an important factor related to sapling density, with higher sapling density the older the patches, regardless of other factors tested. From our initial results, we suggest that management plans should be designed considering careful evaluations of the real impacts of tree species. In some cases, eliminating exotic species may be a disadvantage and other management measures, such as enrichment plantings, should be preferred instead. Moreover, we believe native species will gradually replace exotic trees when these start senescing.

D7D: COMPLEX INTERACTIONS OF MISTLETOE, ECOSYSTEMS, AND PEOPLE.

The cascade impacts of climate change could threaten key ecological interactions: insights from a keystone mistletoe

Francisco Fonturbel¹, Antonio Lara^{2,3}, David Lobos^{2,4}, Christian Little^{2,5}

¹Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile; ²Universidad Austral de Chile, Valdivia, Chile; ³Center for Climate and Resilience Research, Santiago, Chile; ⁴Fundación FORECOS, Valdivia, Chile; ⁵INFOR, Valdivia, Chile (francisco.fonturbel@pucv.cl; antoniolar@uach.cl; david.lobosvega@gmail.com; little.christian@gmail.com)

Climate change is triggering ecological responses all over the world as a result of frequent, prolonged drought events. The effects of climate change on species distribution and performance have been widely studied in the past decade, but its effects on ecological interactions remain little understood. However, the potential effects on ecological interactions, and particularly pollination and seed dispersal that play a key role in plant reproduction, may be compromising the future viability of many ecosystems. To gain insight into this issue we used a tripartite mutualistic interaction with a hemiparasitic mistletoe (*Tristerix corymbosus*), its pollinator (the hummingbird *Sephanoides sephaniodes*) and its disperser (the relict marsupial *Dromiciops gliroides*). We studied flower and fruit production, and visitation rates of the mutualist animals during average (2012) and dry (2015) austral summers. Drought in our study area affected precipitation and soil water availability. Although pollinator visits did not significantly differ in these summers, during the dry summer flower and fruit production experienced an important decline, as did seed disperser visits. Also, *T. corymbosus* mortality increased from 12% in 2012 to 23% in 2015. This empirical evidence suggests that the cascade effects of climate change may indirectly be hindering ecological interactions in the Valdivian temperate rainforest ecosystem we studied. Due to their specialized plant-animal and plant-plant interactions, mistletoes constitute a good study model for studies on climate change. Long-term research is essential to provide the knowledge necessary to understand how key ecological processes may be affected in a changing (and warming) world.

The African Mistletoe: from noxious weed to cure-all medicine: a synthesis of experience from empirical and indigenous knowledge domains

Ekeoba Matthew Isikhuemen¹, Musa Mohammed², Uche O. Olisaemeka¹

¹University of Benin, Benin City, Nigeria; ²Raw Materials Research and Development Council (RMRDC), Abuja, Nigeria (ekeoba.isikhuemen@uniben.edu; moh2musa@yahoo.com; ucheyonyi@gmail.com)

The term “African Mistletoe” is used for a group of woody hemi-parasitic plants that grow on, and obtain nourishment from shoot/branches of trees and shrubs. These parasites confer high nuisance value and cause serious damage to host plants resulting in economic and production losses. However, they are valuable in ethnomedicine – act as safety-net and/or booster to healthcare security for herbal medicine users. This paper examines the uses and phytochemical constituents of leaves of mistletoe obtained from selected trees/shrubs in Edo State, Nigeria. Data were collected through Key informants’ interview/questionnaire and laboratory investigations. The Result of socio-economic survey revealed that herbalists, vendors and dispensers/users treat diverse ailments (diabetes, hypertension, cancer, diuretic, ulcer, memory loss, inflammatory conditions, irregular menstruation, epilepsy, arthritis, etc.) with leaves of mistletoe. These are largely obtained from cultivated fruit- and wild trees/shrubs – *Azadirachta indica* L. (Neem), *Citrus sinensis* L. (Sweet Orange), *Spondias monbin* L. (Hog-plum), *Persea americana* (Mill.) (Avocado), *Psidium guajava* (Linn.) (Guava), etc. The outcome of laboratory analysis of mistletoe leaves and twigs of host plants revealed varying amounts of metabolites (alkaloid, anthraquinone, cyanogenic glycoside, flavonoid, phenol, saponins, tannin, etc.). The juxtaposition of socio-economic and laboratory surveys indicated that the mistletoe species, *Phragmanthera capitata*, associated with Hog plum and Guava trees had more metabolites (alkaloids, anthraquinones, flavonoids, phenol, tannins, and saponins) than other host plants. Although this study did not produce enough empirical evidence to substantiate the use of mistletoe as cure-all for ailments, further investigation on host specificity and/or plant – mistletoe associations is recommended.

Comparative wood anatomy of Brazilian mistletoes genera of Loranthaceae

Victor Sabinelli¹, Luiza Teixeira-Costa¹, Gregório Ceccantini¹

¹Universidade de São Paulo, Sao Paulo, Brazil (sibinelli95@gmail.com; luiza.teixeirac@gmail.com; gregorio@usp.br)

Parasitic plants are organisms able to obtain some nutrients from other plants, often causing a significant impact on their host's fitness. Parasitic plants may cause great losses on crop productivity or disturbances in the dynamics of natural environments. Many functional and morphological features are responsible for the success of these plants in nature. Wood anatomy is one major aspect, given the stem wood provides connection between the haustoria (sucking organs) and the parasite's crown. Wood structure associated to stomata functioning play a major role in sap supply and transport security. The Loranthaceae is one of the largest parasitic groups, gathering the largest number of genera within the Santalales order. It comprises both root and stem hemiparasites. In Brazil 12 genera occur naturally, distributed in different biomes and habitats. The present work aimed to extend the knowledge on wood anatomy of Loranthaceae by studying and comparing all Brazilian genera. The morphological profile of the parasitic stem wood shows great diversity regarding vessel lumen size (≤ 50 up to ≥ 200 μm), with vessel dimorphism common, i.e. wider vessels associated with very narrow vessel elements and/or tracheids; also, diverse types of vessel groupings and well-developed banded parenchyma; very thick-walled fibres, and tall rays. These features seem to be associated with the evolution of the group, that had a change of habitat from root to stem parasitism, given that most of them are not shared with the basal root parasite *Gaiadendron punctatum*.

Morphogenesis and evolution of mistletoes' haustoria

Luiza Teixeira-Costa¹ , Gilberto Ocampo² , Gregório Ceccantini¹ 

¹Universidade de São Paulo, São Paulo, Brasil; ²Universidad Autonoma de Aguascalientes, Aguascalientes, Mexico (luiza.teixeirac@gmail.com; gilberto.ocampo.uaa@gmail.com; greg@usp.br)

Mistletoes, shrubby to arboreal parasitic plants infesting the above-ground organs of their hosts, have evolved at least three times within the Santalales. Currently accounted to include 89 genera, representing nearly half of the diversity within the order, this parasitic life form has been successful in infesting a wide array of hosts and colonizing all forested continents. Such success can be partially attributed to the emergence and specialization and of different types of host-parasite connection via an organ known generically as *haustorium*. Details obtained from broad studies on the morphogenesis of mistletoe haustoria in different species were used for a phylogenetic analysis of ancestral character state reconstruction, which was coupled with divergence time estimations for all clades within Santalales. Our results suggest that the change from root to aerial parasitism could have been facilitated by a common background for haustorium development shared by root parasites and epicortical root-forming mistletoes. From an ancestor with either root or epicortical root haustoria, drier climates may have acted as a driver for the expansion and specialization of mistletoe's endophytic tissues, leading to the emergence of a structure known as cortical strands, which help proliferating the parasite within the host bark. This crucial evolutionary step probably conferred great advantages to mistletoes, enabling groups such as Visceae to expand to a wider distribution, regardless of climatic conditions. The development of cortical strands would have also promoted host tissue proliferation, leading to the formation of convergent haustorium types known as woody galls and woodrose formations.

Urban mistletoe: The final frontier in ecological restoration?

David Watson¹, Lee Harrison², Melinda Cook³, Rodney van der Ree²

¹Charles Sturt University, Albury, Australia; ²City of Melbourne, Melbourne, Australia; ³University of Technology, Sydney, Sydney, Australia (dwatson@csu.edu.au; lee.harrison@melbourne.vic.gov.au; lizzieb_lou01@hotmail.com; rodney.vanderree@melbourne.vic.gov.au)

Although often presumed to be ecologically barren, cities can provide safe havens for biodiversity. As well as supporting populations of native species, urban green spaces contribute to the well-being of people living and working in cities, and there is an emerging understanding of the reciprocal benefits of making our cities 'greener'. Despite being the second largest city in Australia, Melbourne has an extensive network of parks, gardens and street trees, collectively an urban forest comprising some 70,000 trees. As part of a broader initiative to increase the value of these managed habitats to wildlife, The City of Melbourne council in partnership with Charles Sturt University conducted a mistletoe inoculation program to measure the ecological and potential social benefits of mistletoes in urban areas. Instead of replacing established exotic trees with indigenous species, can adding mistletoe to street trees make significant improvements to biodiversity? Here we review the first two years of the project, demonstrating that as well as boosting resource availability for wildlife, adding mistletoe to the urban forest will increase amenity of streetscapes for Melbournians. In addition to being important components of woodlands and forests, mistletoes are well suited for urban restoration initiatives, buffering climatic extremes and affording valuable opportunities for educating the general public about nature.

Mistletoe dispersing birds rely on spatial-memory and established search images to find fruiting mistletoes

Melinda Cook¹, Andrea Leigh¹, David Watson²

¹University of Technology Sydney, Sydney, Australia; ²Charles Sturt University, Albury-Wodonga, Australia (melinda.cook01@gmail.com; andrea.leigh@uts.edu.au; dwatson@csu.edu.au)

Mistletoes are characteristically patchy, grow at low densities and can be difficult to discern within host canopies. Yet, they are consistently visited by a suite of fruit eating birds that find them and disperse their seeds. To investigate the behavioural basis to this pattern, we combined observational studies of mistletoe visitation with experimental manipulation of mistletoe locations in semi-arid woodland in Southern Australia, removing entire mistletoe plants from their host and affixing them in novel locations. Comparing visitation to mistletoes placed in primary host trees (*Acacia*) with mistletoes placed in adjacent trees which do not act as hosts (*Callitris*) demonstrated that some birds used the host tree rather than the mistletoe itself as the primary search image. Relocated mistletoe received comparable levels of visitation by specialist Mistletoebirds influenced by the number of fruits on the mistletoe clumps but significantly fewer visits by dietary generalists and opportunists including the generalist Spiny-cheeked Honeyeater, one of the principal mistletoe vectors for dispersal in this system. Rather than using visual cues, these birds were relying on recent experience and fine-grained spatial memory to locate fruiting mistletoe plants. In addition to explaining observed patterns of host preference in this system, this host-mediated foraging behaviour may contribute to observed patterns of host mimicry in this system, birds visiting both infected and uninfected hosts to search for cryptic mistletoes, increasing dispersal effectiveness and iteratively selecting for mistletoes which more closely resemble their hosts.

Wood anatomy of Santalales: Is there a convergent syndrome in mistletoe's wood structure related to parasitism evolution?

Gregorio Ceccantini¹ , Victor Sibinelli¹, Luiza Teixeira-Costa^{1,2} 

¹Universidade de São Paulo, Sao Paulo, Brazil; ²Harvard University Herbaria, Cambridge, USA (gregorio@usp.br; sbinelli95@gmail.com; luiza.teixeirac@gmail.com)

The order Santalales comprises both parasitic and non-parasitic plants under strong controversy about the internal relationship and circumscription of families in the past ten years (ca; 6 up to 21). They totalize almost 2000 spp in ca. of 151 genera, with a habit diversity ranging from totally holoparasitic underground non-woody herbs, such as Balanophoraceae, typical autotrophic trees, endophytic herbs, typical mistletoes (*Psittacanthus*, *Viscum*), up to giant hemiparasitic trees as sandalwood (*Santalum*). This work aimed compare the structure of the woody representants, understand its diversity and test if there are an assemblage of features typic of the 'mistletoe' habit, considering as mistletoe an hemiparasitic plant growing on the stem of a woody host. For doing so, wood samples of dozens of genera have been collected in the past decade, in nature, herbaria and xylaria trying to understand their anatomy. Comparing mistletoes and non-mistletoe parasitic plants, a convergent organization arises what might be called as a 'parasitic wood anatomy syndrome'. Most woods show extremely short vessel elements (70 µm long), several arrangements of vessel grouping (number and form of groups), high vessel frequency, association with perivascular tracheids. Fibres are very thick-walled and axial parenchyma usually is paratracheal and abundant. The features found to suggest that their hydraulic systems are very redundant and safe, capable of working in very low water potentials with minimal failure. This set of characters is very recurrent and indicates convergent evolution in hemiparasitic plants driven by the habit of growing on trunks of other plants.

Did mammals bring the first mistletoes into the tree-tops?

David Watson¹

¹Charles Sturt University, Albury, Australia (dwatson@csu.edu.au)

As the only woody parasitic plants that attach to host canopies, the growth habit of mistletoes represents a key innovation. How this aerially-parasitic habit originated is unknown—mistletoe macrofossils are relatively recent, from long after they adapted to canopy life and evolved showy bird-pollinated flowers, sticky seeds within bird-dispersed fruits and woody haustoria to attach to host branches. By integrating fully-resolved phylogenies of the most diverse mistletoe lineages, I align the timing and sequence of these events, demonstrating that the shift from root-parasitic shrub to aerial hemiparasite predates the evolution of their contemporary avian dispersers. Reconciling this mismatch with recent research on dispersal ecology, I identify two groups as the most likely original dispersal agents; basal primates for the Viscaceae in the Cretaceous and Microbiotherian marsupials for the Loranthaceae in the Eocene. Having colonized the canopy, subsequent mistletoe evolution and diversification coincided with the rise of nectar and fruit-dependant birds.

The European mistletoe in Sonoma County California, USA

David Shaw¹, Christopher Lee²

¹Oregon State University, Corvallis, USA; ²California Department of Forestry and Fire Protection, Fortuna, USA (dave.shaw@oregonstate.edu; christopher.lee@fire.ca.gov)

The European mistletoe (*Viscum album*) was introduced to Sebastopol, Sonoma County, California, USA in about 1900 by the horticulturist Luther Burbank to develop a trade in ornament and medicinal tincture. The mistletoe has since spread from the point of introduction on hardwood trees, especially non-native hardwoods in yards and farms. Surveys of the mistletoe were done in 1971, 1986, and 1991. We re-surveyed the distribution of *V. album* in Sonoma County in February 2019, providing a ~119-year estimate of spread. The estimated area encompassed by mistletoe-infected hosts increased greatly, from 184 km² in 1991 to 606 km² in 2019, although the furthest distance from origin was only 24.6 km. Although the mistletoe has intensified, it has not jumped great distance. The dominant vegetation of the uplands in the region is coniferous trees (*Sequoia sempervirens*, *Pseudotsuga menziesii*) and *Quercus* species in the white oak group. These native trees are not hosts, and therefore restrict the spread. However, non-native-to-California hosts such as *Malus* spp. *Robinia pseudoacacia*, *Acer saccharinum* are commonly colonized, as well as the native trees of riparian areas, including *Populus fremontii*, *Alnus rubra*, *Salix lasiandra* and *Fraxinus latifolia*. The mistletoe has been associated with decline of heavily infected hosts such as *P. fremontii*, and is a significant pest on multiple hosts. It appears that urban forest areas, such as Santa Rosa (population ~175,000) and native riparian forests in Sonoma County are most threatened by this invasive mistletoe but vectors of the seed apparently do not travel great distances.

D7e: DISEASE AND ENVIRONMENT INTERACTIONS ASSOCIATED WITH FOREST DECLINE

A recent fungal introduction event revealed by the current genetic landscape of *Raffaelea quercus-mongolicae* population in South Korea

Dong-Hyeon Lee¹, Sun Keun Lee¹, Ji-Hyun Park¹, Sang-Tae Seo¹, Sang-Hyun Lee¹

¹Division of Forest Insect Pests and Diseases, National Institute of Forest Science, Seoul, Republic of Korea (leedh2009@korea.kr; lskyou@korea.kr; jhpark10@korea.kr; stseo@korea.kr; shlee4@korea.kr)

Raffaelea quercus-mongolicae is a mycangial symbiont of a wood boring ambrosia beetle, *Platypus koryoensis* (Coleoptera: Curculionidae: Platypodidae), which is believed to be associated with oak mortality in South Korea. Despite the fact that the oak mortality has continued to spread across the country since its first discovery of the disease in 2004 and the significant impact that the pathogen has been on forest ecosystem in the country, little is known regarding its biology of the fungus. During a recent survey carried out to investigate the status of the oak wilt disease in Jeju island, Korea, visible signs of bark beetle attack, including bark beetle frass and galleries, were consistently observed on *Quercus serrata*, and *R. quercus-mongolicae* was successfully recovered from the tree. To infer whether the fungus has been introduced from the inland areas of Korea to the Jeju island, the genetic diversity and population structure of the *R. quercus-mongolicae* isolates collected from various geographical regions and hosts in Korea were investigated using a combination of eight microsatellite markers designed from the genome of the fungus in this study. The results showed that low levels of genetic diversity were found for the population of *R. quercus-mongolicae* from the Jeju island, compared to those from the inland areas of the country. This suggests that a limited number of individuals have recently been introduced into the Jeju island, indicating that a novel disease problem might occur in the area.

Quantifying southern pine decline: the role of *Leptographium terebrantis*

John K. Mensah¹, Mary A. Sword Sayer², Ryan L. Nadel¹, George Matusick³, Zhaofei Fan¹, Lori G. Eckhardt¹

¹Auburn University, Auburn AL, USA; ²USDA Forest Service, Pineville/Louisiana, USA; ³New York City Department of Environmental Protection, Bureau of Water Supply, Natural Resources Division, New York, USA (jkm0042@auburn.edu; msword@fs.fed.us; ryan.nadel@auburn.edu; gmatusick@dep.nyc.gov; zzf008@auburn.edu; eckhlg@auburn.edu)

Pinus taeda L. (loblolly pine), one of the economically important and predominant timber species in the Southeastern United States but suffers from growth decline and mortality. Southern pine decline is one of the disease complexes associated with root-feeding bark beetles and their ophiostomatoid fungal associate after predisposition by environmental stressors. Nonetheless, the role of the bark beetle vectored fungi in southern pine decline remains unresolved among researchers. In contributing to the ongoing debate, a study was designed to evaluate the role of the root pathogen, *Leptographium terebrantis* and quantify the amount of growth decline associated with the pathogen. The study was installed in a 13-year-old loblolly pine plantation at Eufaula, Alabama and dendrometer bands were permanently installed on the trees to measure radial growth on a monthly basis. Artificial inoculations were done using sterilized and *L. terebrantis* colonized toothpicks to simulate the natural feeding habits of bark beetles. Twenty-one months of post inoculation treatment, the pathogen caused a 16.3% reduction in basal area increment and 13% mortality in the high inoculum treatment trees. The results demonstrate that the pathogen, *L. terebrantis* is involved in loblolly pine decline.

Ceratocystis wilt affecting Eucalyptus plantations in Riau, Indonesia

Leonardo Oliveira¹, Álvaro Durán¹, Pantun David Gaol¹, Danar Wicaksono¹

¹April Asia Agri RGE Technology Center, Pangkalan Kerinci, Indonesia (fioteoliveira@yahoo.com.br; alvaro_duran@aprilasia.com; pantun_gaol@kerinci.lcl; danar_wicaksono@kerinci.lcl)

Ceratocystis wilt is one of the most important diseases on woody plants worldwide. In Southeast Asia, this fungal disease was able to decimate forest plantations of *Acacia mangium*, making unviable the commercial establishment of this crop in the region. As an alternative to this problem, *Eucalyptus* species have been widely planted in mineral soils. Recently, wilting, die-back, xylem discoloration, epicormics shoots sprouting along the stem and consequently death of eucalyptus trees were observed in clones planted in the province of Riau, Indonesia. Infected plant material was examined in the laboratory and *Ceratocystis* sp. was isolated by carrot baiting method. Inoculation of the fungus into healthy plants with subsequently re-isolation was conducted to fulfill Koch's postulate which successfully confirmed the pathogenicity of *Ceratocystis* on *Eucalyptus*. To understand the economical impact of this disease, an extensive survey was conducted. Three clones were identified as susceptible to *Ceratocystis* wilt. Infections have started either from the roots or by stem wounds possibly caused by boring insects, bark cracking or mechanical damage. Infection levels ranged from 1% to 42%, depending on the area or susceptibility of a given clone. Disease progression studies conducted in two compartments planted with the most susceptible clone showed that the disease incidence has increased in 10 months from 15% to 40%, in average, but still low levels of mortality. To successfully control this disease, susceptible clones were removed from the genetic deployment program and a screening system has been implemented for the selection of resistant clones.

Occurrence of chlorosis and mortality in Pinus taeda trees in Southern Brazil / Ocorrência de clorose e mortalidade em árvores de Pinus taeda na região Sul do Brasil

Celso Garcia Auer¹, João Bosco Vasconcellos Gomes¹, Antonio Francisco Jurado Bellote¹, Guilherme de Castro Andrade¹, Susete Rocio Chiarello Penteado¹, Erich Schaitza¹, Alvaro Figueredo dos Santos¹

¹Embrapa Florestas, Colombo, Brasil (celso.auer@embrapa.br; joao.bv.gomes@embrapa.br; antonio.bellote@embrapa.br; guilherme.andrade@embrapa.br; susete.penteado@embrapa.br; erich.schaitza@embrapa.br; alvaro.santos@embrapa.br)

Desde 2014, uma clorose de acículas vem sendo constatada em árvores adultas de *Pinus taeda*, em localidades da região Sul do Brasil, notadamente no estado de Santa Catarina. Os sintomas começam a serem constatados em plantios com 10 anos de idade, na forma de tufo de acículas cloróticas em ramos e ponteiros e, em situações extremas, mortes de árvores com idades acima de 16 anos. Ações sistemáticas com parcelas de monitoramento e de mitigação foram estabelecidas para caracterização do problema. Exames de árvores doentes revelaram: i) raízes mais grossas com lesões escuras e ii) baixa presença e/ou, ausência de raízes de absorção vivas e de ectomicorrizas ativas. Também, se observou baixa incidência de insetos associados. Isolamentos feitos a partir de amostras de raízes de árvores sintomáticas e de solo revelaram a presença de fungos e oomicetos. Análises preliminares de nutrientes em acículas doentes não constataram relações de causa e efeito sobre a nutrição das árvores. Sítios com a presença de árvores com clorose ocorrem em sua grande maioria em solos desenvolvidos de rochas eruptivas básicas/intermediárias, mas também sem uma aparente relação de causa e efeito. Assim, a clorose do *Pinus* no Brasil é ainda um problema de caracterização difusa e etiologia desconhecida. Inferências iniciais vislumbram uma interação biótica/abiótica, envolvendo agente patogênico, regime hídrico e química do solo.

How anthropogenic activities have predisposed a keystone tree species to a native co-evolved pathogen to cause a severe and widespread canker disease

Sarah Sapsford^{1,2}, Giles Hardy², Treena Burgess², Trudy Paap^{3,2}

¹University of Canterbury, Canterbury, New Zealand; ²Murdoch University, Perth, Australia; ³University of Pretoria, Pretoria, South Africa (sarah.sapsford@gmail.com; g.hardy@murdoch.edu.au; t.burgess@murdoch.edu.au; trudy.paap@fab.up.ac.za)

Quambalaria coyrecup is a native pathogen that causes a devastating canker disease in the endemic and keystone tree *Corymbia calophylla* (Marri) in the Southwest of Western Australia. In the last 20 years, the impact and severity of this pathogen has increased substantially throughout the range of marri over thousands of square kilometers. Why is this pathogen that co-evolved with its host now so devastating? To answer this question, we used Manion's 'tree decline spiral' as a template to examine the possible predisposing, inciting and contributing factors that could be linked to increased occurrence and severity of the canker disease. We looked at anthropogenic pressures including fragmentation, pesticides and fertilizer inputs, physical and chemical soil changes, changes in mycorrhizae and other soil microflora, the presence of *Phytophthora* species, and the role of a drying and warming climate on the incidence and severity of the disease. We found anthropogenic pressures to play a key role in the disease syndrome, together with changes in key soil nutrients such as phosphorous, ammonium nitrogen, zinc, sodium, and iron, changes in mycorrhizal communities and richness, pH, overstorey diversity, stand basal area and the presence of *Phytophthora* species with canker incidence and severity. These together with their interactions with the host and pathogen will be discussed in detail.

The physiological effects of *Phytophthora agathidicida* infection on New Zealand kauri (*Agathis australis*) water relationsSarah Killick¹, Cate Macinnis-Ng¹, Nick Waipara², George Perry¹¹University of Auckland, Auckland, New Zealand; ²Plant and Food Research, Auckland, New Zealand (s.killick@auckland.ac.nz; c.macinnis-ng@auckland.ac.nz; nick.waipara@plantandfood.co.nz; george.perry@auckland.ac.nz)

New Zealand kauri (*Agathis australis*) is one of the world's largest and longest-lived trees and is a cornerstone species in northern New Zealand forests. Recently, kauri has experienced substantial declines due to the newly emergent kauri dieback disease. The disease is caused by a novel pathogen, *Phytophthora agathidicida*, which has spread across most of the natural kauri range. Infected kauri display large bleeding basal cankers followed by crown dieback and eventual tree death. In similar diseases, such as *Phytophthora ramorum* infection in tanoak, drought-like crown symptoms are associated with infection of the xylem leading to hydraulic failure; however, *P. agathidicida* is only known to occur in the phloem and external tissues. To understand the mechanisms by which *P. agathidicida* causes tree mortality and the environmental conditions that promote increased susceptibility, we propose a physiological approach to study of the effects of *P. agathidicida* infection. In this presentation, I will overview the design of this study which uses a combination of field observations, laboratory experiments, and computational modelling. As a new PhD student, I greatly value your feedback on study methodology; please feel free to approach me with any recommendations.

Management of *Erwinia* sp. in *Eucalyptus*: initial studies using *Trichoderma harzianum* and *Paicelomyces lilacinus*Gabriel Leonardi Antonio¹, Lucas da Silva Souza¹, Ródney Lúcio Pinheiro Henrique¹, Izabela Ponso Magalhães¹, Aline Marchetti Silva Matos¹, Ana Carolina Firmino¹¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Dracena, Brasil (gabriel-leonardi@bol.com.br; lucas.souza011996@gmail.com; rodneylucioh@hotmail.com; izabelaponso@gmail.com; aline_marchetti_57@hotmail.com; anacarfir@gmail.com)

The objective of this project was to study the use of *Trichoderma harzianum* and *Paicelomyces lilacinus* in the management of *Erwinia* sp. in soil. The following treatments were carried out for each biological control agent: (A) Eucalyptus plants with roots immersed in the biological agent suspension; (B) Plants placed in the pot with hydrogel incorporated to the biological control agent; (C) Plants placed in the pot and irrigated with the biological control agent; (D) Plants placed in the pot in which the biological control agent was placed directly in the seedling; Two control treatments: (E) seedlings in pots with soil infested only with *Ralstonia* and (F) in pots with soil without bacteria's infestation. All treatments were applied in two eucalyptus clones (SusR and 144 clones). The analyzed variables were mortality rate of Eucalyptus seedlings and dry mass of the plants. When *T. harzianum* was used, no dead plant of the SusR clone for treatment B was observed and there was only 20% mortality of clone 144 in treatments A and B. The fungus *P. lilacinus* was effective only for the SusR clone, where only 16% of plant mortality was observed in treatment A. The increase in the dry mass of the plants was observed in treatments A and B with *T. harzianum* in clone 144. Therefore, the use of *T. harzianum* was better for the sustainable management of *Erwinia*.

Management of *Ralstonia solanacearum* in *Eucalyptus*: initial studies using *Trichoderma harzianum* e *Paicelomyces lilacinus*Ana Carolina Firmino¹, Lucas da Silva Souza¹, Ródney Lúcio Pinheiro Henrique¹, Izabela Ponso Magalhães¹, Aline Marchetti Silva Matos¹, Gabriel Leonardi Antonio¹¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrárias e Tecnológicas, Dracena, Brasil (ana.firmino@unesp.br; lucas.souza011996@gmail.com; rodneylucioh@gmail.com; izabelaponso@gmail.com; aline_marchetti_57@hotmail.com; gabrielleonardirex@gmail.com)

The objective of this project was to study the use of *Trichoderma harzianum* and *Paicelomyces lilacinus* in the management of *R. solanacearum* in soil. The following treatments were carried out for each biological control agent: (A) Eucalyptus plants with roots immersed in the biological agent suspension; (B) Plants placed in the pot with hydrogel incorporated to the biological control agent; (C) Plants placed in the pot and irrigated with the biological control agent; (D) Plants placed in the pot in which the biological control agent was placed directly in the seedling's; Two control treatments: (E) seedlings in pots with soil infested only with *Ralstonia* and (F) in pots with soil without bacteria's infestation. All treatments were applied in two Eucalyptus clones (SusR and 144 clones). The analyzed variables were mortality rate of eucalyptus seedlings and dry mass of the plants. The method of incorporation of the biological control agent influenced the control of *Ralstonia*. Treatments B and C were the most effective. The *T. harzianum* fungus presented only 12% mortality of the SusR clone and 0% and mortality of clone 144 in treatments B and C, respectively. When treatment B was used, fungus *P. lilacinus* presented 25% and 20% dead plants of the SusR clone and clone 144, respectively. The two biological agents increased the dry mass of the plants. Therefore, the use of *T. harzianum* and *P. lilacinus* can serve as a support in the sustainable management of areas where there have been cases of *Ralstonia*.

Emission of CO₂ from soil contaminated with *Ralstonia solanacearum* treated with *Trichoderma* agents associated with fertilizerMarcela Eloi Gomes¹, Heloisa Noemi Bello Paulo¹, Marcela Bergamini Pagoto-Lopes¹, Izabela Ponso Magalhães¹, Paulo Renato De Matos Lopes¹, Gabriel Leonardi Antonio¹, Ana Carolina Firmino¹¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrárias e Tecnológicas, Dracena, Brasil (marcelaeloi14@gmail.com; heloisa.bello@unesp.br; marcela.pagoto@gmail.com; izabelaponso@gmail.com; prm.lopes@unesp.br; gabriel-leonardi@bol.com.br; ana.firmino@unesp.br)

The emission of CO₂ was evaluated in interaction systems between the pathogen *Ralstonia solanacearum* (R) and the biological control agent *Trichoderma stromaticum* (T) associated with a liquid fertilizer (F) in the soil (S). The evaluation of the CO₂ emission was carried out using the Bartha breathalyzer methodology, with 8 treatments (S, S + T, S + R, S + T + R, S + M, S + M + T, S + M + R, S + M + T + R) with 4 replicates each, all of which were maintained in BOD at a temperature of 28 °C and evaluations were performed every 2 days for 30 days. The addition of *Trichoderma* increased the CO₂ emission, but it was observed that the CO₂ emission was higher and more constant in the treatments containing the fertilizer, indicating that this factor has a direct effect on the microbial activity. It is known that *Trichoderma* presents action versatility, and can degrade the cell walls of other microorganisms through the production of enzymes or toxic substances, which may explain the increased respiration of the treatments that involved these fungi since it can intensify its activity in the presence of *Ralstonia* increasing oxygen consumption and CO₂ emissions. When only the pathogen was used in the treatment, lower numerical values were observed, which may be related to the lower activity of the pathogen in the absence of a host.

Effect of temperature and wetting period in germination and appressorium formation of *Colletotrichum* spp. from rubber trees (*Hevea brasiliensis*)

Izabela Ponso Magalhaes¹, Gabriel Leonardi Antonio¹, Ivan Herman Fischer², Edson Luiz Furtado³, Ana Carolina Firmino¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Dracena, Brazil; ²APTA- Centro Oeste, Bauru, Brazil; ³Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brazil (izabelaponso@gmail.com; gabriel-leonardi@bol.com.br; ihfische@gmail.com; edson.furtado@unesp.br; ana.firmino@unesp.br)

The objective of this study was to evaluate the effect of temperature and wetting period on the germination and appressorium formation of two isolates of *C. gloeosporioides* and *C. accutatum* obtained from rubber trees in vitro. Droplets of 40 µL (105 conidia.mL⁻¹) were deposited on plastic petri dishes, incubated in a humid chamber at 20, 25, 30, 35 ± 1 °C and under wet periods of 4, 6, 12 and 24 hours (h). After the established periods, the plates were removed from the humid chamber and the drops were dried; 40 µL of lactoglycerol was deposited on this dry area to quantify the percentages of germinated conidia and appressory. The germination of conidia was observed from 30 °C with minimum wetting period of 4h for *C. accutatum*. For *C. gloeosporioides* the germination of conidia was observed from 25 °C with minimum wetting period of 6h. Appressory formation was observed only in *C. gloeosporioides* between 20 and 30 °C, with a minimum wetting period of 24 h. Increased wetting period resulted in higher percentages of germinated and appressory conidia formed. The optimum temperature range for conidia germination was 25 °C at 30 °C for *C. gloeosporioides* with 24h of wetting. For *C. accutatum* the optimum temperature range for conidia germination was 25 °C at 35 °C, with 24h of wetting. This information can contribute to the understanding of the beginning of the infection in the field since this fungus tolerates high temperatures.

D7f: FOREST MICROBIOME AND FOREST HEALTH

Tree microbiomes: functional roles and impact on forest health

Fred Asiegbu¹

¹University of Helsinki, Helsinki, Finland (fred.asiegbu@helsinki.fi)

Forest trees are known to live in close association with microbial organisms. The nature of this close association can be mutualism or commensalism, parasitism. The term microbiota has been used to describe this ecological community of plant associated pathogenic, mutualistic and commensal microorganisms. Many of these microbiota inhabiting forest trees could have potential impact on the health and disease progression. Comparatively, studies on forest tree microbiomes lags far behind parallel work on agricultural crop and human microbiome projects. Our understanding and perception of plant and tree microbiomes have recently been facilitated due to novel technological advances using metabarcoding and metagenomics approaches. Also the availability of massive DNA databases as well as powerful computational and bioinformatics tools have helped to facilitate data mining by researchers across diverse disciplines. Available data demonstrate that plant bacterial communities are dominated by members of a few phyla (Proteobacteria, Actinobacteria). Interestingly, our survey of bacterial communities of Norway spruce revealed high abundance of the phylum Acidobacteria. Fungal communities of phyllosphere, rhizosphere and surrounding soils also show pronounced differences. In bulk soil, we found that basidiomycota is the dominant fungal group whereas in needle tissues, trunk and suberized roots, Ascomycota is the most prevalent group. Further studies are ongoing to unravel the functional roles of these microbes and their potential impact on forest tree health. It has been acknowledged that phytobiomes play important roles in health and development of diseases. The acquisition of such fundamental knowledge will have huge potential impact in future translation into sustainable forestry management

Metagenomic approaches to examine relationships of soil microbial communities with *Armillaria* root disease

Jane Stewart¹, Bradley Lalande¹, Zaid Abdo¹, John Hanna², Deborah Page-Dumroese², Marcus Warwell², Joanne Tirocke², Mee-Sook Kim³, Ned Klopfenstein²

¹Colorado State University, Fort Collins, USA; ²USDA Forest Service, Rocky Mountain Research Station, Moscow, USA; ³USDA Forest Service, Pacific Northwest Research Station, Corvallis, USA (jane.stewart@colostate.edu; brad.lalande@colostate.edu; zaid.abdo@colostate.edu; jhanna@fs.fed.us; ddumroese@fs.fed.us; mwarwell@fs.fed.us; jtirocke@fs.fed.us; mkim02@fs.fed.us; nklopfenstein@fs.fed.us)

Forests harbor highly complex microbial communities that play diverse ecological roles, potentially including protection from root diseases. Armillaria root diseases are among the most damaging and broadly distributed group of forest diseases in the world, but it is notoriously difficult to manage in forests. Because Armillaria root disease impacts are dependent on complex ecological interactions among the host, soil microbial community, and environment, novel management approaches are needed that consider soil interactions that suppress the disease. Soil metagenomic/transcriptomic methods allow a better understanding of complex interactions among soil microbial communities, environmental factors (i.e., soil properties), tree health, and *Armillaria* spp. (i.e., pathogenic vs. saprophyte) that influence Armillaria root disease in forest ecosystems. Soil cores, *Armillaria* samples, and tree health data were collected in a western white pine (*Pinus monticola*) plantation at the Priest River Experimental Forest in northern Idaho, USA. DNA and RNA were extracted from each soil sample, and the ITS-2 and 16S rDNA regions were sequenced through metagenomic techniques to determine the fungal and bacterial communities. Soil microbial communities were compared in association with two *Armillaria* species: *A. solidipes* (pathogenic) and *A. altimontana* (weak pathogen, saprophyte, and potential biocontrol agent). Ongoing analyses are determining if microbial populations differ in relation to *Armillaria* species associated with diseased/healthy trees and with varying soils properties. Results for this study will be applied to develop novel management approaches for suppressing Armillaria root disease by favoring beneficial microbial communities with potential biocontrol activity against *Armillaria* pathogens and enhance forest resilience.

Effects of European monocultures and multispecies forests on specific soil fungal communities depends on tree traits and implies changes in soil nutrients functionality

Luis Daniel Prada Salcedo^{1,2}, Thomas Reitz³, Anna Heintz-Buschart^{2,4}, Kezia Goldmann², François Buscot^{2,4}

¹Leipzig University, Leipzig, Germany, Germany; ²UFZ-Helmholtz-Centre for Environmental Research, Department of Soil Ecology, Halle (Saale), Germany; ³UFZ-Helmholtz-Centre for Environmental Research, Department of Soil Ecology, Leipzig, Germany, Germany; ⁴German Centre for Integrative Biodiversity Research (iDiv), Leipzig, Germany, Germany (luis.salcedo@ufz.de; thomas.reitz@ufz.de; anna.heintz-buschart@ufz.de; kezia.goldmann@ufz.de; francois.buscot@ufz.de)

At the global scale most forest research focuses on aboveground biodiversity. Consequently, we still lack a deeper understanding of belowground biodiversity. Microorganisms such as fungal communities are closely linked to the dominant tree vegetation due to the often occurring mutualistic relationships. Within the project SoilForEurope, we evaluated how tree diversity or identity affects fungal communities and the soil-system functions. The project's study sites are mature

forests from four different European countries in Finland, Poland, Romania and Italy. They encompass monocultures to multispecies forests and different tree species compositions. Therefore, we extracted fungal ITS rDNA from 320 soil samples. PCR-based amplicon libraries were produced and sequenced using the Illumina MiSeq NGS. Besides, functional effects on C, N and P nutrient cycling were evaluated through soil enzymatic activities. The overall results between multispecies and monocultures plots did not show significant differences of fungal communities within countries. Nonetheless, specific functional fungal groups such as saprotrophs and symbiotrophs increase their alpha diversity under multispecies systems. The community composition differed strongly between countries and its differences are rather driven by the tree identity than by tree diversity. Moreover, changes in fungal diversity are reflected at functional stages: higher nutrients dynamics were displayed in multispecies plots. The trees influence over fungal communities is mainly due to roots and revealed in traits like nitrogen content or specific root length. This showed the consequences of decreasing tree biodiversity or forest compositions can impact not only fungal biodiversity, but also forest functionality.

Disturbance and extreme weather events impact soil microbial processes and fungal communities in a mountain beech forest

Mathias Mayer¹, Markus Gorfer², Bradley Matthews¹, Harald Berger³, Andrea Bittner¹, Hans Sandén¹, Boris Rewald¹, Klaus Katzensteiner¹, Douglas L. Godbold¹

¹University of Life Sciences and Natural Resources, Institute of Forest Ecology, Vienna, Austria; ²Center for Health & Bioresources, AIT Austrian Institute of Technology GmbH, Tulln, Austria; ³Symbiocyte, Tulln, Austria (mathias.mayer@boku.ac.at; markus.gorfer@ait.ac.at; bradley.mathews@boku.ac.at; harald.berger@symbiocyte.com; andrea.bittner@students.boku.ac.at; hans.sanden@boku.ac.at; boris.rewald@boku.ac.at; klaus.katzensteiner@boku.ac.at; douglas.godbold@boku.ac.at)

In mountainous regions forests are important ecosystems for slope stabilization and provision of drinking water for a growing world population. Shallow soils overlying limestone bedrock, as can be observed on slopes, are especially vulnerable to degradation and erosion. Microbial processes and fungal communities were studied in a mountain beech forest in the Austrian Calcareous Alps over the course of four years. Girdling and clearcut treatments and years with extreme summer drought allowed us to study effects of disturbances and climate change scenarios on functioning and composition of soil microbial communities. Soil physicochemical characteristics like high pH and high content in organic carbon lead to a distinct soil fungal community, which is dominated by saprophytic ascomycota. Ectomycorrhizal abundance is low and shows deviating patterns from other beech stands in Europe. Seasonal variation seems to strongly shape the ectomycorrhizal community, while summer drought can promote the abundance of potentially pathogenic fungi. Effects can still be observed in spring and after summer drought. This finding is in line with a well known increase in diseases upon extreme weather events. Disturbances increase litter decomposition and lead to a decrease in the abundance of ectomycorrhizal fungi. Taken together the results highlight the risks imposed by extreme weather events and disturbance to ecosystem services provided by mountain forests.

Comparison of microbial communities across the bulk soil, rhizosphere and fine root endosphere of declining English oak trees

Kelly Scarlett^{1,2}, Corinne Whitby², Xiangming Xu³, David Clark², Greg Deakin³, Elena Vanguelova¹, Sandra Denman¹

¹Forest Research, Surrey, United Kingdom; ²University of Essex, Colchester, United Kingdom; ³NIAB East Malling Research, Kent, United Kingdom (kelly.scarlett@forestry.gsi.gov.uk; cwhitby@essex.ac.uk; xiangming.xu@emr.ac.uk; dclark@essex.ac.uk; greg.deakin@emr.ac.uk; elena.vanguelova@forestry.gsi.gov.uk; sandra.denman@forestry.gsi.gov.uk)

Oak declines are serious and widespread disorders threatening native British oak (*Quercus robur* and *Q. petraea*) in England. The causes of decline are thought to involve complex interactions of abiotic and biotic agents resulting in the deterioration of tree condition. Soil microbe communities contribute significantly towards tree health with both bacteria and fungi playing a vital role in cycling of essential elements as well as mobilization, acquisition and translocation of nutrients. Oak fine roots are the primary sites of nutrient import and they rely on close, often symbiotic, relationships with associated soil microbial communities. Fine roots and their associated microbial communities have both direct and indirect effects on each other, however the relationship between cause and effect on microbial community changes is often very complex. In this study we test the hypothesis that tree health modulates the oak fine root microbiome. In 7 sites across England, we characterised the fungi and bacteria in the bulk soil, rhizosphere soil and fine root endosphere of symptomatic and asymptomatic oak trees using high throughput Illumina sequencing. We are comparing between these co-occurring communities with the aim to understand the relationship between tree health and the soil biotic environment.

Are there hopes for European elms?

Alessia Pepori¹, Priscilla Bettini², Alberto Santini¹ 

¹Institute for Sustainable Plant Protection, Sesto fiorentino, Italy; ²Department of Biology, University of Florence, Firenze, Italy (alessia.pepori@ipspp.cnr.it; priscilla.bettini@unifi.it; alberto.santini@cnr.it)

In Europe as in North America elms are devastated by Dutch elm disease (DED), caused by the alien ascomycetes *Ophiostoma ulmi* and *O. novo-ulmi* (ONU). Pathogen dispersal and transmission are ensured by local species of bark beetles (*Coleoptera: Curculionidae, Scolytinae*), which established a novel association with the alien fungi. Elm bark beetles also transport fungi of the genus *Geosmithia*, that are commonly found in scolytids' galleries colonized by ONU. Widespread horizontal gene transfer between ONU and *Geosmithia* was recently observed. In order to define the relation between these two fungi in the DED pathosystem, ONU and *Geosmithia* species from elm, including a GFP-tagged strain, were grown in dual culture and mycelial interactions were observed by light and fluorescence microscopy. Growth and sporulation of ONU resulted significantly higher in the presence of *Geosmithia* than in its absence. Signs of mycoparasitism by *Geosmithia* on ONU hyphae, such as formation of coilings, appressoria-like branches, pseudopod-like structures or short hooks, were commonly observed at microscopy. Finally, the addition of spores of *Geosmithia* species to suspensions of ONU spores used for artificial inoculations significantly reduced DED symptoms. A close and stable relation was observed between the two fungi, which may be classified as mycoparasitism by *Geosmithia* on ONU. These results prove the existence of a new component in the complex of organisms involved in DED, which might be capable of reducing the disease impact. If this activity will be confirmed, it will then be possible to exploit it to control the spread of the disease.

What is causing beech leaf disease? A metabarcoding approach

Carrie Ewing¹, Cristina Rosa², Maria-Soledad Benitez³, Lucy Stewart^{4,3}, Jason Slot¹, Pierluigi (Enrico) Bonello¹

¹The Ohio State University, Columbus, OH, USA; ²The Pennsylvania State University, University Park, PA, USA; ³The Ohio State University/Ohio Agricultural Research and Development Center, Wooster, OH, USA; ⁴Agricultural Research Service, United States Department of Agriculture, Wooster, OH, USA (ewing.244@buckeyemail.osu.edu; ccr2@psu.edu; benitezponce.1@osu.edu; lucy.stewart@ars.usda.gov; slot.1@osu.edu; bonello.2@osu.edu)

First discovered in 2012, beech leaf disease (BLD), a currently undiagnosed and seemingly lethal disease, is affecting American beech trees (*Fagus grandifolia*) in forests in the northeastern United States. The initial symptoms of the disease appear in the lower canopy foliage as a dark, green interveinal banding pattern, while the later symptoms are solidly darkened leaves that are shrunken and crinkled. BLD poses a significant threat to global forests as similar symptoms were detected on American, European (*F. sylvatica*), and oriental (*F. orientalis*) beech species in Ohio nurseries. These symptoms and the distribution patterns of BLD do not fit an abiotic disorder, thus it is suspected that BLD is caused by a microorganism. To uncover the causal agent, we are using a comparative metabarcoding approach to profile the microbial communities in symptomatic and asymptomatic leaves in areas of infestation, as well as leaves from areas not known to be affected by disease. Specifically, we are employing next generation sequencing and associational analysis of leaf microbiomes based on 16S rDNA and the ITS region of total beech leaf DNA to screen for bacteria, phytoplasmata, and fungal communities, using the Illumina MiSeq platform. To screen for viruses, rRNA-depleted multiplexed libraries are being sequenced on the Illumina HiSeq platform. The microbial communities will then be compared by symptom type and known libraries of each pathogen type to potentially determine a known or unknown pathogen most closely associated with BLD.

The elusive convergence of endophyte diversity and tree vitality: Will we ever understand it?

Johanna Witzell¹, Michelle Cleary¹, Benedicte Albrechtsen², David Macaya-Sanz³, Diem Nguyen⁴, Marta Agostinelli¹, Baiba Matule¹, Juan A. Martín⁵

¹Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Alnarp, Sweden; ²Umeå University, Department of Plant Physiology, Umeå, Sweden; ³West Virginia University, Morgantown, USA; ⁴Uppsala University, Department of Organismal Biology, Systematic Biology, Uppsala, Sweden; ⁵Universidad Politécnica de Madrid, Departamento de Sistemas y Recursos Naturales ETSI de Montes, Forestal y del Medio Natural, Madrid, Sweden (johanna.witzell@slu.se; michelle.cleary@slu.se; benedicte.albrechtsen@plantphys.umu.se; akansh@gmail.com; diem.nguyen@ebc.uu.se; marta.agostinelli.@slu.se; bale0001@stud.slu.se; juan.martin.garcia@upm.es)

Vitality of a tree reflects the strength of the active processes that enable its growth and reproduction, despite the environmental stress that it is experiencing. Understanding the dynamics and variations in tree vitality is essential in tree care in urban environments, where the trees are often exposed to high stress. Forest management strategies could also benefit of more detailed knowledge about the factors contributing to tree vitality, especially as the climate change and new and emerging pests and pathogens are amplifying the stress in forest settings. Vitality is often measured using physiological or growth responses, or judged by visual assessments. A potential indicator of tree vitality, and a trait affecting or being affected by it, is also the diversity of associated microbes, such as asymptomatic, endophytic fungi. In a series of studies during the past ten years, we have addressed the relation between endophytic fungi and tree health and vitality, focusing especially on perennial organs, bark and wood (younger, active xylem tissues). The studied tree species include *Quercus robur*, *Fraxinus excelsior*, *Populus* spp., and *Ulmus* spp., grown in orchards, peri-urban and production forest settings, or in greenhouse. The vitality of the trees was compromised by unspecific factors or by pathogens, including *Phytophthora* spp., *Hymenoscyphus fraxineus*, *Venturia tremulae*, and *Ophiostoma* spp. Endophyte diversity was characterized by culture-dependent techniques or by direct sequencing. A synthesis of the results is presented and discussed in relation to a theoretical model for practical possibilities to utilize endophytes in resilience-oriented forest management.

D7g: FOREST PATHOGEN MIGRATION IN A GLOBALIZED ECONOMY

A diverse set of forest pathogens is emerging in the Pacific region and causing havoc

Philip Cannon¹

¹State and Private Forestry, United States Forest Service, Vallejo, USA (pcannon@fs.fed.us)

Historically, trees growing on islands in the Pacific region had escaped contact with many tree pathogens because of the sheer remoteness of these islands. However, with increasing levels of commerce and travel three pathogens have now found their way to some of these islands and are causing major damage. The pandemic strain of the rust *Austropuccinia psidii* arrived in Honolulu in 2006 and spread quickly to every major island in Hawaii. This fungus can infect 20 of Hawaii's 39 myrtaceous species. Since then, this pandemic strain has also spread to Australia and New Zealand where it has infected hundreds of additional myrtaceous species. There are at least 8 other strains of *A. psidii*. *Ceratocystis lukuohia* and *C. huliohia* are new *Ceratocystis* species discovered in Hawaii. Currently they are causing massive amounts of mortality to the ohia tree (*Metrosideros polymorpha*), a species constituting 80% of the natural forest of Hawaii. The etiology and management of this disease is complicated because boring dust of ambrosia beetles tunneling into infected xylem tissue appears to be involved in the spread of this disease. *Pyrrhoderma noxium* (*Phellinus noxius*) is an exceptionally aggressive root rot pathogen that has now been found on most major island groups in the Pacific (except Hawaii). This pathogen can attack and kill over 100 of the most common species found on these islands. The detection of this fungus is easy but the eradication of infection foci, so far, has proven laborious.

Stopping the spread of myrtle rust

Beccy Ganley¹

¹The New Zealand Institute for Plant and Food Research Ltd, Te Puke, New Zealand (beccy.ganley@plantandfood.co.nz)

Myrtle rust, caused by the rust fungus *Austropuccinia psidii*, is a highly invasive pathogen that affects a wide range of taxa within Myrtaceae. Plant movement associated with trade in the early 1900's saw the first spread of this pathogen beyond its native range and in the last two decades, increased globalisation has enabled it to spread further across a range of Myrtaceae-diverse countries in the southern hemisphere. In each instance its introduction has caused serious damage to a wide range of Myrtaceae species. The pathogen was first reported in New Zealand in 2017 and is thought to have spread from Australia via wind-borne spores. Based on the learnings from Australian experience with this disease New Zealand was able to prepare for a myrtle rust incursion, this included the development of a Myrtaceae barcoding database for plant species present in New Zealand, which was of great assistance in the incursion response. Although New Zealand undertook an immediate incursion response with successful localised eradication in some regions, full eradication of *A. psidii* was not possible

and the response subsequently was transitioned to long-term management. Whilst the focus is now on disease management, our border biosecurity fight against myrtle rust is not over. With numerous strains of this pathogen present worldwide the need to prevent further spread of different rust strains is paramount and relies on a global effort.

Factors influencing growth, sporulation and virus transfer in *Cryphonectria parasitica* isolates from Castilla and León (Spain)

Paula Zamora¹, Alejandro González-Casas¹, M. Dueñas¹, Roberto San Martín², Julio J. Diez²

¹Centro de Sanidad Forestal de Calabazanos. Consejería de Fomento y Medio Ambiente. JCyL. Polígono de Villamuriel, Villamuriel, Spain; ²University of Valladolid, Palencia, Spain (zamora.paula@gmail.com; agonza16@tragsa.es; zamora.paula@gmail.com; rsmartin@ieo.uva.es; jdcasero@pvs.uva.es)

Globalization is increasing the spread of forest diseases. *Cryphonectria* canker is nice example of the effect of the globalized economy and the migration of invasive species. On the other hand, *Cryphonectria parasitica* is one of the few diseases that can be managed by biological control agents. So, the use of *Cryphonectria hypovirus* CHV1 in the biological control of chestnut blight, caused by the fungus *Cryphonectria parasitica*, has reduced the impact of the disease in Europe. In this study, we investigated growth and sporulation of the fungus and horizontal transmission of the virus at different temperatures. We infected four isolates of *C. parasitica* with hypovirus subtypes CHV1-F1 and CHV1-I, to determine the influence of virus subtype. We assessed growth of fungal colonies and horizontal transmission of the virus at 15 °C and 25 °C. Colony growth was affected by an interaction between vc type and virus at both 15 °C and 25°C. However, horizontal transmission of the virus was only influenced by vc type, and spore production was only affected by the virus subtype. Vertical transmission was also influenced by the fungal isolate and virus subtype. Growth of the fungal isolates varied depending on the virus subtype with which they were infected. This supports the theory that fungal host and virus subtype strongly influence transmission and dissemination of hypovirulence. Selection of the fungal isolate is therefore very important because the genotype of isolates belonging to specific vc types may influence the prevalence of hypovirulence in *C. parasitica*. This is an important issue for the control of chestnut blight spread.

Interconnected global populations of forest pathogens created through anthropogenic spread

Bernard Slippers¹, Emma Steenkamp¹, Fahimeh Jami¹, Michael J. Wingfield¹

¹FABI, University of Pretoria, Pretoria, South Africa (bernard.slippers@fabi.up.ac.za; emma.steenkamp@fabi.up.ac.za; fahimeh.jami@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za)

Despite the development of increasingly strict biosecurity measures during the course of the past two decades, the rate of introduction and emergence of invasive tree pathogens continue to increase. Population genetics studies show that many of these pathogens have globally distributed genotypes and that they establish seemingly unstructured global populations. These population genetic patterns can be explained only by introductions of large numbers of genotypes and/or multiple introductions over time. The apparent scale and frequency of these introductions increase the threat that these invasions pose, for example through increased rates of evolution of these pathogens and their potential to overcome host resistance and environmental variation. Here we analyze common patterns emerging from population genetics and phylogeographic studies of selected globally distributed forest pathogens to visualize the growing interconnected “worldwide web” of forest pathogens. Furthermore, we consider mechanisms that facilitate the movement and establishment of these pathogens, in particular, latent infections in live plant material.

Understanding the invasion of ash dieback: Are there lessons to be learned?

Michelle Cleary¹, Stephen Woodward²

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²University of Aberdeen, Aberdeen, United Kingdom (michelle.cleary@slu.se; s.woodward@abdn.ac.uk)

The alien invasive fungus (*Hymenoscyphus fraxineus*) has resulted in severe dieback and mortality of European ash (*Fraxinus excelsior*) throughout much of its natural distribution range in northern and central Europe. The disease was first noticed in Poland (and Lithuania) around 1992. A lag time between its first observations and confirmation of the causal agent took 14 years, and then another lag of four years to confirm that it was indeed a cryptic species that differed from the ‘misidentified’ causal agent – its native European relative *Hymenoscyphus albidus*. In parallel, the fungus was discovered in Japan where it was known to exist since about 1993, but under a different name: *Lambertella alibda* which occurs on decaying rachises of the native *Fraxinus* (*Fraxinus mandshurica*). Examination of type specimens from Europe and Japan showed that they were indeed conspecific. Population studies of *H. fraxineus* in Europe show high genotypic diversity suggesting an outbreeding mating system and long-range dispersal via ascospores, and low allelic richness and low differentiation among European populations of *H. fraxineus*. Pathogen genetic diversity across Europe and in eastern populations, reveals a strong bottleneck in Europe and studies points to the founding by two divergent haploid individuals. Though it is not known, likely *H. fraxineus* arrived into eastern Europe on nursery stock of *F. mandshurica* which has been widely planted as an amenity species in urban areas and botanical gardens across Europe. Several lessons can be learned from this now ‘text-book’ example to prevent future incursions.

Mitigating forest pathogen introductions through a horticultural accreditation scheme. Is it feasible?

Mike Dunn¹, Mariella Marzano¹, Tim Pettitt², Jack Forster³, Sarah Green¹

¹Forest Research, Roslin, United Kingdom; ²University of Worcester, Worcester, United Kingdom; ³Forest Research, Farnham, United Kingdom (michael.dunn@forestry.gov.uk; mariella.marzano@forestry.gsi.gov.uk; t.pettitt@worc.ac.uk; jack.forster@forestry.gsi.gov.uk; sarah.green@forestry.gsi.gov.uk)

The large-scale movement of live plant material through the horticultural trade is recognised as a recurrent pathway for the introduction and spread of tree pathogens. Threats such as *Hymenoscyphus fraxineus*, *Phytophthora ramorum* and *Xylella fastidiosa* have prompted calls for preventative measures and monitoring programmes at key points of the horticultural supply chain. An accreditation scheme underpinned by best biosecurity practice represents one approach to delivering these recommendations. Through surveys and in-depth interviews, we examine the receptiveness of the UK’s horticultural stakeholders to adopting several biosecurity practices which our sampling and analysis show to mitigate tree pathogen related risks. We then consider what implications the perceived barriers and benefits associated with these practices have for establishing a scheme that is both impactful and appealing. We further assess the feasibility of an accreditation scheme underpinned by these practices through analysis of responses not only from industry, but also the country’s plant-buying public. Specifically, we examine levels of support for the establishment of an accreditation scheme designed to mitigate the introduction and spread of forest pathogens, and assess whether consumers are likely to alter their purchasing behaviour in order to support such a scheme. We conclude by summarising the challenges and opportunities of establishing an accreditation scheme in the sector, and provide recommendations for the scheme’s breadth and administration, as well as the framing required to generate appeal among the plant-buying public.

Effective forest protection is a multifaceted endeavour

Michael Ormsby¹, Tod Ramsfield², Beccy Ganley³

¹Ministry for Primary Industries, Wellington, New Zealand; ²Canadian Forest Service, Edmonton, Canada; ³Plant and Food Research, Te Puke, New Zealand (michael.ormsby@mpi.govt.nz; tod.ramsfield@canada.ca; beccy.ganley@plantandfood.co.nz)

With changing trade patterns and forest stewardship as a result of globalisation, an successful example of a multifaceted response to a new pathogen incursion could serve as a model to prevent future introduction of exotic organisms. This presentation will focus on the various contributing factors that resulted in the identification and mitigation of a potentially devastating pathogen; *Fusarium circinatum*. As members of the team that were involved with the detection and with the benefit of hindsight and contemplation, we outline what we feel were the important contributing factors that lead to the successful outcome.

D7h: IMPROVING TREE HEALTH IN URBAN FORESTS FOR HUMAN WELL-BEING

Urban trees facilitate the establishment of alien forest insects

Manuela Branco¹, Pedro Nunes¹, Rosário Fernandes¹, Alain Roques², Christophe Orazio³, Hervé Jactel⁴

¹ISA, Lisbon, Portugal; ²INRA, Orléans, France; ³EFL, Cestas, France; ⁴INRA, Cestas, France (mrbranco@isa.ulisboa.pt; pedrocatelanunes@hotmail.com; mrfernandes@isa.ulisboa.pt; alain.roques@inra.fr; christophe.orazio@efi.int; herve.jactel@inra.fr)

We investigate whether urban trees are main facilitators of establishment of alien forest insects. Based on scientific literature and a pan European database on alien invasive species we analysed where introduced forest insects were first detected in European countries. In total 508 first country-specific records were retrieved. We collected site location data, tree cover density and urban landscape suitable habitats (green areas with trees) in buffers (of 500 m radius) around detection points. Large majority of first records were found in urban or peri-urban areas (within 10km from city limits), varying from 81% for bark beetles and wood borers to 92 % for sap feeders and seed or fruit feeders. Only 7% of the cases were found in forests far from cities. Some reports were in rural areas and nurseries. Site types of first detection in cities were highly variable including, public parks, street trees, zoos and botanical gardens. More than 72% of the cases occurred in sites with less than 20% of tree cover proportion in term of surface. More than 50% of the cases in urban areas had less than 10% proportion of suitable habitat. We conclude that urban forest areas and urban trees are hotspots for the establishment of forest pests and that should be intensely surveyed.

Urban trees: effective solutions to reduce increasing ozone levels in cities

Pierre Sicard¹, Evgenios Agathokleous², Valda Araminiene³, Elisa Carrari⁴, Yasutomo Hoshika⁴, Alessandra De Marco⁵, Elena Paoletti⁴

¹ARGANS, Biot, France; ²Research Faculty of Agriculture, Hokkaido University, Sapporo, Japan; ³Lithuanian Research Centre for Agriculture and Forestry, Institute of Forestry, Girionys, Lithuania; ⁴Consiglio Nazionale delle Ricerche, Sesto Fiorentino, Italy; ⁵ENEA, Rome, Italy (psicard@argans.eu; evgenios_ag@hotmail.com; valda.araminiene@mi.lt; eli.carrari@gmail.com; hoshika0803@gmail.com; alessandra.demarco@enea.it; elena.paoletti@cnr.it)

Cities have to cope with the challenges due to poor air quality impacting human health and citizen well-being. The annual mean concentrations of tropospheric ozone increased by on average 0.16 ppb per year in cities worldwide over the period 1995-2014. *Green urban infrastructure* can improve air quality by removing ozone. To efficiently reduce ozone in cities, it is important to define suitable urban forest management, including proper species selection, with focus on the removal ability of ozone and other air pollutants, biogenic emission rates, allergenic effects and maintenance requirements. This review aims to i) quantify ozone removal by urban vegetation categorized into trees/shrubs and green roofs; ii) rank 95 urban plant species based on the ability to maximize air quality and minimize disservices, and iii) provide novel insights on the management of urban green spaces to maximize urban air quality. Trees showed higher ozone removal capacity (3.4 g m⁻² year⁻¹) than green roofs (2.9 g m⁻² year⁻¹) on average with lower installation and maintenance costs. To overcome present gaps, a novel Species-specific Air Quality Index (S-AQI) of suitability to air quality improvement is proposed for tree/shrub species. We recommend city planners to select species with an S-AQI>8, i.e. with high ozone removal capacity, ozone-tolerant, resistant to pests and diseases, tolerant to drought and non-allergenic (e.g. *Acer* sp., *Carpinus* sp., *Larix decidua*). Green roofs can be used to supplement urban trees in improving air quality in cities. Urban vegetation, as a cost-effective and nature-based approach, aids in meeting clean air standards and should be taken into account by policy-makers.

Insect and pathogen invasions: from urban environment to natural forests

Trudy Paap¹, Massimo Faccoli², Alberto Santini³ 

¹Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²Department of Agronomy, Food, Natural Resources, Animals and Environment (DAFNAE), University of Padova, Padova, Italy; ³Institute for Sustainable Plant Protection – C.N.R., Sesto fiorentino, Italy (trudy.paap@fabi.up.ac.za; massimo.faccoli@unipd.it; alberto.santini@cnr.it)

Urban trees are increasingly appreciated for the many benefits they provide. However, as concentrated hubs of human-mediated movement, urban landscapes are often the first point of contact for alien insects and pathogens. Once established in urban environments there is potential for populations to build, and dispersal can proceed to natural forests. Consequences of these invasions include damage to natural ecosystems, costly attempts at eradication and post establishment management. Here we present two case studies of alien pests which used urban forests as bridgeheads to invade natural environments. After their arrival most species of alien wood-boring beetles spread in surrounding forests with an invasion success strongly correlated to the landscape characteristics, in terms of forest cover and forest composition. The Asian ambrosia beetle *Xylosandrus compactus* (Coleoptera Scolytinae) was first recorded in Europe in 2011 in urban parks of Naples (central Italy). Since 2016, strong outbreaks were recorded in the Circeo Italian National Park, representing the first report of the black twig borer in European natural forests. *Ceratocystis platani* (CP) causes a vascular wilt and canker disease of *Platanus* spp. The fungus, native to North America, was introduced during WWII into Europe. CP penetrates the host through wounds or by root anastomosis. CP caused widespread mortality of London plane in Italy, France and Switzerland, but the most dramatic impact has been in Greece. Once established in urban trees, it jumped to natural stands of oriental plane, killing each year thousands of trees that do not exhibit any sign of resistance.

Top-down control of insect herbivory in urban trees: does tree diversity matter?

Bastien Castagneyrol¹, Yasmine Kadiri¹, Hervé Jactel¹, Alain Paquette²

¹INRA, Cestas, France; ²UQAM, Montreal, Canada (bastien.castagneyrol@inra.fr; yasmine.kadiri@inra.fr; herve.jactel@inra.fr; alain.paquette@gmail.com)

Trees and tree diversity are increasingly acknowledged as key components of human wellbeing in urban ecosystems. Yet, pest insects can cause major damage and affect urban tree health. It has been proposed that tree diversity can reduce insect herbivory in forest through an increase in the diversity and activity of herbivore enemies. However, whether such benefits of tree diversity also occur in cities is still ignored. We addressed this question by quantifying insect herbivory in six tree species in parks of Montreal City (Canada) growing among conspecific or heterospecific neighbouring trees and by counting predation marks on dummy caterpillars. Insect herbivory and predator activity both varied among parks and tree species. Predator activity in spring correlated negatively with insect herbivory in mid-summer, suggesting a top-down control of herbivores by natural enemies. Differences among parks and tree species were partially mediated by changes in tree diversity and density. Our results show that predators can contribute to reduce herbivore damage on urban trees and provide insights into management options likely to favor this biological control.

Managing urban trees and forests under the threats of climate change, urbanization, and pollution

Iulia Milena Almeida Yakouchenkova¹, Gerhard Sardemann¹, Annika Fricke¹, Sarah Meyer-Soylu¹, Helena Trenks¹, Colette Waitz¹, Oliver Parodi¹, Andreas Seebacher¹, Jürgen Kopfmüller¹, Christine Rösch¹, Axel Albrecht², Andreas Matzarakis³, Martin Reuter⁴, Bernd Stähler⁵, Volker Stelzer¹, Somidh Saha¹
¹Karlsruhe Institute of Technology, Karlsruhe, Germany; ²Forest Research Institute of Baden-Württemberg, Freiburg, Germany; ³German Weather Service, Offenbach-Frankfurt, Germany; ⁴Municipality of Rheinstetten, Rheinstetten, Germany; ⁵Municipality of City Karlsruhe, Karlsruhe, Germany
 (iulia.yakouchenkova@kit.edu; gerhard.sardemann@kit.edu; annika.fricke@kit.edu; sarah.meyer@kit.edu; helena.trenks@kit.edu; colette.waitz@kit.edu; oliver.parodi@kit.edu; andreas.seebacher@kit.edu; juergen.kopfmuller@kit.edu; christine.roesch@kit.edu; axel.albrecht@forst.bwl.de; andreas.matzarakis@dwd.de; martin.reuter@rheinstetten.de; bernd.staehler@gba.karlsruhe.de; volker.stelzer@kit.edu; somidh.saha@kit.edu)

Cities and heavily urbanized areas in Germany are facing the challenge of preserving their green spaces (“green lungs”) under pressure from growing population and expanding infrastructure. At the same time, the vulnerability of cities to climate change-induced extreme weather events such as drought and heat waves has been increasing. Forests in urban areas reduce air pollution, mitigate heat stress and provide other ecosystem services. But they too are vulnerable to climate change and air pollution (e.g. NOx). Therefore, there is an urgent need to assess the resilience of urban trees and forests to climate change and pollution impacts in order to reduce vulnerability. Significant trade-offs may exist between conflicting management goals in urban trees and forest management which should be minimized through participatory decision making. In this context, participation of civil society, research institutions, local public institutions, and other stakeholders is of vital importance for future adaptation planning for urban green areas. In this presentation, we will present an innovative transdisciplinary concept to increase the resilience of urban trees and forests to multiple stressors of climate change and pollution. We will demonstrate how we could combine basic research, applied research, policy research, governance, and civil society under a transdisciplinary framework. We will present a case of on-going research in the city of Karlsruhe, Germany which is funded by the “Future Cities” program of the German Government. Our presentation may motivate international researchers, city planners, and policy makers to formulate similar transdisciplinary research for urban trees and forests in other cities.

Falling trees in Belo Horizonte: analysis of health conditions in individual trees / A ocorrência de queda de árvores em Belo Horizonte: análise das condições fitossanitárias dos indivíduos

Marina Souza¹, Agnus Bittencourt², Angeline Martini³

¹CEMIG, Belo Horizonte, Brazil; ²Prefeitura Municipal de Belo Horizonte, Belo Horizonte, Brazil; ³Universidade Federal de Viçosa, Viçosa, Brazil
 (mourasouzam@gmail.com; agnus@pbh.gov.br; martini.angeline@gmail.com)

As árvores urbanas proporcionam inúmeros benefícios para a população, contribuindo significativamente para a melhoria da qualidade de vida. Contudo, nos últimos tempos, foram frequentes os transtornos ocasionados por queda de árvores nas grandes cidades, tornando-se fundamental realizar investigações sobre este assunto. Desta forma, o objetivo da presente pesquisa foi analisar as condições fitossanitárias dos indivíduos arbóreos que caíram no município de Belo Horizonte. Para isso, os dados foram coletados por meio de amostragem aleatória após a ocorrência das quedas, entre os anos de 2015 e 2018. As variáveis coletadas foram: porte, condição de plantio, local de ruptura; qualidade da copa, troco e colo; presença de pragas ou sinais de doença. A análise, realizada em 69 exemplares arbóreos indicou que apenas 20,3% das árvores apresentaram problemas fitossanitários, desencadeados principalmente pelo ataque do besouro metálico e por cupins nas raízes. A maioria das árvores foram plantadas em calçadas e apresentavam grande porte (76,8%), com boas condições de copa (88%), tronco (88%) e colo (95%), não evidenciando problemas, sendo a ruptura ocorrida principalmente nas raízes (82,6%). Conclui-se, portanto, que a condição fitossanitária da árvore não deve ser o foco principal na análise de risco, pois na maioria dos casos de queda não se constatou este problema. A condição de plantio que promove a falta de espaço ou a dificuldade de enraizamento no solo urbano, teve relação mais expressiva com os casos de queda, evidenciando a dificuldade de ancoragem em árvores de grande porte.

About the effects of an climate change adapted species selection for the cooling ability of roadside trees

Laura Stratopoulos¹, Chi Zhang², Swantje Duthweiler¹, Karl-Heinz Häberle², Thomas Rötzer², Stephan Pauleit²

¹Weihenstephan-Triesdorf University of Applied Sciences, Freising, Germany; ²Technical University of Munich, Freising, Germany
 (laura.stratopoulos@hswt.de; forestrychi.zhang@tum.de; swantje.duthweiler@hswt.de; haeberle@wzw.tum.de; thomas.roetzer@lrz.tu-muenchen.de; pauleit@wzw.tum.de)

The role of trees in city cooling has warranted much attention based on concerns over climate change and urban expansion. Simultaneously, there is an interest in introducing species from dry habitats to cope with the increasing risks of drought under climate change. The physical performances of six frequently planted species, originating from two contrasting habitats, were tested in a drought experiment. We (1) investigated if species from drier habitats are more drought tolerant than species that have evolved in Central European woodlands under a temperate climate regime and (2) discussed the effect of tolerance on the cooling potential of these trees. Native species from mesic habitats maintained only 48% of their controls sap flux and of these species, *Tilia cordata* had the worst performance with premature leaf senescence. Species from drier habitats had less reduction in sap flux (60%) but lower stem growth, possibly favouring (fine) root development into deeper soil layers, as observed for *Tilia tomentosa*. Species' performance was obviously linked to within-plant carbon partitioning. A particularly high root:shoot ratio measured for *Acer campestre* made it presumably less susceptible to droughts. Higher stem water exploitation and stronger

regulation of water use at high evaporative demand were further reaction patterns that likely helped species from dry habitats maintain good physiological functions. Therefore, even under sustained drought, we expect them to have a high cooling capacity. Consequently, we recommend to plant them in extreme urban environments and to use the native habitat as a criterion to diversify and improve species selection.

Can forests take the heat? Managing pests and ecosystem services in urban landscapes

Steven Frank¹

¹North Carolina State University, Raleigh, USA (sdfrank@ncsu.edu)

Urban forests provide important benefits to urban residents and in mitigating climate change. However, US urban forests are shrinking due in large part to arthropod pests which are more abundant and damaging in urban than rural forests. Our hypothesis was that elevated temperatures and drought due to impervious surface cover drive arthropod pest abundance through several ecological mechanisms. We found that the urban heat island effect increases scale insect survival and that high temperatures create a phenological mismatch between scale insects and their parasitoids. This reduces biological control and increases scale reproduction. Finally, heat and drought stress combine to increase scale insect fecundity by 50 percent in sites with the most impervious surface cover. To counter these effects we developed impervious surface thresholds that planners and planters can use when designing sustainable urban landscapes.

D7i: PATTERNS IN FOREST INSECT HERBIVORY

Biases in studies of spatial patterns in insect herbivory

Elena L. Zvereva¹, Mikhail V. Kozlov¹

¹University of Turku, Turku, Finland (elezve@utu.fi; mikoz@utu.fi)

The properties of the human mind are responsible for a number of biases that affect the quality of scientific research. However, scientists working in the fields of ecology and environmental science rarely take these biases into account. We conducted a meta-analysis of data extracted from 125 publications comparing woody plant damage by defoliating insects in different environments in order to understand the extent to which our knowledge on spatial patterns in herbivory is affected by various biases. The effects sizes (ESs) decreased with increases in the numbers of plant species involved in the study, with 61% lower ESs for herbivory estimated on all plants growing in study plots compared to herbivory on selected species. When all leaves from a tree or branch were sampled for measurements of herbivory or when random or systematic selection protocols were applied, ESs were 74% smaller than in cases of more subjective haphazard selection. In addition, ESs were 97 and 135% greater when the person conducting sampling and measuring was aware of the research hypothesis or sample origin, when compared with situations when the observer was blinded to these factors. We concluded that our ecological and environmental knowledge is considerably biased due to an unconscious tendency of researchers to find support for their hypotheses and expectations. Cognitive biases can be avoided by applying randomization procedures in sampling and blinding of research hypotheses and sample origins, and these measures should be seen as obligatory to prevent false general conclusions in subsequent research synthesis.

How much leaf do insects eat? Patterns in herbivory and florivory for tropical plants

Tatiana Cornelissen^{1,2}, Maria Gabriela Boaventura¹, Cassio Pereira¹, Gisele Mendes¹

¹Universidade Federal de Minas Gerais, Belo Horizonte, Brasil; ²Universidade Federal de São João Del Rei, Sao Joao del Rei, Brazil (tatiana@ufsj.edu.br; mgabiboaventura@ufmg.br; cassio.cardozo@hotmail.com; giselemm@ufmg.br)

Herbivory has been shown to shape plant evolutionary paths, to affect plant population dynamics, community organization and ecosystem functioning. Insect herbivory, although ubiquitous, remains largely undocumented for tropical plants, which are host to more and sometimes more specialized herbivores, which might inflict higher damage. We reviewed the evidence for levels of herbivory for tropical plants based upon the published literature over the past 25 years and also collected data using a standardized protocol to evaluate herbivory and florivory levels for common tree species in tropical forests in Brazil. Herbivores removed approximately 12% ($11.18 \pm 2.61\%$) of leaf area of 61 plant species in 30 botanical families based upon published data. For data sampled using a standard protocol, a total of 3,791 leaves and 3,025 flowers were measured. Florivory, contrary to the expectations, exhibited highest tissue losses (7.6%) compared to herbivory (6.13%) for 14 plant species. These two antagonistic interactions occurred independently, but exhibited a direct relationship with functional traits of leaves and flowers, as herbivory levels were directly related to the specific leaf area (SLA) and florivory was positively related to corolla morphology, leaf duration and plant apparency. Plants without extra-floral nectaries (EFNs) were not patrolled by ants and exhibited much higher damage ($10.29 \pm 0.53\%$) than plants with EFNs ($4.81 \pm 0.28\%$) for six plant species examined in a single family. Our data shows that levels of herbivory in the tropics might have been underestimated by previous inventories and mechanisms shaping its occurrence and variation are under investigation.

Re-evaluating determinants on leaf herbivory of woody plants at global scale based on machine learning algorithm

Jian-Feng Liu¹, Qi Wang², Ze-Ping Jiang¹

¹Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China; ²Guangdong Institute of Eco-Environmental and Soil Sciences, Guangzhou, China (liujf2000cn@126.com; jenniferqi520@gmail.com; jiangzp@caf.ac.cn)

Herbivory rates are influenced by multiple biotic and abiotic factors. Quantifying the relative importance of these factors and how they interact are of great importance to elucidate driven mechanism and forecast associated carbon loss in the terrestrial ecosystems. In the present study, we compiled a large herbivory dataset ($n=1478$, including 788 species, 432 genus and 128 families) around the world from previous studies and corresponding environmental factors (e.g., bioclimatic and UVB variables), as well as phylogenetic age. The machine learning algorithm, Random Forest regressions, was used to identify relative importance and interaction between factors on leaf herbivory rate of woody plants. Our results showed that phylogenetic age accounted for the most important factor on herbivory variations, followed by soil organic carbon content (SOC) and mean UVB of the lowest month. Partial dependent analysis further revealed that leaf herbivory rates decreased nonlinearly with an increase of phylogenetic age and SOC, but increased with mean UVB of the lowest month. And Leaf herbivory rates increased more markedly toward the equator at the north hemisphere relative to the south hemisphere. These results would improve our understanding on geographical pattern of leaf herbivory.

Latitudinal variation in herbivory: hemispheric asymmetries, the role of climatic drivers and leaf traits

Shuang Zhang¹, Yuxin Zhang¹, Keming Ma¹

¹State Key Laboratory of Urban and Regional Ecology, Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing, China (shuangzhang@rcees.ac.cn; yxzhang@rcees.ac.cn; mkm@rcees.ac.cn)

We tested the latitudinal herbivory hypothesis (LH hypothesis) and the relationship of temperature, precipitation and leaf traits to herbivory. Based on a large dataset from more than 1000 plant species, our results show that herbivory decreased with latitude and increased with temperature only in the Northern Hemisphere. At the interspecific level herbivory had a hump-shaped relationship with leaf lifespan and a positive relationship with leaf size. Surprisingly, our data show that nutritional traits have little relationship to herbivory. Our study provides new insights relevant to the recent debate on the LH hypothesis and leaf trait–herbivory relationships. These findings are especially helpful in explaining the general patterns of herbivory detected on the global scale.

Humans don't eat leaves: human population reduces herbivory in the Mediterranean ecosystem

Juan Antonio Hernández-Agüero¹, Ildefonso Ruiz-Tapiador², Luis Cayuela¹

¹Universidad Rey Juan Carlos, Móstoles, Spain; ²Universidad Politécnica de Madrid, Madrid, Spain (juan.aguero@urjc.es; ildefonso.ruiztapiador@upm.es; luis.cayuela@urjc.es)

The degree of urbanization directly affects both biodiversity and abundance of animals and plants. Pollution may decrease the diversity of herbivorous insects but also the abundance of their predators. Moreover, it also increases the abundance of a few specialized herbivores. This would ultimately result in higher herbivory in urban areas. In this study, we investigated herbivory in leaves of six species, including *Quercus ilex*, in 12 natural and semi-natural areas along a population density gradient in Mediterranean woodlands of Spain. Our gradient encompasses unpopulated areas included within protected sites to the most populated city of the country. We used linear mixed models to assess the effect of population density on leaf damage while accounting for the autocorrelation of samples taken within the same site. Opposite of our expectations, we found an effect between the population density and the leaf damage, in which the more populated areas have lower levels of herbivory. This could be due to a reduction of both biodiversity and abundance of insects as a result of the synergistic effects of fragmentation and isolation of urban and peri-urban forests in addition to the effects of pollutants.

Temporal dynamics of associational resistance in mixed forests

Bastien Castagnyrol¹, Mikhail V. Kozlov², Charlotte Poeydebat¹, Maude Toigo¹, Hervé Jactel¹

¹INRA, Bordeaux, France; ²Univ. Turku, Turku, Finland (bastien.castagnyrol@inra.fr; mikoz@utu.fi; charlotte.poeydebat@inra.fr; maude.toigo@inra.fr; herve.jactel@inra.fr)

Tree diversity is one of the drivers of forest resistance to herbivores. Most of current understanding of diversity-resistance relationship comes primarily from short-term studies. At yet, knowing whether tree diversity effects on herbivores is maintained over time is important for perennial ecosystems like forests. We addressed the temporal dynamics of the diversity-resistance relationship by conducting a six-year survey of pine attacks by the pine processionary moth (*Thaumetopoea pityocampa*, PPM) in a tree diversity experiment where we could disentangle tree composition vs. host density effects. During the first years after planting the trees, PPM attacks on maritime pine (*Pinus pinaster*) were reduced in presence of birch (*Betula pendula*), a fast-growing non-host tree (i.e., associational resistance). This effect maintained but faded with time as pines eventually grew taller than neighbouring birches. The probability of individual pine trees being repeatedly attacked year after year also decreased in mixed pine – birch stands. Pine density had a positive effect on stand colonisation by PPM, and a negative effect on the proportion of attacked trees. Year-to-year variability in individual pine probability of attack also increased with pine density, attacks being spread over a larger number of host trees. Collectively, these results unravel the independent contribution of tree species composition and host density to tree resistance to herbivores. We show both processes had directional changes with time. These results indicate that the resistance of planted forests herbivores can be improved by carefully choosing the composition of mixed forest and the timing of species planting.

Positive outcomes between herbivore diversity and tree survival: effects of management on a Patagonian forest

Marcos Nacif¹, Thomas Kitzberger², Lucas Garibaldi¹

¹UNRN-IRNAD, S. C. de Bariloche, Argentina; ²CRUB-INIBIOMA, S. C. de Bariloche, Argentina (mnacif@unrn.edu.ar; kitzberger@gmail.com; lgaribaldi@unrn.edu.ar)

Sustainable forest management aims to enhance biodiversity and tree productivity. However, trade-offs may exist between these objectives, such as when insect diversity and associated herbivory decreases tree growth and survival. In addition, biodiversity and tree productivity can show non-linear responses to management intensity, making applied recommendations even more challenging. We studied the effects of thinning intensity on leaf damage diversity (as a proxy of insect folivore diversity), leaf damage frequency, growth and survival of planted trees in a North Patagonian shrubland (Argentina). We randomly applied four levels of thinning intensity (0, 30, 50, and 70% of basal cover removal) to experimental plots, and followed the responses during two years. Generalized mixed-effects models were estimated for each response variable. Leaf damage diversity and frequency showed non-linear responses to thinning, both increasing at intermediate thinning intensities. Such responses were consistent for contrasting feeding guilds, different diversity indexes, and during the two study years. Despite greater leaf damage (around 45% of the leaves were damaged), plant survival also showed a non-linear response to thinning, with higher values at intermediate thinning intensities during the two years. Similarly, planted trees grew more at intermediate thinning intensities, but only during the second year (tree growth increased linearly with thinning intensity during the first year). In North Patagonian shrublands, trees may face less competition for light and soil resources at intermediate thinning intensities, while at high thinning intensities water stress typical of dry Patagonian summers could reduce tree survival. Such benefits were not offset by the greater leaf damage observed at intermediate thinning intensities. Therefore, certain intermediate levels of forest management can provide the double service of increasing arthropod biodiversity and maximizing tree survival and growth.

Insect defoliation rates and human land use in forests in the southern Peruvian Andes

Norma Salinas^{1,2}, Eric Cosío³, Yolvi Valdez¹, Alex Nina¹, Percy Chambi¹, Vicky Huaman⁴, Gloria Rayme⁴, Melania Mendez⁴

¹Laboratorio de Ciencias Ecosistémicas, Instituto de Ciencias de la Naturaleza, Territorio y Energías Renovables, Pontificia Universidad Católica del Perú (Perú), Lima, Peru; ²School of Geography and the Environment, Environmental Change Institute, University of Oxford, Oxford, United Kingdom; ³Sección Química, Pontificia Universidad Católica del Perú (Perú), Lima, Peru; ⁴Escuela de Biología, Facultad de Ciencias, Universidad Nacional de San Antonio Abad del Cusco (Perú), Cusco, Peru (nsalinasr@pucp.pe; ecosio@pucp.pe; yvaldez1@pucp.pe; anina@pucp.pe; percychambip@gmail.com; vickyhq@gmail.com; glori_3@hotmail.com; melanimv.123@gmail.com)

Peru is a megadiverse country where the combination of tropical latitude, mountain ranges, and ocean upwelling (Humboldt current) generates a large diversity of climates. Despite their harsh climate, the Andes mountains have had highly diverse forests which have undergone massive land-use changes since human settlement with severe impacts on biota and forest structure. To evaluate the impacts of land use changes on the stability of the interactions between trees and plant feeding insects, we quantified the percentage of leaf area lost to or affected by defoliation (chewing insects). This was carried out in three types of forest: pristine or semi-natural, plantation, and urban or peri-urban forests around the city of Cuzco. The selected tree species was *Escallonia resinosa* which can be found in all aforementioned categories of forests around Cuzco. Our results show that defoliation rates increased in urban forests by 65-85% and in plantation forests by 0-40% when compared to natural forests, and that defoliation rates correlate negatively with plant diversity. We conclude that land use change and deficient management results in significant plant biomass losses in urban and plantation forests. The reduction in plant biodiversity and human forest management patterns can affect the presence and activity of insectivorous birds affecting both the productivity and the structure of these forest systems.

D7j: PHYTOPHTHORAS AS EMERGENT FOREST THREATS IN THE HUMAN-WILDLAND INTERFACE.

Exotic *Phytophthora* species are being systematically introduced in California wildlands during restoration projects

Matteo Garbelotto¹, Laura Sims^{1,2}

¹University of California, Berkeley, USA; ²Louisiana Tech University, Ruston, USA (matteog@berkeley.edu; simsla@latech.edu)

This study describes the identification of several *Phytophthora* species previously found in San Francisco Bay Area nurseries from multiple sites at the urban wildland interface within the greater San Francisco Bay Area. Isolation success was highest from the three plant species *Diplacus aurantiacus* (sticky monkey-flower), *Ceanothus thyrsiflorus* (blueblossum), and *Frangula californica* (California coffeeberry), growing in restoration sites and in adjacent disturbed sites. Isolation success instead was zero in control undisturbed “natural” areas adjacent to infested sites. In order to confirm plant production facilities were the source of the *Phytophthora* strains isolated from restoration sites, genetic and phenotypic analyses were performed on *Phytophthora crassamura*, one of the most common species identified during the course of this and other studies. Results indicated that field isolates were genetically identical to those found in plant production nurseries. Furthermore, resistance to fungicides such as phosphites and mefenoxam was identified in a select number of isolates found both in plant production facilities and wildland sites, further corroborating a “nursery” origin of wildland infestations. Spatial landscape-level analysis identified patterns of *Phytophthora* spread consistent with an outward expansion from sites that were planted and with topography, although the presence of some species was not associated with water accumulation patterns. *Phytophthora* species assemblages were site-specific and possibly related to site type, nursery where plants were grown, and time since planting. To our knowledge, this is one of the first studies providing robust evidence that exotic *Phytophthoras* are being systematically introduced through the use of infected plants in restoration projects.

PHYTO-THREATS: an analysis of *Phytophthora* communities in plant nurseries

Sarah Green¹, David Cooke², Debbie Frederickson-Matika¹, Mike Dunn¹, Beatrix Clark^{2,3}, Eva Randall², Peter Thorpe^{2,3}, Leighton Pritchard², Peter Cock², Tim Pettitt⁴, Alexandra Schlenzig⁵, Jane Barbrook⁶

¹Forest Research, Roslin, United Kingdom; ²James Hutton Institute, Dundee, United Kingdom; ³University of St Andrews, St Andrews, United Kingdom;

⁴University of Worcester, Worcester, United Kingdom; ⁵SASA, Edinburgh, United Kingdom; ⁶APHA, York, United Kingdom (sarah.green@forestry.gsi.gov.uk; david.cooke@hutton.ac.uk; debbie.frederickson@forestry.gsi.gov.uk; michael.dunn@forestresearch.gov.uk; beatrix.clark@hutton.ac.uk; eva.randall@hutton.ac.uk; pj16@st-andrews.ac.uk; leighton.pritchard@hutton.ac.uk; peter.cock@hutton.ac.uk; t.pettitt@worc.ac.uk; alexandra.schlenzig@sasa.gsi.gov.uk; jane.barbrook@apha.gsi.gov.uk)

PHYTO-THREATS is a multidisciplinary project which aims to address global threats from invasive *Phytophthora* species through understanding drivers of emergence and opportunities for mitigation through nursery best practice. One of the project's objectives is to examine the distribution and diversity of *phytophthoras* in plant nursery systems in Britain and to relate *Phytophthora* community composition to key factors such as nursery size, management practice and geographical location. Fifteen partner nurseries operating a range of management practices were intensively sampled across Britain between 2016 and 2018, resulting in 59 sampling missions and over 4000 root and water samples. In addition, a broader scale survey involving 101 nurseries nationwide was undertaken over the same time period resulting in 653 root samples. Samples were tested for *Phytophthora* DNA using a nested PCR targeting the *Phytophthora* ITS1 region. The species assemblage in each positive sample (approximately 50% of all samples) was then determined using an Illumina metabarcoding approach which involved the development and validation of a bioinformatics pipeline and custom curated database of verified *Phytophthora* ITS1 sequences. Sample results were reported back to each nursery manager as soon as available along with advice on the implications of each species detected and suggested improvements to management practice. Data will be presented on *Phytophthora* findings in relation to the key factors outlined above and linked to *Phytophthora* data from natural ecosystems in Britain as part of other, concurrent projects. The risk of transmission of species through trade and from nursery to wider landscapes will be discussed.

Urban forests: bridge-heads and sentinels for *Phytophthora* introductions

Treena Burgess¹, Trudy Paap², Giles Hardy¹

¹Murdoch University, Perth, Australia; ²University of Pretoria, Pretoria, South Africa (tburgess@murdoch.edu.au; trudy.paap@fabu.up.ac.za; g.hardy@murdoch.edu.au)

Recent studies of the routes of worldwide introductions of alien organisms suggest that many widespread invasions could have stemmed not from the native range, but from a particularly successful invasive population, which serves as the source of colonists for remote new territories. This phenomenon is known as the bridgehead effect. Urban forests are an attractive proposition to invasive pests; they consist of a mixture of native and exotic plant species, the environmental conditions are often not ideal for the tree resulting in stress which is further exacerbated by weed pressure, salinity, drought, excess nutrients, the heat island effect and fragmentation. In addition, the urban forest consists of a range of environments from intensely managed spaces to conservation areas. We have studied this phenomenon in Perth, Western Australia a city situated in one of the world's biodiversity hot spots (the south-west botanical province). Due to the huge impact of *Phytophthora cinnamomi* in the region, there has been extensive sampling within natural vegetation over 40 years providing an incomparable background data set. Urban studies have only just begun and yet more than twice the number of species have been found associated with declining trees within the city compared to native vegetation in the whole of the south-west of Western Australia.

Early detection of tree declines in urban and natural landscapes associated with *Phytophthora* diseases using airborne remote sensing systems

Giles Hardy¹, Treena Burgess¹, Mohammed Baidhani¹, Paul Barber²

¹Murdoch University, Perth, Australia; ²ArborCarbon, Perth, Australia (g.hardy@murdoch.edu.au; t.burgess@murdoch.edu.au; m.baidhani@murdoch.edu.au; p.barber@arborcarbon.com.au)

Numerous *Phytophthora* species cause devastating diseases in a broad range of tree and shrub species across urban and natural landscapes worldwide. Early diagnosis is critical for effective mitigation and implementation of management strategies to minimise their spread and impact. Remote sensing of vegetation health using hyperspectral and multi-spectral imagery from satellite, fixed-wing aircraft and unmanned vehicles (drones) increasingly offer high-resolution, cost-effective and robust ways of monitoring the presence, impact and spread of plant diseases. In addition, these tools can be used to monitor the effectiveness of fungicides and other management tools associated with re-routing tracks, roads and other hygiene or quarantine measures. This talk will discuss the use of narrowband multi-spectral imagery together with on-ground diagnostics using traditional and molecular methods to detect the presence of *Phytophthora* species in urban and natural landscapes together with continued monitoring to follow the effectiveness of management strategies. A number of different urban and natural landscapes together with different *Phytophthora* species will be discussed.

The emergence of *Phytophthora* species as foliar pathogens of forest plantations

Nari Williams¹, Stuart Fraser¹, Mireia Gomez-Gallego¹, Rebecca McDougal², Ian Hood¹, Lindsay Bulman¹

¹Scion, Rotorua, New Zealand; ²Scion, Rotorua, New Zealand (nari.williams@scionresearch.com; stuart.fraser@scionresearch.com; mireia.gomez@scionresearch.com; rebecca.mcdougal@scionresearch.com; ian.hood@scionresearch.com; lindsay.bulman@scionresearch.com)

Since the year 2000, the emergence of *Phytophthora* species as significant foliar pathogens of forest trees has challenged paradigms for the management of the diseases this group of pathogens cause within forest plantations. *Phytophthora pinifolia*, *P. pluvialis* and *P. ramorum* are all now recognized as having significant impact within conifer plantations in Chile, New Zealand and the United Kingdom, respectively, while other species including *P. lateralis*, *P. kernoviae*, *P. fallax* and *P. captiosa* have each been demonstrated as potentially significant pathogens of trees within forest plantations. The aerial nature of these pathogens in contrast to soil-borne activity of most *Phytophthora* species has seen them emerge rapidly with few limitations to their spread following establishment. This talk will discuss the recognition and emergence of *Phytophthora* pathogens impacting the foliage of plantation forest species with focus on *Phytophthora pluvialis* as the cause of a new disease, red needle cast on radiata pine and Douglas-fir plantations in New Zealand. An update will be given on the current status of the disease and responses by local foresters and researchers in managing the impacts of these pathogens of forest productivity.

Anthropogenic activities mediate pathogen movement and alien invasions into new and natural environments contributing to the formation of new hybrid species

Angela Dale^{1,2}, Nicolas Feau², Jean Bérubé³, Julien Ponchart⁴, Guillaume Bilodeau⁵, Richard Hamelin²

¹FPIInnovations, Vancouver, Canada; ²University of British Columbia, Vancouver, Canada; ³Natural Resources Canada, Quebec, Canada; ⁴Université Laval, Quebec, Canada; ⁵Canadian Food Inspection Agency, Ottawa, Canada (angela.dale@fpinnovations.ca; feaunico@mail.ubc.ca; jean.berube@rncan-nrcan.gc.ca; julien.ponchart.1@ulaval.ca; guillaume.bilodeau@canada.ca; richard.hamelin@ubc.ca)

Globalization and anthropogenic activities often result in human-mediated dispersal of pathogens causing a breakdown in biogeographic barriers and change in the range and distribution of species. Outside of high profile invasions, the general impact of anthropogenic activities on plant pathogen communities is still poorly understood. To study the effect of anthropogenic impacts, we compared pathogen communities in urban, natural and interface (e.g. parks) environments. We surveyed communities of oomycetes, using metabarcoding and *Phytophthora*, using metabarcoding and baiting methods. Oomycetes are a class comprising important crop and tree pathogens including *Phytophthora*, a genus comprising some of the world's most destructive pathogens. *Phytophthoras* introduced from nurseries or spread by human movement have caused landscape level outbreaks. Diversity and abundance in both groups was highest in human impacted urban environments and lowest in natural environments, while interface environments were intermediate. Urban environments had the largest proportion of sites where the plant pathogenic genus *Phytophthora* was found and also the largest number of unknown and hybrid *Phytophthora* species. The higher frequency of hybrids suggests that expanding *Phytophthora* species ranges could result in more opportunities for hybridization. The taxa overlap between urban and interface environments was five to seven times higher than between urban and natural environments. Our data suggests urban/natural interface areas likely act as bridges for invasion into natural environments. This could impact both natural biota and natural ecosystem processes. Shifting patterns in Oomycete communities could interfere with natural ecosystem processes and result in an increase in disease or ecosystem declines.

Division of labor among *Nasutitermes corniger* termites in the deterioration of forest species / Divisão de trabalho de cupins da espécie *Nasutitermes corniger* na deterioração de espécies florestais

Amanda Silva Soledade¹, Rimer Oliveira Maduro¹, Norma Bustamante¹, Rogério Fonseca¹

¹Universidade Federal do Amazonas, Manaus, Brasil (rogeriofonseca@ufam.edu.br; rimer.oliveira@gmail.com; ncbustamante@gmail.com; rogeriofonseca@ufam.edu.br)

Os cupins ou térmitas são insetos eussociais, que formam colônias com sobreposição de gerações, cuidado cooperativo da prole e divisão de trabalho. Para estudar a divisão de trabalho da espécie *Nasutitermes corniger* foi identificado um cupinzeiro na área do viveiro florestal, na Universidade Federal do Amazonas, coletado os cupins para cada experimento e levados ao laboratório para a realização dos testes. Foram realizados 6 experimentos para realizar a divisão de trabalho, comportamento exploratório, cuidado com os ovos, cuidado larval, cuidados com a rainha e frequência de alarme. As operárias fazem a maior parte dos trabalhos na colônia como cuidado com a rainha, larvas, alimentação das outras castas e reparação das paredes das colônias quando estas eram destruídas. Os soldados além da defesa do cupinzeiro também podem apresentar cuidado larval, porém com menos frequência do que o observado pelas operárias. As larvas são frágeis e não sobreviveriam sem o cuidado da colônia, quando colocadas em placa de petri apresentaram dificuldade de locomoção, mas o mesmo não foi observado quando estavam sobre superfícies ásperas. A rainha por apresentar dificuldade de locomoção precisa ficar cercada por operárias que a alimentam e fazem sua higiene por meio da trofalaxia de modo a manter a saúde da rainha do cupinzeiro. É necessário desenvolver estudos semelhantes em outros biomas e utilizando novos gêneros para que se possa alcançar um parecer final sobre a divisão de trabalho dos cupins, especialmente em espécies florestais de interesse madeireiro.

Temporal patterns of airborne *Phytophthora* spp. in a woody plant nursery area detected using real-time PCR

Duccio Migliorini¹, Luisa Ghelardini², Nicola Luchi¹, Francesco Pecori¹, Paolo Capretti², Alberto Santini¹ 

¹Institute for Sustainable Plant Protection – C.N.R., Sesto fiorentino, Italy; ²Dipartimento di Scienze delle Produzioni Agroalimentari e dell'Ambiente DiSPAA, University of Florence, Firenze, Italy (duccio.migliorini@ipspp.cnr.it; luisa.ghelardini@unifi.it; nicola.luchi@ipspp.cnr.it; francesco.pecori@ipspp.cnr.it; paolo.capretti@unifi.it; alberto.santini@cnr.it)

In this study, spore trap monitoring was applied to provide a proof of concept for the use of qPCR to detect *Phytophthora* in aerial samples and provide valuable information for epidemiological studies in nurseries. Two qPCR TaqMan assays were developed to detect pathogen DNA: the first used a generic probe to detect *Phytophthora* spp., and the second was based on a specific probe for detecting *P. ramorum* and *P. lateralis*. All samples tested positive for the genus *Phytophthora*, although *P. ramorum* and *P. lateralis* were not detected. In late spring and in autumn, two main peaks of *Phytophthora* sporulation were observed. Peaks were preceded by rainfall, high relative humidity, and mild temperature. From mid-May to the end of August, *Phytophthora* DNA detected in the air increased with relative humidity, while it decreased with increasing mean temperature. There was also a positive correlation between *Phytophthora* DNA detected and rainfall in the same period. No significant correlations between *Phytophthora* DNA and temperature or rainfall were found from the end of August to December. Our results are in agreement with those obtained with classical diagnostic methods based on microscopy, but the approach used here enabled rapid detection and relative quantification of the target organisms, thus assisting in the implementation of disease management strategies.

The role of *Phytophthora* in urban Bushland decline in Southeast Australia

Craig Nitschke¹, Muhammad Farrakh Nawaz², Linda Parker¹, Stefan Arndt¹

¹The University of Melbourne, Richmond, Australia; ²University of Agriculture Faisalabad, Faisalabad, Pakistan (craign@unimelb.edu.au; kf_uaf@yahoo.com; parker.l@unimelb.edu.au; sarndt@unimelb.edu.au)

Maroondah Council in Southeast Australia have raised concern about the decline of adult Eucalypt trees, particularly in some of their managed reserves. Multiple factors may be contributing to Eucalyptus decline in these reserves including drought, herbivory, and disease. We conducted a broad scale investigation of tree decline in 35 parks and reserves and found a wide spread decline of eucalypts and ubiquitous presence of *Phytophthora*. To determine if *Phytophthora* was contributing to the decline in eucalypts 10 healthy and 10 declined trees were selected randomly within two reserves and tested for the occurrence of the pathogen. We also measured physiological traits of healthy and declined trees. Declined trees all had infected roots, while > 50% of healthy trees also had *Phytophthora* in the roots. No differences in physiological traits of healthy or declined trees was found. Healthy and declined trees had the same water status, the same level of maximum drought stress and the same nutrient status. Declined trees had slightly lower starch concentration but a similar non-structural carbohydrate concentration. It is likely that *Phytophthora* infection decreased nutrient and water uptake, but this was compensated by leaf area adjustment by shedding leaves thereby minimizing water and nutrient requirements. The widespread presence of *Phytophthora* in urban green spaces has consequences for management and urgent action is required to minimize the spread of the disease and long-term action should be considered to future proof the green spaces to minimize a further spread of the pathogen.

D7k: PINE PITCH CANKER: STRATEGIES FOR MANAGEMENT OF *FUSARIUM CIRCINATUM* IN GREENHOUSES AND FORESTS (PINESTRENGTH)

COST Action FP1406: pine pitch canker: strategies for management of *Gibberella circinata* in greenhouses and forests (PINESTRENGTH)

Jorge Martín-García^{1,2}, Stephen Woodward³, Renaud Ioos⁴, Eeva Vainio⁵, Margarita Elvira-Recuenco⁶, Mercedes Fernandez², Jarkko Hantula⁵, Paolo Capretti⁷, Anna Maria Vettraino⁸, Rosa Raposo⁶, Andrea Vaninni⁹, Tugba Dogmus⁹, Artur Alves¹, Verica Vasic¹⁰, Marta Vasconcelos¹¹, Pablo Martínez-Alvarez¹², Julio J. Fusarium circinatum (teleomorph: *Gibberella circinata*) was first detected in North America, since when the pathogen has spread into Central and South America, South Africa, Asia and, more recently, Europe. *F. circinatum* is now considered the most important pathogen affecting *Pinus* seedlings and mature

trees in many countries globally; asymptomatic seedlings may be planted out, resulting in very serious losses in forests. The main aim of PINESTRENGTH is to establish a European-focused network to increase knowledge of the biology, ecology and pathways of spread of *F. circinatum*, to examine the potential for the development of effective and environmentally-friendly prevention and mitigation strategies and to deliver these outcomes to stakeholders and policy makers. To that end, a multidisciplinary approach is being taken, including researchers, forest managers and policy makers from 35 countries to date. Furthermore, any interested party is encouraged to join this COST Action, participating in some of the six Working Groups (WG1 The pathogen-diagnosis, WG2 Interactions with other forest pests and pathogens, WG3 Pathway of disease spread, WG4 Pest risk analyses, WG5 Management of the disease in forest and nurseries and WG6 Coordination, identifying research gaps and dissemination). For further information, please check <http://www.pinestrength.eu/>.

First report of pitch canker caused by *Fusarium circinatum* in Portuguese pine forest: detection, eradication and management

Helena Bragança¹, Eugénia Andrade¹, Eugénio Diogo¹, Clara Fernandes¹, Luis Fernandes², Diana Paiva^{2,3}, António Portugal^{2,3}, Dina Ribeiro⁴

Fusarium circinatum, the causal agent of Pine Pitch Canker is one of the most aggressive pathogens for pine. The fungus, considered to be native in America, was detected in several countries in America, Asia and also in South Africa. In Europe, the fungus was first reported in Spain, and then in Italy, France and Portugal. After the first detection in Portugal in 2007, an action plan was implemented by the Portuguese forest authority (ICNF), following EU regulation (Commission Decision 2007/433/EC). In the scope of that plan, an intensive survey was implemented every year (in nurseries, forests and seed production Centre) and hundreds of samples were analysed in three national laboratories. During consecutive years, positive results were only found in nurseries and none in forest samples. In 2016, a positive result was recorded by INIAV Mycology laboratory in an allotment of *P. radiata* seeds. Tracing the track of those seeds, a deep survey was done on the *P. radiata* provenance forest site. Despite few symptomatic trees were observed in that area, *F. circinatum* was detected for the first time in forest samples. Also in 2016, the fungus was detected in another site of young *P. radiata* trees in the center of Portugal. After these two records in field, nine years after the first detection in Portugal, ICNF forced the eradication of these two foci and intensified the management in field using a combination of tools and procedures to control and prevent the disease's spread in forest.

Pine nursery: and transplanting-disease associated with *Fusarium circinatum* in South Africa

Andrew Morris¹, Nicky Jones², Emma Steenkamp³
¹Institute for Commercial Forestry Research, Pietermaritzberg, South Africa; ²Sappi Forests Research, Hilton, South Africa; ³University of Pretoria, Pretoria, South Africa (andrew.morris@icfr.ukzn.ac.za; nicky.jones@sappi.com; emma.steenkamp@up.ac.za)

The pitch canker fungus (PCF), *Fusarium circinatum*, that has become distributed around the globe, is well known as the cause of resinous stem cankers of pine. In South Africa, PCF is also the cause of nursery and post-planting disease mortality. PCF was first identified in a forestry nursery in South Africa in 1990 and within a decade was found in all forest nurseries in the country. Production of the two main pine species planted, *Pinus patula* and *P. radiata*, was severely impacted. Following the nursery infections, post-planting mortality, up to two years after planting, was observed associated with PCF. Genetic diversity studies on PCF indicated that subsequent outbreaks of pine pitch canker disease in established plantations in South Africa were associated with nursery incidence of PCF. This presentation reviews the industry and research response to this serious problem. Post-planting mortality was shown to result from asymptomatic, infected planting stock despatched from nurseries rather than tree-to-tree infection processes in-field. Two interventions were developed to combat the disease. Firstly, hygiene measures were identified to reduce nursery inoculum to levels that thus diminishing not only nursery disease losses but also asymptomatic infection incidence and transplant mortality in field. Secondly, planting stock, genetically tolerant to PCF was developed for certain planting sites in the form of *P. patula* x *P. tecunumanii* hybrids. Development of a genetically diverse, asexual PCF population presents challenges for continued control of this disease. The presentation reflects on the importance of industry and academic collaboration and opportunities for further research.

Differential gene expression of *Pinus radiata* infected by an isogenic strain of *Fusarium circinatum* harbouring mitovirus FcMV2-1 and mycovirus-free

Cristina Zamora-Ballesteros^{1,2}, Alex Douglas³, Julio Diez^{1,2}, Jorge Martín-García^{1,4}
¹Sustainable Forest Management Research Institute, University of Valladolid – INIA, Palencia, Spain; ²Department of Vegetal Production and Forest Resources, University of Valladolid, Palencia, Spain; ³School of Biological Sciences, University of Aberdeen, Aberdeen, United Kingdom; ⁴Department of Biology and CESAM (Centre for Environmental and Marine Studies), University of Aveiro, Campus Universitário de Santiago, 3810-193, Aveiro, Portugal (cristinazamoraballesteros@gmail.com; a.douglas@abdn.ac.uk; jdcasero@pvs.uva.es; jorgemg@pvs.uva.es)

Pinus radiata is one of the most economically important pine species in the world due to its fast growth rate. Nevertheless, in turn, this conifer specie is the most susceptible host to Pine Pitch Canker disease caused by the fungal pathogen *Fusarium circinatum*. The fact that there are no effective means of controlling this devastating disease has led the search for new measures such as virocontrol. The infection of *F. circinatum* by putative mycoviruses apparently reduces the percentage of spore germination and mycelial growth, although it does not seem to affect the size of the lesions caused in *P. radiata* seedlings. In this investigation, mRNA sequencing (RNA-Seq) is used to identify differentially expressed genes during the interaction of *P. radiata* with isogenic strain of *F. circinatum* infected by mitovirus FcMV2-1 and free of mycoviruses including uninfected plants. The essay was carried out at two time points (4 and 11 days post inoculation) in order to obtain a more comprehensive view of the fungal invasion. Transcriptome analysis showed altered gene expression during the different interactions in the pathosystem formed by virus-fungus-plant.

An integrative toolbox to decipher defence mechanisms in *Pinus* species with differential responses to *Fusarium circinatum* infection: from physiology to Omics

Joana Amaral¹, Barbara Correia¹, Mónica Escandón¹, María Ángeles Castillejo¹, Luis Valledor², Jorge Martín-García^{1,3}, Artur Alves¹, Glória Pinto¹
¹Department of Biology and CESAM, University of Aveiro, Aveiro, Portugal; ²Department of Organisms and Systems Biology, University of Oviedo, Oviedo, Spain; ³Sustainable Forest Management Research Institute, University of Valladolid—INIA, Palencia, Spain (jsamaral@ua.pt; bscorreia@ua.pt; m.escandon.martinez@gmail.com; bb2casam@uco.es; valledorluis@uniovi.es; jorge.martin@ua.pt; artur.alves@ua.pt; gpinto@ua.pt)

Pine pitch canker, caused by *Fusarium circinatum*, represents a considerable threat to conifer forests worldwide and is currently associated to significant economic losses. Although essential for the development of disease mitigation strategies, little research focused on host susceptibility/tolerance mechanisms has been conducted. Therefore, we aim to explore the response of *Pinus* spp. with contrasting responses to *F. circinatum* infection using a multidisciplinary approach. A highly susceptible and a relatively tolerant pine species (*Pinus radiata* and *Pinus pinea*, respectively) were artificially infected with the pathogen and several analyses were carried out for both species when infected *P. radiata* seedlings exhibited disease symptoms. Morpho-physiological, hormonal and oxidative stress-related changes were assessed, as well as targeted gene expression, proteomic and metabolomic profiles, and epigenetic variation. Several species-specific responses were found by applying this holistic methodology. These are likely to be correlated with the outcome of *F. circinatum* infection for each species. Moreover, the integration of the data obtained and the construction of networks provide a comprehensive overview of pine defence mechanisms upon *F. circinatum* attack, defining new interaction, signalling pathways and related targets according to species susceptibility. These studies contribute to fulfil knowledge gaps on tree stress responses and allow developing markers for the implementation of environmentally sound integrated pest management solutions to control pine pitch canker.

Composition of endophytic community at different heights in *Pinus radiata* trees inoculated with *Fusarium circinatum*

Carmen Romeralo¹, Esteban Torres², Román Moreno², Jordán Muñoz², Pablo Martínez-Alvarez², Jorge Martín-García³, Julio Díez²
¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²University of Valladolid, Palencia, Spain; ³University of Aveiro, Aveiro, Portugal (carmenromeralo@gmail.com; estosa93@outlook.es; roman.moreno.helguera@gmail.com; ejordanmunoz@hotmail.com; pmtnez@pvs.uva.es; jorgemg@pvs.uva.es; jdcasero@pvs.uva.es)

The endophytic community is mainly composed by fungi and bacteria that live inside the trees without causing any visible symptom and together with the epiphytes conform the microbiome of a plant. The microbiome is currently considered as an integral determinant of a plant phenotype, and influencing ecologically important characteristics of the host, such as stress or disease tolerance. It has been shown that the structure and diversity of endophyte communities depend on the host, the geographical location and abiotic and biotic factors. However, there is a lack of studies investigating the vertical stratification of endophyte communities. In this study we analyze the composition of the endophyte communities in different heights of several *Pinus radiata* trees previously inoculated with the forest pathogen *Fusarium circinatum*, responsible for the Pine Pitch Canker disease. The total DNA was extracted and subjected to a NGS analysis with the Illumina platform. A total of 536 taxa of fungi were obtained in the 20 samples analyzed. We observed that the communities of endophytes were similar in the heights of 15, 65 and 115 cm but different from the species found at 165 cm and from the samples collected in the branches. The results of this study can provide further knowledge of the ecology of fungal endophytes and their paper as biological antagonists.

Fusarium circinatum: a great challenge in nursery production and the establishment of *Pinus radiata* plantations in Chile

Rodrigo Ahumada¹, Alessandro Rotella¹
¹Bioforest SA., Concepcion, Chile (rodrigo.ahumada@arauco.cl; alessandro.rotella@arauco.cl)

Fusarium circinatum is present in *Pinus radiata* nurseries in Chile since 2001 when was first reported by Wingfield et al (2001). The fungus is present in most of the *P. radiata* nurseries and is well-established despite the permanent effort made to reduce its negative impact in plant production and plantations establishment. This pathogen is still confined to nurseries and there is no evidence of the pitch canker disease in plantations in Chile or in other country in South America where is present. Monitoring is focused to have early detection in plantations and for that a national effort is made by forestry companies and the government, with special attention to insects that could be associated with *F. circinatum*, like the small banded pine weevil *Pissodes castaneus*, among others. *Fusarium circinatum* in Chile has very low genetic diversity and only one mating type, probably related with a low number of introductions into the country. Some initiatives have been made to select genetic material of *P. radiata* tolerant to *F. circinatum* and also on the definition of risk areas where *P. radiata* could have high stress, allowing the fungus its expression. Good practices at the nursery are crucially important to reduce the amount of inoculum, and these practices should include a rigorous elimination of symptomatic plants, sanitization of machines, tools, hands and shoes of the workers. A combination of tools whit chemical and biological fungicides, bioestimulants, sanitization and quality plant improvement, show that is possible to reduce mortality during the plantations establishment.

Advances on *Fusarium circinatum* research: a case studies of COST FP 1401 STMS

Tomasz Oszako¹, Katerina Davydenko², Kristina Raitelaityte³, Roberto Faedda⁴, Katarzyna Sadowska⁵, Tadeusz Malewski⁶, Dymitri Voitka⁷, Magdalena Gawlak⁸, Julio Javier Díez Casero⁸, Pola Wartalska¹

Pathogenicity tests with Polish and Lithuanian Scots pine provenances were carried out revealing tolerance of some of them to *Fusarium circinatum* infections performed via wounds and via soil. While 3 month-old seedlings were not successfully infected (no symptoms and positive results of pathogen DNA tests in the tissue of roots and shoots) in contrast to the older plants (1 year-old and more), which showed external symptoms of disease (and positive DNA tests). Interaction between soil borne fungi *Fusarium* genus and *Phytophthora* species revealed different reaction of *F. circinatum* and other species of *Fusaria*, sometime stimulating growth of its mycelium another time inhibiting it. SEM photographs show the interaction zones. Biological control with the use of bacteria *Bacillus subtilis* and hyper parasite *Trichoderma asperellum* was quite efficient in dual organism tests in vitro. Detection and identification of pathogens with an electronic nose is a promising tool for quarantine organisations. Chromatograms from GCMS reveal specific substances differencing fungi from oomycetes.

Disclosing effective methods in the *Pinus* spp. seeds treatment to the Pine Pitch Canker prevention

Daniela Ferreira^{1,2}, Teresa Pinto^{3,4}, Maria João Gaspar^{2,5}, Paula Seixas Oliveira^{1,4}, Fernando Raimundo^{3,4}, Rosário Anjos^{3,4}, Helena Bragança⁶, Dina Ribeiro⁷, Luís Miguel Ferreira Martins^{1,4}

Fusarium circinatum is a fungus and is the causal agent of the Pine Pitch Canker. It affects different *Pinus* spp. and is characterized by resinous lesions and branch dieback, causing reduced growth and extensive tree death. *Fusarium circinatum* may also be present in *Pinus* spp. seeds without showing symptoms and its detection in nurseries results in the inhibition of sale for a period of two years. Thus, it is essential to determine the most efficient methods in the treatment/elimination of *F. circinatum* in *Pinus* spp. seeds. Here, we used seeds from *P. pinaster*, *P. radiata* and *P. pinea*, inoculated with *F. circinatum* to analyze the effects of different concentrations of hydrogen peroxide (H₂O₂), sodium hypochlorite (NaClO), thiophanate-methyl and difenoconazole. In order to prove the efficiency of the treatment, the seeds were plated in specific medium and incubated at 22°C during 7 days; after that, the *Fusarium* spp. colonies were transferred to PDA and SNA medium, for morphological identification; it was also extracted DNA from the PDA colonies and it was performed a PCR reaction with *F. circinatum* specific primers. The treatment with H₂O₂ (20% and 30%) was the one with the best outcome in all *Pinus* spp. seeds tested. With this treatment, we were able to eliminate the presence of *Fusarium circinatum* in all the tested seeds, being a reproducible result. Furthermore, it was possible to observe germinating seeds in the DCPA medium in 7 days of growth, which means that the H₂O₂ treatment might not affect the germination capacity.

Gene expression profile of *Fusarium circinatum* in response to the infection of the putative Mitovirus FcMV1

Cristina Zamora-Ballesteros^{1,2}, Brenda Wingfield³, Jorge Martín-García^{4,5}, Julio Diez^{1,2}

¹Sustainable Forest Management Research Institute, University of Valladolid – INIA, Palencia, Spain; ²Department of Vegetal Production and Forest Resources, University of Valladolid, Palencia, Spain; ³Department of Genetics, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa; ⁴Department of Biology and CESAM (Centre for Environmental and Marine Studies), University of Aveiro, Campus Universitário de Santiago, 3810-193, Aveiro, Portugal; ⁵Sustainable Forest Management Research Institute, University of Valladolid—INIA, Avenida de Madrid 44, 34071, Palencia, Spain (cristinazamoraballesteros@gmail.com; brenda.wingfield@up.ac.za; jorgemg@pvs.uva.es; jdcasero@pvs.uva.es)

Virus infections generally are ubiquitous in major fungal families including plant-pathogenic fungi. The effects of these mycoviruses range from asymptomatic to detrimental conferring hypovirulence to their host. Three different mycoviruses of the genus *Mitovirus* has been identified infecting Spanish isolates of the conifer pathogen *Fusarium circinatum* (FcMV1, FcMV2-1 and FcMV2-2). Mitoviruses has been associated with the hypovirulence phenomenon in many phytopathogenic fungi, motivating the study of *F. circinatum* mycoviruses in an attempt to limit the effects of the devastating Pine Pitch Canker disease. Although the presence of mitoviruses does not seem to affect the size of the lesions caused by *F. circinatum*, it does so reducing the percentage of spore germination and mycelial growth. Thus, metabolic activity reduction could be related to the presence of mitoviruses but it is necessary the use of more accurate methods to determine their effect beyond the visible symptoms. The development of new tools based on host genome studies helps to address the intellectual challenge of understanding the fungal–virus interactions. For the purpose to identify genes linked to the presence of the mitovirus FcMV1, standard differential expression analysis was carried out using RNA-Seq. Total RNA from virus-infected and cured isogenic *F. circinatum* strains was isolated and sequenced. CLC Genomics Workbench V7.5 was used to perform the bioinformatic analysis. As a result, 14 genes were differentially expressed in response to mitovirus FcMV1 infection. Our analysis provides further detailed insights into mitovirus-*F. circinatum* interaction.

Fusarium species associated with bark beetles in *pinus radiata* plantations affected by Pine pitch canker

Diana Bezos¹, Pablo Martínez-Alvarez¹, Antonio Sanz-Ros¹, Jorge Martín-García¹, Mercedes Fernández¹, Julio J. Diez¹

¹Universidad de Valladolid, Palencia, Spain (diana.bezos@uva.es; pmtnez@pvs.uva.es; asanzros@gmail.com; jorgemg@pvs.uva.es; mffernan@agro.uva.es; jdcasero@pvs.uva.es)

Fusarium species, as well as other endophytic or pathogenic fungi forming fungal communities, have been reported to be phoretically associated with bark beetles vectors worldwide. This is the case of *Fusarium circinatum*, the causal agent of pine pitch canker, which threatens *Pinus radiata* plantations in northern Spain. The main objective of this study was to study the fungal communities present on bark beetles and their galleries in pine pitch canker diseased stands with special attention to *Fusarium* species. Ten funnel traps and 12 piles of logs were displayed in a *P. radiata* plot affected by *F. circinatum*. Traps were baited with different attractive compounds, four with ptyol and six with ethanol and α -pinene. In addition, fresh green shoots with *Tomicus piniperda*'s feeding galleries were collected from the ground in 25 *P. radiata* affected plots. Collected insects and gallery tissues were processed and cultured with the aim of isolating and identifying associated fungi. A total of 24 different fungal species were obtained from the bark beetles galleries from logs and shoots while 18 were obtained from the insects' exoskeleton. Ten different *Fusarium* species were isolated from tissues and insects. *Fusarium circinatum* was isolated from bark beetles exoskeletons (1.05% of the *P. pubescens*) and from their galleries (3.5% of *T. piniperda*'s feeding gallery). These results are an approach to the fungal communities associated with bark beetles in *P. radiata* PPC diseased stands in northern Spain, suggesting an association between bark beetles and *Fusarium* species, which is highlighted by the presence of *F. circinatum* in *T. piniperda*'s galleries.

Vertical transmission of *Fusarium circinatum* mitoviruses FcMV1 and FcMV2-2 via microconidia

Carmen Romeralo¹, Diana Bezos², Pablo Martínez-Alvarez², Julio Diez²

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²University of Valladolid, Palencia, Spain (carmenromeralo@gmail.com; dianabezos@gmail.com; pablomtnez@hotmail.com; jdcasero@pvs.uva.es)

Pine Pitch Canker disease, caused by the pathogenic fungus *Fusarium circinatum*, affects conifer species worldwide. However, the virulence of the pathogen may be affected by the presence of mycoviruses. The aim of this laboratory-based study was to investigate the probability and rate of transmission of *F. circinatum* mitoviruses FcMV1 and FcMV2-2 via microconidia. Ten isolates of mitovirus-infected *F. circinatum* were subcultured to produce a total of 100 single-spore colonies (ten replicates per isolate). The total RNA and cDNA obtained from each spore isolate (monosporic culture) were amplified by PCR

with specific primers for detection of *F. circinatum* mitoviruses FcMV1 and FcMV2-2. The mitoviruses were detected in a high percentage of the individual spore isolates (between 60% and 100% depending on the fungal isolate). However, the probability of transmission was not statistically significantly associated with either the *F. circinatum* isolate or the viral strain. A high proportion of transmission via microconidia is critical for development of a biological control program against Pine Pitch Canker (PPC) disease in forests. However, further studies are needed to establish the effect of these mitoviruses on the virulence of *F. circinatum*.

Unravelling pathogenicity and resistance mechanisms in the *Pinus* spp / *Fusarium circinatum* pathosystem

Jorge Martín-García^{1,2}, Joana Amaral¹, Emigdio Jordan Muñoz-Adalia^{2,3}, Julio Javier Díez^{2,3}, Glória Pinto¹, Artur Alves¹

¹Department of Biology and CESAM, University of Aveiro, Aveiro, Portugal; ²Sustainable Forest Management Research Institute, University of Valladolid—INIA, Palencia, Spain; ³Department of Plant Production and Forest Resources, University of Valladolid, Palencia, Spain (jorge.martin@ua.pt; jsamaral@ua.pt; ejordanmunoz@hotmail.com; jdcasero@pvs.uva.es; gpinto@ua.pt; artur.alves@ua.pt)

Nowadays, European forests are exposed to a high number of invasive alien pathogens. Among them, *Fusarium circinatum* is considered as one of the most important pathogens of conifers globally. Little is known regarding the infection and defense mechanisms involved in this pathosystem, even though this information is crucial to develop management strategies. Interspecific variation in pine susceptibility against *F. circinatum* is the key to identify the genes involved in these mechanisms. In the present study three pine species (*P. radiata*, *P. pinaster* and *P. pinea*) were selected according to a negative gradient of susceptibility. RT-qPCR was used to identify the differential expression of 8 target genes (5 from the pathogen and 3 from the host) according to the host species at two different sampling points (12 and 20 days after inoculation). Differential expression of *F. circinatum* pathogenicity genes was dependent on the host species and sampling point. In particular, the lowest and highest expression level of *F. circinatum* genes were found in *P. radiata* and *P. pinea*, respectively. This concurs with the susceptibility of these pine species. An opposite pattern was found between both pine species according to disease progression (12 vs; 20 dpi), which seems to point out that seedlings could not avoid infestation but the resistant species (*P. pinea*) could develop any resistance mechanism to prevent its progress. Pathogenesis-related genes of the host showed significant differential expression according to the species, but no effect of the sampling point was found.

Biodiversity of fungal endophytic community in several pine species previously inoculated with *Fusarium circinatum*

Carmen Romeralo¹, Esteban Torres², Román Moreno², Jordan Muñoz², Pablo Martínez-Alvarez², Jorge Martín-García³, Julio Díez²

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²University of Valladolid, Palencia, Spain; ³University of Aveiro, Aveiro, Portugal (carmenromeralo@gmail.com; estosa93@outlook.es; roman.moreno.helguera@gmail.com; ejordanmunoz@hotmail.com; pmtnez@pvs.uva.es; jorgemg@pvs.uva.es; jdcasero@pvs.uva.es)

The microbiome of a plant is composed of endophytic (internal) and epiphytic (external) microbes, mainly bacteria and fungi. The endophytic community (i.e. organisms that live inside the plant without causing any visible symptom) is increasing in importance because their interaction with the host and with other organisms such as pathogens. It is known that the degree of tolerance of a host to a certain pathogen is a combination of genetic resistance, the environment and the microbes that live inside the plant. In the present study we focus on the diversity of fungal endophytic communities in different pine species (*Pinus radiata*, *P. pinaster*, *P. sylvestris*, *P. nigra* and *P. uncinata*) previously inoculated with the forest pathogen *Fusarium circinatum* and grown in the same environment. The study of fungal species was carried out with NGS (Next Generation Sequencing) technologies. The results of our study showed that existed a common core microbiome among all the samples that was composed of several endophytic fungi: *Alternaria alternata*, *Pleospora herbarum*, *Cryptococcus terreus* and *Cladosporium sphaerospermum*. We also found differences between the endophytic communities of each pine species being the community of *Pinus uncinata* the one that presented more dissimilarities with the others. The results of our study could provide valuable information about species composition and the role of the fungal species as biological antagonists of forests pathogens.

In recent decades, the myrtle rust pathogen, *Austropuccinia psidii*, has spread worldwide on diverse myrtaceous species. Genetic and genotypic diversities within and among *A. psidii* populations were evaluated in Brazil and other areas of myrtle rust emergence in the Americas and Hawaii. Several unique multilocus genotypes (MLGs) were identified by microsatellite markers, which were grouped into nine distinct genetic clusters: C1 - diverse hosts in Central America,

Caribbean, and USA-Hawaii, and USA-California; C2 - eucalypts (*Eucalyptus* spp.) in Brazil/Uruguay and rose apple (*Syzygium jambos*) in Brazil; C3 - eucalypts in Brazil; C4: from diverse hosts in USA-Florida; C5 - Java plum (*Syzygium cumini*) in Brazil; C6 - guava and Brazilian guava (*Psidium guineense*) in Brazil; C7 - pitanga (*Eugenia uniflora*) in Brazil; C8 - allspice (*Pimenta dioica*) in Jamaica and sweet flower (*Myrrhinium atropurpureum*) in Uruguay; and C9 - jaboticaba (*Myrciaria cauliflora*) in Brazil. One C1 MLG was associated with multiple hosts and diverse geographic regions. The C1 and C4 cluster are considered as a "Pandemic biotype," associated with myrtle rust emergence in Central America, Caribbean, USA-Florida/Hawaii, Australia, China-Hainan, New Caledonia, Indonesia, and Colombia. Geographic locations with suitable climate for *A. psidii* that are at risk from invasion were predicted using maximum entropy bioclimatic modelling using 19 bioclimatic variables, documented occurrences of *A. psidii*, and sets of genetic clusters (subnetworks, considered as biotypes). When assessing the invasive threats posed by *A. psidii* around the globe, it is important to consider the genetic diversity of *A. psidii* and its biotypes.

Myrtle rust: impact on native Australian Myrtaceae and associated plant communities

Geoff Pegg¹, Angus Carnegie², Fiona Giblin¹, Louise Shuey¹

¹Horticulture & Forestry Science, Department of Agriculture & Fisheries, Brisbane, Australia; ²NSW Department of Primary Industries - Forestry, Sydney, Australia (geoff.pegg@daf.qld.gov.au; angus.carnegie@dpi.nsw.gov.au; fiona.giblin@daf.qld.gov.au; louise.shuey@daf.qld.gov.au)

Austropuccinia psidii (myrtle rust) has long been considered a significant threat to Australian plant industries and ecosystems. The rust was first detected in Australia in April 2010 on the central coast of New South Wales and has continued to spread with detections extending from Tasmania in the south, Cape York Peninsula in the North East, and west to Arnhem Land in the Northern Territory. The current host list for Australia includes >350 species from 57 genera. *Austropuccinia psidii* severely affects key species in natural ecosystems, with localised extinctions recorded (*Rhodomyrtus psidioides* and *Rhodamnia rubescens*) and with many species no longer ecologically functional. Our studies have demonstrated severe impacts of myrtle rust on native plant communities. *Austropuccinia psidii* has caused significant disturbance in lowland subtropical rainforest and wet sclerophyll environments where Myrtaceae dominate the rainforest understorey. Similar impacts have been recorded in coastal heath environments affected by wildfire (*Melaleuca nodosa*, *Leptospermum* spp.) with severe decline in once dominant species and little evidence of regeneration potential. Keystone species such as *Melaleuca quinquenervia* are also being impacted, with tree deaths and reduced flowering rates recorded. Future research programs are required to identify and monitor species and plant communities at greatest risk of decline. The implementation of a disease screening and tree breeding program may be required for some species as without intervention, regaining lost genetic diversity within these populations may not be possible. The rate of decline of some species is alarming and retaining viable germplasm for conservation purposes is essential.

The impact of myrtle rust in New Zealand

Beccy Ganley¹, Julia Soewarto², Roanne Sutherland²

¹The New Zealand Institute for Plant and Food Research Ltd, Te Puke, New Zealand; ²Scion, Rotorua, New Zealand (beccy.ganley@plantandfood.co.nz; julia.soewarto@scionresearch.com; roanne.sutherland@scionresearch.com)

Austropuccinia psidii was first found in New Zealand in spring 2017 and an incursion response was immediately instigated. During this response Myrtaceae across large areas of New Zealand were surveyed for the presence of myrtle rust. The disease has now spread across the majority of the North Island and the top of the South Island, and is known to be present in urban and native trees. Long-term monitoring plots have been established in native forests to determine the impact of myrtle rust on foliage, flowers and fruits of mature trees and on seedling survival. The monitoring plots established have focused on one of New Zealand's most susceptible native species *Lophomyrtus bullata* (ramarama) and its natural hybrids with *Lophomyrtus obcordata* (rohutu), but also include a range of other myrtaceous plants present within the plots such as *Metrosideros* spp. and *Leptospermum scorparium*. Here we discuss the impact this disease has had on the plant species in these plots and the implications for native New Zealand Myrtaceae, as well as the long-term surveillance and management options underway for this disease.

Alternative fungicides for the control of myrtle rust on *Metrosideros excelsa*

Karanjeet Sandhu¹, Amin Pathan², Mark Kimberley², Robert Park¹

¹University of Sydney, Sydney, Australia; ²Ministry for Primary Industries, Rotorua, New Zealand (karanjeet.sandhu@sydney.edu.au; amin.pathan@mpi.govt.nz; mark.kimberley@scionresearch.com; robert.park@sydney.edu.au)

Myrtle rust caused by fungus *Austropuccinia psidii* was first detected in Australia and New Zealand in 2010 and 2017 respectively. Pathogen *A. psidii* with vast host range can be determinantal to numbers of potentially vulnerable native species of Myrtaceae. *Metrosideros excelsa* 'Nana' an evergreen native tree, also known as pohutukawa and culturally significant to Māori people, is highly susceptible to myrtle rust. Greenhouse replicated trials were conducted to assess preventative and curative efficacy of different fungicides against myrtle rust on *M. excelsa* 'Nana' plants. Nineteen treatments included six fungicides alone (AmistarXtra, Bayfidan 250 EC, Dedicatêa, Radialâ, Sapolâ and tea tree oil based organic fungicide TimorexGold®), each fungicide plus adjuvant 'Hasten' and 'Spreadwett' separately and only water treated controls. Treatments were applied 7 and 14 days before inoculation (DBI) and at 7, 14 and 21 days after inoculation (DAI) using 500 L ha⁻¹ spray volume with Generation III spray booth. Post inoculation treatments were resprayed at 10 days interval from the previous treatment. Percent leaf area infected (%LAI) with active sporulation on abaxial side of leaves was recorded at 14DAI. All fungicides significantly reduced %LAI as compared to controls in both pre and post inoculation treatments. Treatments at 7DBI followed by 7DAI were most effective and 21DAI timing was least effective. Among the fungicides, Amistar®Xtra was most effective and TimorexGold® was least effective in reducing %LAI. Both adjuvants didn't make any difference and results suggested that fungicides efficacy is reduced if used beyond 7DBI and 7DAI spray timings.

Chemical and physical foliar response of *Corymbia citriodora* subsp. *variegata* inoculated with two pathogen species

Flavia Sarti Bonora¹, Andrew Hayes¹, David Lee¹, Helen Nahrung¹

¹University of the Sunshine Coast, Sunshine Coast, Australia (fsartabo@usc.edu.au; rhayes@usc.edu.au; dlee@usc.edu.au; hnahrung@usc.edu.au)

Spotted gums (*Corymbia* spp) are a valuable source of commercial timber, gaining importance in South Africa, Brazil, China and Australia. In Australia, spotted gums are severely damaged by the endemic fungal pathogen *Quambalaria pitereka* which infects new foliage, causing spotting, necrosis and distortion. Myrtle rust (*Austropuccinia psidii*), a highly invasive exotic fungal pathogen, also infects spotted gums and has been present in Australia for less than a decade. Both pathogen can reduce tree fitness and productivity. As well as differing co-evolutionary histories with spotted gums, the two pathogens have different mechanisms of infection and colonization, with *Q. pitereka* entering via stomata and only growing intercellularly, and *A. psidii* penetrating directly through the cuticle, entering the cell and producing haustoria. Both pathogens exhibit significant variation in their infection of spotted gum provenances. Leaf oil compounds such

as terpenes are recognized for their fungicidal effects and may support plant protection strategies against fungal pathogens. Fungal pathogens may also affect - and be affected by - leaf physical traits such as leaf toughness. Seedlings of *Corymbia citriodora* subsp. *variegata* were inoculated with spores of *Q. pitereka*, *A. psidii* or no spores. Leaf samples were collected when the seedlings were showing signs of infection. We determined leaf toughness and leaf oils were identified by gas chromatography-mass spectrometry. This research examined the variation of fungal susceptibility and the interaction of pathogens with plant leaf oils and physical traits for *Q. pitereka* and *A. psidii*, considering their different mechanisms of infection.

Does *Austropuccinia psidii* reproduce sexually in Australia?

Alistair R. McTaggart¹, Louise Shuey², Stuart Fraser³, Andre Drenth¹, Geoff Pegg²

¹University of Queensland, Brisbane, Australia; ²Department of Agriculture and Fisheries, Brisbane, Australia; ³Scion, Rotorua, New Zealand
(a.mctaggart@uq.edu.au; louise.shuey@daf.qld.gov.au; stuart.fraser@scionresearch.com; a.drenth@uq.edu.au; geoff.pegg@daf.qld.gov.au)

Invasions and epidemics of *Austropuccinia psidii* are caused by its clonal spore stage, urediniospores. Recombination was thought uncommon, even in areas in which it was native. In a previous study, we showed that basidiospores (the gametic spores) of *A. psidii* infected species of Myrtaceae and sexual reproduction was part of its life cycle. We supported this finding with evidence that recombination and infection of Myrtaceae by basidiospores occurred in natural ecosystems of New Zealand and South Africa. We used three lines of evidence to test for sexual reproduction, the sexual stage was present, there was high genotypic diversity and there was no linkage between microsatellite loci. Our current study tests whether sexual reproduction has occurred in Australia. We have sampled single pustules at one location over several years. We will screen over 50 single pustules with 12 microsatellite markers to determine whether the population at this field site is recombinant. Our research findings so far show that teliospores and basidiospores play a role in the life cycle and spread of disease. We have flagged questions relevant to Eucalyptus forestry such as whether different strains of *A. psidii* can outcross and overcome disease resistance.

Assessment of the susceptibility of native New Zealand Myrtaceae to infection by the South African strain of *Austropuccinia psidii*

Julia Soewarto¹, Chanatda Somchit¹, Esna Du Plessis², Irene Barnes², Michael J. Wingfield², Michael Bartlett¹, Peter Scott³, Elizabeth Miller¹, Louise Shuey⁴, Nick Waipara⁵, Ginna Granados², Roanne Sutherland¹, Beccy Ganley³

¹SCION, Rotorua, New Zealand; ²Forestry and Agricultural Biotechnology Institute (FABI), Pretoria, South Africa; ³The New Zealand Institute for Plant & Food Research Ltd, Te Puke, New Zealand; ⁴Horticulture & Forestry Science, Department of Agriculture & Fisheries, Brisbane, Australia; ⁵The New Zealand Institute for Plant & Food Research Ltd, Auckland, New Zealand (julia.soewarto@scionresearch.com; chanatda.somchit@scionresearch.com; esna1706@gmail.com; irene.barnes@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za; michael.bartlett@scionresearch.com; peter.scott@plantandfood.co.nz; elizabeth.miller@scionresearch.com; louise.shuey@daf.qld.gov.au; nick.waipara@plantandfood.co.nz; ginna.granados@fabi.up.ac.za; roanne.sutherland@scionresearch.com; beccy.ganley@plantandfood.co.nz)

At least nine strains of *Austropuccinia psidii* (the myrtle rust pathogen) are known to occur internationally. Most of these are found in Central and South America and specifically associated with hosts in the Myrtaceae family. However, two aggressive and unique strains has been reported outside the presumed native range of *A. psidii*. One strain, known as the pandemic strain, infects a wide spectrum of hosts and has an extensive geographical range. It has been found in Colombia, California, Hawaii, Indonesia, Australia, New Caledonia and more recently in New Zealand. The other myrtle rust strain occurs in South Africa, where it infects both native and introduced Myrtaceae. Knowledge regarding the level of susceptibility of native Myrtaceae to the different strains of *A. psidii* and the biology of the pathogen is essential to address the best management options for Myrtle rust in New Zealand. In this study, we considered the levels of resistance and/or susceptibility of four native New Zealand species (*Leptospermum scoparium*, *Metrosideros excelsa*, *Kunzea linearis* and *K. robusta*) to the South African strain of *A. psidii*. Seeds from geographically distant populations were collected for screening that was conducted in a greenhouse in South Africa. The results revealed interspecific variability in susceptibility to the South African *A. psidii* strain, with the *Kunzea* species more tolerant and/or resistant than the other tested species. This study demonstrated the potential threat that the South African *A. psidii* strain could have in native forests, nurseries and plantations in New Zealand.

D7m: FOREST HEALTH CHALLENGES FROM GLOBALISATION AND CLIMATE CHANGE

BioSurveillance of Alien Forest Enemies: the bioSAFE initiative

Richard Hamelin¹

¹The University of British Columbia, Vancouver, Canada. Université Laval, Quebec city, Canada (richard.hamelin@ubc.ca)

The world's forests face unprecedented threats from invasive insects and pathogens that can cause large irreversible damage to the ecosystems. This threatens the capacity to provide long-term fibre supply and ecosystem services that range from carbon storage, nutrient cycling, water and air purification, soil preservation and maintenance of wildlife habitat. The key to reduce this threat is via vigilant biosurveillance to increase preparedness and facilitate early interventions. This requires collecting and sharing data that can be used to rapidly and accurately identify samples from various life stages of insects and pathogens and assign them to taxa and sources so that pathways of introduction can be discovered. Assessing the risk that is posed by alien species also requires a better understanding of the traits underlying invasiveness. Genomics provides a toolbox that can address some of these challenges. The BioSAFE (BioSurveillance of Forest Alien Enemies) project is developing a pipeline to generate genomic tools that will provide accurate identification of pests and pathogens, assign outbreak or survey samples to putative sources to identify pathways of spread and assess risk based on traits that impact the outbreak outcome. These next generation biosurveillance tools will help prevent and contain future forest pest and disease outbreaks.

Inter-institutional cooperation for the management of forest's health issues

Patrícia Machado¹

¹Indústria Brasileira de Árvores, São Paulo, Brasil (patricia.machado@iba.org)

The world trade has increased the risk of pest's outbreaks. Exotic pests, when introduced in new areas, may be responsible for economic and environmental damages. In this sense, a properly forest biosecurity management can avoid, or at least, minimize the risk of introducing and spreading pests in a country. Different initiatives have been organized for several countries, but information sharing is necessary to increase the efficiency of activities. In Brazil, different entities such as companies, research institutes, and government agencies have been working together for the management of forest's health issues. This cooperation for the benefits of planted forest health has achieved results more efficiently, increased the access to stakeholders, and provided technical and institutional representation for the Brazilian planted tree sector.

Scotland's Plant Health Centre: a multi-sectoral response to challenges from globalisation and climate change

Chris Quine¹ , Ian Toth², Sonia Humphris², Fiona Burnett³, Peter Hollingsworth⁴

¹Forest Research, Edinburgh, United Kingdom; ²James Hutton Institute, Dundee, United Kingdom; ³SRUC - Scotland's Rural College, Edinburgh, United Kingdom; ⁴Royal Botanic gardens Edinburgh, Edinburgh, United Kingdom (chris.quine@forestresearch.gov.uk; ian.toth@hutton.ac.uk; sonia.humphris@hutton.ac.uk; fiona.burnett@sruc.ac.uk; phollingsworth@rbge.org.uk)

Plants underpin many ecosystem services. However, these contributions can be disrupted by pests and diseases and disruption is increasing as a result of changing climates and introductions through trade; some of these problem species have wide host ranges or complex life-cycles impacting vegetation across many environments. We describe the development of a novel co-ordinated approach taken by the Scottish Government to tackle these challenges through a Centre of Expertise for Plant Health. The Centre brings together expertise from natural environment and horticulture, forestry and woodlands, agriculture, drawing on a range of skills from social sciences to mathematical modelling to focus on those risks most pertinent to Scotland, and the plants of most importance to its natural heritage, economy and social wellbeing. We will summarise recent studies initiated by the Centre including assessments of the threats of the bacterial pathogen *Xylella fastidiosa* which has over 500 host plant species worldwide and is currently causing major economic losses in Europe. For this and other threats, the Centre's activities will include a focus on understanding possible routes of entry into Scotland, the ability to spread to and infect our major plant species under our climatic conditions, as well as the best methods for control and when to implement them, and how to involve stakeholders to minimise the risk. We will conclude with a summary of the benefits of a cross-sectoral approach for forestry, and lessons learnt in the operation of the Centre.

Improving the international regulatory framework for managing alien invasive species in trade

Michael Ormsby¹

¹NZMPI, Wellington, New Zealand (michael.ormsby@mpi.govt.nz)

With the international trade of forest products comes the risk of the movement of pests that can be extremely damaging to forest ecosystems and forest economies. Although impacts of biological invasions may be local, at least at first, the causes of introduction are mostly international. International phytosanitary guidelines have been created to help countries that import wood products develop import requirements to minimize pest movement. There are numerous international and regional instruments, binding and nonbinding, which have been developed to deal with the problem of the movement of alien invasive species, however there are gaps in the current international framework. In particular there is a need for regional and global support for countries that lack sufficient resources to implement effective phytosanitary systems. This presentation discusses various initiatives that could reduce the resource burden of regulatory frameworks to improve implementation and therefore reduce global impacts of biological invasions in forests.

Collaborative strategies to reduce the introduction of exotic *Eucalyptus* pests in Brazil

Luis Renato Junqueira¹, Leonardo Rodrigues Barbosa², Patrícia Machado³, Jose Cola Zanuncio⁴, Luiz Alexandre Nogueira de Sá⁵, Carlos Frederico Wilcken⁶

¹Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Indústria Brasileira de Árvores, São Paulo, Brasil; ⁴Universidade Federal de Viçosa, Departamento de Entomologia/BIOAGRO, Viçosa, Brasil; ⁵Laboratório de Quarentena "Costa Lima", Embrapa Meio Ambiente, Jaguariúna, Brasil; ⁶Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agronômicas, Departamento de Proteção Vegetal, Campus Botucatu, Botucatu, Brazil (renato@ipef.br; leonardo.r.barbosa@embrapa.br; patricia.machado@iba.org; zanuncio@ufv.br; luiz.sa@embrapa.br; carlos.wilcken@unesp.br)

The introduction of exotic pests has increased over time due to the growing traffic of people and goods. Just in the last decade, three new eucalypt pests were introduced in Brazil. Responsibility for biosecurity must be shared between government and productive sector, seeking for prevention or contingency of these invaders, avoiding their dispersion to main productive zones in the country. In this regard, the planted forests sector in Brazil has developed a collaborative work, involving research institutions, productive sector and government. Once well consolidated, cooperative research between academy and forest companies has brought besides productivity gains, new tools for pest management, especially biological control programs development. In addition, the BiCEP (Biological Control for Eucalyptus Pests) project was launched in 2013 as an alliance among research institutes from Australia, Brazil, South Africa and Portugal to share information about management of exotic pests and research about new pests and their natural enemies, providing essential knowledge to prevent new introductions or enable their early detection. The access and relevance understanding of this information by government is essential to improve national biosecurity, role played by sectoral associations. Finally, the establishment of partnerships and approximation among different institutions has generated positive signs for reduction of exotic pest introductions in the long-term.

Genome sequencing uncovers mitotic recombination and rapid evolution in the sudden oak death and sudden larch death pathogen, *Phytophthora ramorum*

Angela Dale^{1,2}, Nicolas Feau², Sydney Everhart^{3,4}, Guillaume Bilodeau⁵, Javier Tabima⁴, Renate Heinzmann², Clive Brasier⁶, Brett Tyler⁴, Niklaus Grünwald⁴, Richard Hamelin^{2,7}

¹FPInnovations, Vancouver, Canada; ²University of British Columbia, Vancouver, Canada; ³University of Nebraska, Lincoln, USA; ⁴Oregon State University, Corvallis, USA; ⁵Canadian Food Inspection Agency, Ottawa, Canada; ⁶Forest Research, Farnham, United Kingdom; ⁷Université Laval, Quebec, Canada (angela.dale@fpinnovations.ca; feau@ubc.ca; everhart@unl.edu; guillaume.bilodeau@canada.ca; caifaz01@gmail.com; renate.heinzmann@ubc.ca; live.brasier@forestry.gsi.gov.uk; brett.tyler@oregonstate.edu; grunwald@science.oregonstate.edu; richard.hamelin@ubc.ca)

Genome sequencing is an important tool to monitor outbreaks of invasive species and to understand how evolution and adaptation may occur. Many invasive alien species rapidly adapt to new environments, overcoming small population numbers and reduced genetic diversity. *Phytophthora ramorum*, an Oomycete forest pathogen causing sudden oak and sudden larch death is one such invader. It is limited to asexual reproduction within four lineages, and presumed clonal. We sequenced 107 genomes to monitor pathogen spread and to determine how this pathogen might be able to adapt to new environments with such limitations. Two mechanisms acting at the genomic level may contribute to adaptability and invasiveness in this pathogen. Within lineages, mitotic recombination (MR) associated with transposons and low gene density has generated runs of homozygosity (ROH), resulting in novel genotypic diversity. One ROH enriched in putative pathogenicity genes was fixed in lineage NA1. An independent ROH affected the same scaffold in lineage EU1 suggesting an MR hotspot and selection target. Between the lineages, non-core regions (not shared by all lineages) may undergo rapid evolution. These regions were enriched in putative pathogenicity genes and transposons. There was a striking pattern of gene loss, including all effectors, in the non-core genome of lineage EU2. Furthermore, effectors were under positive selection. *P. ramorum* lineages are diverging via a rapidly evolving non-core genome and the invasive asexual lineages are not clonal, but display genotypic diversity caused by MR. This provides important insights into evolution and potential for adaptation in invasive pathogens.

What economics can tell us about pest in forest?

Montagne-Huck Claire¹, Brunette Marielle¹

¹INRA, BETA, Nancy, France (claire.montagne-huck@inra.fr; marielle.brunette@inra.fr)

Insect pests are important forest disturbance agents, reshaping forests and having large economic, environmental, and social impacts. Such hazards are likely to increase in the near future due to rising temperatures and an increased recurrence of major climatic events. Human activities, such as international trade, are also likely to increase pests displacement rates. As a result, populations have to adapt their activities and decisions to the presence of forest pests, as an integral part of sustainable forest management. In this paper, we provide a literature review on how economics deal with pests. We realized a systematic research by keywords, and we selected more than 100 economics paper dealing with pests in forest. We provide some descriptive statistics of the database by country, pest, journal, year of publications, etc. One of the main results is that a large part of the literature deals with bark beetle outbreaks in North America. In addition, we provide a categorization and analysis of the literature in three parts: i) How economic theory understand pests (externalities, public goods, etc.); ii) what are the economic impacts of pests (on timber market, local/regional economies, residential/property value, tourism, ecosystem services, etc.); iii) how economic analysis can advise and evaluate pest management programs (organization, techniques, etc.). We also provide a discussion about public policy implications and gaps in the literature.

Can 3-PG be used to assist forest managers assessing the impact of defoliation?

João Rua¹, Susana Barreiro¹, Manuela Branco¹, Margarida Tomé¹

¹Universidade de Lisboa, Instituto Superior de Agronomia, Centro de Estudos Florestais, Lisboa, Portugal (joao.c66@gmail.com; smb@isa.ulisboa.pt; mrbranco@isa.ulisboa.pt; magatome@isa.ulisboa.pt)

The 3-PG model predicts GPP from light intercepted taking into account environmental effects through multiplicative modifiers for climate, soil and water availability. NPP is estimated as a constant fraction of GPP and allocation to roots, leaves and woody biomass pools depends on the environment and tree age. Eucalypt plantations are of extreme economic importance in Portugal and with globalisation and climate change *Gonipterus platensis* became a serious threat. Being 3-PG a growth model based on light interception and, consequently, on leaf biomass, a methodology based on leaf biomass reduction was developed to simulate the impact of this defoliation on stand growth. Two sets of scenarios, for the period of time during which the insect is active, were defined considering defoliations occurring every year in spring and both in spring and autumn, and starting at different stand ages. Under each scenario, five defoliation levels were tested ranging from 0% to 100% considering the first attack to occur from age 2 until age 10. The preliminary results suggest the potential of the 3PG model as a management support tool that will enable forest managers to study not only the best timing for insecticide application as well as the trade-offs of pesticide application during a rotation period. The next steps will encompass field plot monitoring to validate the magnitude of volume losses resulting from defoliations and to study changes in allocation patterns resulting from pest attacks.

Expansion of altitudinal range in a forest pest: can parasitoids track their hosts?

Jose Antonio Hódar¹, Luis Cayuela²

¹Universidad de Granada, Granada, Spain; ²Universidad Rey Juan Carlos, Madrid, Spain (jhodar@ugr.es; luis.cayuela@urjc.es)

Gradients in elevation impose changes in environmental conditions, which in turn modulate species distribution and abundance as well as the interactions they maintain. Along the gradient, interacting species (e.g. predators, parasitoids) can respond to changes in different ways, and experience different climatic conditions from one year to another. This study aims to investigate how egg parasitism of a forest pest, the pine processionary moth (PPM), *Thaumetopoea pityocampa* (Denis et Schiffmüller, 1775), vary along an altitudinal gradient (120-2050 m.a.s.l.) in a mountain range of SE Spain, including areas of recent altitudinal expansion, for a seven years period. We used generalized linear mixed effects models to ascertain the effect of altitude on three response variables, namely rate of parasitism, and probability of occurrence of two parasitoid species: a PPM specialist, *Baryscapus servadeii* (Dom.), and a generalist species *Ooencyrtus pityocampae* (Mercet). Results showed a decrease of rate of parasitism, and probability of occurrence of the two main parasitoid species with altitude, although decline was more severe for *B. servadeii*. In a context of climate warming scenario, and with PPM in clear process of altitudinal and latitudinal expansion, it is crucial to mitigate this process by enabling the synchronization of the PPM-parasitoids interaction. This can be done by reducing the possibilities of PPM progression and, simultaneously, favouring the establishment of parasitoids, for example by increasing tree diversity at the PPM expansion areas.

D7n: BIOLOGICAL INVASIONS, BIODIVERSITY, AND ECOSYSTEM SERVICES - 2

Exploring global patterns of bark and ambrosia beetle invasions and their relationships with international trade

María Victoria Lantschner¹, Juan C. Corley¹, Andrew M. Liebhold²

¹Instituto de Investigaciones Forestales y Agropecuarias Bariloche (INTA-CONICET), Bariloche, Argentina; ²USDA Forest Service, Northern Research Station, Morgantown, WV, USA (lantschner.v@inta.gov.ar; elmallin@gmail.com; aliebhold@fs.fed.us)

Invasion by non-native insects are increasing worldwide, often with strong negative economic and ecological impacts on forest ecosystems. Understanding the global patterns and processes driving invasions of forest insects is important for predicting future invasions and improving mitigation strategies. Bark and ambrosia beetles (Coleoptera: Curculionidae, Scolytinae) are a large and diverse group of insects commonly recognized as important forest pests and invaders. In this study, we analyze historical global invasion patterns of scolytines, by evaluating the number of species native to each biogeographic region (i.e., Palearctic, Indo-Malay, Nearctic, Neotropic, Afrotropic, Austro-Pacific) that have invaded other regions, and we explore relationships between invasion patterns and historical volumes of trade between regions during the period 1870-2014. We found that there are a total of 120 species that have established outside of their native range. The Palearctic region was the largest source of invasive species (50), followed by the Indomalayan region (32), comprising 7.7% and 3.1% of the native species pool of these regions respectively. In contrast, the Nearctic region was the region that received the greatest number of non-native species (68), followed by the Neotropic (46). The largest trade volume (40% of the global total) occurred between the Nearctic and the Palearctic regions. We found a significant regression between the number of species that invaded from one region to another, and the trade volume between these regions. We conclude that bark beetles have successfully invaded forest systems worldwide, and that global trade is likely to strongly influence invasion patterns in the future.

Teratosphaeria leaf diseases: a major threat for eucalypts plantations in Uruguay

Carlos Perez¹, Gustavo Balmelli², Sofía Simeto², Nazaret Ramirez¹, Robert Blanchette³, Michael J. Wingfield⁴

¹Facultad de Agronomía, Universidad de la República, Paysandu, Uruguay; ²INIA Uruguay, Tacuarembó, Uruguay; ³Department of Planta Pathology, University of Minnesota, Saint Paul, USA; ⁴FABI, University of Pretoria, Pretoria, South Africa (caperez@fagro.edu.uy; gbalmelli@tb.inia.org.uy; ssimeto@inia.org.uy; nazaret.berrutti@gmail.com; robertb@umn.edu; mike.wingfield@up.ac.za)

Many *Teratosphaeria* species are associated with leaf diseases on *Eucalyptus* spp. (Myrtaceae). However, only a few of these are major pathogens that cause serious losses, particularly to plantation forestry globally. Several species in the Teratosphaeraceae and Mycosphaeraceae species are known to occur in Uruguay where they cause leaf and shoot diseases on *Eucalyptus* plantations, but most are of minor importance. However, two species have had a serious negative impact on the performance of certain *Eucalyptus* species. Since its first detection in 2007, *Teratosphaeria nubilosa* has eliminated *Eucalyptus globulus* from the available species for pulpwood production. Species substitution has been the main management tool for this pathogen resulting in negative consequences such as limited access to external markets. More recently, in 2011, *Teratosphaeria pseudoeucalypti* was reported causing leaf blight that has resulted in severe defoliation and death of established *Eucalyptus camaldulensis*, *E. tereticornis*, and their hybrids. This pathogen was first described in Australia in 2010 and simultaneously reported in Argentina, Brazil and Uruguay four years later. This disease is a serious threat to Uruguayan plantations and has already imparted a significant social and economic impact in the country where it has damaged urban parks and plantations used for shelter and shade for livestock production. These two examples of serious diseases caused by *Teratosphaeria* spp. have highlighted that accidentally introduced non-native pathogens can have in a country. They have also raised concerns that such pathogens could threaten the many native Myrtaceae found natural forest ecosystems in Uruguay.

Red Gum Lerp Psyllid (*Glycaspis brimblecombei*) prevalence, host damage and host preference in Central Highlands of Kenya

Miriam Gathogo¹

¹KEFRI (Kenya Forestry Research Institute), Nairobi, Kenya (gathogomiriam@gmail.com)

Glycaspis brimblecombei (Hemiptera:Psyllidae) locally termed as Red Gum Lerp Psyllid (RGLP) has been a pest of significant importance since its invasion in Kenya forestry systems in 2014. A survey in the Central Highlands of Kenya was carried out to determine spread, host damage and species preference by Red Gum Lerp Psyllid. A transect cutting through Counties in Central Highlands Ecoregion of Kenya including Kiambu, Murang'a, Nyeri, Embu, Kirinyaga, Meru, Laikipia and Nyandarua Counties was laid to enable data collection. The spread determined by taking coordinates of assessed *Eucalyptus* trees and degree of attack, determined through assigning different damage category levels on different *Eucalyptus* spp. and hybrid clones growing in Kenya, were the key parameters assessed in this study. Collected data was managed using MS excel and analyzed using SPSS and results presented using descriptive charts and tables. Results showed that the drier parts of Central Highlands of Kenya including Embu, Kirinyaga and some parts of Meru counties had heavier infestation of RGLP compared to other counties studied, with Tharaka Nithi which receive more rainfall compared to other regions having lesser infestation. Preference was majorly on *E. camaldulensis*, followed by Clones and *E. saligna*. The frequent damage levels were at category 1 and 2 on *E. camaldulensis* trees. Information from this study will inform implementation of bio-control, identification of natural-control-release sites, the time of release and identification of host plant resistant species for sustainable management of RGLP in the forestry systems of Kenya.

The emergence of a forest pest: a transdisciplinary approach

Bart Nyssen¹, Frank Moulart², Constanza Parra Nova², Bart Muys², Erik Mathijs²

¹Bosgroep Zuid Nederland, Heeze, Netherlands; ²University of Leuven, Leuven, Belgium (b.nyssen@bosgroepen.nl; frank.moulart@icloud.com; constanza.parra@kuleuven.be; bart.muys@kuleuven.be; erik.mathijs@kuleuven.be)

Since the 1980's invasion ecology has made a strong progress. Today we understand rather well how ecological invasions take place. Crucial for the further development of invasion ecology is interdisciplinary collaboration since this subject spans a wide spectrum of biological and social science topics. Especially the understanding of when, why and how invasive species become a threat needs close scientific collaboration exceeding the borders of ecological and biological sciences. This paper presents the results of a transdisciplinary collaboration of authors with a background in forest management and ecological, sociological, geographical and economic research. The insights from this transdisciplinary work will be presented centred around the case how Black cherry (*Prunus serotina*) - introduced to North-West Europe in 1623 - became a 'forest pest', a threat to Belgian, Dutch and German forests 350 years later. Research in social and ecological sciences shows that a broad range of conditions must be present to make an event happen. The potential of an introduced tree species to become invasive is only realised under the proper settings. Structuralist approaches emphasise the causal analysis of the conditions under which the event takes place and behavioural studies stress the role of agency causing the event to take place. The ASID approach, developed in interdisciplinary collaboration, overcomes this structure-agency dichotomy and offers a way to understand why after 350 years an introduced species emerges as an invasive species. This approach offers a tool for further investigation into the social-ecological context of specific ecological invasions.

Towards a strategy to combat the Polyphagous Shot Hole Borer (PSHB) invasion in South Africa

Wilhelm de Beer¹, Trudy Paap¹

¹Forestry and Agricultural Biotechnology Institute, FABI, Pretoria, South Africa (wilhelm.debeer@fabi.up.ac.za; trudy.paap@fabi.up.ac.za)

The impact of the Polyphagous Shot Hole Borer (PSHB) and its Fusarium fungal symbiont on forest ecosystems in South Africa is alarming. The beetle-fungus combination was first detected killing London plane trees in the KwaZulu-Natal province in early 2017. Since then infestations have been observed on more than 80 species of trees in seven of the nine provinces. These include commercial pecan orchards in the Northern Cape, and many common street and garden tree species in urban areas in six of the provinces. Most concerning are native trees that are infested and dying in urban and natural forests. The impact of all other serious tree pests that South Africa had to deal with in the past, was restricted to the agriculture and forestry sectors. Now, for the first time the country has to deal with a pest that ignores all boundaries, including those between climatic regions, or host tree genera, or orchards, commercial plantations, natural forests, streets, parks, and gardens. Current frameworks in government and other institutions for monitoring, reporting, impact assessment, research, control measures, management strategies, funding, and legislation, are not adequate to deal with the PSHB invasion. A coordinated, national strategy and network is needed to combat the PSHB, or else valuable resources and time will be wasted while the pest is destroying our trees and expanding its territory. Attempts are being made from within and outside government structures to align the different strategies with the needs and agendas of stakeholders.

Towards the resolution of taxonomic species complexes by an integrated approach: the case of the ambrosia beetle (*Euwallacea fornicatus*)

Demian F. Gomez¹, James Skelton¹, Sedonia Steining², Richard Stouthamer³, Paul Rugman-Jones³, Wisut Sittichaya³, Robert Rabaglia⁴, Jiri Hulcr¹
¹University of Florida, Gainesville, USA; ²USDA, Gainesville, USA; ³University of California, Riverside, USA; ⁴USDA-Forest Service, Washington, USA
 (demiangomez@ufl.edu; skelto3@gmail.com; m.sedonia@gmail.com; richards@ucr.edu; paulrj@ucr.edu; wisut.s@psu.ac.th; rabaglia@fs.fed.us; hulcr@ufl.edu)

Many forest pests defy standard species concepts and are difficult to identify. Some of the most morphologically cryptic, economically damaging, and frequently intercepted pests are ambrosia beetles, such as *Euwallacea fornicatus* (Curculionidae: Scolytinae), a complex of genetically divergent pests. All lineages within this complex are considered morphologically identical, their identification relies on DNA, and only common names are used, which is problematic for detection and management. The objectives of this work were to reconstruct relationships between clades and populations, find morphological characters for delimiting the genetic lineages, and propose taxonomic species. Rather than using the traditional taxonomic species concept tied to a single reference individual, we classify individuals to putative species by the correlation between multiple morphological features and phylogenetic placement using multivariate analysis. The integrated molecular and morphological evidence suggested four clades that differ morphologically, but with overlap. The morphological corroboration of this species complex now allows for the proper naming of the different genetic lineages based on museum material. The following names are proposed: *E. fornicatus* (Eichhoff 1868) (= 'Tea Shot Hole Borer Clade a'); *E. fornicator* (Eggers 1923), stat. rev. (= 'Tea Shot Hole Borer Clade b'); *E. whitfordiodendrus* (Schedl 1942), stat. rev. (= 'Polyphagous Shot Hole Borer'); and *E. kuroshio* Gomez and Hulcr, sp. nov. (= 'Kuroshio Shot Hole Borer'). This approach delivers a practical, evidence-based guidance for species delineation that can address overlapping variation in morphological characters of an emerging pest species complex.

Molecular tools advance the management of invasive gall-forming wasps associated with plantation forestry

Gudrun Dittrich-Schroder¹, Brett P Hurley¹, Michael J. Wingfield¹, Bernard Slippers²
¹Forestry and Agricultural Biotechnology Institute (FABI) and Department of Zoology and Entomology, University of Pretoria, Pretoria, South Africa;
²Forestry and Agricultural Biotechnology Institute (FABI) and Department of Department of Biochemistry, Genetics and Microbiology, Pretoria, South Africa
 (gudrun.dittrich@fabi.up.ac.za; brett.hurley@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za; bernard.slippers@fabi.up.ac.za)

Effective management of invasive insect pests relies on fast and accurate identification. Accurate identification is frequently delayed or not possible due to the shortage of taxonomists and the shortcomings of morphological comparisons for identifying cryptic lineages. Molecular tools, such as common sequence barcoding methods can assist to overcome these challenges. Sequence databases are, however, often poorly curated and incomplete with reference to emerging pest species, for example for insect pests associated with *Eucalyptus* plantation forestry. Many recently introduced gall-forming *Eucalyptus* pest species lack taxonomic descriptions, and detailed information regarding their biology is sparse or unknown. The existence of cryptic species further complicates the identification of these pests. To address the increasing number of invasive insect pests of *Eucalyptus* plantation forestry, a forest insect mitochondrial (FIMT) online database was developed. This database facilitates the identification of unknown specimens through sequence comparisons with a curated database of identified insect pests. This information can be essential for management of these invasive species through breeding or biological control, which may be highly species specific.

Expansion of a native invasive plant is modulated by soil decomposers

Junwei Luan¹, Shirong Liu², Siyu Li¹, Joann Whalen³, Scott Chang⁴, Jingxin Wang⁵, Yi Wang¹
¹International Centre for bamboo and Rattan, Beijing, China; ²Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China; ³Department of Natural Resource Sciences, Macdonald Campus, McGill University, Ste-Anne-de-Bellevue, Canada; ⁴Department of Renewable Resources, University of Alberta, Edmonton, Canada; ⁵West Virginia University, Division of Forestry and Natural Resources, Morgantown, USA
 (junweiluan@icbr.ac.cn; liusr@caf.ac.cn; siyu_li0723@163.com; joann.whelen@mcgill.ca; scott.chang@ualberta.ca; jingxin.wang@mail.wvu.edu; wangyi@icbr.ac.cn)

The impacts of non-native/exotic invasive species on ecosystem processes and functions have been extensively studied, less recognized but also common are "native invaders" that become invasive in their native range due to human-mediated processes. However, we have limited knowledge on how the invasion of natives alter the ecosystem process, and if the hypothesized mechanisms that provide non-native invasive species an advantage are the same for native invaders. There is a general belief that non-native plant invasion is the results of a positive feedback on litter decomposition, whether native invaders could also adopt this positive feedback strategy is unknown. Furthermore, how invasive plants interact with the decomposer community and environment to stimulate litter decomposition is poorly understood. Bamboo expansion has been widely reported across the world, most of times as a native invader, provide us an opportunity to elucidate abovementioned questions. We chose seven locations across a national scale along a climatic gradient (15.6–24.5 °C), in each location, sites with different bamboo density (pure bamboo forest, forest expanded by bamboo, local forest) were established in order to conduct both in situ and reciprocal decomposition experiment. Soil biota community was manipulated by employing three mesh sizes litter bags or microcosms, enable us to distinguish three increasingly complete decomposer communities (small, medium-sized and complete). By investigating mass loss and nutrient release of all our decomposition experiments, to answer above-developed questions.

D70: PATTERNS IN FOREST INSECT HERBIVORY - 2

Main factors influencing insect attacks of debarked-medicinal plants in Lama Forest Reserve and Lokoli swampy forest

Yvonne T. Cakpo^{1,2}, Judith Korb², Brice Sinsin¹, Chabi Djagoun³
¹Laboratory of Applied Ecology/University of Abomey-Calavi (Benin), Abomey-Calavi, Benin; ²Faculty of Biology I/ University of Freiburg, Freiburg, Germany; ³Laboratory of Applied Ecology/University of Abomey-Calavi (Benin), Cotonou, Benin (ycakpo@gmail.com; judith.korb@biologie.uni-freiburg.de; bsinsin@gmail.com; dchabi@gmail.com)

The spatio-temporal variability of tree attacks by foraging xylophagous insects has been studied on most debarked-medicinal tree species in Lama Forest Reserve and in Lokoli swampy forest in Benin. For achieving that, different factors such as habitat type (crop fields, degraded forest and non-degraded forest), season (dry and rainy season), debarking level (T0: control, T1: 10*20cm² and T2: 20*50cm²), and tree species (*A. leiocarpa*, *D. guineense*, *D. mespiliformis*,

F. trichopoda, *K. africana*, *L. barteri*, *L. acida* and *S. owariense*) were considered. Data were collected during one year (from October 2014 to November 2015) using both interception and emergence traps. Per season, 72 and 81 traps were established in Lama and Lokoli respectively. Data collected were abundance of insects, presence or absence of insect holes, number of insect hole recorded on the tree. Four different orders (Coleoptera, Hymenoptera, Diptera and Blattodea) were collected including 284 morpho-species with 3771 insect individuals. The present study showed that habitat type, season, debarking level and tree species had significant effects on xylophagous attacks as well as the severity (number of insect holes) of those attacks and the abundance of xylophagous insects. High xylophagous diversity was recorded in degraded-forest and crop fields while non-degraded forests were lesser invaded in xylophagous beetles. Xylophagous insect attacks increased in crop fields and in degraded forest during rainy season on large debarking surface trees. Which implies debarking of most vulnerable medicinal tree species must be done during dry season in small patches.

Quantifying Ormiscoodes outbreaks in Southern Chile: combining remote sensors and field validation

Sergio Estay^{1,2} , Roberto Chávez², Alvaro Gutierrez⁴, Ronald Rocco³

¹Universidad Austral de Chile, Valdivia, Chile; ²Center of Applied Ecology and Sustainability, Santiago, Chile; ³Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile; ⁴Universidad de Chile, Santiago, Chile (sergio.estay@uach.cl; roberto.chavez@pucv.cl; bosqueciencia@gmail.com; r.roccogatica@gmail.com)

Although abundant literature of insect outbreaks exists in the Northern Hemisphere, studies for the Southern Hemisphere are rare. Recently, massive outbreaks of the native moth *Ormiscoodes amphimone* (Fabricius) (Lepidoptera: Saturniidae) have been reported in the southern cone of South America. *Ormiscoodes amphimone* (Lepidoptera: Saturniidae) is a native phytophagous moth (Fig; 2) feeding on several host plants such as *Nothofagus spp.*, *Populus spp.*, among many other tree species. These *O. amphimone* outbreaks have defoliated large areas of temperate forests, raising great concern among local inhabitants, but yet the spatio-temporal patterns of these events have not been evaluated. Here we quantify the extension of the massive *O. amphimone* outbreaks occurred in the Aysén region (Southern Chile) in the period 2000-2017. Remote sensing detections were strongly in agreement with field observations and showed that massive outbreaks of *O. amphimone* are among the largest biotic disturbances in the forests of the Southern Hemisphere. Considering only field-confirmed outbreaks, the defoliated area reached 164⁰⁰⁰ hectares in total between 2000 and 2017, with some years reaching over 20⁰⁰⁰ ha defoliated in a single locality. The estimation of the spatial impact of *O. amphimone*, and its recurrence, represents the first step for the search of management alternatives of this massive disturbance.

Polyphagozerra coffeae (Lepidoptera: Zeuzerinae: Cossidae): identification, notes on biology, natural enemies, damage characterization, and addition of Eucalyptus (Myrtaceae) as a new host in Indonesia

Wagner Tavares¹, Srikumar Kkadan¹, Ade Hendrik¹, Rianza Asfa¹, Marthin Tarigan¹, Álvaro Durán¹

¹Asia Pacific Resources International Holdings Ltd., Pangkalan Kerinci, Indonesia (wagnermaias@yahoo.com.br; sreeku08@gmail.com; adameizon9@gmail.com; rianza_asfa@kerinci.lcl; marthin_tarigan@aprilasia.com; duransandoval@gmail.com)

The red coffee borer, *Polyphagozerra* (= *Zeuzerra*) *coffeae* (Lepidoptera: Zeuzerinae: Cossidae) is one of the most destructive lepidopteran borer in the world. The objective of this study was to identify the species name and evaluate some biological parameters of *P. coffeae* in the laboratory. Also, the natural enemies were identified and the damage caused on Eucalyptus (Myrtaceae) commercial plantations by this pest was characterized in Riau, Indonesia. Caterpillars and pupae of *P. coffeae*, obtained from Eucalyptus spp. plantations, were reared in a laboratory on ripe apple fruits, *Malus pumila* (Rosaceae). Male moths were identified as *P. coffeae* after aedeagus (male genitalia) analysis. Five groups of natural enemies were recovered from the *P. coffeae* stages: the hyperparasitoid *Brachymeria* sp. (Hymenoptera: Chalcididae), the gregarious parasitoids *Cossidophaga* sp. (Diptera: Tachinidae) and a eulophid (Hymenoptera: Tetrastichinae) species, a nematode (Nematoda), and a fungus entomopathogen. The damage caused by *P. coffeae* on the Eucalyptus trees was evident when tree tops were hanging and fallen, and presence of galleries and pupation chambers. Adult longevity (\pm SD) was 5.88 \pm 0.54 days. Each 1.66 \pm 0.28 day old female was able to lay an average of 591.80 \pm 126.33 eggs. Caterpillars stayed in the tree stem longer than 60 days. The pupal stage lasted 18.96 \pm 1.44 days. The current study adds *E. pellita* and *E. pellita* \times *E. grandis* as new hosts of *P. coffeae* and describes several knowledge aspects of *P. coffeae* as a pest of Eucalyptus in Riau, Indonesia.

Does Paropsis atomaria larval feeding induce chemical responses in Corymbia citriodora subsp. variegata?

Flavia Sarti Bonora¹, Helen Nahrung¹, David Lee, Andrew Hayes¹

¹University of the Sunshine Coast, Sunshine Coast, Australia (fsartabo@usc.edu.au; hnahrung@usc.edu.au; dlee@usc.edu.au; rhayes@usc.edu.au)

Corymbia citriodora subsp. *variegata* (CCV) is promising for hardwood plantations in areas considered marginal for many commercial forestry species, as it presents desirable field performance, wood quality and form and suits a range of site conditions. The eucalypt tortoise beetle *Paropsis atomaria* Olivier (Coleoptera: Chrysomelidae) is a major pest of eucalypt plantations in Queensland, including areas planted with CCV. *P. atomaria* can cause severe defoliation in young trees, reducing plantation productivity and quality. Studies with *Corymbia* spp demonstrated that plant secondary metabolites, such as terpenes, are correlated with arthropod herbivory and can be effective as insect growth inhibitors. Changes in plant chemistry can occur in plants as a response to herbivory, potentially reducing further damage. To provide a better understanding of plant-herbivore interactions and possible resistance mechanisms, this study evaluated the chemical response of CCV challenged by *P. atomaria*. Seedlings of CCV were submitted to one of three treatments: no damage; mechanical damage and *P. atomaria* larval damage. After 15 days seedlings were removed from the treatments and leaf samples were analysed to determine the leaf-oil gas chromatography-mass spectrometry. The results revealed that *P. atomaria* larval feeding induced chemical response in CCV with up-regulation of waxes and down-regulation of terpenoids. The same pattern was not observed on plants under mechanical damage, suggesting an interaction between plant-herbivore.

Four species of mirid bugs (Hemiptera) and parasitism of Helopeltis bradyi by Leiophron sp. (Hymenoptera: Braconidae) on Eucalyptus (Myrtaceae) commercial plantations in Indonesia

Srikumar Koda Kkadan¹, Wagner Tavares¹, Ade Hendrik¹, Irfan Pasaribu², Marthin Tarigan¹, Alvaro Duran¹

¹Asia Pacific Resources International Holdings Ltd., Pangkalan Kerinci, Indonesia; ²PT Toba Pulp Lestari Tbk., Porsea, Indonesia (sreeku08@gmail.com; wagnermaias@yahoo.com.br; ameizon_hendrik@kerinci.lcl; irfan_pasaribu@globalnet.lcl; marthin_tarigan@aprilasia.com; duransandoval@gmail.com)

Mirid bugs (Hemiptera: Miridae) are important pests of young and old *Eucalyptus* (Myrtaceae) trees in Indonesia. Young *Eucalyptus* plantations are mainly affected by *Helopeltis* (Hemiptera: Miridae). This damage resulted in die-back of young shoots, curling, deformed, and drying, usually irrespective of the clones. In North Sumatra, damage of *Eucalyptus* is associated to *Helopeltis bradyi* Waterhouse despite the presence of *H. theivora* in the region. Important alternate host plants as reservoirs of *H. bradyi* in vicinity to *Eucalyptus* plantations were *Coffea* sp. (Rubiaceae), *Persea* sp. (Lauraceae), *Psidium guajava* (Myrtaceae), and

Theobroma cacao (Malvaceae). *Leiophron* sp. (Hymenoptera: Braconidae) is reported as an important parasitoid with parasitism of 25.71% on the *H. bradyi* nymph and adult individuals sampled. *Helopeltis theivora* Waterhouse were recorded as the only species affecting Eucalyptus plantations in Riau Province, so far no other *Helopeltis* spp. was identified in the Province. *Ragwelellus festivus* Miller was reported for the first time damaging Eucalyptus trees in Riau, North Sumatra and East Kalimantan of Indonesia. *Pachypeltis* sp. was also recorded along with *Helopeltis* species and *R. festivus* in North Sumatra and Riau Provinces. Sex pheromone traps using virgin female body extract were developed for *H. bradyi* and *H. theivora* and found to be compelling in attraction and trapping. Insecticides belonging to synthetic pyrethroid group and others applied using sprayers and foggers found to be effective against these pests. Four species of mirid bugs damaging Eucalyptus trees and the parasitoid *Leiophron* sp. were reported for the first time in Indonesia.

Population progression of *Eucalyptus* leaf roller complex and *Helopeltis theivora*, and factors affecting their chemical control in young *Eucalyptus* plantations in Riau, Indonesia

Srikumar Koda Kkadan¹, Wagner Tavares¹, Rianza Asfa¹, Ignatius Andri Ferlianda¹, Marthin Tarigan¹, Alvaro Duran¹

¹Asia Pacific Resources International Holdings Ltd., Pangkalan Kerinci, Indonesia (sreeku08@gmail.com; wagnermais@yahoo.com.br; rianza_asfa@kerinci.lcl; ignatius_ferlianda@kerinci.lcl; marthin_tarigan@aprilasia.com; duransandoval@gmail.com)

Eucalyptus leaf roller complex (Lepidoptera: Tortricidae) and *Helopeltis theivora* Waterhouse (Hemiptera: Miridae) cause severe damage on juvenile foliage of *Eucalyptus* (Myrtaceae) plants. Population progression of leaf roller and *H. theivora* on *E. pellita* and *E. grandis* × *E. pellita* plantations was studied based on the damage incidence and severity in six locations in Riau Province, Indonesia. Leaf roller infestation on *E. pellita* and *E. grandis* × *E. pellita* clones commenced from three weeks after planting (WAP). Incidence remained maximum (80-100%) from four to 12 WAP. Decline in population commenced since 14 WAP and reached further low in 16 WAP. Severity of infestation reached extreme (84%) through five to nine WAP. *Helopeltis theivora* infestation instigated from six WAP and advanced from 12 WAP. Incidence reached maximum (80%) in 15 WAP and declined in 18 WAP. Crosses of *E. grandis* and *E. pellita* were found to be more susceptible to leaf roller and *H. theivora* infestation than pure *E. pellita*. Currently insecticide application is sole remedy for control of leaf roller and *H. theivora* outbreaks. Analysis (January 2017 to May 2018) indicated that rainfall (>15 mm) affected negatively the efficiency of spraying insecticides. There was also significant relationship between control size area and rounds of insecticide application. Current study formulated effective management strategies for leaf roller complex and *H. theivora*.

Herbaria as distorting mirrors in studies of insect herbivory

Vitali Zverev¹, Irina Sokolova², Mikhail V. Kozlov¹, Alexander Egorov³, Mikhail Goncharov⁴, Elena Zvereva¹

¹University of Turku, Turku, Finland; ²Komarov Botanical Institute, St. Petersburg, Russian Federation; ³St. Petersburg State University, St. Petersburg, Russian Federation; ⁴St. Petersburg Chemical-Pharmaceutical University, St. Petersburg, Russian Federation (vitzve@utu.fi; isokolova@yandex.ru; miko@utu.fi; egorovfta@yandex.ru; mgonch@mail.ru; elezve@utu.fi)

Herbaria were recently advertised as reliable sources of information on historical changes in plant damage by insects and pathogens. Our aim was to explore, whether the levels of insect herbivory occurring in nature can be invoked from herbarium specimens. Losses of leaf area to insects in herbarium specimens collected by botany students (4.87%) were significantly lower than losses measured from ecological samples (7.96%) collected simultaneously in unbiased way. The differences in herbivory between herbarium specimens and ecological samples varied with plant species and increased with the increase in plant damage; as the result, there was no correlation between leaf damage in herbarium specimens and the actual level of herbivory. Curators asked to select one of two specimens for museum collections generally preferred specimens with lower leaf damage. Both collectors and curators significantly differed in their attitudes to plant damage, from careful selection of branches with nearly undamaged leaves to neglecting the extent of leaf damage by insects or even preferring specimens with high infestation by identifiable herbivores, e.g. leaf miners. We conclude that leaf damage measured from herbarium specimens not only underestimates field herbivory, but is not proportional to the level of damage that occurred in nature at the time of sampling due to multiple factors that cannot be controlled in data analysis. In terms of quantitative data on overall losses of leaf area to insects, herbaria act as distorting mirrors, and therefore cannot be recommended for studying past levels of herbivory.

Herbivory reduction through plant-spider associations in undergrowth species in a cloud forest of Peru

R. Jaemy Romero-Herrada^{1,2} 

¹Universidad Austral de Chile, Valdivia, Chile. ²Departamento de Ecología, Museo de Historia Natural, Universidad Nacional Mayor de San Marcos, Lima, Peru (roy.romero@alumnos.uach.cl)

One of the most successful anti-herbivory strategies for plants has been to establish mutualistic relationships with predators that consume herbivores, such as spiders. The success of spiders in herbivory reduction may be related to their ability to prey on various herbivore guilds. Despite the strong impact that spiders exert on the density and spatial distribution of herbivores, the effect they have on host plants is variable and dependent on environmental conditions. In this sense, you will seek to determine if the association with spiders has an effect on the proportion of herbivory presented by juvenile plants of three common shrub species of the undergrowth of the cloud forests of Peru through three altitude levels (2400, 2600 and 2800 m.a.s.l.). These species are: *Hedyosmum cuatrecazanum* Occhioni. (Chloranthaceae), *Miconia* sp. (Melastomataceae) and *Psychotria* sp. (Rubiaceae). To evaluate this effect I established two Bayesian models, one where the effect of the association is included in a generalized manner and another where the effect of the association is dependent on the species. The proportion of herbivory presented by spider-associated plants (mean ± SD = 0.041 ± 0.031) was lower than the proportion of herbivory in non-associated plants (mean ± SD = 0.076 ± 0.048). I found a significant herbivory reducing effect when plants are associated with spiders in all three species and for both models. Additionally, I observed that the greatest herbivory reducing effect occurs in *Hedyosmum cuatrecazanum*-spider associations, and that the reducing effect on *Miconia* sp. and *Psychotria* sp. is similar.

Sprout dynamics in *Ormiscodes amphimone*: the role of the thermal landscape as an environmental force in the Aysen region of Chile / Dinámica de brotes de *Ormiscodes amphimone*: rol del paisaje térmico como forzante ambiental en la Región de Aysén, Chile

Nicolhole Atero¹

¹Universidad Austral de Chile, Valdivia, Chile (nicolhole.af@gmail.com)

La dinámica de brotes de insectos ha cambiado en las últimas décadas como consecuencia del aumento de la temperatura, generando severas repercusiones en el funcionamiento de los bosques. Recientemente, se han observado brotes masivos de la polilla nativa *Ormiscodes amphimone* en los bosques Patagónicos de

América del Sur. En este estudio se evaluó el rol del paisaje térmico como forzante ambiental en la fenología de *O. amphimone* en la Región de Aysén, Chile. Se utilizaron datos de temperatura del proyecto MERRA-2 para reconstruir el paisaje térmico de los últimos 15 años, utilizando los grados-días acumulados (GDA) como proxy de la idoneidad térmica, y mediante un modelo logístico, se estimó la probabilidad de tener un brote en función de los GDA en cada localidad. Además, se construyó un modelo fenológico regional para conocer la respuesta térmica de *O. amphimone* respecto a los GDA. Los GDA muestran un patrón heterogéneo en toda la región, lo que hace que la fenología de *O. amphimone* sea altamente variable entre localidades, y que la probabilidad de ocurrencia de brotes este determinada por distintos umbrales térmicos. Finalmente el modelo fenológico sugiere una relación positiva entre la acumulación térmica y la abundancia poblacional relativa de la especie, sin embargo, esta relación es específica para cada sitio. Este estudio es un primer paso en el desarrollo de herramientas para evaluar el riesgo de brotes en todo el territorio, y de este modo, optimizar las estrategias de manejo para minimizar el impacto de esta plaga en América del Sur.

Susceptibility of three commercially significant Amazonian trees to termite attack (Isoptera: Insecta) / Susceptibilidade de três árvores amazônicas de interesse comercial ao ataque de térmitas (Isoptera: Insecta)

Diulio Andrew Torres de Souza^{1,2}, Norma Cecília Rodrigues Bustamante¹, Rayssa Gomes Vasconcelos¹, Luiz de Moura Neto¹, João Victor Barros Wezen¹

¹Universidade Federal do Amazonas, Departamento de Ciências Florestais Manaus, Brazil; ²Instituto Nacional de Pesquisas da Amazônia, Manaus, Brazil (diulio51@gmail.com; ncbustamante@gmail.com; rayssagomes85@gmail.com; luizmouraneto@yahoo.com.br; jaowezen@gmail.com)

O conhecimento acerca do comportamento de térmitas em relação às espécies florestais amazônicas de interesse comercial ainda é incipiente. O presente estudo objetivou avaliar a susceptibilidade de cupiúba (*Goupia glabra*), guariúba (*Clarisia racemosa*) e marupá (*Simarouba amara*), ao ataque de *Nasutitermes surinamenses*, *Nasutitermes corniger* e *Cornitermes acignathus*. Foram confeccionados corpos-de-prova (estacas) de cada espécie, totalizando 108 estacas. As mesmas foram numeradas, pintadas com diferentes cores na extremidade e tiveram o volume, peso úmido e densidade básica, determinados. Para a obtenção do peso seco, as amostras foram separadas por espécie e acondicionadas em estufa (103°C). No Campus-UFAM, instalou-se 3 áreas amostrais, cada uma com 12 pontos próximos a atividade térmica. Ao redor de cada ponto, foram enterradas 3 estacas (1 por espécie). Aos 90 e 120 dias, foram removidas 6 estacas por espécie, de cada área, que passaram pelo processo de secagem; 55% das madeiras estavam infestadas, a espécie marupá, apresentou a maior frequência de ocorrência de térmitas (81%), guariúba (44%) e cupiúba (39%). O marupá sofreu maior ataque de *N. surinamenses* e *N. corniger*, enquanto que a cupiúba foi a menos infestada. Já *C. acignathus* demonstrou maior atração pelas estacas de marupá e guariúba.

The relationship between the distribution range of *Nothofagus* species and herbivore species richness in Chile / Relación entre la amplitud del rango de distribución de especies del género *Nothofagus* y la riqueza de especies herbívoras en Chile

Daniela López¹, Carmen Paz Silva¹, Carlos Riquelme², Sergio Estay^{1,3}

¹Universidad Austral de Chile, Valdivia, Chile; ²Pontificia Universidad Católica de Chile, Santiago, Chile; ³Centro de Ecología Aplicada y Sustentabilidad (CAPES), Santiago, Chile (danyelalopez@gmail.com; carmenpazsilva@gmail.com; carlosriquelmemv@gmail.com; sergio.estay@gmail.com)

El género *Nothofagus* en Sudamérica se extiende desde los 30° a los 56° S. En Chile, las especies arbóreas que componen el género *Nothofagus* presentan diferentes amplitudes de su rango de distribución, se caracterizan por tener hojas tanto hojas caducas como perennes, y albergar diferentes especies de herbívoros, los cuales depredan las especies arbóreas generando diferentes tipos de daño. En este trabajo, nosotros evaluamos la relación entre la amplitud del rango de distribución de ocho especies del género *Nothofagus* y la riqueza de especies herbívoras, cuantificando el mecanismo de daño predominante. Nosotros encontramos una relación débil entre la amplitud del rango de distribución y la riqueza de especies herbívoras que depredan las especies arbóreas ($r = 0.60$, I.C. [-0.19, 0.92]). En total, se cuantificaron 145 especies herbívoras que depredan al género *Nothofagus*, y el mecanismo de daño predominante fue la defoliación ~ 30 %. En términos especie – específico, *Nothofagus dombeyi*, fue la especie arbórea que presentó la mayor presión de depredación, i.e. una mayor riqueza de especies defoliadoras asociadas a esta especie.

Ambrosia and bark beetle community along with latitudinal gradient: temporal dynamics of the community and phylogenetic effects of plants on the community

Naoto Kamata^{1,2}, Sunisa Sanguansub², Yong Peng¹, Teerapong Saowaphak³, Sawai Buranapanichpan³, Anut Buranapanichpan^{1,4}

¹The University of Tokyo, Furano, Japan; ²Kasetsart University, Kamphaeng Saen, Thailand; ³Chiang Mai University, Chiang Mai, Thailand; ⁴Royal Department of Agriculture Thai, Bangkok, Thailand (kamatan@uf.a.u-tokyo.ac.jp; agrssss@ku.ac.th; pengyong@uf.a.u-tokyo.ac.jp; agitswph@gmail.com; sawai.b@cmu.ac.th; turtlekung@hotmail.com)

Ambrosia and bark beetles are recognized as important forest insect groups because they sometimes cause devastating damage to forest ecosystems. Our aim is to clarify ambrosia and bark beetle community and their relationship with host plants along with a latitudinal gradient. In this paper, comparison among three locations, 2 sites in Japan and 1 in Thailand, will be introduced. Ethanol baited traps ('traps') and bait logs were used in this study. Seasonal changes in the community obtained by the traps and a relationship between phylogenetic distance of host plants and community similarity of the beetles obtained by the bait logs were compared among the three sites. The species richness captured by the traps tended to decrease with latitude. In Thailand, beetles were captured throughout the season but not in Japan. Seasonal dissimilarity tended to be greater but annual dissimilarity tended to smaller with latitude. Changes in the community (turnover rate) was greater in Thailand than Japan, partly because of the faster life cycle duration, partly because of the more rapid changes in the breeding material, as a result of higher average temperatures. Beetles have to disperse and seek out new breeding sites more frequently in Thailand than in Japan. Results of the bait log experiment also support the hypothesis. A negative correlation between the phylogenetic distance between host plants and similarity in the beetle community was stronger in Japan. The community tended to be more equivalent with latitude.

Mixed plantation and insect herbivory across a harvesting gradient in North Patagonian forest

Marcos Nacif¹, Lucas Garibaldi¹, Carolina Quintero¹

¹UNRN-IRNAD, S.C. de Barilche, Argentina (mnacif@unrn.edu.ar; lgaribaldi@unrn.edu.ar; quintero.carolina@gmail.com)

Sustainable forest management should optimize tree productivity and biodiversity conservation. However, it is unknown how different tree species and their associated herbivores respond to a gradient of forest extraction or if exists an optimum harvesting level for plant performance and herbivore guild diversity. In an experimental management program in Patagonian shrublands, were planted *Austrocedrus chilensis*, *Nothofagus alpina*, *N. pumilio*, *N. antarctica*, *N.*

dombeyi and *N. obliqua*, in plots with different harvesting intensities. Plant survival, growth and leaf damage of herbivore guilds were measured. Mixed model effects were used. The plants survived more and grew better at intermediate harvesting intensities. Two groups of plants presented similar consumption patterns, coincidentally with their phylogenetic proximity. These responses were obtained with different guilds. *N. obliqua* and *N. alpina* were more consumed at intermediate harvesting intensities, and *N. pumilio*, *N. antarctica* and *N. dombeyi* were more consumed at lower harvesting intensities. A non-deciduous species was the less consumed (*N. dombeyi*). Diversity patterns are similar to herbivory rates (not for *N. dombeyi* in the second year). Intermediate harvesting is optimal for plant performance and herbivore guild diversity. In a productive forest scenario, harvesting is necessary, also ensure herbivore guild diversity.

D7p: FOREST HEALTH

Silver nanoparticles stimulate the formation of ectomycorrhizae in seedlings of pedunculate oak (*Quercus robur* L.)

Marta Aleksandrowicz-Trzcinska¹, Jacek Olchowik², Marcin Studnicki³, Alexander Urban⁴

¹Department of Forest Protection and Ecology, Faculty of Forestry, Warsaw University of Life Sciences, Warsaw, Poland; ²Department of Plant Pathology; Faculty of Horticulture, Biotechnology and Landscape Architecture; Warsaw University of Life Sciences, Warsaw, Poland; ³Department of Experimental Design and Bioinformatics, Faculty of Agriculture and Biology, Warsaw University of Life Sciences, Warsaw, Poland; ⁴Department of Botany and Biodiversity Research, Faculty of Life Sciences, University of Vienna, Vienna, Austria (marta_aleksandrowicz_trzcinska@sggw.pl; jacek_olchowik@sggw.pl; marcin_studnicki@sggw.pl; alexander.urban@univie.ac.at)

Metal nanoparticles are gaining ever-wider application in agriculture and forestry, as alternatives to chemical agents used as fertilisers, growth stimulators and pesticides, establishing a need for eco-toxicological risk assessment of these agents. We tested the effects of foliar-applied silver nanoparticles (AgNPs) on chlorophyll a fluorescence and on abundance and species composition of ectomycorrhizal (ECM) colonisation. The application of AgNPs at concentrations of 5, 25 and 50 ppm was found to stimulate the formation of mycorrhizae in seedlings of pedunculate oak, with the highest effect at intermediate concentrations (25 ppm). There were non-linear effects on the relative abundance of ECM fungal species. The proportion of dominant *T. terrestris* was highest in the control group, whereas the shares of ECM formed by the two other species, *S. brunnea* and *P. involutus*, were higher in the treatments with intermediate and maximal concentrations of AgNPs, respectively. Maximum quantum yield of photosystem II (Fv/Fm) assessed by chlorophyll a fluorescence measurements revealed slight debilitation of oak seedlings irrespective of the application of AgNPs and their concentrations. This result offered an indirect indication that photosynthesis capacity had no influence on the level of mycorrhization. We hypothesise that foliar AgNPs treatments at concentrations below thresholds of acute toxicity and in the absence of significant effects on chlorophyll a fluorescence may still exert significant influence on biotic interactions including mycorrhizal symbioses by impacting plant hormonal balance, particularly ethylene, and regulatory pathways involved in host control of ECM colonisation.

Biochemical characterization of bacterioses diseases in nurseries and plantations of *Eucalyptus* spp.

Daniella Flávia Said Heid Schettini Silva¹, Helena Piedade Farsoni¹, Sharlles Christian Moreira Dias², Anderson Jones Bobko², Luciano Flávio Neves Ramos², Celso Luis Marino³, Edson Luiz Furtado¹

¹Departament of Plant Protection, São Paulo State University, Botucatu, Brazil; ²Eldorado Brasil Company, Três Lagoas, Brazil; ³Departamento of Genetics, São Paulo State University, Botucatu, Brazil (daniellafviaschettini@gmail.com; helenap_farsoni@hotmail.com; sharlles.dias@eldoradobrasil.com.br; anderson.bobko@eldoradobrasil.com.br; luciano.ramos@eldoradobrasil.com.br; cl.marino@unesp.br; edson.furtado@unesp.br)

Brazil is a world reference in eucalyptus production due to its action based on sustainability, competitiveness and innovation. Accordingly, factors that affect production, such as diseases caused by pathogenic biotic agents, including those of fungal and bacterial origin, need to be studied. Bacteria encompass a group of pathogens of complex morphological differentiation, requiring studies to characterize them. Among the methods for separating bacterial groups, the biochemical characterization allows to distinguish these according to their characteristics, such as types of respiration, production of specific enzymes or carbohydrates, among others. Thus, 39 pathogenic isolates obtained through eucalyptus seedlings with symptoms of die-back and wilting and lesions on the branches, petiole and midrib were evaluated biochemically, in order to evaluate the pathogen group. Consequently, these isolates were submitted to the tests proposed by Schaad (2001), such as potassium hydroxide or Gram test (positive or negative), oxidation and fermentation test, hypersensitivity to tobacco (*Nicotiana tabacum*), pectinolytic enzyme production, reductive phosphatase activation, reduction of nitrate to nitrite, production of carbohydrates from mannitol and production of catalase. Therefore, the tests demonstrated the bacterium is Gram negative, that is, pathogenic. In addition, the results of the tests of the oxidation and fermentation, reductive phosphatase, nitrate to nitrite reduction, mannitol and catalase were positive and for pectinolytic enzyme production and hypersensitivity to tobacco were negative, indicating the isolates belong to the group of the Enterobacteria.

Parasitism of three species of eulophid gall wasps by eupelmid, eulophid, eurytomid, and torymid on *Eucalyptus* (Myrtaceae) commercial plantations in Sumatra, Indonesia

Wagner Tavares¹, Srikumar Kkadan¹, Ade Hendrik¹, Marthin Tarigan¹, Jupiter Abad², Álvaro Durán¹

¹Asia Pacific Resources International Holdings Ltd., Pangkalan Kerinci, Indonesia; ²Toba Pulp Lestari, Porsea, Indonesia (wagnermaias@yahoo.com.br; sreeku08@gmail.com; ademeizon9@gmail.com; marthin_tarigan@aprilasia.com; jupiter_abad@tobapulp.com; duransandoval@gmail.com)

Eulophid gall wasps are a threat to the *Eucalyptus* (Myrtaceae) commercial plantations around the world. The objective of this study was to identify species of gall wasps and their associated parasitoids besides the parasitism level on galls collected from commercial *Eucalyptus* plantations in Sumatra, Indonesia. The gall wasps recovered were *Leptocybe invasa* Fisher & La Salle (Tetrastichinae), *Ophelimus eucalypti* (Gahan) and *Ophelimus maskelli* (Ashmead) (Ophelminae), all belonging to the family Eulophidae. The parasitoid *Megastigmus* Dalman (Torymidae: Megastigminae) emerged from the galls of *L. invasa*; *Aprostocetus* Westwood (Tetrastichinae), *Chrysonotomia* Ashmead, *Closterocerus chamaeleon* (Girault) (Entedoninae), *Quadrastichus* Girault (Tetrastichinae: Eulophidae), *Eupelmus* Dalman (Eupelmidae: Eupelminae), *Eurytoma* Illiger (Eurytomidae: Euritominae), and *Megastigmus* from the galls of *O. eucalypti*; and *C. chamaeleon* and *Megastigmus* from the galls of *O. maskelli*. The parasitism on *O. eucalypti* and *O. maskelli* was 30.23 and 100.00%, respectively. *Closterocerus chamaeleon*, native to Australia, shows the ability to parasitize the galls of both *Ophelimus* species therefore with a greater parasitism level on *O. maskelli*, and *Megastigmus* parasitizes all gall wasp species. As far as is known, no activity of artificial introduction of parasitoids of *Eucalyptus* gall wasps was conducted in Indonesia so far, indicating a natural introduction of parasitoids or origin of some of them to Sumatra and adaptation to parasitize the introduced gall wasp species. The maintenance of parasitoid species, combined with the selection of resistant and tolerant plant genotypes are management measures being currently adopted to control the *Eucalyptus* gall wasps in Sumatra, Indonesia.

Modeling the invasive capacity of *Chilecomadia valdiviana* / Modelamiento de la capacidad invasora de *Chilecomadia valdiviana*Carlos Riquelme^{1,2}, Carmen Paz Silva³, Daniela López³, Sergio A Estay^{2,3}¹Pontificia Universidad Católica, Santiago, Chile; ²Center of Applied Ecology and Sustainability (CAPES), Santiago, Chile; ³Universidad Austral de Chile, Valdivia, Chile (carlosriquelmemv@gmail.com; carmenpazsilva@gmail.com; danyelalopez@gmail.com; sergio.estay@gmail.com)

Las especies invasoras actualmente son una amenaza para la biodiversidad y para la economía a nivel global. Debido a los cambios ambientales, la transformación del hábitat y el incremento del comercio internacional las especies invasoras han logrado expandirse y establecerse en todo el mundo. Una especie potencialmente invasora es *Chilecomadia valdiviana*, una polilla de la familia Cossidae nativa de Chile que en su estado larval es de hábitos xilófagos generando galerías en los árboles afectados. Se ha descrito que *C. valdiviana* utiliza principalmente especies nativas, sin embargo se ha detectado su presencia en árboles del género *Eucalyptus*, generando pérdidas económicas. Para evaluar la capacidad de invasión de este insecto se utilizó un modelo de distribución de especies utilizando el programa R y el paquete “dismo”. Se utilizaron 19 variables disponibles en la base de datos Worldclim, a las cuales se les realizó un análisis de correlación para eliminar las que estuvieran altamente correlacionadas. El valor del AUC obtenido fue sobre 0.7 lo que indica un gran valor predictivo del modelo. El resultado del modelo indica que *C. valdiviana* tiene una alta capacidad invasora.

***Quambalaria eucalypti* a new pathogen of *Eucalyptus globulus* in Northern hemisphere**Helena Bragança¹, Eugénio Diogo¹, Lucinda Neves², Carlos Valente³, Luis Bonifácio¹, Alan Phillips⁴¹Instituto Nacional de Investigação Agrária e Veterinária I.P. (INIAV I.P.), Quinta do Marquês, 2780-159 Oeiras, Portugal; ²Altri Florestal SA, Quinta do Furadouro, 2510-582 Olho Marinho, Portugal; ³RAIZ, Navigator, Quinta de S. Francisco, Ap; 15, 3801-501 Eixo-Aveiro, Portugal; ⁴Universidade de Lisboa, Faculdade de Ciências, Biosystems and Integrative Sciences Institute (BioISI), Campo Grande, 1749-016 Lisboa, Portugal (helena.braganca@iniav.pt; eugenio.diogo@iniav.pt; l.oliveira.neves1@gmail.com; carlos.valente@thenavigatorcompany.com; helena.braganca@gmail.com; alan.jl.phillips@gmail.com)

The *Eucalyptus* pathogen *Quambalaria eucalypti* has been reported from several subtropical and tropical countries of the Southern Hemisphere. During the course of a nationwide monitoring program aimed at the detection of pathogens in commercial eucalypt plantations in Portugal, *Q. eucalypti* was found affecting *Eucalyptus globulus*. The identity of the pathogen was confirmed by sequence analyses of the internal transcribed spacer (ITS) region of the rDNA operon, as well as morphological characteristics. *Quambalaria eucalypti* is widespread throughout the eucalypt producing areas of Portugal. Pathogenicity studies revealed that different host genotypes showed various degrees of susceptibility to the pathogen. To our knowledge, this is the first report of *Q. eucalypti* on *Eucalyptus* spp. in Portugal and in the Northern hemisphere.

Determination of within-tree distribution of the witches' broom pathogen *Taphrina wiesneri* in *Prunus yedoensis* using loop mediated isothermal amplification (LAMP) detectionSun Keun Lee¹, Ji-Hyun Park¹, Dong-Hyeon Lee¹, Sang-Tae Seo¹, Sang-Hyun Lee¹¹Division of Forest Insect Pests and Diseases, National Institute of Forest Science, Seoul, Republic of Korea (lskyou@korea.kr; jhpark10@korea.kr; leedh2009@korea.kr; stseo@korea.kr; shlee4@korea.kr)

Flowering cherries trees, including (*Prunus yedoensis*), an important landscape tree species in South Korea, have been widely planted for urban forests (park, garden, etc.) and street trees in the country. One of the most damaging diseases of *P. yedoensis* is the witches' broom disease caused by *Taphrina wiesneri*, an ascomycetous fungus. When the tree is infected by *T. wiesneri*, abnormal growth occurs on affected branches of the tree, resulting in the witches' broom symptom, and the branches no longer bloom. Pruning out infected parts of the tree has been commonly used to prevent the disease from spreading. To determine where the pruning cuts should be made, we investigated the distribution of *T. wiesneri* within the *P. yedoensis* tree based on a loop-mediated isothermal amplification (LAMP) technique, targeting the ITS rDNA region of the pathogen. To determine whether the LAMP technique developed in this study could specifically detect the pathogen from the infected areas of the tree, its specificity was confirmed by testing the other *Taphrina* species together. Wood samples were obtained at every interval of five centimeters from all branches and main stems of three affected trees. *Taphrina wiesneri* was detected in the wood samples up to ten centimeters above and below the brooms in the symptomatic branches. Therefore, pruning out infected branches more than 10 cm below the brooms would help managing infected trees. The results also indicate *T. wiesneri* would easily spread by ascospores between trees or branches.

Potential of endophyte-mediated resistance against *Austropuccinia psidii*Julia Soewarto¹, Beccy Ganley¹, Fernanda Jacobo², Roanne Sutherland¹, Hayley Ridgway²¹SCION, Rotorua, New Zealand; ²Plant and Food Research, Lincoln, New Zealand (julia.soewarto@scionresearch.com; rebecca.ganley@scionresearch.com; fernanda.jacobo@plantandfood.co.nz; roanne.sutherland@scionresearch.com; hayley.ridgway@plantandfood.co.nz)

The impact of endophytes of myrtaceous species on infection and epidemiology of *Austropuccinia psidii* (myrtle rust) is unknown. Preliminary work on *Leptospermum scoparium* substantiates a functional role for endophytes in growth, chemistry and plant protection. Additional work has shown that endophytes can mediate resistance against rust fungi in other pathosystems, thus suggesting a potential for using endophytes as biocontrol agent against *A. psidii*. In this research we test the hypothesis that the endophyte communities within myrtaceous species differ between species, site and tissue and that some plant genotypes contain members antagonistic towards *A. psidii*. Foliar samples (leaves and stems) from healthy *Leptospermum scoparium*, *Lophomyrtus bullata* and *Metrosideros excelsa* have been collected from three different locations in New Zealand. A curated collection of >500 culturable endophytes has been generated, proportionally comprising approximately 50% bacteria, 10% actinobacteria and 40% fungi. DNA from replicate plants and plant tissues, at multiple sites, have been prepared for DNA extraction, with subsequent amplicon sequencing (Illumina) to be used to describe the full foliar endomicrobiome of these species. From this data multivariate analysis will be used to identify taxa that correlate with plant susceptibility both within and across myrtaceous species. In parallel with microbial community analysis, the antifungal potential of key cultured taxa will be determined through *in vitro* assays as a primary selection criteria. The completion of this work will identify microbial endophytes that may strengthen plant resistance to *A. psidii* and have the potential to play a long-term role in the effective management of myrtle rust.

D7q: MISTLETOES AND FOREST HEALTH

Hosts and distribution range of juniper dwarf mistletoe (*Arceuthobium oxycedri*) in the Crimean Peninsula

Yuliya Krasylenko^{1,2}, Oleg Kukushkin³

¹Institute of Food Biotechnology and Genomics, National Academy of Sciences of Ukraine, Osipovskogo St., 2a, 04123, Kyiv, Ukraine; ²Centre of the Region Haná for Biotechnological and Agricultural Research, Department of Molecular Biology, Šlechtitelů 27, 783 71, Olomouc, Czech Republic; ³Department of Herpetology, Zoological Institute of Russian Academy of Sciences, Saint Petersburg, Russian Federation (j_krasylenko@ukr.net)

Juniper dwarf mistletoe (*Arceuthobium oxycedri* (DC.) M. Bieb; Viscaceae) is a semi-parasitic species parasitizing at the Crimean Peninsula *Juniperus deltoides* as a principal host, and *J. excelsa* and *Platycladus orientalis* as secondary ones. Basing on the detailed surveys on *A. oxycedri* range in 2013–2018 it was found that heterogeneously distributed populations of hemi-parasite are confined predominantly to the Southern and South-East Coast, as well as to the South-Western Foothills, generally coinciding with the range of *J. deltoides*. According to Maxent modelling, *A. oxycedri* range is limited by such climatic factors as average temperature of the most humid and the driest seasons, precipitation of the driest month, and annual amplitude of temperatures (Krasylenko et al., 2017; Kukushkin et al., 2017). It is noteworthy that host infection pattern is patchy, since the heavily infested trees neighbour the completely unaffected ones even within one mountain slope. Moreover, the sole *J. deltoides* trees parasitized by *A. oxycedri* were found at a distance of circa 0.5–1 km from the infested localities, probably, due to ornithochory. Exclusively negative impact of *A. oxycedri* on host at the Crimea is doubtful, since both components of host-parasite system are related to Quaternary refugia of thermophilic plants and to this extent are relics. Currently, *A. oxycedri* dissemination rate is lower than the host one, its distribution is limited, and junipers lifespan in natural biotopes is compromised by multiple (a)biotic stress factors. Therefore, *A. oxycedri* “behaves more like a hyena, than a wolf”, and is hardly a key factor of host decline.

Effects of gap harvest on ectomycorrhizal fungal biodiversity and pine seedling growth

Lill Eilertsen¹, Anders Dahlberg², Lina Nilsson¹, Johanna Urzua¹, Nicklas Samils³, Judith Felten¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²Swedish University of Agricultural Sciences, Uppsala, Sweden; ³Bergvik Skog AB, Falun, Sweden (lill.eilertsen@slu.se; anders.dahlberg@slu.se; lina.nilsson@slu.se; johanna.urzua@slu.se; nicklas.samils@bergvikskog.se; judith.felten@slu.se)

The majority of temperate and boreal forest trees live in symbioses with ectomycorrhizal fungi (EMF). Considering the significance of EMF for forest soils, tree growth and health, their conservation is ecologically important. Clear-cutting, that is the predominant forest harvest practice in Sweden, strongly affects the presence and composition of EMF communities in soils. How fungi are affected by alternative harvesting and forest management strategies is debated. Here we focus on gap-harvest as an alternative harvesting practice using DNA amplicon sequencing, currently the most accurate technique to identify fungi in soil. We compare the effect of gap-size (35, 50, 70m/Ø) on seedling growth and EMF biodiversity in humus and mineral soil at an experimental site installed by Bergvik Skog AB in Middle Sweden. To provide both the forest industry as well as conservationists and scientific research with a more rapid and inexpensive method for fungal identification in soil samples, we are also developing a method using hand-held spectroscopic devices. To validate this method, results on sensitivity and specificity of fungal identification in soil samples, will be compared to data from DNA-amplicon sequencing. This has the potential to allow vast data acquisition on effects of forest management and harvesting practices on EMF biodiversity, as well as to enable routine measurements for matching EMF inoculum for nurseries to the EMF composition at sites of out-planting. The long-term aim of this project is to provide novel tools and research-based guidelines for more sustainable forestry where EMF and their potential benefits are taken into account.

Radial and axial variation on the wood structure of some ‘giant’ mistletoes: three species of Loranthaceae

Victor Sibinelli¹, Luiza Teixeira-Costa¹, Gregório Ceccantini¹

¹Universidade de São Paulo, São Paulo, Brasil (sibinelli95@gmail.com; luiza.teixeirac@gmail.com; gregorio@usp.br)

Mistletoes, from a hydraulic perspective, show one of the most interesting examples of xylem structure. These plants can develop a “chimeric sap transport system”, which comprises both host and parasite woods. At the connection site there is a complex structure generally called haustorium, that connects cells of host and parasite. Additionally, these parasites may cause an overload for the transport capacity, since they usually bear stomata in both leaf faces, which low gas exchange control. Therefore, the capacity to regulate and adjust the transport system is a key factor in determining the probability of survival of a parasitic plant. This work investigated whether and how the wood structure of some mistletoes varies within the stem topology. Three Loranthaceae species with variation in size and form, but all with relatively large dimensions were studied either radially or axially. *Psittacanthus robustus* is a woodrose-forming shrub with thick branches up to 3 m long and 4 cm in diameter; *Tripodanthus acutifolius*, a lianescent/tree species that reaches several meters; and *Struthanthus flexicaulis*, a decurrent shrub with very flexible and long stems. Our data suggest that, at least the thickest calibre species (*P. robustus* and *T. acutifolius*) indeed reached a state of wood maturity. In the case of *Struthanthus flexicaulis*, our data suggest that one of two things might be occurring: i) there is a reduction on the mean vessel diameter, lowering the risk of cavitation; ii) there is an increase in the total vessel density, increasing the redundancy of the system

Ectomycorrhizal community composition changes along to silver fir (*Abies alba* Mill.) phenological stages in Slovenia

Tina Unuk¹, Domen Finžgar¹, Rok Damjanic¹, Tine Grebenc¹, Hojka Kraigher¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia (tina.unuk@gozdis.si; domen.finžgar@gozdis.si; rok.damjanic@gozdis.si; tine.grebenc@gozdis.si; hojka.kraigher@gozdis.si)

The timing of leaf phenology is one of the most important characteristics for tree growth and survival. In most forest tree roots form symbiotic associations with mycorrhizal fungi, however till date still little is known about effects of mycorrhizal fungi on tree phenology and *vice versa*. The aim of this study was to analyze ectomycorrhizal fungal community of silver fir and changes in abundance linked to phenology. The phenological stages of silver fir trees were followed weekly for two years, and along these, 5 soil cores per individual observed silver fir tree were analyzed for ectomycorrhizal symbionts, which were further identified using Sanger sequencing of an individual ectomycorrhizal morphotype. Analyses of beta diversity between phenological stages revealed significant differences in the overall ectomycorrhizal community between dormancy and bud bursting, whereas there is an overlap between ectomycorrhizal community in dormancy and full needle expansion as well as between bud bursting and full needle expansion. Abundance analyses of ectomycorrhizal species between phenological stages revealed higher abundances of *Russula ochroleuca*, *Tomentella stiposa*, *Tomentella sublilacina* and *Tylospora fibrillosa* during bud bursting, which are ectomycorrhizal species for which the presence of manganese peroxidase and/or laccase has already been suggested or confirmed. Our results indicate a need for more detailed analyses of possible presence of mentioned enzymes, as well as any hormonal regulation among ectomycorrhizal species associated with bud burst and silver fir trees. The presentation contributes to the aims and means of the project LIFE13 ENV/SI/000148.

Effects of the parasitism of the mistletoe *Struthanthus martianus* (Loranthaceae) on the reduction of increment in *Tipuana tipu* (Leguminosae): evidence of a systemic effects by one single parasitized branch

Evelyn Pereira Camargo¹, Eduardo Mineo Iegawa¹, Luiza Teixeira-Costa¹, Gregorio Ceccantini¹

¹Universidade de São Paulo, São Paulo, Brasil (camargoevelyn@usp.br; eduardoiegawa@usp.br; luiza.teixeirac@gmail.com; gregorio@usp.br)

The mistletoe species *Struthanthus martianus* (Loranthaceae) is a generalist hemiparasite native to Brazil. Among its many host species, it is frequently observed to infest an urban tree species named *Tipuana tipu* (Leguminosae), originally endemic species to Northern Argentina. Given to the clearly marked semi-porous growth rings, *T. tipu* is widely used in dendrochronological analyses. In the present study, we have analyzed the influence of the parasite *S. martianus* on the annual growth rates of *T. tipu*. From infested trees, both parasitized (PB) and non-parasitized branches (NPB) were sampled. Branches from non-infested trees (NIT) were also sampled and analyzed. Our results show that, despite the overall decrease in growth rates for all analyzed samples, during the five most recent rings, both PB and NPB a faster decrease in growth rates was detected, which was indicated by the slope of the adjusted growth curve. This recent decrease could correspond to the moment in time when the presence of the parasite starts affecting host branch growth. Also, this is evidence of a systemic effect, since branches without a parasite also respond in growth decrease. However, phenological observations of other host-parasite pairs in the same area show no increase in death rates of neither host branches, nor the trees themselves. This suggests a mild effect of *S. martianus* when compared to other mistletoe species, such as *Arceuthobium* spp. and *Phoradendron* spp. Further whole-tree dendrochronological analyses could improve our understanding of the growth dynamics of parasitized trees, especially in tropical and/or urban areas.

'Large' mistletoe parasitism in a conifer host: anatomy of the interface between *Psittacanthus cf schiedeana* and *Pinus hartwegii*

Mariana Oliveira-da-Silva¹, Luiza Teixeira-Costa¹, Gregório Ceccantini¹

¹University of São Paulo, Institute of Biosciences, Department of Botany, Rua do Matão 277, 05508-090, São Paulo, Brazil (mariana.oliveira.silva@usp.br; luiza.teixeirac@gmail.com; gregorio@usp.br)

Mistletoes of the genus *Psittacanthus* (Loranthaceae) are large-sized hemiparasites that infest a wide range of hosts, including conifers. However, similar to what has been observed for other Loranthaceae species, the relationship between *Psittacanthus* spp. and conifers are rare, thus not often analyzed. As part of a larger effort to understand how angiosperm parasitic plants are able to establish vascular connections with conifer hosts, this work aimed at analyzing the anatomy of the host-parasite interface between *Psittacanthus cf schiedeana* and *Pinus hartwegii*. Light, confocal and electron microscopy were used in conjunction with x-ray computed tomography. Our results showed that the general morphology and the three-dimensional structure of the host-parasite connection were similar to what has been reported for *Psittacanthus* and another angiosperm-host associations. Detailed anatomical analyses revealed that the mistletoe attaches the host xylem conduits via parenchyma cells, bridging the parasite vessel elements and the tracheids of the host. This pattern contrasts with the direct xylary (from one tracheal element to another) reported for *Psittacanthus* sp.–angiosperm host associations, as well as for *Arceuthobium* sp.–conifer host associations. Being composed of tracheids, the vascular system of *P. hartwegii* offer higher resistance to sap flux, which probably would require the parasite to reach a lower-than-usual water potential in order to diverge sap flux towards itself. By establishing vascular connections with the host via parenchyma cells, which normally contain various solutes, this might lower cell water potential even more than the usual, allowing *P. cf schiedeana* to be able to successfully infest *P. hartwegii*.

Effects of the parasitism of the mistletoe *Phoradendron bathyoryctum* (Santalaceae) on the increment of tree rings in urban trees of *Cedrela fissilis* (Meliaceae)

Eduardo Mineo Iegawa¹, Evelyn Pereira Camargo¹, Gregório Ceccantini¹, Luiza Teixeira-Costa¹

¹University of Sao Paulo, Sao Paulo, Brazil (eduardoiegawa@usp.br; camargoevelyn@usp.br; gregorio@usp.br; luiza.teixeirac@gmail.com)

Dendrochronology is the study of tree-rings and their use for estimating information on the growth of the analyzed plants and also the environment in which it happened. In the present work we have analyzed the increment rate (growth-ring width) of branches of the host tree *Cedrela fissilis* (Meliaceae) parasitized by the mistletoe *Phoradendron bathyoryctum* (Santalaceae). Based on previous analyses of *C. fissilis* trees, showing no significant effect of this parasitism on the main trunk, this time we have chosen to analyze parasitized branches (PB), non-parasitized branches of otherwise parasitized trees (NPB), and branches from healthy, non-parasitized trees (NPH). Despite the relatively young age of the analyzed branches, we observed that during the period (2009 – 2011) in which NPH individuals grew less, both PB and NPB individuals grew more. This inverse growth pattern could indicate a short-term positive effect of the parasite not only on the infested branch but also on other branches of the same tree. However, highly infested trees were still observed to die, probably due to long-term effects of the parasite *P. bathyoryctum*. Probably those effects could overcome punctual positive ones on host branch growth, such as continuous and prolonged high hydric stress for the branch and the whole plant since it's known that a parasite can demand as much water as a host.

Undetected endophytic fungi as a quarantine risk to commercial *Eucalyptus* plantations in Colombia

Ginna Marcela Granados¹, Alistair R. McTaggart², Carlos Alberto Rodas³, Jolanda Roux⁴, Michael J. Wingfield¹

¹Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²Queensland Alliance for Agriculture and Food Innovation, University of Queensland, Queensland, Australia; ³Smurfitkappa Colombia, Yumbo, Colombia; ⁴Sappi, Hilton, South Africa (ginna.granados@fabi.up.ac.za; a.mctaggart@uq.edu.au; carlos.rodas@smurfitkappa.com.co; jolanda.roux@sappi.com; mike.wingfield@up.ac.za)

Healthy plant tissues pose a cryptic quarantine threat to global forests and forestry because undetected endophytic fungi can be moved with them. Host shifts between Melastomataceae and Myrtaceae by different species of Cryphonectriaceae has increased the host range of a number of important stem canker pathogens. For example, species of *Chrysosporthe*, which cause serious canker diseases on commercially planted *Eucalyptus*, also occur as asymptomatic endophytes in native Myrtaceae. The aim of this study was to identify possible species of Cryphonectriaceae that occur as endophytes in four native hosts from Colombia and two that have been introduced from Brazil. Healthy branches of each Melastomataceae host were collected from five provinces in Colombia, and then incubated between 2 to 4 weeks to stimulate production of Cryphonectriaceae fruiting bodies. Isolates were identified based on DNA sequence data for two gene regions. The results revealed three species of Cryphonectriaceae namely *Aurapex penicillata*, *Chrysosporthe inopina* and *C. cubensis*. Host specificity was not observed for species of Cryphonectriaceae on Melastomataceae. *Aurapex penicillata* is now known as an endophyte in four species, and *C. inopina* and *C. cubensis* were endophytic in three hosts each. *Chrysosporthe cubensis* was also found in symptomatic lesions on native *M. rubiginosa*. Native and introduced tree species in the Melastomataceae that occur naturally alongside *Eucalyptus* plantations could thus act as a reservoir of potential pathogens to commercial plantations. This has important implications on quarantine programs regarding the movement of latent, endophytic pathogens in apparently healthy plant material.

D7r: FOREST AND URBAN TREE HEALTH

Phytophthora-damage in deciduous forests of Southern Sweden: from genes to landscapeJohanna Witzell¹ , Michelle Cleary¹ ¹Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Alnarp, Sweden (johanna.witzell@slu.se; michelle.cleary@slu.se)

Phytophthora-pathogens have recently emerged as a challenging forest health problem in southern Sweden, reducing the vitality of trees and leading to instability and premature mortality. The invasive behavior of these pathogens, and their ability to adapt to different conditions result in a forest disease problem that has a potential to profoundly worsen the conditions for forest production and conservation. Starting in 2010-2011, extensive *Phytophthora*-damages were registered on European beech (*Fagus sylvatica*) in urban settings and national parks in southern Sweden. Using field site surveys of symptomatic trees, classical isolation techniques and sequencing of soil and tissue samples we mapped *Phytophthora*-damage on beech and identified the causal agents. Oomycete diversity was determined by sequencing ITS environmental DNA (eDNA) from stem tissues and soil (multiplex-sequenced using 454- and Illumina MiSeq), while isolates were identified via Sanger sequencing. Results revealed the presence of *P. plurivora*, *P. cactorum*, *P. syringae*, *P. cambivora*, and *P. gonapodyides*. This was the first time *P. gonapodyides* has been associated with stem damages on beech in Sweden. Alarmingly, there are now indications that the disease front for *Phytophthora* spp. is advancing in the landscape, and *Phytophthora*-pathogens are increasingly affecting also other tree species than beech. The spreading pathways and consequences of *Phytophthora*, as well as management options in urban and production forest settings are discussed.

First report of cottonwood leaf beetle *Chrysomela scripta* (Coleoptera: Chrysomelidae) in South AmericaCarlos Wilcken¹, Amanda de Souza¹, Carolina Jorge²¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil; ²Universidad de La Republica (UDELAR), Tacuarembó, Uruguay (carlos.wilcken@unesp.br; agroamandarodrigues@yahoo.com.br; carolina.jorge@cut.edu.uy)

The insect pest invasions in forest plantations were significantly increased in the latest decades. The forestry genera most planted for commercial purposes in the world are Eucalyptus, Pinus, *Populus*, *Acacia*, *Toona*, among others. In South America species of *Populus* and *Salix* are secondary in importance to industry but are commonly used as urban trees. The leaf beetles of the Chrysomelidae family are the main insect pest affecting poplar plantations in North America, especially of the genus *Chrysomela*, where *Chrysomela scripta* is considered the most harmful species. *C. scripta* is endemic of North America, being more abundant in poplar plantations in the United States. The aim of this work was to report for the first time the presence of *C. scripta* in Brazil. In July, 2016 some beetles unidentified were observed feeding in trees of *Salix nigra* and *Populus deltoides* in an urban area of Botucatu municipality in São Paulo State, Brazil, causing complete defoliation. In June 2017 were observed in Piracicaba. Adults, larvae, pupae and eggs were collected and reared in laboratory. These specimens were identified as the exotic species *Chrysomela scripta* (Coleoptera: Chrysomelidae). This is the first detection of this exotic pest outside their natural range is important for the development of the sanitary surveillance strategies to prevent the expansion of this species and evaluate their impact in *Salix humboldtiana*, a native species. Studies to determine the bioecology and distribution of *C. scripta* in Brazil are ongoing.

Improving diagnostics for *Xylella fastidiosa*, a potential threat to UK's treesSundeep Kaur¹, Alex Lewis¹, Caroline Gorton¹, Ruth Chitty¹, Ana Pérez-Sierra¹, Sietse van der Linde¹¹Forest Research, Alice Holt Lodge, Farnham, Surrey GU10 4LH, United Kingdom (sundeep.kaur@forestry.gov.uk; alex.lewis@forestry.gov.uk; caroline.gorton@forestry.gov.uk; ruth.chitty@forestry.gov.uk; ana.perez_sierra@forestry.gov.uk; sietse.vanderlinde@forestry.gov.uk)

The bacterium *Xylella fastidiosa* has a large host range including over 500 plant species. Broadleaf tree hosts such as oak (*Quercus*), plane (*Platanus*) and elm (*Ulmus*) have already been identified in *Xylella* affected regions in North America. Some trees can be infected with low-level or asymptomatic symptom expression and could potentially act as reservoirs of the pathogen in the wider environment, possibly asymptotically. Current diagnostics rely on *X. fastidiosa*-specific real-time PCR assays for detection (EPPO PM7/24(3)). The diagnostic process relies on DNA extraction from potentially infected plant tissue and sample processing is labour intensive and time-consuming. In real-time PCR detection trials with various tissue types and different potential host trees, it was found that the sensitivity of the molecular detection varied markedly between tissue type and tree host. This is most likely due to varying amounts of secondary metabolites in foliage of some of the key tree hosts which inhibit detection assays and affect sensitivity. Positive *Xylella* detection is followed by multilocus sequence typing for subspecies identification. Subspecies of *X. fastidiosa* show a varying degree of host-specificity and subspecies identification is therefore important in case of a new outbreak. The aim of this study is to make adjustments to current DNA extraction protocols and real-time assays to reduce sample processing time and improve overall detection sensitivity and efficiency on trees. These improvements can be applied to newly developed diagnostic technologies which will aid tree health inspectors during an outbreak situation.

A project for a *Eucalyptus* sentinel garden in the Mediterranean island of Sardinia (Italy)Giuseppe Brundu¹, Arturo Cocco¹, Vanessa Lozano¹, Roberto Mannu¹, Ignazio Floris¹¹Department of Agriculture, University of Sassari, Sassari, Italy (gbrundu@tin.it; accoco@uniss.it; vlozano@uniss.it; rmannu@uniss.it; ifloris@uniss.it)

Sentinel plants and sentinel gardens are commonly located close to high risk areas in order to timely detect signs and symptoms of novel pest attacks. They are an important part of the post-border surveillance toolbox and can be carried out for early detection of recently-introduced, non-native species, therefore increasing chances of eradication and control. Occasionally, sentinel plants and sentinel gardens may also help in identifying new associations between pests and planted trees. Many non-native trees used in planted forest are successful because they have been separated from their natural enemies. However, when plantation trees are reunited with their coevolved pests, which might be introduced accidentally, or when they face novel pests to which they have no resistance, substantial damages can be observed. Among non-native trees, eucalypts play a very important role in the economies of many countries, including the Mediterranean and Europe, but there might be also environmental, economic and social concerns associated with their widespread use, namely on biodiversity, water and soil resources. Plantations of eucalypts have increased during the last 50-70 years and have experienced a steady increase of pest problems as well. Fairly large numbers of native pests and pathogens have also adapted to feed on or infect eucalypts in the non-native range. Considering the importance of this group of species for the southern Italian region, the Sardinian Regional Authority, Environmental Directorate supported the establishment of a *Eucalyptus* sentinel garden in the Mediterranean island of Sardinia (Italy). We here describe its preliminary planning and establishment phases.

Ecological restoration and protection of ant fauna in an Andean forest (Bello, Colombia) / Restauración ecológica y protección de la mirmecofauna en un bosque andino (Bello, Colombia)

David Felipe Bulla Guaqueta¹, Jaime Polanía¹, Carolina Serna¹

¹Universidad Nacional de Colombia, Medellín, Colombia (dfbullag@unal.edu.co; jhpolaniav@unal.edu.co; csernac@unal.edu.co)

En el corregimiento San Félix (Bello, Colombia), a 2510 msnm, con 17 °C promedio, se desarrollan ganadería y agricultura. Los campesinos atacan las “plagas”, especialmente hormigas, con productos organofosforados (“Lorsban”), su uso excesivo ha reducido drásticamente la diversidad local. Este estudio se enfocó en la diversidad de hormigas en un terreno en proceso de restauración (mediante estacas y núcleos que, desde 2015, han generado un bosque secundario + de 1 ha), cuyas áreas circundantes siguen siendo fumigadas regularmente. El muestreo consistió en 14 trampas de caída: siete en el costado sur y el resto en el norte del terreno; se dispusieron también dos trampas Winkler, una por cada costado. Las trampas fueron recogidas 48 horas después. Se colocaron 14 cebos de proteína por 90 minutos. Las muestras fueron conservadas en alcohol al 70% y llevadas al laboratorio de Ecología y Manejo de Vida Silvestre de la Universidad Nacional de Colombia Sede Medellín, donde fueron identificados representantes de las subfamilias Myrmicinae y Dolichoderinae (mayoritariamente del género *Linepithema*). Los géneros de Dolichoderinae presentan hábitos arborícolas y sus especies suelen dominar incluso hasta 4.000 msnm, mientras las de Myrmicinae muestran variedad de adaptaciones ecológicas. Ambas logran coexistir, ya que sus hábitos de forrajeo y formas de nidificación son diferentes. También se encontró abundancia de representantes de órdenes Dermaptera y Collembola, y de los filos Annelida y Mollusca. Esta fauna puede presentarse porque: (i) el bosque secundario actúa como barrera para el insecticida y protege el ecosistema, y (ii) hay mayor disponibilidad de materia orgánica.

Effects of environmental pollution on the physiological and biochemical responses of Roadside Trees

Hana You¹, Myeongja Kwak², Suyoung Woo², Jongkyu Lee²

¹University of California, Davis, California, USA; ²University of Seoul, Seoul, Republic of Korea (hnyou@ucdavis.edu; 016na8349@hanmail.net; wsy@uos.ac.kr; gpl90@naver.com)

Environmental pollution is an important issue in metropolitan areas. Roadside trees are directly affected by various source of pollution, to which they show numerous responses. This experiment was conducted to identify the responses of *Ginkgo biloba* and *Platanus occidentalis* grown in three different environmental conditions and to assess the possibility of using plant physiological and biochemical parameters as a bio-monitoring factor in urban areas. *Ginkgo biloba* and *Platanus occidentalis* are the most abundant roadside tree species in Seoul, the capital city of Korea. The physiological, biochemical and morphological parameters of the roadside trees in High pollution (RH), Low pollution (RL) and Green space (RG) were investigated. RH showed the lowest photosynthetic rate, nitrogen use efficiency, and photo pigment content of the three, and water use efficiency, leaf temperature, ion leakage, and malondialdehyde contents were highest in high polluted condition. The stomatal size, density and closure of the trees did not differ significantly among the RH, RL, and RG. In this study, photosynthetic rate showed a positive correlation with chlorophyll and carotenoid content, whereas it showed a negative correlation with relative ion leakage and leaf temperature. This study was carried out with the support of Development of urban forest management and management technology to reduce air pollutants - Focusing on particulate matter - (Grant No. FE0000-2018-01-2018) from National Institute of Forest Science (NIFoS), Republic of Korea.

Invasion of West Africa sahelian rangelands by the plant *Senna obtusifolia*: ecological dynamics and local resilient strategies in Burkina Faso

Oumarou Ouédraogo^{1,2}, Alhassane Zaré³, Karim Ouédraogo⁴, Anja Linstädter², Gabin Korbéogo⁴, Adjima Thiombiano³

¹Laboratory of Plant Biology and Ecology-University Joseph Ki Zerbo, Ouagadougou, Burkina Faso; ²Range Ecology and Range Management Group, Botanical Institute, University of Cologne, Cologne, Germany; ³Laboratory of Plant Biology and Ecology-University Joseph Ki-Zerbo, Ouagadougou, Burkina Faso; ⁴Group of research on local initiatives - University Joseph Ki-Zerbo, Ouagadougou, Burkina Faso (ouedraogooumar@yahoo.fr; rezareza093@gmail.com; ouedraogo.karim85@yahoo.com; anja.linstaedter@uni-koeln.de; kgabin1@hotmail.com; adjima_thiombiano@yahoo.fr)

Rangelands in Sahelian countries are continuously over-grazed decreasing forage resources and causing rapid environmental changes. The invasion of rangelands by a less palatable plant species, *Senna obtusifolia* could be an indicator of land degradation. This research aims to explore the drivers of invasiveness and evaluate consequences of *Senna obtusifolia* invasion on Sahelian rangelands systems and on rural population's livelihood. Data were collected through an interdisciplinary approach integrating ecological and socio-anthropological methods in three different climate conditions and two land use systems. The relative dominance of *S. obtusifolia* was significantly ($p < 0.001$) influenced by topography, climate conditions, land use patterns and the mix-effect of these environmental factors. The level of land invasion by *S. obtusifolia* affected negatively both the above ground biomass production ($p = 0.002$) and the plant richness ($p < 0.05$) of rangelands. However, the ecological results about the drivers of performance of *S. obtusifolia* were in accordance with the perceptions of local populations. With the scarcity of plant natural resources especially in the Sahel zone, this invasive plant is used for multiple purposes such as food, forage and handicraft. Indeed local populations had in general a positive perception on *S. obtusifolia* in their environment. With its multiple benefits, the surveyed people hide the negative impacts of this species on the production systems of rangelands. The endogenous uses *S. obtusifolia* offer opportunities for the development of innovations and technologies to control its expansion for a sustainable management of sahelian rangelands and help rural populations to be more resilient from land degradation and climate change.

Urban forestry species most likely to fall in Belo Horizonte, Minas Gerais, Brazil / Análise das espécies da arborização urbana com maior frequência de queda em Belo Horizonte, MG

Agnus Bittencourt¹, Marina Souza², Angeline Martini³

¹Prefeitura Municipal de Belo Horizonte, Nova Lima, Brasil; ²Cemig, Belo Horizonte, Brasil; ³Universidade Federal de Viçosa, Viçosa, Brasil (agnus@pbh.gov.br; mourasouzam@gmail.com; martini.angeline@gmail.com)

O correto planejamento e manejo da arborização urbana permite a otimização dos benefícios proporcionados pelas árvores, bem como a diminuição de problemas. Esta pesquisa teve como objetivo identificar as espécies arbóreas com maior ocorrência de queda no município de Belo Horizonte. Para isso, os dados foram coletados por meio de amostragem aleatória após a ocorrência das quedas, entre os anos de 2015 e 2018. Um pesquisador se deslocou ao local, sempre após o registro da queda para realizar a identificação botânica. A análise, realizada em 69 exemplares arbóreos indicou a queda de 24 espécies pertencentes a 10 famílias botânicas. A família que apresentou o maior número de queda dos indivíduos foi Fabaceae, correspondente a 46,3% do total. Sete espécies foram responsáveis por aproximadamente 60% das quedas registradas, destas, destacaram-se as espécies *Pachira aquatica* e *Libidibia ferrea* var. *leiostachya* responsáveis por 10,1% das ocorrências cada uma e *Poincianella pluviosa* (8,7%). Constatou-se um número significativo de quedas caracterizada por indivíduos de espécies nativas do

Brasil (57,6%), sendo 36,4% de espécies nativas da região de Belo Horizonte, 21,2% das demais regiões do Brasil e 42,4% de exóticas. Conclui-se, portanto, que os resultados apontados podem contribuir para a melhoria do planejamento e manejo da arborização na cidade, uma vez que fornece informações sobre as espécies com maior frequência de queda e que por consequência necessitam de maior atenção. Recomenda-se que estudos como este se intensifiquem nas cidades brasileiras para garantir o correto desempenho da arborização, auxiliando na diminuição dos problemas ocasionados pelas árvores urbanas.

D7s: FUNGAL PATHOGENS, CONSERVATION OF FUNGI, AND INSECT CHEMICAL CONTROL

A high resolution phylogeny from the genome data of *Teratosphaeria* leaf and stem pathogens

Janneke Aylward¹, Francois Roets², Leanne Dreyer³, Michael J. Wingfield¹, Brenda D. Wingfield¹

¹Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²Department of Conservation Ecology and Entomology, Stellenbosch University, Stellenbosch, South Africa; ³Department of Botany and Zoology, Stellenbosch University, Stellenbosch, South Africa (janneke.aylward@fabi.up.ac.za; fr@sun.ac.za; ld@sun.ac.za; mike.wingfield@up.ac.za; brenda.wingfield@up.ac.za)

Teratosphaeria (Dothideomycetes: Capnodiales) is a genus of fungi primarily associated with the leaves of *Eucalyptus* hosts. Whereas the majority of species appear not to be important, some *Teratosphaeria* species have emerged as aggressive pathogens causing substantial economic losses in areas where *Eucalyptus* spp. are grown as exotics in plantations. Two of these are unusual in being stem canker pathogens rather than infecting leaves and shoots. The taxonomic relationships for this diverse group are generally poorly resolved, especially at the deeper branches of phylogenetic trees. The aim of this study was to construct a robust phylogenomic tree to resolve the relationships among *Teratosphaeria* species for which whole genome sequences are available. We incorporated seven *Teratosphaeria* species into the phylogenomic tree, using a total of 11 genomes that have been sequenced by our research group. Single-copy, orthologous core genes, shared by all isolates, were identified using the Ascomycota dataset in BUSCO (Benchmarking Universal Single-Copy Orthologs). More than 1000 orthologous genes were used to construct a Maximum Likelihood phylogeny with RaXML. The resultant phylogenomic tree provided strong support for internal branches that were poorly supported in single-gene trees.

Life cycle and field epidemiology of the rust pathogen *Uromycladium acaciae* on *Acacia mearnsii*

Stuart Fraser^{1,2}, Alistair McTaggart^{1,3}, Jolanda Roux¹, Michael J. Wingfield¹

¹Department of Plant and Soil Sciences, Tree Protection Co-operative Programme (TPCP), Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²Scion, Rotorua, New Zealand; ³Queensland Alliance for Agriculture and Food Innovation, The University of Queensland, Brisbane, Australia (stuart.fraser@scionresearch.com; a.mctaggart@uq.edu.au; jolanda.roux@gmail.com; mike.wingfield@fabi.up.ac.za)

Uromycladium acaciae causes a rust disease that threatens black wattle (*Acacia mearnsii*) forestry in South Africa. Little is known regarding the life cycle or field epidemiology of the pathogen. Knowledge on these aspects is required in order to develop an integrated pest management programme for this disease. Disease monitoring and spore trapping were undertaken at three infected plantations of *A. mearnsii* in Mpumalanga. These studies considered the following hypotheses based on observations from prior controlled experiments: (i) uredinia and telia of *U. acaciae* are not conspecific; (ii) teliospores of *U. acaciae* are the main dispersal agents (rather than basidiospores) and spread mainly under wet conditions, (iii) conditions during the summer wet season (October – March) will be optimal for dispersal of teliospores and infection by basidiospores. Observations supported all three hypotheses. Spermogonia and telia co-occurred regularly on both developing and fully developed plant tissues, whereas uredinia were observed only on fully expanded leaves. Spermogonia and uredinia were not observed co-occurring without telia. Furthermore, single nucleotide polymorphisms and indels of rDNA in uredinia were not present in next-generation sequences from telia. Teliospores were observed abundantly on spore traps. There was a positive relationship between relative humidity and abundance of teliospores. There was a polynomial relationship between rainfall and abundance of teliospores, with a predicted peak in abundance of teliospores at c; 9 mm rain day⁻¹. Although teliospores were observed on traps at all trapping periods, the greatest abundance of teliospores were observed towards the end of the wet season in February-March 2017.

Fusarium circinatum on non-pine hosts enhance the global threat of pine pitch canker

Darryl Herron^{1,2}, Emma Steenkamp^{1,2}, Brenda Wingfield^{1,2}, Michael J. Wingfield^{1,2}

¹FABI, Pretoria, South Africa; ²University of Pretoria, Pretoria, South Africa (darryl.herron@fabi.up.ac.za; emma.steenkamp@up.ac.za; brenda.wingfield@up.ac.za; mike.wingfield@fabi.up.ac.za)

Since the original discovery of the pitch canker fungus, *Fusarium circinatum*, in the United States of America in 1945, the pathogen has spread to almost every continent on the planet. Originally a pathogen of *Pinus* species and *Pseudotsuga menziesii*, we now know that it can also colonise non-coniferous plants, including different grass and herbaceous plant species, as an endophyte. In South Africa, we investigated this endophytic association by identifying the *Fusarium* species inhabiting sixteen species of grass occurring in the understory of pitch canker-affected *Pinus patula* trees in a commercially managed plantation. Isolates were identified using their morphological characteristics as well as by phylogenetic inference based on DNA sequences for the beta-tubulin and translation elongation factor-1-alpha gene regions. A number of important *Fusarium* species were recovered from these grasses, including *F. circinatum*, which was found on five of the sixteen grass species examined. The cryptic occurrence of *F. circinatum* in non-coniferous plants highlights a need to consider the role that other plant species might play in its biology and distribution. It also raises a quarantine threat that has not been fully considered in the past. This is amplified by the fact that new and highly virulent genotypes of the pathogen could easily be introduced into countries where *F. circinatum* is known to occur. Such introductions of novel and virulent genotypes would set back already established breeding programmes that have focused on limiting the damage caused by genotypes already in a country.

Volatile organic compounds to identify root and butt rot pathogen *Armillaria* spp.

Nicola La Porta^{1,2}, Claudia M.O. Longa¹, Andrea Corinzia³, Luca Cappellin¹, José Sanchez del Pulgar¹, Franco Biasioli¹

¹IASMA Research and Innovation Centre, Fondazione Edmund Mach, Trento, Italy; ²The EFI Project Centre on Mountain Forests (MOUNTFOR), Trento, Italy; ³University of Catania, Catania, Italy (nicola.laporta@fmach.it; claudia.longa@fmach.it; andrea.corinzia89@gmail.com; luca.cappellin@fmach.it; jose.sanchez@fmach.it; franco.biasioli@fmach.it)

PTRMS-TOF analysis of *Armillaria* volatolic profile was used as molecular tools for the taxonomic identification of six European species of genus *Armillaria*: *A. borealis*, *A. cepistipes*, *A. gallica*, *A. mellea*, *A. ostoyae* and *A. tabescens*. This mycete is known as honey mushroom and it is one of the main opportunistic pathogenic fungus found in many forest and ornamental trees where it causes white root rot. It is also a saprotroph who allows the wood degradation and the easy transfer, by wood trade, the other more than 40 esotic species present in the other continents. Volatile Organic Compounds (VOC) pattern was analyzed for 77 strains of *Armillaria* by PTR-MS-TOF technique in order to discriminate the species. *Armillaria* strain were previously identified by DNA amplification by PCR. Samples were analyzed after 30 days of incubation to allow the mycelial growth on MEA substrate added with silver fir sawdust. Data analysis was performed using univariate and multivariate statistical tools. The analysis of variance (ANOVA) discriminated *A. borealis* by using acetylene concentration and *A. cepistipes* by using hexanal concentration. The distribution of specific masses concentration, as a function of species by boxplots, allows to discriminate *A. tabescens*, *A. borealis*, *A. cepistipes* and *A. mellea*. Principal component analysis allows discriminate the *A. borealis* and *A. tabescens* clusters. The future improvement of this approach is to identify some VOC which can discriminate invasive *Armillaria* species to develop a rapid and accurate identification diagnostic method based on gas chromatographic separation of these VOCs.

A wide host range and high levels of genetic diversity characterise Cryphonectriaceae stem canker pathogens on Myrtales in Southern China

Wen Wang¹, Michael J. Wingfield², ShuaiFei Chen¹

¹China Eucalypt Research Centre (CERC), Chinese Academy of Forestry (CAF), ZhanJiang, China; ²Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa (wangwencerc@126.com; mike.wingfield@fabi.up.ac.za; cercsf@126.com)

Plantation-grown *Eucalyptus* (Myrtaceae) and other trees residing in the Myrtales have been widely planted in Southern China. These fungal pathogens include fungi of Cryphonectriaceae that are well-known to cause stem and branch canker disease on Myrtales trees. During recent disease surveys in southern China, fruiting structures with typical characteristics of the Cryphonectriaceae were observed on the surfaces of cankers on stems and branches of Myrtales trees. In this study, a total of 206 Cryphonectriaceae isolates were identified based on comparisons of DNA sequence of the partial LSU gene, ITS region of the nuclear ribosomal DNA gene, two regions of the β -tubulin (*BT2/BT1*) gene and the translation elongation factor 1-alpha (*TEF-1a*) gene region, as well as their morphological characteristics. The results showed that eight species reside in four genera of Cryphonectriaceae occurring on five genera of Myrtales. These included *Celoportha cerciana* from a *Eucalyptus grandis* hybrid clone, *C. eucalypti* from *Syzygium jambos* (Myrtaceae), *C. guangdongensis* from *S. jambos*, *C. syzygii* from *E. grandis* hybrid clones, *Psidium guajava* (Myrtaceae), *S. hancei*, *S. jambos* and *S. samarangense*. The notorious pathogen *Chrysosporthe deuterocubensis* was identified from *E. grandis* hybrid clones, *Melastoma candidum* (Melastomataceae), *M. sanguineum*, *P. guajava*, *S. jambos* and *S. samarangense*. A novel species of *Aurifilum* was isolated from *Terminalia neotaliala* (Combretaceae) and an undescribed genus including two species of Cryphonectriaceae were identified from *E. grandis* hybrid clones. This study revealed an unexpected and surprising level of Cryphonectriaceae diversity on a wide-range of Myrtales hosts in southern China.

Designing chemical control measures against fungus gnats in log yards

Guilherme Schnell Schühli¹, Wilson Reis Filho², Susete do Rocio ChiarelloPenteado¹

¹Embrapa Colombo, Colombo, Brasil; ²Epagri, Florianópolis, Brasil (guilherme.schuhli@embrapa.br; wilson.reis@colaborador.embrapa.br; susete.penteado@embrapa.br)

For the production of wood panels, it is important to keep the continuous supply of logs to the plant. Therefore, the factories usually maintain log yards (*Pinus elliottii* and *P. taeda*) where these logs are arranged in piles. The environmental conditions provided by these piles predispose the boom of large populations of fungus gnats (Sciariidae) (as *Bradysia matogrossensis*, *Euricrium varians* and *E. edwardsi*). These insects cause discomfort to the workers, disturbing the operation of the plant and impacting the surrounding urban areas. Based on the observation of the chemical treatments adopted by the companies and a small scale experiment, we present here a strategy for the control. We recommend the use of Carbamate (80%) and Pyrethroid (40%) in alternate applications (in order to manage the effects of biological resistance). Alpha-cypermethrin (12%) and Fipronil (18%) may also be an alternatives tools to reach individuals that may acquire resistance due to chemical selection. The chemicals may be applied with a manual knapsack sprayer, nonetheless, mist blower or agricultural cannon sprayer will perform better. These chemicals can also be applied at a cargo disinfection arch, treating the load on the trucks at the entrance to the yard. This would minimize the colonization of the piles and increase the treated surface area. We advise against the use of organophosphates since there is cross-resistance with the pyrethroid and also due to its greater toxicity to vertebrates.

Threats and mitigation to macrofungi (Mushroom) conservation in the Mount Cameroon Region, Central Africa

Tonjock Rosemary-Kinge¹, Afui Mathias Mih²

¹Department of Biological Sciences, Faculty of Science, The University of Bamenda, Bamenda, Cameroon; ²Department of Botany and Plant Physiology, Faculty of Science, University of Buea, Buea, Cameroon (rosemary32us@yahoo.com; mathias.afui@ubuea.cm)

Mount Cameroon is found in the South West Region of Cameroon and is diverse with macrofungi species which have socio-economic functions as food and medicine, and also play essential roles in ecosystem functioning such as in decomposition and forming mycorrhizae association. Inhabitants of this region depend on the forest for their livelihood. This study was carried out for 2 years to assess the threats to macrofungi conservation in the mount Cameroon Region and provide solutions to the communities for mitigation. Interviews, questionnaires and focus group discussions were carried out in ten communities living around the Mount Cameroon forest reserves. The major reasons accounted for threats to macrofungi were habitat degradation due to landslides and volcanic eruptions, climate change, over harvesting of some edible and medicinal mushrooms, deforestation for farmlands by the locals and oil palm cultivation by multinational companies, settlement expansion due to urbanization and fire outbreaks by the local communities around Mount Cameroon region. It was found that, though there are laws and policies on biodiversity conservation in Cameroon, these laws are not being implemented with regards to fungi conservation and this can expose fungi to the risk of extinction. Solutions proposed and carried out for mitigation were implementation of in situ conservation methods, cultivation of the over harvested species on local substrates with the communities and planting of fast growing leguminous trees for multipurpose usage to limit deforestation. The government was encouraged to enact and implement laws regarding the conservation of fungi.

Phytogeographical and sociolinguistical patterns of the diversity, distribution and uses, of wild mushrooms in Côte d'Ivoire, West Africa

N'golo Abdoulaye Kone^{1,2} , Bakary Soro¹, Linda Patricia Louyounan Vanié-Léabo³, Souleymane Konate¹

¹Nangui Abrogoua University, Abidjan, Côte d'Ivoire; ²Comoe Research Station, Bouna, Côte d'Ivoire; ³Felix Houphouët Boigny University, Abidjan, Côte d'Ivoire (ngolo197804@yahoo.fr; s.y.bakary.1@gmail.com; lindaleabo@hotmail.fr; konatesoul.sn@univ-na.ci)

Many fungal species in tropical Africa are useful, with high added value and play essential roles in the structure and dynamic of ecosystems. However, the diversity, distribution and use by local populations of these Non-Timber Forest Products and their respective habitats are still very poorly understood in sub-Saharan Africa in general and more specifically in Côte d'Ivoire. This study aims at inventorying the wild useful mushrooms of Côte d'Ivoire within its major protected areas and their respective surrounding sociolinguistic groups according to climatic and phytogeographical gradients. Field and ethnomycological surveys were conducted. Sixty eight useful wild fungal species, belonging to 17 families and 23 genera, were listed and collected. Four categories of usage were reported by the rural people, with a dominance of food and medicinal uses. Fifty six species were reported to be used as food and 16 species as medicinal fungi. These uses varied not only from one sociolinguistical group to another but also from a visited village to another. These mushrooms were either saprotrophic or symbiotic. *Auricularia* sp3, *Psathyrella tuberculata* and *Termitomyces* spp. were found as the most commonly used mushrooms. Mushrooms are relatively well known and used by the Ivorian people within the main phytogeographic zone of the country. These people also have an interest in all the functional groups with an important phytogeographic zone-fungal specific used species. However, protected areas seem to represent the last sanctuaries of these organisms due to high rate of loss of natural habitats.

D7t: FOREST HEALTH

Ceratocystidaceae on trees in China and their potential threat to plantation tree health

FeiFei Liu^{1,2}, Irene Barnes¹, Michael J. Wingfield¹, ShuaiFei Chen²

¹Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²China Eucalypt Research Centre (CERC), Chinese Academy of Forestry (CAF), ZhanJiang, China (feifei.liu@fabi.up.ac.za; irene.barnes@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za; shuaifei.chen@gmail.com)

Species in the genus *Ceratocystis* occurs on a wide range of hosts and a global distribution, and they include important tree pathogens. However, little is known regarding the species, their diversity, origin or impact of these fungi in China. Recently, large numbers of *Ceratocystis* isolates and those in the closely related genus *Huntia* (Ceratocystidaceae) have been collected from different hosts in five provinces of China. In this study, we identified these species and considered their relative pathogenicity. More than 500 *Ceratocystis* and *Huntia* isolates were obtained from different tree hosts, including freshly cut stumps and wounds of *Acacia* species, *Cunninghamia lanceolata* and Eucalyptus species, as well as from some rotten corms of *Colocasia esculenta* (taro). Morphological and DNA sequence comparisons revealed three novel species of *Ceratocystis*, including *C. cercfabiensis* from Eucalyptus species, *C. collisensis* from *Cu. lanceolata* and *C. changhui* from *Co. esculenta*, as well as nine novel species of *Huntia*, including *H. confusa* from *Acacia* species, *H. ani*, *H. bellula*, *H. eucalypti*, *H. fabiensis*, *H. fecunda*, *H. glaber*, *H. inaequabilis* and *H. meiensis* from Eucalyptus. Pathogenicity tests showed that *C. cercfabiensis* is pathogenic to Eucalyptus, *C. changhui* can cause black rot on taro corms, and nine *Huntia* species produce lesions on Eucalyptus seedlings although they are not considered aggressive pathogens. The results of the study substantially advances our understanding of the host range and distribution of these important genera in China.

Identifying and mapping termites of the genus *Nasutitermes* Dudley (Termitidae: Nasutitermitinae) in an urban forest fragment in Manaus, Brazil / Mapeamento e identificação de cupins do gênero *Nasutitermes* Dudley (Termitidae: Nasutitermitinae) em árvores de um fragmento florestal urbano em Manaus

Luiz Neto¹, Norma Bustamante¹, Rayssal Vasconcelos¹, Diulio de Souza¹

¹Universidade Federal do Amazonas, Manaus, Brasil (luizmouraneto@yahoo.com.br; ncbustamante@gmail.com; rayssagomes85@gmail.com; diulio51@gmail.com)

Espécies de *Nasutitermes* estão entre as mais abundantes que podem se alimentar de madeiras, devido a existência de bactérias capazes de promover a hidrólise de celulose e xilema no intestino. No entanto, o desequilíbrio ambiental, contribui para que estas demostrem características de nocividade. Por meio do presente estudo, objetivou-se mapear espécies de cupins deste gênero, a fim de obter informações de distribuição e possível preferência por espécies arbóreas específicas. Foram selecionadas 3 áreas no Campus-UFAM: Faculdade de Educação Física e Fisioterapia (T1), Prefeitura (T2) e Bloco U (T3). Árvores com cupinzeiros encontradas nestas áreas, foram identificadas e georreferenciadas. Amostras de cupins foram acondicionadas em frascos contendo álcool 70%, para posterior identificação mediante comparação com chaves ilustradas, nos Laboratórios de Preservação da Madeira (UFAM) e de Entomologia (INPA). No T1 foram identificadas 4 árvores com cupins arborícolas: castanha-do-brasil (*Bertholletia excelsa*), mangueira (*Mangifera indica*), buxixu (*Licania poeppigii*) e buxixu-anil (*Miconia regelii*). No T2, 2 mangueiras (*M. indica*) e um tachi-branco (*Tachigali vulgaris*) e no T3, 4 mangueiras. Quanto às espécies de cupim, a mais frequente foi *Nasutitermes surinamenses*, sendo encontrada em todas as árvores no T2 e T3. No T1, a mesma espécie ocorreu na castanha-do-brasil e no buxixu, enquanto que na mangueira e no buxixu-anil, foram encontradas *Nasutitermes corniger* e *Cornitermes acignathus*, respectivamente. As mangueiras demonstraram maior susceptibilidade ao ataque de cupins, sugerindo que o formato do tronco e dos ramos, as tornam mais atrativas aos cupins por oferecer maior quantidade de alimento e condições para que os ninhos sejam instalados.

Comparison of genomes in closely related *Ceratocystis* pathogens of trees

Brenda Wingfield¹ , Irene Barnes¹ , Conrad Trollip¹ , Magriet van der Nest¹ , Aquillah Kanzi¹ , Michael J. Wingfield¹ 

¹University of Pretoria, Pretoria, South Africa (brenda.wingfield@fabi.up.ac.za; irene.barnes@fabi.up.ac.za; conrad.trollip@fabi.up.ac.za; magriet.vandernest@fabi.up.ac.za; aquillah.kanzi@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za)

The taxonomic history of *Ceratocystis* (Ceratocystidaceae), a genus that includes important pathogens of trees is complex and remains a topic of active debate. This is largely because many of the commonly used species recognition concepts (morphological, biological) are inconclusive or violated in this genus. Species delineation in *Ceratocystis* has relied predominantly on genealogical concordance phylogenetic species recognition (GCPSR) using multiple markers, including the Internal Transcribed Spacer (ITS) region, β -tubulin and translation elongation factor 1- α . Recent research has, however, provided evidence of intragenomic variation in the ITS region and genealogical discordance in the placement of isolates belonging to what has been referred to as the Latin-American clade (LAC).

This phylogenetic incongruence is not limited to the LAC and increasing numbers of new *Ceratocystis* species are revealing similar problems. In this study, we examined the level of phylogenetic incongruence in *Ceratocystis* using a phylogenomics approach, and explored the potential role of hybridization as the source of the incongruent signal. The results once again showed that incongruence is common in *Ceratocystis*, particularly for species of the LAC, which was typified by three equally represented topologies. The role of hybridization as the possible source of discordance requires further research. This is because, the results of this study could also be explained by high levels of shared ancestral polymorphism in this recently diverged lineage. This study is the first to apply a phylogenomics approach to resolve species boundary questions in *Ceratocystis* and the results will contribute to our understanding of important pathogens which cause tree diseases.

QTLs and the genes linked to growth rate differences in *Fusarium circinatum*, the pine pitch canker pathogen

Brenda Wingfield¹ , Lieschen de Vos¹ , Stephanie van Wyk¹ , Benedicta Swalarsk-Parry¹, Michael J. Wingfield¹ , Emma Steenkamp¹ 
¹University of Pretoria, Pretoria, South Africa (brenda.wingfield@fabi.up.ac.za; lieschen.devos@fabi.up.ac.za; stephanie.vanwyk@fabi.up.ac.za; benny.swalarsk@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za; emma.steenkamp@fabi.up.ac.za)

More than a 100 genome sequences are now available for *Fusarium* and in some cases numerous isolates of a single species have been sequenced. Understanding the functions of the proteins coded by the genes in the genome sequences, especially in non-model species, is becoming an increasingly important aspect of disease management and this will clearly be more so in the future. Using a combination of whole genome sequences and a genetic linkage map for a hybrid cross between the pine pitch canker pathogen *Fusarium circinatum* and *F. temperatum*, we have identified some key genes involved in growth rate differences in these two species. Genome sequence data were used to map two Quantitative Trait Loci (QTLs) for growth in culture. One QTL allowed for the identification of a five gene indel specific to *F. circinatum*. The second QTL involves an indel of two genes only in some *F. circinatum* isolates. Further investigations of these QTLs will enable a better understanding of fungal growth in *F. circinatum* and potentially, also regarding the basis of pathogenicity in *F. circinatum* and *F. temperatum*.

Ophelimus eucalypti (Gahan) (Hymenoptera: Eulophidae) insect associated with gall on the *Eucalyptus* sp. (Myrtaceae) plantation in North Sumatra, Indonesia

Mutiara Harapan¹, Omar Syaref², Alvaro Jorge Duran Sandoval³, Adventris Lestarina Hutagaol¹, Marthin Tarigan³, Wagner Souza Tavares³, Jupiter Muro Abad¹
¹Toba Pulp Lestari, Kerenci, Indonesia; ²Toba Pulp Lestari, Porsea, Indonesia; ³April Asia, Kerinci, Indonesia (irfan_pasaribu@tobapulp.com; omar_syaref@tobapulp.com; alvaro_duran@aprilasia.com; adventris_hutagaol@tobapulp.com; marthin_tarigan@aprilasia.com; wagner_tavares@aprilasia.com; jupiter_abad@tobapulp.com)

Many species of *Eucalyptus* is attacked for different pest. The gall wasp is one of those that can be very aggressive and with big damage for plantations. The *Ophelimus eucalypti* is one wasp that attack *Eucalyptus* and produce a gall as reaction of plant tissue. Biology is actually known for a relatively small number of species as reported in *Eucalyptus botryoides* Sm. and *E. saligna* Sm. in New Zealand since 1924. The damage of this insect in commercial plantation can be direct in the susceptible plants, due the high infestation. For the other side, for those clones resistant, can occur a reaction in the plants and abnormal stress that affect growth a new shoots emission. In this research, we found the gall from eucalypts hybrid, which has *E. urophylla* with other species *E. grandis* and *E. pellita*. The preferences for oviposition and gall development were determined on young leaves and various age growing on eucalypts plant. Mostly the female oviposited randomly in the margin of leaf. Totally, *O. eucalypti* takes around 35- 40 days for fix the stage from egg until adult. After ovoposition, around 3 to 5 day the wasp emerge as larvae. Some insects are associated with gall, it's emerged from gall which collected from some locations, like *Pteromalidae*, *Torymidae*, *Eulophidae* and *Eurytomidae*. These insects identified by morphological characters and some are reported in literature as a parasitoid of gall wasp. The knowledge of this life cycle important to direct the different studies and screening of resistant *Eucalyptus*.

Dry weight and fat content of spruce bark beetles *Ips typographus*, L., (Coleoptera) during different stages of dispersal

Frank Bohlander¹
¹University of Applied Sciences, Erfurt, Germany (frank.bohlander@fh-erfurt.de)

Dry weight and fat content in male and female spruce bark beetles (1) freshly emerged from a lap rearing, caught inside forest with (2) pheromone slot traps, (3) avoiding pheromone traps and caught with accompanying passive flight traps (4) landing on trap trees, and (5) walking on trap trees for an unknown time, were analysed. Male and female beetles from (1) the lap rearing had a dry weight of 5,2 mg (+/- 0,23) and 4,8mg +/- 0,24). Males and females from (2) pheromone slot traps 4,5 mg (+/-0,8) and 4,2 (+/-0,8), respectively. In case of (3) passive flight traps, males weight 4,7 mg (+/-0,6) and females 4,1 mg (+/-0,8). Males landing on trap trees 4,7 mg (+/- 0,9) females 4,5 mg (+/-0,9) and (5) 4,2 mg (+/- 0,8) and 4,6 mg (+/- 0,6), respectively. The content of lipids in the bark beetles was measured in acyl ester equivalents (nmol/mg dry weight) The males and females of the five groups (1-5) showed noteworthy differences. (1) 976/886 nmol/mg; (2) 369/365; (3) 624/539; (4) 452/445; (5) 460/361. Moreover, the amount of acyl ester equivalents within the 4 groups from the forest showed high variances. Due to the different energetic status beetles could be differentiated. Beetles caught with pheromone traps seemed to be strongly exhausted, whereas beetles caught by passive traps had the highest average reserves. In accordance with other findings *Ips typographus* seems to be more susceptible to pheromone signals when his energetic reserves decrease.

Genetic analyses reveal signatures of host specialization and recent host shifts in the *Ceratocystis manginecans* complex

FeiFei Liu^{1,2}, Tuan A. Duong¹, Irene Barnes¹, Michael J. Wingfield¹, ShuaiFei Chen²
¹Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²China Eucalypt Research Centre (CERC), Chinese Academy of Forestry (CAF), ZhanJiang, China (feifei.liu@fabi.up.ac.za; tuan.duong@fabi.up.ac.za; irene.barnes@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za; shuaifei.chen@gmail.com)

Large-scale population structure analyses of pathogens can shed light on their diversity, migration patterns and evolutionary history. This could be particularly important for fungal pathogens such as *Ceratocystis manginecans* and *C. eucalypticola* (*C. manginecans* complex), that are known to occur on different continents and are able to spread to new regions and plant hosts relatively easily. In this study, ten microsatellite markers were used to determine the genotypes of 500 isolates residing in the *C. manginecans* complex from *Acacia* spp., *Eucalyptus* spp., *Mangifera indica* and *Punica granatum* across a wide geographic range in nine countries. Principal coordinate analysis, Bayesian clustering analysis and Bruvo's distance analysis revealed two major genetic clusters among the isolates considered. One of these clusters consisted of isolates associated with *Eucalyptus* and *Punica* and the other cluster was made up of isolates associated with

Acacia and *Mangifera* hosts. We used approximate Bayesian computation (ABC) to compare different competing scenarios describing ancestral relationships among the four host-associated populations. The results suggested that the *Eucalyptus*-associated population is the most likely source of established populations on other hosts. The results also highlighted the fact that the *Mangifera*-infecting population probably originated via a recent host jump from populations on *Acacia*, and that the *Punica*-infecting population could have originated from populations on *Eucalyptus*.

D8c: THE ROLE OF TREE RELATED MICROHABITATS IN FOREST ECOSYSTEMS

Tree-related microhabitat spatial patterns in European beech-dominated forests

Laurent Larrieu^{1,2}, Benoît Courbaud³, Michel Goulard¹, Wilfried Heinz¹, Daniel Kraus⁴, Thibault Lachat⁵, Sylvie Ladet¹, Fabien Laroche⁶, Jörg Müller^{7,8}, Yoan Paillet⁶, Andreas Schuck⁹, Jonas Stillhard¹⁰, Miroslav Svoboda¹¹

A Tree related Microhabitat (TreM) is a distinct, well-delineated morphological singularity occurring on living or standing dead trees. It constitutes a crucial substrate or life site for species. TreMs are widely recognized as key features for biodiversity. Since TreMs are not to be found on every tree, their spatial distribution within a forest may affect TreM associated communities related to dispersal capacities of some taxa. However, these spatial patterns are not well known, either in old-growth or in managed forests. We assessed the spatial distribution of eleven TreM groups in European beech-dominated forests both in forests that have not been harvested for at least 100 years and in forests still ongoing management today. We made the assumptions that (i) we can detect spatial patterns in unmanaged forests, (ii) tree-dbh (diameter at breast height) spatial distribution is the main driver of TreM spatial distribution and (iii) management affects these patterns. We did not highlight any consistent spatial pattern, neither in managed nor in old-growth forests. The effect of dbh on TreM occurrence depended on both TreM and forest status. Plot features matters for explaining the occurrence of most of the TreMs. Considering the 10,000 ha natural forest of Uholka (Ukraine) as a case study, we highlighted a significant spatial aggregation for crown deadwood within the whole forest, but we did not find aggregation for the other TreMs.

Modelling the occurrence of tree-related microhabitats in managed uneven-aged forest stands over time

A Tree related Microhabitat (TreM) is a distinct, well-delineated morphological singularity occurring on living or standing dead trees, that constitutes a particular and crucial substrate or life site for species. TreMs are essential to support forest biodiversity. The retention of some trees bearing TreMs is increasingly prescribed in sustainable forest management guidelines. However, this may not be sufficient to ensure an appropriate density and diversity of TreMs to support TreM-dwelling taxa over time. Indeed, trees that are harvested often either display TreMs or have the potential to develop them over time (future habitat trees). Moreover, little is known about the dynamic process of TreM's formation at the tree level. Most of the TreM data currently available are cross-sectional data (trees are observed only once) making it more difficult to estimate TreM formation rates. In this presentation we show how to estimate the probability of a new TreM being formed during tree growth by adapting statistical survival analysis approaches. Using a harmonized European TreM database, we analyze variations in the probability of formation of a new TreM on a tree of a given DBH for 11 different groups of TreMs and different groups of tree species. Then, using Samsara, a spatially-explicit individual-based forest stand model, we show how thinning regimes influence the TreM profile of uneven-aged mixed stands of spruce, fir and beech over time.

Structural complexity in managed and unmanaged mountain forests after management cessation: effects on the habitat suitability for indicator bird species

Veronika Braunisch^{1,2}, Stefanie Roder², Joy Coppes¹, Kurt Bollmann³

¹Forest Research Institute of Baden-Wuerttemberg, Freiburg, Germany; ²University of Bern, Bern, Switzerland; ³Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, Switzerland (veronika.braunisch@jee.unibe.ch; steroder@hotmail.com; joy.coppes@forst.bwl.de; kurt.bollmann@wsl.ch)

Increasing the proportion of unmanaged forests in multi-functional forest landscapes is a primary goal of national and international conservation strategies. However, the development of structural features and associated habitat suitability for forest species after management cessation is unknown. We evaluated these effects on key habitat characteristics of four mountain forest bird species indicative of different structural components: Capercaillie (*Tetrao urogallus*), Hazel grouse (*Bonasa bonasia*), Three-toed woodpecker (*Picoides tridactylus*) and Pygmy owl (*Glaucidium passerinum*) across four mountain regions in Central Europe. Habitat suitability was modelled based on 300 forest sites selected independently of their management status, and predicted to an independent dataset of 42 strictly protected forests. We compared forest reserves to managed forests with species presence or absence with regard to habitat suitability and key habitat structures and related both to the time since reserve designation. For all species, except Pygmy owl, habitat suitability in reserves was significantly higher than in managed forests with species' absence, but not different from managed forests with species presence. For the species associated with open forest structures (Capercaillie, Hazel grouse, Pygmy owl) habitat suitability decreased significantly in the first three decades after reserve designation, when the relatively young forests grew dense, and increased afterwards. No such correlation was found for the Three-toed woodpecker associated with deadwood and

barkbeetle infestations following temporally unpredictable disturbance events. Structural characteristics varied greatly in abundance and distribution, but only open structures were related to the “reserve age”. We therefore recommend focusing on mature, near-natural and structurally diverse forests when designating new reserves.

Effects of clumped versus dispersed retention of potential habitat trees

Thomas Asbeck¹, Jürgen Bauhus¹, Christian Messier²

¹University of Freiburg, Freiburg, Germany; ²University of Quebec, Quebec, Canada (thomas.asbeck@waldbau.uni-freiburg.de; juergen.bauhus@waldbau.uni-freiburg.de; ch.messier@gmail.com)

The question whether it is more advantageous for biodiversity conservation to retain live habitat trees in clumped or dispersed distribution has occupied forest ecologists and managers alike. To identify the most valuable live retention trees, a common approach is to quantify tree-related microhabitats (TreMs). In this paper, we asked whether a) abundance and richness of TreMs differs between live potential habitat trees in either clumped or dispersed distribution, and b) whether the abundance of fifteen groups of TreMs is related to the type of distribution of potential habitat trees (clumped or dispersed). The fifteen groups of TreMs are based on varying creation processes and include for instance woodpecker cavities, rot holes or crown deadwood. For few TreMs such as rot holes, twig tangles, nests and burrs and cankers weak relationships to different degrees of clumping were identified. Overall abundance, richness and the abundance of TreMs in four groups increase with slope, altitude and DBH. These results show that it is more important to select the right retention trees in the appropriate numbers rather than focusing on grouping them within 1 ha stands.

Water and the conservation of wide-ranging Forest Red-tailed Black-Cockatoos in a drying climate

Michael Craig^{1,2}, Tony Kirkby³, Vicki Stokes⁴, Michael Renton¹, Ron Johnstone³, Geoff Barrett⁵, Richard Hobbs¹

¹University of Western Australia, Nedlands, Australia; ²Murdoch University, Murdoch, Australia; ³Western Australian Museum, Welshpool, Australia; ⁴Birdlife Australia, Floreat, Australia; ⁵Department of Biodiversity, Conservation and Attractions, Crawley, Australia (michael.craig@uwa.edu.au; akirkby@ytown.com.au; vicki.stokes@birdlife.org.au; michael.renton@uwa.edu.au; ron.johnstone@museum.wa.gov.au; geoff.barrett@dbca.wa.gov.au; richard.hobbs@uwa.edu.au)

Spatio-temporal reductions in water availability, due to climate change, are likely to have significant effects on forest fauna, particularly for species that need to drink regularly. We investigated how water availability influenced forest fauna by examining the nesting ecology of the threatened Forest Red-tailed Black-Cockatoo (*Calyptorhynchus banksii naso*) in the northern jarrah forest of southwestern Australia, a region that has experienced a 25% decline in rainfall in recent decades. We located 156 cockatoo nests across three jarrah forest landscapes and related their spatial location to variables at the hollow, tree, site and landscape scales and compared them to similar hollow-bearing trees containing no nests. At the landscape scale, we found nests were no closer to granite outcrops, roads or watercourses than unused trees but were significantly closer to both ephemeral and permanent drink sites, suggesting cockatoos locate nests to increase access to water during their nesting cycle. These results suggest numbers of suitable nesting hollows may decline in the future as reduced water availability renders potentially suitable hollows unsuitable. We conducted additional work investigating the potential of water as a management tool to offset reductions in water availability by placing artificial water points at various sites in the northern jarrah forest. We found that artificial water points are utilised by cockatoos, which suggests providing water appears to be an effective management tool to offset reductions in water availability. It should be considered more widely as a forest management tool to better conserve forest fauna under a drying climate.

Does forest biodiversity respond to pulses of saproxylic microhabitats induced by tree dieback: a case study in mountain French silver fir forests

Christophe Bouget¹, Laurent Larrieu², Laurent Burnel², Lopez-Vaamonde Carlos³, Moliard Carl¹, Jerome Molina², Guillem Parmain¹, Grégory Sajdak⁴, Lucas Sire⁵, Jerome Willm²

¹Irstea, Nogent-sur-Vernisson, France; ²INRA, Toulouse, France; ³INRA, Orleans, France; ⁴CRPF, Toulouse, France; ⁵IRBI, Tours, France (christophe.bouget@irstea.fr; laurent.larrieu@inra.fr; laurent.burnel@inra.fr; carlos.lopezvaamonde@inra.fr; carl.moliard@irstea.fr; jerome.molina@inra.fr; guilhem.parmain@irstea.fr; gregory.sajdak@crpf.fr; lucas.sire.17@gmail.com; jerome.willm@inra.fr)

Forest diebacks are likely to increase in response to climate change, with increased frequency and intensity of droughts. In line with climate change scenarios, ecoclimatic modelling predicts a decrease in the range of silver fir, a drought-sensitive species, in its southern limit in the French Pyrenees. Diebacks are expected to induce a pulse of resources potentially favorable to certain forest species, e.g. tree-related microhabitats (TreM) for saproxylic species. The impact of forest dieback on biodiversity has nonetheless been poorly studied. As part of the international Clintree project, we set up a balanced sampling design of 56 plots crossing the intensity of local silver fir dieback and the salvage logging of weakened or dead trees. Detailed stand structure metrics and insect communities sampled by Malaise traps (insect MOTUs) or flight-interception traps (saproxylic beetles) have been measured. The structure of fir stands was affected by the level of decline, and to a lesser extent by salvage logging. We indeed observed a slight increase in CWD and in some TreM-bearing trees (crown deadwood, annual polypores, trunk rot holes) with dieback intensity, and a slight decrease in some TreM-bearing trees (crown deadwood, annual polypores) in salvaged compared with unharvested plots. However, these stand changes did not strongly affect local insect assemblages. Guilds of TreM-associated insects did not increase in abundance or richness with dieback-induced increase in resources. In conclusion, forest changes through dieback result in habitat and resource changes with still hard-to-predict impacts at the stand scale on a major reservoir of biodiversity.

Water-filled tree holes as model system to study management effects on insect communities and related functions in temperate forests

Martin Gossner¹, Mykola Jaremchuk², Vasyl Chumak², Thibault Lachat¹, Jana Petermann³

¹Swiss Federal Research Institute WSL, Birmensdorf, Switzerland; ²Uzhgorod National University, Uzhgorod, Ukraine; ³University of Salzburg, Salzburg, Austria (martin.gossner@wsl.ch; kolya.yaremchuk.1995@mail.ru; chumak.vasyl@yahoo.com; thibault.lachat@bfs.ch; jana.petermann@sbg.ac.at)

Forest ecosystems are strongly affected by management. Predicting the consequences of management for biodiversity and ecosystem functions is, however, challenging due to the complexity of these ecosystems. Here, we used water-filled tree holes, which are abundant tree microhabitats in temperate forest ecosystems, as model system to study the effects of forest management on entire insect communities and the functions they provide. The food-webs in these aquatic microcosms comprise many trophic levels of specialized larval insect species, which are simple enough to allow studying the whole system, but sufficiently complex to derive results that can be transferred to larger ecosystems. We found that management strongly affected insect communities in these microcosms by altering resource and habitat availability at different spatial scales as well as habitat diversity. Moreover our results suggest that functions, i.e. decomposition, measured by artificial tree holes, and predation by terrestrial predators, measured by fake larvae, might also be altered by forest management. We conclude that aquatic micro-ecosystems are both, interesting and important habitats in themselves and useful model systems for studying effects of forest management on entire communities.

Substrate specific restoration promotes saproxylic beetle diversity in boreal forest set-aside

Joakim Hjältén¹, Ruaridh Hägglund¹

¹Department of Wildlife, Fish and Environmental Studies, Swedish University of Agricultural Sciences, Umeå, Sweden (joakim.hjalten@slu.se; ruaridh.hagglund@sweco.se)

In many parts of the boreal biome intensive forest management has resulted in profound changes in forest structure, tree species composition and dead wood availability, and by so negatively affecting forest biodiversity. Restoration of degraded forest habitats is therefore of high priority. Consequently, it is of utmost importance to develop cost-efficient restoration methods. We have therefore initiated ecological restoration experiment aimed at increasing the variety and volume of dead wood in voluntary set-asides (FSC certification requirements) by mimicking the two natural disturbances, forest fire and small scale gap dynamics. We studied how tree species and substrate type, i.e. the way in which a tree was killed (cut, girdled, tipped over or cut to produce a high stump), affect species composition, abundance and species richness of saproxylic beetles. We found that species composition differed between tree species in burned as well as gap-cut stands, and that tree posture, i.e. standing or downed trees, also affected species composition in gap-cut stands. In addition, abundance and species richness differed between tree species in gap-cut stands, generally being higher in spruce than in pine and birch. Based on our results we recommend a wider practice of dead wood creation involving a multitude of tree species and tree postures, through mimicking natural disturbances in the management of boreal forests. Furthermore, we suggest that voluntary set-asides provide an excellent opportunity for restoration as they are already available and restoration cost can therefore be kept at a minimum or totally avoided as in this study.

How to deal with tree microhabitats in daily forest management? Different tools to implement conservation aspects related to microhabitats into forestry

Frank Krumm¹, Rita Büttler², Laurent Larrieu³, Thibault Lachat⁴

¹Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, Switzerland; ²Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Lausanne, Switzerland; ³INRA, Toulouse, France; ⁴Bern University of applied sciences, Zollikofen, Switzerland (frank.krumm@wsl.ch; rita.buetler@epfl.ch; laurent.larrieu@inra.fr; thibault.lachat@bfs.ch)

The need to address biodiversity protection measures into forest management is widely accepted among foresters and society as the loss of species and habitat structures is still ongoing on a big scale. Management practices and education have been focusing for a long time on timber production. Consequently, knowledge and awareness about processes related to tree microhabitats are not sufficiently present. Various initiatives across Europe are aiming to enhance information for a broad variety of target groups including forest practitioners, decision makers and scientists from different sectors, students as well as other potentially interested/relevant communities and other stakeholders. Martelloscopes, delineated, rectangular plots in forests where all trees are numbered, mapped and recorded, have been further developed as a training tools for virtual tree selections with a focus on biodiversity conservation. All recorded trees are economically and ecologically assessed and have a price tag and an ecological value. This so called ecovalue is evaluated based on a tree microhabitat catalogue based on a widely accepted typology. Different projects have taken this further and software tools are released or under development. Publications, especially tailored for practitioners are distributed among foresters and increase the awareness for tree microhabitats and biodiversity relevant structures. The presented tools aim for supporting improved decision making capabilities addressing the integration of biodiversity aspects into forest management. Practical implementation can be altered by many factors and the introduced tools cover mostly the lowest level of implementation, the selection of trees during thinning (including habitat trees)

Predictors of Microhabitat Frequency and Diversity in Mixed Mountain Forests in South-Western Germany

Grossmann Josef^{1,2}, Juliane Schultze¹, Jürgen Bauhus², Patrick Pyttel²

¹Forest Research Institute Baden-Wuerttemberg, Freiburg, Germany; ²Albert-Ludwigs-Universität, Freiburg, Germany (josef.grossmann@waldbau.uni-freiburg.de; juliane.schultze@forst.bwl.de; juergen.bauhus@waldbau.uni-freiburg.de; patrick.pyttel@waldbau.uni-freiburg.de)

Tree-related microhabitats are an important determinant of forest biodiversity. Habitat trees, which typically provide many microhabitats such as hollows, crown dead wood, etc., are therefore selected to maintain those structural attributes within managed forests. To what extent the occurrence of microhabitats on potential habitat trees may be predicted from common tree attributes is a question of high practical relevance. Until now, most studies have attempted to predict the quantity of microhabitats at the tree or forest stand level. In our study, we aimed at explaining microhabitat occurrence from a qualitative perspective by considering their diversity. Tree diameter at breast height (dbh), tree species, and canopy class were useful predictors of microhabitat diversity. Microhabitat diversity on broadleaved trees was on average higher than in conifers of the same diameter. In contrast to microhabitat quantity, microhabitat diversity saturated towards higher dbh levels. Microhabitat diversity in beech trees of lower tree canopy classes was found to be surprisingly high. Habitat trees support not only more, but also more diverse, microhabitats in comparison to crop trees. Considering these findings on microhabitat distribution, the selection of habitat trees within Central European mixed mountain forests can be significantly improved.

FRA 2020 Remote Sensing Survey - participatory approach for generation of global and regional forest area statistics

Anssi Pekkarinen¹, Adolfo Kindgard¹, Valeria Contessa¹, Lars Gunnar Marklund²

¹Food and Agriculture Organization of the United Nations, Rome, Italy; ²Swedish University of Agricultural Sciences, Umeå, Sweden
(anssi.pekkarinen@fao.org; adolfo.kindgard@fao.org; valeria.contessa@fao.org; marklundlg@gmail.com)

FAO has been monitoring the world's forests at 5 to 10 year intervals since 1946. The Global Forest Resources Assessments (FRA) are now produced every five years to provide a comprehensive analysis on world's forests and their changes. These assessments are based on Country Reports prepared by officially nominated National Correspondents. Since 1990, FRA has complemented the information collected through the country reporting process with global and regional analyses of the world's forest resources using remote sensing. With better access to a growing archives of satellite imagery, and increasing availability of new tools that facilitate image processing and interpretation, remote sensing can now allow more efficient assessments of status and changes in tree cover and land use than ever before. First FRA remote sensing assessments were done in a centralized manner. Later, in FRA 2010, a more participatory model was introduced and the national experts were invited to validate the pre-classified results. The FRA 2020 Remote Sensing Survey takes this participatory process to the next level. A global sample of roughly 430,000 sampling units, allocated using a stratified sampling scheme based on tree cover change and Global Ecological Zones, will be visually interpreted by the national experts through a series of interpretation workshops, using an innovative tool developed by FAO and NASA with the support of USAID and Google. This paper will present the methodology, approach and current status of the FRA 2020 Remote Sensing Survey as well as share some of its implementation experiences and preliminary findings.

Overview of the assessment framework: the GuidosToolbox Workbench (GWB)

Peter Vogt¹

¹European Commission, Ispra, Italy (peter.vogt@ec.europa.eu)

The GuidosToolbox Workbench (GWB) is a collection of popular image analysis routines packaged as command-line tools for Linux server applications. The ten routines provide feature mapping and quantitative summary assessments of digital land cover data for a variety of topics, locating and measuring morphological pattern, fragmentation, accounting, distance, contagion and landscape mosaic. The conceptual ideas are summarized, followed by a sample application showing a continental assessment of forest fragmentation selected by Forest Europe as a key indicator to assess the state of forests and measuring the progress toward sustainable forest management at regional and national level. Forest Europe aims at a close collaboration with FAO's Global Forest Resource Assessment, through harmonizing data collection and assessment tools to accurately reflect temporal evolutions and evaluate achievements towards the 2020 targets of sustainable forest management of European forests.

Interpreting fragmentation, morphological pattern, and landscape mosaic in national and global forest assessments

Kurt Riitters¹

¹USDA Forest Service, Research Triangle Park, USA (kriitters@fs.fed.us)

High-resolution maps of forest and land cover support harmonized, detailed mapping and assessment of landscape patterns at global scale. The conceptual models and implementations of three aspects of pattern are summarized, followed by illustrations and interpretations of results produced by the popular Guidos Toolbox and Workbench software in national and global assessments. The USA country report for the Montréal Process interprets fragmentation using the multi-scale FAD (forest area density) analysis, while the USA RPA (Resources Planning Act) national assessment additionally considers MSPA (morphological pattern) and LM (landscape mosaic). Global results are illustrated for fragmentation using 30-m forest maps, and for landscape mosaic using 300-m global land cover maps.

Integrating maps of forest fragmentation and landscape mosaics with national forest inventory plot data

Jennifer Costanza¹, Kurt Riitters², Peter Vogt³

¹North Carolina State University, Research Triangle Park, NC, USA; ²USDA Forest Service, Research Triangle Park, NC, USA; ³European Commission Joint Research Centre, Ispra, Italy (jkcostan@ncsu.edu; kriitters@usda.gov; peter.vogt@ec.europa.eu)

Changing land use and fragmentation of forest ecosystems threaten the ability of forests to provide ecosystem services. Tools and software such as GuidosToolbox Workbench (GWB) provide metrics with which to examine patterns of land-use and forest fragmentation. However, assessment of the impacts of those patterns on forests depends on the integration of those tools with *in-situ* data. We demonstrate how metrics and maps from GWB can be used in conjunction with forest inventory data. We used data from over 100,000 forest plots in the USDA Forest Service's Forest Inventory and Analysis (FIA) database to examine the landscape context of forest ecosystems across the conterminous U.S. For spatial neighborhoods surrounding each FIA plot, we extracted information from maps of forest fragmentation and landscape mosaics from GWB. We examined the degree to which those GWB metrics varied by forest type and ownership. We found that forest types in the eastern U.S. and those owned by families, rather than industry or government, were more likely to exist within fragmented landscapes, suggesting both threats and opportunities for those forests and their associated ecosystem services. Our results demonstrate that integrating *in-situ* inventory data with maps of spatial patterns can lead to critical information regarding the effects of landscape spatial patterns on forest ecosystems and the services they provide. It is our hope that this national case study will prompt similar assessments in other countries where forest inventory or other plot data exist, thus expanding the integration of *in-situ* data with maps of spatial patterns.

Prioritization analysis of riparian forest corridors in the Brazilian National Forest Inventory

Maria Augusta Doetzer Rosot¹, Jéssica Caroline Maran², Marilice Cordeiro Garrastazú¹, Yeda Maria Malheiros de Oliveira¹, Luziane Franciscon¹, Nicola Clerici³, Peter Vogt⁴, Naissa Batista da Luz⁵, Joberto Veloso de Freitas⁶

¹Embrapa Florestas, Colombo, Brasil; ²FAO, Curitiba, Brasil; ³Universidad del Rosario, Bogotá, Colombia; ⁴Joint Research Centre, Ispra, Italy; ⁵Universidade Federal de Uberlândia, Uberlândia, Brasil; ⁶Serviço Florestal Brasileiro, Brasília, Brasil (augusta.rosot@embrapa.br; jess.maran@gmail.com; marilice.garrastazu@embrapa.br; yeda.oliveira@embrapa.br; luziane.francison@embrapa.br; nicola.clerici@urosario.edu.co; peter.vogt@ec.europa.eu; naissa@gmail.com; joberto.freitas@florestal.gov.br)

The landscape component in the Brazilian National Forest Inventory (NFI-BR) evaluates habitat quality and spatial structure in national Landscape Sample Units (LSUs), established in a grid of 40 x 40 km. The analysis includes indices for riparian environments as a measure of their structural connectivity as forest corridors, the degree of human pressure acting on them and the extension of protected areas within those zones. LULC maps of twenty LSUs in Southern Brazil were used as pilot samples to conduct a Morphological Spatial Pattern Analysis (MSPA) and derive the following indices: Structural Corridors Index (SCc), showing the proportion of *core* and *bridge* MSPA categories within the riparian zone; the Structural Corridors under Pressure Index (CPC), to identify areas where structural corridors are subject to anthropogenic influences; and the Structural Corridors under Pressure Protection Index (UCPC), identifying corridor areas under anthropogenic pressure but with little or no legal protection. These indices were converted into ranking scores to prioritize riparian areas for conservation and landscape restoration. Three of the 20 pilot LSUs exhibited standardized values of UCPC, close to 1, thus indicating a critical conservation status for these areas.

Forest disturbances in the Brazilian Amazon: large-scale monitoring based on cloud-computed remote sensing analysis

René Beuchle¹, Yosio Edemir Shimabukuro², Andreas Johannes Langner¹, Peter Vogt¹, Silvia Carboni³, Klara Janouskova⁴, Thais Almeida Lima⁵, Frédéric Achard¹

¹European Commission, Joint Research Centre (JRC), Ispra, Italy; ²Brazilian National Institute for Space Research (INPE), São José dos Campos (SP), Brazil; ³GFT ITALIA Srl., Milan, Italy; ⁴ARHS Developments S.A., Luxembourg, Luxembourg; ⁵University of British Columbia, Forest Sciences Centre, Vancouver, Canada (rene.beuchle@ec.europa.eu; yosio.shimabukuro@inpe.br; andreas-johannes.langner@ec.europa.eu; peter.vogt@ec.europa.eu; silvia.carboni@ext.ec.europa.eu; klara.janouskova@ext.ec.europa.eu; tha.almeida.lima@gmail.com; frederic.achard@ec.europa.eu)

The disturbances of forest cover by processes like selective logging and forest fires are very common in tropical forest. These disturbances heavily affect forest functionalities, lead to a decrease of forest biomass and contribute to greenhouse gas emissions. However, the quantification of the disturbance extend remains a challenging task because disturbed forest areas do not consist in a long-term conversion to another land use, but often undergo fast regrowth and thus are easily detectable only for a limited amount of time. We have applied a novel approach based on the Δ rNBR index, which maps the loss of forest canopy on a yearly basis by a multi-image analysis with cloud computing on Google Earth Engine. We have analysed 12 years of forest disturbances (2000-2011) over large area of interest (ca; 414,000 km²), defined by the intersection of the Mato Grosso State border and the Brazilian Amazon biome. We assessed the logging and fire intensity by applying a grid of 300 m × 300 m spatial resolution over the mapped disturbance pixels. In 2016, more than 220,000 km² (53,3%) were covered by forest within the area of interest, thereof more than 38,000 km² (17,3%) were disturbed by selective logging within the 12 years analysed, ranging from 1,819 km² (2009) to 6,984 km² (2005). The burned forest added up to 18,711 km² (8,4%) during this period, the smallest forest area burned in 2001 (68 km²) the largest area in 2007 (10,258 km²).

Five decades of boreal forest disturbance in Ontario, Canada

Tarmo Remmel¹, Marc Ouellette²

¹York University, Toronto, Canada; ²Ontario Forest Research Institute, Sault Ste. Marie, Canada (remmel@yorku.ca; marc.ouellette@ontario.ca)

The boreal forest biome in Ontario encompasses approximately 76 M ha across seven eco-regions that are defined by geo-climatic variability and gradients within the province. Located within this biome is the Area of Undertaking (AOU), a zone of highly regulated and monitored extractive forest activities that delineates our area of interest. There exists great concern over the state of the forests within the AOU, with a desire to understand the disturbances affecting them, their recovery, and any resultant dynamic patterns in space and time given the integrated ecological, financial, and physical processes involved. Just the sheer area involved has enormous implications on the economy, environmental quality, carbon sequestration, and recreation; these underscore the need to consistently collect and summarize information in the context of improving management activities and decision making surrounding this resource. We have produced a consistently processed dataset, at 120 m spatial resolution (1.44 ha), of annual disturbances (harvesting and fire) for the entire AOU from 1972-2018 and developed a workflow for annually updating this database. All base data comes from Landsat imagery (MSS, TM, ETM+, OLI) and are cross-referenced with supporting documentation and datasets to produce confidence attributes for each mapped location. Our spatio-temporal dataset provides a consistent means for assessing spatial patterns, fragmentation rates, impacts of management decisions, climate change trends, and various ecological states and implications through nearly 5 decades.

Forests and trees in national adaptation plans (NAPs)

Alexandre Meybeck¹, Vincent Gitz¹, Julia Wolf¹

¹CIFOR, Bogor, Indonesia; ²FAO, Rome, Italy (a.meybeck@cgiar.org; v.gitz@cgiar.org; julia.wolf@fao.org)

The national adaptation plan (NAP) process was established under the UNFCCC in 2010. Least developed and other developing countries prepare (NAPs) that identify and address medium- and long-term adaptation needs. Some developed countries have prepared similar documents. The objective of this presentation is to give some preliminary insights on how forests and trees are considered in the NAPs. It will successively consider the way forests and trees are integrated in the process, the measures aimed at the adaptation of forests and trees and how they are used for the adaptation of other sectors. Most NAPs are organized by sectors, with forests and trees being often included in the biodiversity sector, with significant exceptions like for Chile where planted forests are part of the silvoagropastoral sector. The main risks identified for forests and trees in the NAPs are increased climate variability, increased heat and drought, increased risk of extreme events, salinity in coastal areas, forest fires, pests and invasive species. The main measures promoted are sustainable forest management, biodiversity conservation, monitoring and risk management systems, conservation and sustainable management of genetic resources and to anticipate future changes. In almost all sectors figure measures that promote forests and trees as an adaptation mean, for a great variety of purposes that can be gathered in three main groups: natural resources management, agriculture, and protection of cities; however often omitting the consequences for forestry and the necessary enabling environment. This analysis leads to some important conclusions, with consequences for both research and policy making.

Multisource and multiscale earth observation of biodiversity in Boreal Forests

Petteri Vihervaara¹, Timo Kumpula², Arto Viinikka¹, Sonja Kivinen², Topi Tanhuanpää², Anton Kuzmin², Sarita Keski-Saari², Peter Kullberg¹, Pekka Hurskainen¹, Laura Mononen², Aleksi Ritakallio², Pasi Korpelainen²

Earth observation techniques to estimate biodiversity in boreal forests are improving rapidly. The aims and selected findings presented here are to: (i) collect cutting-edge EO data at various spatial and temporal; (ii) develop and produce novel remotely sensed indicators of BD variables and variables for C-sequestration. Different variables describing biodiversity and ecosystem properties are produced using a multi-sensor approach. We will utilize 1) optical satellite images (e.g. Sentinel, Landsat), 2) airborne laser scanning and hyperspectral data, and 3) unmanned aircraft systems (UAS). Optical remote sensing covers large geographical areas at 10-30 m spatial resolution and temporal span of several decades. Laser scanning is a superb method to capture the 3D structure of forested ecosystems with sub-meter accuracy and has been used in growing numbers to study wildlife habitats and BD. Hyperspectral data (HySpex) is used to characterize tree species recognition and identification, and to collect information from spectral traits. Integrating multisource and multiscale remote sensing (RS) data and methods allows studying forest BD and C-sequestration related questions in great detail. Novel UAS methods contribute for bridging the gap in EO between field and airborne measurements and providing ultra-high spatial and temporal resolution imagery for detailed assessment of different ecosystems properties. Field data (e.g. species diversity, canopy foliar traits) has been collected from the airborne and UAS sites. Deriving spectral traits from various RS data can provide detailed valuable information for BD research. In addition, the use of lidar data allows studying traits related to forest and vegetation structure in 3D.

Essential biodiversity variables informed by earth observation technologies

¹Bangor University, Bangor, United Kingdom; ²UN Environment World Conservation Monitoring Centre (UNEP-WCMC), Cambridge, United Kingdom; ³University of Cambridge, Cambridge, United Kingdom; ⁴University of Zurich, Zurich, Switzerland; ⁵Finnish Environment Institute (SYKE), Helsinki, Finland; ⁶University of Eastern Finland, Joensuu, Finland; ⁷Università degli Studi di Firenze, Florence, Italy; ⁸University of British Columbia, Vancouver, Canada (r.valbuena@bangor.ac.uk; brian.o'connor@unep-wcmc.org; flo.zellweger@gmail.com; felix.morsdorf@geo.uzh.ch; petteri.vihervaara@ymparisto.fi; will.simonson@unep-wcmc.org; matti.maltamo@uef.fi; fiona.danks@unep-wcmc.org; gherardo.chirici@unifi.it; nicholas.coops@ubc.ca; dac18@cam.ac.uk)

Observations of biodiversity and ecosystem status are relevant to evaluating progress towards many of the targets set by the three Rio Conventions and the UN Agenda 2030. However, the multi dimensionality of biodiversity is difficult to measure and a suite of indicators are necessary to track changes in all aspects of biodiversity for monitoring and evaluating progress towards these targets. A set of Essential Biodiversity Variables (EBVs) has therefore been proposed to standardise how biodiversity is measured, some of which can be observed with Earth Observation (EO). Here we investigated the potential of LiDAR to retrieve EBVs on vegetation structure and draw some general conclusion about the use of EO for EBVs. Firstly, almost any type of global observation will be geographically biased, with significant gaps in tropical areas and plentiful observations for North America, Europe and Australia. Secondly, there is no single type of observation with global coverage at a suitable temporal recurrence. As a result, the retrieval of EBVs in practice will require the combination of different datasets. Thus, we advocate for a system architecture that can accommodate disparate observations as inputs to EBVs, which should allow for evaluation of uncertainties and bias in EBV estimations, as these will vary spatially. A standardized framework for observing terrestrial ecosystem morphological traits for incorporating disparate types of LIDAR data from any platform is proposed, with applications for Sustainable Development Goal 15, in particular indicators 15.1.1 (forest area as a proportion of total land area) or 15.2.1 (sustainable forest management).

The added value of multi-temporal Sentinel-2 data detailed forest monitoring in the Wienerwald Biosphere Reserve

Markus Immitzer¹, Sebastian Böck¹, Francesco Vuolo¹, Harald Brenner², Clement Atzberger¹

¹University of Natural Resources and Life Sciences, Vienna (BOKU), Institute of Surveying, Remote Sensing and Land Information (IVFL), Vienna, Austria; ²Biosphärenpark Wienerwald Management GmbH, Tullnerbach, Austria (markus.immitzer@boku.ac.at; sebastian.boeck@boku.ac.at; francesco.vuolo@boku.ac.at; hb@bpww.at; clement.atzberger@boku.ac.at)

Detailed knowledge about tree species composition is of great importance for forest management. The European Sentinel-2 (S2) satellites provide data with unprecedented spectral, spatial and temporal resolution. Here, we investigate the potential benefits of using high temporal resolution data for classification of five coniferous and seven broadleaved tree species in a diverse Central European Forest. To run the classification, 18 cloud-free S2 acquisitions were analyzed in a 2-step approach. The available scenes were first used to partition the study area into six broad land-cover classes. Subsequently, additional classification models were created separately for the coniferous and the broadleaved class, taking into account all 262,143 possible permutations of the 18 S2 scenes. Each model includes a stepwise recursive feature reduction. Individual mono-temporal tree species accuracies range from 48.1% (January 2017) to 78.6% (June 2017). Compared to the best mono-temporal result, the multi-temporal analysis approach improves the out-of-bag overall accuracy by 11 and 12 percentage points for the coniferous and the broadleaved tree species, respectively. Remarkably, a combination of 6-7 scenes achieves a model quality equally high as the model based on all data; images from April until August proved most important. The classes European Beech and European Larch attain the highest user's accuracies of 96.3% and 95.9%, respectively. The most important spectral variables to distinguish between tree species are located in the red (coniferous) and SWIR bands (broadleaved), respectively. Overall, the study highlights the potential of multi-temporal S2 data for species-level classifications in middle European forests.

Airborne Laser Scanning to detect Tree-related Microhabitats in order to support the conservation of biodiversity

Giovanni Santopuoli¹, Marco Marchetti¹, Mirko Di Febbraro², Bruno Lasserre²

¹Università degli Studi del Molise, Campobasso, Italy; ²Università degli Studi del Molise, Pesche, Italy (giovanni.santopuoli@unimol.it; marchettimarco@unimol.it; mirkodifabbraro@gmail.it; lasserre@unimol.it)

Maintain and enhance the conservation of biodiversity is one of the most important aims of the Sustainable Forest Management, among the multiple goods and services that forest ecosystems provide to human wellbeing. However, monitoring forest biodiversity is a challenging task due to field inventory activities are strongly expensive and time consuming. In addition, inventory data often appear inadequate to assess the biodiversity value of forests and it is necessary to develop new approaches and methods to promote the conservation of biodiversity and at the same time to ensure the provision of other ecosystem services. This study aims to demonstrate how Airborne Laser Scanning data can contribute to assess forest biodiversity through the detection of Habitat Trees. We describe an experimental approach to detect the abundance of Tree-related Microhabitats using LiDAR cloud points and correlated them with ALS metrics. The frequency and abundance of these particular niches, such as cavities, dead branches, injuries and woods, allow to identify Habitat Trees, which play a significant role for the conservation of biodiversity. Four statistical models were implemented to assess and map the biodiversity value in a mixed and multi-layered forest in Central Apennine, Italy. Results show that the RMSE and R² values for Habitat Trees ranging between 3.37 - 4.51 and 0.6 - 0.8 respectively, while for Tree-related Microhabitats ranging between 5.8 - 6.9 and 0.6 - 0.8 respectively. This study was supported by the project "FRESH LIFE—Demonstrating Remote Sensing integration in sustainable forest management" (LIFE14 ENV/IT/000414).

Biodiversity assessment in a tropical deciduous forest in Mundumulai National Park in India using AVIRIS-NG data

Margarita Huesca¹, Maria J. Santos², Raman Sukumar³, Susan L. Ustin¹

¹Center for Spatial Technologies And Remote Sensing (CSTARS), University of California Davis, USA, Davis, USA; ²University Research Priority Program in Global Change and Biodiversity and Department of Geography, University of Zurich, Zurich, Switzerland; ³Centre for Ecological Sciences, Indian Institute of Science in India, Bangalore, India (mhuescamartinez@ucdavis.edu; maria.j.santos@geo.uzh.ch; rsuku@iisc.ac.in; slustin@ucdavis.edu)

Global biodiversity loss is one of the major threats to ecosystems, their functions and services across the world. There is an urgent need to develop effective tools to estimating biodiversity. Recent studies have explored the potential of remote sensing to estimate biodiversity, as spectral variability is expected to correlate with biodiversity. Most studies used multispectral data to estimate species richness and diversity, finding significant correlations with poor or low predictive power. Few studies used image spectroscopy data, achieving stronger relationships and predictive power. Here we build on the later approach to estimate diversity across a moisture gradient, from moist tropical deciduous forests to dry deciduous forests in Mudumalai National Park in India. The Park has 7 long-term plots and one 50-ha plot which we used to validate the results. We propose a new method using AVIRIS-NG imagery. Then we use both a K-means unsupervised classification and a random forest classification to assign each pixel to a spectral class and calculate the agreement between the two methods. The procedure is then repeated for several numbers of classes and plot sizes to determine optimum mapping unit to estimate α -diversity. We find that the optimum mapping unit is close to 1 ha. β -diversity was estimated with Bray-Curtis dissimilarity index. α and β -diversity achieved highest accuracies in dry and wet deciduous forests while being underestimated in degraded moist deciduous forests. The greatest advantage of this method over previous methods is that our procedure determines the maximum species richness without knowing the area a priori.

Assessing aboveground carbon sequestration potential of trees in agroforestry systems in Southern Africa using 3D data

Rafael Bohn Reckziegel¹, Anton Kunneke², Christopher Morhart¹, Jonathan P. Sheppard¹, Hans-Peter Kahle¹

¹Chair of Forest Growth, University of Freiburg, Freiburg im Breisgau, Germany; ²Department of Forest and Wood Science, Stellenbosch University, Stellenbosch, South Africa (rafael.bohn.reckziegel@iww.uni-freiburg.de; ak3@sun.ac.za; christopher.morhart@iww.uni-freiburg.de; jonathan.sheppard@iww.uni-freiburg.de; hans-peter.kahle@iww.uni-freiburg.de)

Due to its location and socio-economic context, Southern Africa is especially vulnerable to the impacts of climate change and is expected to face severe economic, social and environmental challenges in the approaching decades. Agroforestry systems (AFS) are expected to be part of the solution as innovative, sustainable and flexible land use systems capable of adapting to a changing climate, positively influencing agricultural production and food security, facilitate carbon capture and storage while moderating negative climatic influences on rural livelihoods. An important attribute of promoting AFS in African landscapes is the carbon sequestration potential of the tree component. We describe an approach using Terrestrial Laser Scanning (TLS) to estimate the aboveground carbon sequestration potential of tree species growing in African AFS. This innovative non-destructive methodology uses 3D point cloud data derived from single trees collected with a TLS device, which has been proven to be an effective and precise procedure for the assessment of biomass. For that purpose the tree volume data are used as basis for calculating the biomass together with species specific wood densities. Validation is undertaken utilising a destructive approach, sample trees are felled and accurately weighed to generate precise ground truth data. The TLS derived biomass models for single trees will be used to model the aboveground carbon sequestration potential of different AFS management scenarios in the Southern Africa region.

Biodiversity assessment based on unmanned aerial vehicle approach in boreal forests

Anton Kuzmin¹, Pasi Korpelainen¹, Petteri Vihervaara², Arto Viinikka², Sonja Kivinen¹, Topi Tanhuanpää¹, Sarita Keski-Saari¹, Peter Kullberg², Laura Poikolainen¹, Aleksi Ritakallio¹, Timo Kumpula¹

¹University of Eastern Finland, Joensuu, Finland; ²Finnish Environment Institute (SYKE), Helsinki, Finland (anton.kuzmin@uef.fi; pasi.korpelainen@uef.fi; petteri.vihervaara@ymparisto.fi; arto.viinikka@ymparisto.fi; sonja.kivinen@uef.fi; topi.tanhuanpaa@helsinki.fi; sarita.keski-saari@uef.fi; peter.kullberg@ymparisto.fi; laura.poikolainen@uef.fi; aleksi.ritakallio@gmail.com; timo.kumpula@uef.fi)

European aspen (*Populus tremula*) is a keystone species for boreal forests biodiversity, where large-sized trees are most valuable for maintaining a diverse group of other species and may host hundreds of animal and plant species, many of which are threatened in Fennoscandia. Due to a low economic value and sparse and scattered occurrence of aspen species in boreal forests, there is a lack of information on the spatial and temporal distribution from national forest inventories, which hamper efficient planning and implementing sustainable forest management practices and conservation efforts. Nowadays airborne remote sensing techniques are commonly used for biodiversity assessment over the large areas, however, operational costs of data acquisition are still relatively high and there is strong dependence on the availability and quality of field data. New unmanned aerial vehicle (UAV) based remote sensing proved to be very efficient in providing ultra-high spatial and temporal resolution imagery for detailed forest properties assessment at reasonable costs and serve as a supplement or even able to replace part of the currently required field work to support biodiversity assessments. In this study, the main objective was to recognize individual European aspen trees in old-growth boreal forests in conservation area and estimate its structural properties based on the combination of spectral bands and structural features extracted from UAV data. The results were compared with the airborne laser scanning and hyperspectral data-based methods.

A Land Surface Phenology monitoring system for forest conservation using a non-parametric approach and open access data and software

Roberto O. Chávez¹, Sergio A. Estay², Matías Olea¹, José Lastra¹, Ignacio Díaz-Hormazábal³, Diego Valencia³

¹Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile; ²Universidad Austral de Chile, Valdivia, Chile; ³Corporación Nacional Forestal, Santiago, Chile (roberto.chavez@pucv.cl; sergio.estay@uach.cl; matias.olea@pucv.cl; jose.lastra@pucv.cl; ignacio.diaz@conaf.cl; diego.valencia@conaf.cl)

Land surface phenology (LSP), or the recurring seasonal ‘greening’ and ‘browning’ cycle of the vegetated surface, has been defined as one of the Essential Biodiversity Variables in the framework of the Convention on Biological Conservation. Monitoring LSP is one of the simplest and most efficient ways to detect and geographically spatialize the effects of climate change on forests. Currently, satellite imagery make possible cost-efficient monitoring of LSP at different spatial and temporal scales, but available parametric methods are limited to describe all possible annual cycles of different forest types and also lack of reliability measures. Here, we introduce a non-parametric Forest LSP monitoring system for conservation purposes based on (a) the ‘*npphen*’ R-package for LSP reconstruction and anomaly detection and (b) the ‘*shiny*’ R-package for web mapping implementation. Advantages of ‘*npphen*’ are: its flexibility to describe any LSP pattern (suitable for any forest type), it handles time series or raster stacks with and without gaps, and it provides confidence interval for the expected LSP at yearly basis, useful to judge the anomaly magnitude. The web platform was implemented to research the conservation status of Mediterranean forests from the La Campana National Park in Central Chile. Significant anomalies from the natural LSP in the last 18 years occurred mainly outside the National Park, which is an indication of a good conservation status. Our method constitutes a valuable alternative for a cost-efficient near-real-time monitoring system for the National Network of Protected Areas in Chile or for other conservation areas in the world.

Investigating impacts of forest cover change on biodiversity using time-series remote sensing data

Elizabeth Green¹, William Simonson¹, Valerie Kapos¹, Mike Harfoot¹, Samantha Hill¹, Robin Freeman², Louise McRae², Karen Mo³, Pablo Pacheco⁴, William Baldwin-Cantello⁵

¹UNEP-WCMC, Cambridge, United Kingdom; ²Institute of Zoology, Zoological Society of London, London, United Kingdom; ³WWF-US, Washington, DC, USA; ⁴WWF-International, Washington, DC, USA; ⁵WWF-UK, Woking, United Kingdom (elizabeth.green@unep-wcmc.org; will.simonson@unep-wcmc.org; val.kapos@unep-wcmc.org; mike.harfoot@unep-wcmc.org; samantha.hill@unep-wcmc.org; robin.freeman@ioz.ac.uk; louise.mcrae@ioz.ac.uk; karen.mo@wwfus.org; pablo.pacheco@wwf.org; wbaldwincantello@wwf.org.uk)

Remote sensing has greatly improved our ability to monitor forest cover change globally, but may mask below-canopy processes, such as defaunation, that can affect forest health and carbon storage. We investigated whether we could detect a relationship between remote-sensing derived tree cover data and forest vertebrate populations using time-series abundance data from the Living Planet Database. Using both a long-term low resolution tree cover data set (MEASURES VCF5KYR) and a shorter term high resolution dataset (Hansen), we assessed the relationship between forest vertebrate population change and tree cover change, matching the data in space and time. We also assessed the impacts of additional pressures such as human population density, road density and accessibility on forest populations, and repeated the analyses limiting the abundance data to forest specialists. We found little evidence of a consistent effect of tree cover change on forest populations when all populations were analysed together or when reducing the data to only include forest specialists. However, time-series analyses of individual forest specialist populations showed that some populations are closely aligned to tree cover change. Further, by reviewing the supporting literature associated with forest specialist populations, we identified several examples of additional drivers of population change that may have masked a relationship with tree cover change. While remote-sensing derived tree cover datasets are invaluable for assessing changes in forest cover, the importance of below-canopy forest biodiversity monitoring must not be overlooked when assessing forest health and integrity.

Improving biodiversity monitoring using satellite remote sensing derived indicators

Sandra Luque¹ 

¹Irstea UMR TETIS, Montpellier, France (sandra.luque@irstea.fr)

The increasing availability of open access satellite images provides enhanced possibilities with frequent revisit times, high/very high spatial resolution and multispectral information. We face new challenges to tackle, in terms of processing and software needs for biodiversity and conservation activities. Multi-temporal Remote Sensing (RS) observations are particularly relevant to automatically quantify, habitat loss, degradation and fragmentation. They also help to optimize field data collection by focusing on relevant sites, with dramatically improved cost-effectiveness ratios. Ten candidate variables derived from space-based remote sensing have been recently identified, known as remotely sensed EBVs (RS-EBVs) or now more commonly “RS-enabled EBVs” (Skidmore et al., 2015, Pettorelli et al., 2016, Luque et al 2018). We show here, the interest of taking advantage of multiple RS data sources offering complementary spatial resolutions and revisit capabilities to focus on a number of candidate EBVs. The idea is to provide examples of a generic method to derive indicators based on: i) ecosystem distribution, ii) land cover, iii) heterogeneity, iv) primary productivity and v) vegetation phenology. One major current challenge for an improved contribution of RS to conservation is to strengthen multiple collaborative frameworks among remote sensing scientists, conservation biologists and ecologists in order to increase the efficiency of methodological exchange and draw benefits for successful conservation planning strategies. The presentation will serve to conclude the session and provide a take home message to tackle challenges ahead in order to improve biodiversity monitoring and mitigation measures.

D8f: INVASIVE SPECIES IN FOREST ECOSYSTEMS, CAUSES, CONSEQUENCES, UTILIZATION AND MANAGEMENT OPTIONS

Invasive plants of forest ecosystems: impacts and management options

Daizy Rani Batish¹, Shibu Jose²

¹Panjab University, Chandigarh, India; ²University of Missouri, Missouri, USA (daizybatish@yahoo.com; joses@missouri.edu)

Invasive plants are fast proliferating within and around forests- one of the most important terrestrial ecosystems providing numerous ecosystem services to mankind. All types of forests, viz. tropical, sub-tropical, temperate and alpine, are threatened by the establishment of invasive species, mainly the woody perennials e.g. *Acacia* spp., *Pinus* spp., *Prosopis* spp., *Robinia pseudoacacia*, *Broussonetia papyrifera*, *Leucaena leucocephala*, and *Lantana camara*, etc. These invasive plants spread gregariously reducing the carrying capacity of the forests and altering their natural structure and composition. These also hamper forest productivity, reduce local biodiversity and have a profound effect on the ecosystem services; therefore, having serious ecological and economic implications.

Their presence even hinders the restoration efforts and other conservation-related operations in the forest areas. Furthermore, disturbances posed by changing climate and increased anthropogenic activities have aggravated the spread of invasive alien species in forest ecosystems. The ecological implications of the invasive species, therefore, demand strong management strategies based on an integrated approach involving constant monitoring of alien species, large scale operations for the mechanical/chemical/biological removal of invasive plants and rehabilitation of the infested areas. This not only requires global attention and cooperation among developed and developing countries and strict legal framework but also the participation of the local people, NGO's, multi-stakeholders, and forest authorities.

The impact of *Sirex noctilio* in Canada

Jeremy Allison¹

¹Natural Resources Canada, Sault Ste Marie, Canada (jeremy.allison@canada.ca)

The woodwasp *Sirex noctilio* was discovered in Canada over a decade ago. Permanent impact assessment plots in Ontario, CA suggest that to date it has not been a significant mortality agent in pine forests in Canada, a situation that differs from some pine forests in the southern hemisphere. Manipulative oviposition trials and life-table studies suggest that high levels of mortality occur in the egg and early larval stages in pine forests in Canada. Factorial exclusion caging trials suggest that exposure to the biotic community significantly reduces *S. noctilio* brood production in Ontario but not in South Africa where pines are introduced and have a limited biotic community associated with them. The results of these studies will be presented and discussed with respect to the variable impact *S. noctilio* has had in its invaded range.

Effect of introduced species on forest regeneration: the case of Isla del Coco National Park, Costa Rica

Luis Guillermo Acosta Vargas¹ , Rafael Bonilla Mata¹, Adriana E. Rovere², Jorge Camacho Sandoval¹

¹Instituto Tecnológico de Costa Rica, Cartago, Costa Rica; ²INBIOMA, CONICET-Universidad Nacional del Comahue. Centro Regional Universitario Bariloche, Bariloche, Argentina (lacosta@itcr.ac.cr; rbonillam24@gmail.com; adrirovere@gmail.com; jorge.camacho.s@gmail.com)

Isla del Coco National Park is an oceanic island in the Eastern Pacific with tropical rain forest and high endemism. Deforestation and the introduction of flora and fauna species have impacted on the development and regeneration of its forest. We present the results of four exclosures established in a deforested area invaded by bushes and liana, where we applied treatments simulating gap dynamics for stimulating natural regeneration; and conducted an analysis of tree regeneration including data of forest permanent monitoring plots (PMP). We monitored regeneration within the exclosures; outside the exclosures herbivores consumed the regeneration after the first measure. *Cecropia pittieri* tree was the most successful reaching a density of 438 trees/ha. The other tree species do not regenerate or reported a minimum amount, this indicated a depleted seed bank and lack of seed dispersion due to the lack of dispersers. The liana *Entada gigas* showed high invasion capacity, growing 1.6±0.2 m/month from the edges of the remaining vegetation. The regeneration survey within PMP showed a low number of the canopy species: 166 seedlings/ha, 67 saplings/ha; instead, shrubs of Melastomataceae has the higher amount of regeneration 1478 seedlings/ha, 467 saplings/ha, this replacement implies the loss of the composition and structure of the forest. Conserving the forest will require control of herbivores and invasive plants, and a program of reproduction and planting of tree species to overcome the poorly presented ecosystem services of the seed bank and seed dispersal.

Invasive insect and disease threats to United States tree species and geographic patterns of their potential forest impacts

Kevin Potter¹ , Maria Escanferla², Robert Jetton³

¹Department of Forestry and Environmental Resources, North Carolina State University, Research Triangle Park, NC, USA; ²Department of Forestry and Environmental Resources, North Carolina State University, Raleigh, NC, USA; ³Camcore, North Carolina State University, Raleigh, NC, USA (kpotter@ncsu.edu; mescanf@ncsu.edu; rmjetton@ncsu.edu)

Diseases and insects arguably pose the most destructive threat to North American forests. Recently, exotic invasive insects and diseases have wreaked extensive ecological damage and caused billions of dollars of economic impacts. As part of an effort to identify United States tree species and forests most vulnerable to such epidemics, we compiled a list of up to the five most serious insect and disease threats for 419 United States tree species and assigned a severity rating for each of the 1378 host and insect/disease combinations. We then combined this list with data from a spatially unbiased and nationally consistent forest inventory to assess potential ecological impacts of insect and disease infestations. Specifically, potential host species mortality for each host/agent combination was used to weight species importance values on 133,000 Forest Inventory and Analysis plots across the conterminous 48 United States which, when summed on each plot, represent an estimate of the proportion of existing importance value that could be lost on the plot. Plot estimates were then used to identify statistically significant geographic hotspots of potential forest impacts associated with insects and diseases in total. We found different patterns of potential impacts for insects than for diseases, and for exotic versus native insects. In particular, invasive insects, given their current geographic extents, should have the most impact in the Northeast, the Northwest, and along the Gulf Coast. Their impacts could increase greatly, however, if they infest the entirety of their hosts' distributions.

A decision support system (DSS) for risk assessment and mitigation of forest invasive alien species (FIAS) in Canada

Valentine Lafond¹, Gregory Paradis¹, Vivek Srivastava¹, Federico Lingua¹, Stefanie Lumnitz¹, Verena C. Griess¹

¹University of British Columbia, Faculty of Forestry, Department of Forest Resources Management, Vancouver, Canada (valentine.lafond@ubc.ca; gregory.paradis@ubc.ca; vivek.srivastava@ubc.ca; federico.lingua@ubc.ca; stefanie.lumnitz@ubc.ca; verena.griess@ubc.ca)

With over 347 million hectares of forested area, Canada contains 9% of the world's forests, 24% of the world's boreal forests, and is one of the world's largest forest products exporters. Canada's forests and forest sector are vulnerable to forest invasive alien species (FIAS), with surveillance and mitigation efforts being particularly challenging given the large area of forest lands in the country. Decision Support Systems (DSS) can greatly facilitate invasion risk assessment and management. Hereby, the development and use of DSS is often limited by a lack of knowledge on FIAS ecology, especially regarding "invasiveness traits" (e.g. dispersal capacity). New opportunities arise from the use of genomics tools, which allow deriving such information from intercepted FIAS, thus allowing the integration of genomics informed data into DSS. We developed a model-based DSS framework for FIAS risk assessment and mitigation in Canada that allows to pipeline FIAS trait information derived from genomics and project potential impacts of FIAS invasions on forest ecosystem services (e.g. timber production, recreation). We illustrate its implementation and use for Asian Gypsy Moth (*Lymantria dispar asiatica*) invasions in British Columbia, using genomics-derived information on flight capacity from intercepted AGMs. The DSS provides stakeholders with essential information facilitating the identification and prioritization of areas at risk, estimation of potential socio-economic impacts of FIAS invasion, and comparison and selection of mitigation scenarios.

Reducing the invasibility of forests: Silvicultural strategies for integrating Black cherry

Bart Nyssen¹, Jan Den Ouden², Kris Verheyen³, Erik Mathijs⁴, Bart Muys⁴

¹Bosgroep Zuid Nederland, Heeze, Netherlands; ²Wageningen University, Wageningen, Netherlands; ³University of Ghent, Ghent, Belgium; ⁴University of Leuven, Leuven, Belgium (b.nyssen@bosgroepen.nl; jan.denouden@wur.nl; kris.verheyen@ugent.be; erik.mathijs@kuleuven.be; bart.muys@kuleuven.be)

Forest managers are confronted with a seemingly endless flow of new species, the one more invasive than the other. The ease with which some of these species settle and prosper in particular forests, while other forests remain nearly immune to them, raises the question whether invasions are caused by the invasiveness of the new species or the invasibility of the receiving ecosystem. Understanding the link between traits making a tree species potentially invasive (invasiveness) and the ecosystem features leading to invasion (invasibility) offers tools to integrate potentially invasive tree species into forest ecosystem. We use the case of Black Cherry (*Prunus serotina*) to illustrate the role of silviculture in using the opportunities invasive tree species offer for integration into the forest ecosystem. This North American species became the foresters worst enemy in Europe 350 years after its introduction in 1623. Two decennia of fiercely fighting the species proved in vain. Triggered by this observation, Dutch and Belgian foresters and researchers closely collaborated to develop approaches to restore forest ecosystems invaded by Black cherry. Production of Black cherry quality timber, followed by under-planting with more shade tolerant indigenous tree species as a transitional phase towards a more resilient mixed forest, was the basis for this integration strategy. This management strategy of utilizing an invasive species offers a perspective for other invasive tree species that are already widespread in the forest ecosystems and cannot be eliminated anymore.

Technical, legal, and public responses to biological plant invasions in European temperate forests

Katharina Lapin¹, Magdalena Langmaier¹, Janine Oettel¹, Herfried Steiner¹, Georg Frank¹

¹Federal Research and Training Centre for Forests, Natural Hazards and Landscape, Vienna, Austria (katharina.lapin@bfw.gv.at; magdalena.langmaier@bfw.gv.at; janine.oettel@bfw.gv.at; herfried.steiner@bfw.gv.at; georg.frank@bfw.gv.at)

The European temperate broad leaf and mixed forests (TF) cover large areas in 21 European countries. Unwanted naturalization of Invasive Alien Species (IAS) can entail risks to the biodiversity and ecosystem functions of TF. The aim of this study is to determine the current spread of IAS in TF and their impact on forest management, review existing technical measures, and discuss the prevailing legal and policy frameworks. The review of technical reports and publications shows that the plant species *Solidago gigantea*, *Robinia pseudoacacia*, *Impatiens glandulifera*, *Fallopia* sp., and *Amorpha fruticosa* are among the most-studied IAS in TF. Among the most-studied impacts are regeneration and changes to site conditions. The construction and use of forest roads as well as harvesting disturbances are considered to be the main pathways for the introduction of IAS into TF. Management measures include general considerations on preventing unintentional introduction and spread, early detection action plans followed by rapid eradication measures, mechanical removal, and the use of plant protection products (herbicides). Prevention measures are considered the most cost-efficient and effective measures. The effectiveness of control measures can be increased by way of integrated control strategies within a long-term management plan. Analysis of legal and policy frameworks shows overlapping responses in international conventions and agreements to address the risks. At the national level, policies and legal responses form a highly complex network of country-specific definitions and strategies. EU Regulation 1143/2014 stipulates an EU-wide ban of IAS of Union concern, including 8 plant species posing relevant risks for TF.

Adaptive management of the invasive shrub *Lonicera maackii* and the herbivore *Odocoileus virginianus* for an endangered species in an old growth urban forest

Robert Loeb¹, Will Peters², Steve Ward²

¹Pennsylvania State University, DuBois, PA, USA; ²Radnor Lake State Natural Area, Nashville, TN, USA (rxl5@psu.edu; will.peters@tn.gov; steve.ward@tn.gov)

The invasive shrub Amur honeysuckle (*Lonicera maackii*) became established in old growth urban forests of Radnor Lake State Natural Area, Nashville, Tennessee, USA in 1980. Also in 1980, the herbivore white-tailed deer (*Odocoileus virginianus*) returned to the Natural Area. The long-term change in all five forest communities found in the Natural Area was a decline in total tree stems from 1974 to 2008 and decimation of the seedling and sapling populations from 1994 to 2008. Amur honeysuckle has been the focus of intensive removal efforts since 2002. Comparison of areas with annual removals for seven years to areas with removal in only one year revealed greater effectiveness with annual treatments. Among the forests of the Natural Area are cedar glades, which contain both the endangered perennial herb wild dill (*Perideridia americana*) and Amur honeysuckle as well as transient white-tailed deer. Amur honeysuckle removals were performed in five cedar glades from 2014 through 2017 and the responses of wild dill and Amur honeysuckle were examined post-treatment in 2018. In all five glades, the post-treatment Amur honeysuckle population was significantly smaller ($p < 0.001$) as compared to pretreatment population. Wild dill increased from pretreatment to post-treatment in all five cedar glades, but the increase was not significant at one cedar glade. The effects of white-tailed deer trampling was demonstrated by declines in the population of wild dill from leaf out (mid-March) to flowering (early May) in 2018. Adaptive management changes considering the research outcomes will be presented.

D8g: RESILIENCE OF TROPICAL FORESTS TO MULTIPLE DRIVERS OF CHANGE: CONTRIBUTING TO A MORE SUSTAINABLE FUTURE

Post fire regeneration of tree species in a Colombian tropical dry forest

Anghy Gutiérrez-Rincón^{1,2}, Angela Parrado-Rosselli^{1,2}

¹Universidad Distrital Francisco José de Caldas, Bogota DC, Colombia; ²Use and Conservation of Forest Diversity Research Group, Bogota DC, Colombia (angutierrezr@correo.udistrital.edu.co; aparrador@udistrital.edu.co)

Fire is a frequent and crucial disturbance in some tropical dry ecosystems such as savannas and tropical dry forest (TDF) in central-America. However, little is known about the capacity of inter-Andean dry forests to recover after a fire. Therefore, we compare the composition and structure of sexual regeneration between burned and unburned sites and evaluate the rates of mortality, recruitment, and growth of woody tree species after a fire in a tropical dry forest of the upper Magdalena river valley in Colombia. We install 75 plots of 2 x 2 m where we register and identify all woody individuals in burned and unburned sites. Every three months we recorded and measure the individuals found in 25 plots of burned sites. Results showed that species richness was lower in burned sites, but the number of individuals was significantly higher than in unburned areas. The mortality rate of the post-fire regenerated community was 0.91%, while the recruitment rate was 1.93%, which suggests a good post-fire establishment. In the burned sites, recruited species exhibited similar growth rates. Based on

the natural regeneration index (TNR), species were classified as fire tolerant-species (e.g. *Astronium graveolens*, *Eugenia procera* and *Swartzia trianae*); fire-stimulated species (e.g. *Casearia corymbosa*, *Cordia alliodora* and *Machaerium capote*) and sensitive species (e.g. *Posoqueria* sp., *Guarea guidonia*, and *Piptadenia* sp.). Our results suggest that some inter-Andean TDF tree species can survive and regenerate after fire, and therefore they should be considered in restoration programs, in light of future and more frequent forest fires due to climate change.

Miombo woodland regeneration dynamics after slash and burn agriculture and human settlement in Mozambique

Frédérique Montfort, Marie Nourtier, Clovis Grinand, Corentin Mercier

Nitidae, Montpellier, France (f.montfort@nitidae.org; m.nourtier@nitidae.org; c.grinand@nitidae.org; c.mercier@nitidae.org)

Miombo woodland is the most extensive tropical dry forest formation in Africa, considered as a major biodiversity hotspot but is facing important threats including deforestation due to subsistence agriculture. To mitigate these impacts, passive or assisted forest regeneration is a key solution but little is known on the dynamics of this particular biome. The objective of this study was to analyze Miombo regeneration dynamics in the surroundings of the Gilé National Reserve in Mozambique. The landscape in the area is dominated by slash-and-burn agriculture with strong regeneration dynamics and some areas present long term forest regrowth due to past human migration in the 80's. We sampled 19 plots in mature Miombo forest and 63 regeneration plots from 1 to 40 years old, located over two distinct areas characterized by two dominant soil types. We observed that, changes in richness and species diversity are more linked to the age of the fallow and to anthropic pressure than to the edaphic conditions. Floristic differentiation begins after 10 years of growth, depending on the soil type. Miombo forest dominant trees species were observed as the dominant species of all the re-growing plots, whatever their age. Species richness, floristic composition and structure of the old fallows (30-40 year) are similar to those present in the mature forest, indicating a strong regeneration capacity in the absence of human pressure. This study provides new insights for the elaboration of passive forest restoration techniques adapted to Miombo woodland.

Primary tropical forests, reduced impact logging, and resilience: implications for REDD+ and forest certification

Peter Wood¹, Solveig Firing Lunde²

¹Rainforest Foundation Norway, Vancouver, Canada; ²Rainforest Foundation Norway, Oslo, Norway (peterjwood@gmail.com; solveig@rainforest.no)

In the past decade there has been much debate regarding whether primary tropical forests can be logged in a sustainable way, and whether such activities should qualify for support under REDD+ and certification programmes. While some advocate that reduced impact logging can lead to positive outcomes for the forest, others contest that primary forests should be excluded from these schemes. One of the main reasons cited for preventing further incursions into primary forests, in particular large intact forest areas, is that once access is introduced, it is difficult to prevent unregulated access, illegal logging, and conversion to other land uses. It has also been argued that logging in itself generates significant carbon emissions and creates vulnerability in terms of natural disturbances, most notably drought, fire, and pests. This paper examines the multiple stressors posed by logging in tropical forests and responses observed in different regions, and the ability of these ecosystems to maintain their biodiversity, structure and function. It examines what is known regarding the ability of these systems to maintain their resilience, thresholds and tipping points beyond which tropical forest is unlikely to return to its original condition, and the secondary consequences of introducing access, particularly in areas of poor governance. In light of these findings, recommendations are made as to what role REDD+ and forest certification could play in reversing the decline of tropical forests.

Rethinking tropical forest management in the Anthropocene

Jos Barlow¹

¹Lancaster University, Lancaster, United Kingdom (josbarlow@gmail.com)

Many of the guidelines regarding tropical forest management in sustainable-use or strictly-protected reserves focus on local issues within the area of interest itself, such as setting offtake limits for game or timber and defining the spatial configuration and extent of no-take zones. Yet tropical forests face a period of unprecedented environmental change. This talk will explore recent evidence highlighting the role of multiple interacting threats from climate change, climate shocks, and human land-uses outside of the forest itself - assessing their role in determining biodiversity loss, changing forest composition and limiting forest recovery. Finally, it will explore ways in which management strategies can be modified to more effectively integrate multiple stakeholders across the landscape, and outline ways in which the scientific and practitioner communities can work together to incorporate global environmental change into forest management.

Policy alternatives to address tropical forest degradation

Cecilia Viana¹, Jos Barlow², Joice Ferreira³

¹Rede Amazônia Sustentável, Ilhéus, Brasil; ²Lancaster Environment Centre, Lancaster, United Kingdom; ³Embrapa Amazônia Oriental, Belém, Brasil (cicaviana@gmail.com; jos.barlow@lancaster.ac.uk; joice.ferreira@embrapa.br)

In a rapidly changing environment, forests are exposed to multiple and interacting stressors that can lead to forest degradation. Within policy circles, forest degradation is often assumed to be the initial stage of the deforestation process, and thereby an implicit aspect of deforestation policies. Indeed, forests are often gradually degraded before they reach the final clear-cut state, which is usually the case in the Brazilian Amazon. Yet, there is growing evidence that degraded forests have both impacts and dynamics of their own, regardless if it reaches final stages of deforestation. Degraded forests are a source of greenhouse gas emissions, they are not able to secure biodiversity conservation and the provision of ecosystem services, and they may hinder the livelihoods of forest-dependent peoples. Importantly, degraded forests are more vulnerable to further degradation events. However, despite all evidences, forest degradation is overall neglected by policies. In this presentation, we will use Brazil as a case study to discuss policy alternatives to address the issue of tropical forest degradation. First, we will examine if and how environmental policies implemented in the Brazilian Amazon over the past decades address forest degradation. Second, we will depart from the Brazilian experience to discuss the challenges and opportunities of different alternatives for adequately addressing forest degradation. By examining environmental policies implemented in the Brazilian Amazon and considering scientific findings on forest degradation, we expect to contribute for a sustainable future for tropical forests by diminishing the gap between science and policy.

The effects of increased temperature and drought on wildfires and adaptation needs in Daxing'anling, China

Fengjun Zhao¹, Yongqiang Liu², Lifu Shu¹

¹Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China; ²USDA Forest Service, Athens, USA (zhaofengjun1219@163.com; yliu99@gmail.com; slfhxk@126.com)

Daxing'anling is a densely forested region in northeastern China. It contributes to about half of the burned areas in China. Climate is one of the major wildfire drivers and it has been changing. This study investigates the effects of the changing temperature and drought conditions on wildfires in Daxing'anling and the adaptation needs. Historical wildfire and climate data in the past half a century were used to analyze the temporal trends of wildfires and climate during fire seasons and calculate the correlations between wildfire properties and climate elements. The results indicate a remarkable change in fire season due to climate change. The fire season in this region was used to occur in bimodal peaking in spring and fall with minimal fires during summer. However, the number of fire occurrence decreased in both spring and fall in recent two decades, with larger magnitude in fall. In contrast, the number increased in summer. Most fires in summer were caused by lightning strike, which in turn was related to weather conditions. The changes in fires were mainly due to climate change featured by increased temperature and drought during summer. To adapt this summer fire increase, more fire management efforts in fire safety are needed because more complex and unstable weather in summer would make fire prevention and suppression more difficult and firefighters are expected to expose more to heat waves and elevated ozone conditions.

D8h: TREES OUTSIDE FORESTS IN LANDSCAPE ANALYSIS: IMPORTANCE, DEFINITIONS AND ASSESSMENT STRATEGIES

The role of trees in integrated agricultural-livestock-forestry systems / O papel das árvores nos sistemas de Integração Lavoura-Pecuária-Floresta (ILPF)

Renato Rodrigues¹, Fabiano Balieiro¹, Natassia Armacolo², Júlia Silveira³, Jacqueline Jesus⁴

¹Embrapa Solos, Rio de Janeiro, Brasil; ²Universidade Estadual de Londrina, Londrina, Brasil; ³Universidade Federal de Viçosa, Viçosa, Brasil; ⁴Universidade Federal Fluminense, Niterói, Brasil (renato.rodrigues@embrapa.br; fabiano.balieiro@embrapa.br; nmarmacolo@gmail.com; juliagrazielasilveira@gmail.com; jacqueufmt@gmail.com)

A Integração Lavoura-Pecuária-Floresta consiste em uma estratégia de produção agropecuária que integra sistemas produtivos (agrícolas, pecuários e florestais) dentro da mesma área, com cultivo simultâneo ou sequencial, de forma que haja interação entre os componentes, gerando benefícios mútuos. A configuração desses sistemas (iLP, iLF iPF ou iLPP) é compatível com as diferentes realidades do ambiente rural brasileiro e por isso esses sistemas se mostram tão promissores, apesar de desafios persistirem. Atualmente, menos de 20% da área com ILPF (o que corresponde a menos de 3 milhões de hectares) no Brasil possui o componente florestal e isso precisa mudar para que a paisagem e o produtor rural se beneficiem de bens e serviços a ele associados. É preciso discutir e apresentar aos produtores novas alternativas de sistemas, inserir novas espécies (incluindo nativas), testar novos arranjos de plantios, assim como aproximar mercados para produtos madeireiros e não-madeireiros oriundos desses sistemas. Intensificar a ciclagem de nutrientes, aumentar o sequestro de carbono, mitigar a erosão, amenizar o estresse calórico de animais e melhorar o fluxo gênico em paisagens degradadas são alguns serviços ecossistêmicos incrementados pela presença de árvores em agroecossistemas. O Brasil assumiu compromissos voluntários no âmbito do Acordo de Paris que visam o aumento da área de ILPF no país até 2030. Essa é uma excelente oportunidade para o desenvolvimento de políticas e financiamentos públicos e investimento privado na implantação de plantios de árvores em sistemas agrícolas e pastoris.

Salvaging indigenous trees in Urban Areas: socio-cultural believes of remaining Iroko (*Milicia excelsa*) in Ibadan, Oyo State, Nigeria

Folaranmi Dapo Babalola^{1,2}, Paxie Chirwa²

¹Forest Resources Management, University of Ilorin, Ilorin, Nigeria; ²Forest Science Postgraduate Programme, University of Pretoria, Pretoria, South Africa (babalola.fd@unilorin.edu.ng; paxie.chirwa@up.ac.za)

Indigenous trees have been discovered to be disappearing from urban areas at alarming rates. *Milicia excelsa* is an indigenous trees species in tropical Africa and popularly known as Iroko. The tree is popular for its socio-cultural and economic importance. It has been classified as threatened and relics could only be found in a few locations. A survey of the trees in the city of Ibadan, the capital city of Oyo State in Nigeria, was therefore carried out to determine their distribution as well as the ecosystem services provided by the tree in the city. A total of 65 trees (0.14 trees/km²) were sighted in the city. The trees provide environmental, medicinal, economic, spiritual and ecological services to the people. Topmost of the ecosystem services provided by the trees was provision 'microclimatic environment' in the form of cooling effects (95%) from the heat of the day. However, the people believe that the trees harbour some "spirits" with evidences of sacrifices placed under them. Furthermore, snapping of branches of old trees and roosting by some birds on them cause damage to property hence the trees want them removed. Strategy for proper management of the trees in the city to prevent damage to property and to life is considered imperative. There is also a need for an appropriate policy that protects indiscriminate felling of indigenous trees in the city.

Urban forest landscape metrics of Curitiba-Paraná-Brazil

Mayssa Grise¹, Daniela Biondi¹, Hideo Araki¹

¹Universidade Federal do Paraná, Curitiba, Brasil (mayssamonteiro@gmail.com; dbiondi@ufpr.br; haraki@ufpr.br)

The urban landscape increasingly requires studies that brings a detailed analysis of its composition and configuration through its structural components - matrix, fragments and corridors that, when quantified and analyzed by the metrics calculation, can translate the landscape dynamics. The aimed of this research was to verify the utility of landscape metrics in urban forest spatial pattern characterization of the city of Curitiba-Paraná-Brazil. From the high spatial resolution image (Geoeye) classified, and the subsequent definition of the structural urban components matrix, vegetation fragments and corridors, 16 different landscape configuration metrics were calculated. The metrics that effectively contributed to the *spatial analysis* of the landscape were: Total Area (CA), Landscape Percentage (ZLAND) and Number of Polygons (Nump). The metrics that effectively contributed to the analysis of the *landscape structure* were: Total Edge

(TE), Edge Density (ED), Mean Patch Tdge (MPE) and Shape Index (SI). The Patch Size Standard Deviation (PSSD) and Patch Size Coefficient Variation (PSCoV) translated the variety of structural components inherent to the urban landscape, which is noted by the diversity of anthropic and natural elements that are responsible for the urban ecosystem functioning.

Ensuring sustainable management of trees- on-farms in the off reserve landscape through tree registration and climate smart farming systems in Ghana

Valerie Fumey Nassah¹, George Odame¹, alexander Asare¹

¹Forestry Commission, Kumasi, Ghana (valfn2003@yahoo.co.uk; grodame@gmail.com; abasare99@yahoo.com)

Ghana has a total land area of 238,540 km² made up of two major vegetation zones. Approximately 18% of the country has been set aside as forest reserves and wildlife parks and the remaining 82% is owned by stools, skins and individuals across the country. All naturally occurring trees in off reserve landscapes are vested in the state but they occur in individual and community lands and farms. In the past farmers destroyed these trees because their cocoa farms were destroyed by felling of trees for timber and they could not get compensation or any support from the state. To achieve Ghana's Forest policy goals and objectives of the forest Plantation strategy, Ghana is implementing a programme to provide legal support for farmers, optimize the productivity and sustainability of smallholder farming systems by developing appropriate technologies that involve trees (incorporation of trees-on farm within 3.75 million hectares) and enhances connectivity and biodiversity between the agricultural and forest landscapes. A pilot programme to register all planted and naturally occurring trees at the district level has begun with recent support from Climate Investment Fundthrough Ghana's Forest investment programme(GFIP) to provide options for tree tenure regimes, tree ownership and benefit sharing mechanisms for farmers to plant more trees. This paper highlights the importance of trees on farm for landscape restoration, legal framework and the procedures for tree registration, identified strengths and weaknesses and potential for carbon stock enhancement

Historical tree cover percentage of trees outside forest: methods and challenges for urban tof when using landsat imagery

Nils Nölke¹, Marco Sendner¹, Christoph Kleinn¹

¹University of Goettingen, Göttingen, Germany (nnoelke@gwdg.de; m.sendner@stud.uni-goettingen.de; ckleinn@gwdg.de)

Urban trees are a particular class of "trees outside forests" and they have particularly relevant functions in many urbanized regions and settlements. Accordingly, tree resources management increasingly demands relevant and updated information on urban trees, their cover, diversity, spatial configuration and functions. Even though remote-sensing satellite sensors have, in general, proven very useful for estimating forest and tree cover in many contexts, still many related methodological issues require a closer look, also when it comes to monitor changes in tree cover back in time. This study examines how spatial configuration and spectral reflectance of tree cover may affect the pixelwise tree cover estimation in an urban setting and in turn identifies methodological challenges for the estimation of historical tree cover when establishing time series. We give an example how a global tree cover product "struggles" when the focus is on urban tree cover. Our study area is the rural-urban gradient of the very fast-developing megacity, Bengaluru, India, where we cover a wide range of tree densities and tree spatial configurations. This study area is a perfect ground to shed lights on the issue when estimating continuous tree cover percentage from Landsat time series.

Mapping Trees Outside Forest and their contribution to the above ground biomass

Mostarin Ara¹, Iris Van Duren², Louise Van Leeuwen²

¹Swedish University of Agricultural Science, Alnarp, Sweden; ²University of Twente, Enschede, Netherlands (mostaringem@gmail.com; i.c.vanduren@utwente.nl; l.m.vanleeuwen@utwente.nl)

Trees in non forest setting are coined as Trees Outside Forest (TOF) which is considered as essential resource around the world. TOF provides different social, economic and ecosystem services including carbon and biomass storage. TOF shows unique property as it is part of another land class which makes it difficult in many places to access due to the ownership of private land. Moreover, it is also tedious and expensive to do inventory in a traditional plot based survey because of their spatial position in landscape level. But the method in combination of remote sensing and few ground data can be promising. In this study, we used remote sense based approach using very high resolution imagery to map TOF and their biomass potential in an agriculturally dominant landscape. Object based image analysis was used to delineate TOF cover from other land class and to model their biomass potential. The method shows feasibility for TOF and biomass mapping and it could be a potential supplement of ground inventory data.

Other lands with trees at Brazilian Forest Inventory (NFI-BR)

Marilice Cordeiro Garrastazu¹ , Jéssica Maran^{1,2,3}, Maria Augusta Doetzer Rosot¹ , Yeda Maria Malheiros de Oliveira¹ , Luziane Franciscon¹, Naissa Luz⁴, Denise Cardoso¹, Patricia Póvoa de Mattos¹ , Joberto Freitas³

¹Embrapa Florestas, Colombo, Brasil; ²FAO, Curitiba, Brasil; ³Serviço Florestal Brasileiro, Brasília, Brasil; ⁴Univeridade Federal de Uberlandia, Uberlandia, Brasil (marilice.garrastazu@embrapa.br; jess.maran@gmail.com; augusta.rosot@embrapa.br; yeda.oliveira@embrapa.br; luziane.franciscon@embrapa.br; naissal@gmail.com; denise.cardoso@embrapa.br; patricia.mattos@embrapa.br; joberto.freitas@florestal.gov.br)

National Forest Inventory (NFI-BR) is under development in many Brazilian states, aiming at generating information on forest resources, from natural areas and forest plantations and based on a 5-year measurement cycle. Besides field data collection, the program includes an initiative that comprises remote sensing and landscape scale spatial analysis, which consider aspects such as land use/land cover (LULC). Those are called landscape sample units (LSUs) which are established at each 40 x 40 km. The LSUs are 100km² wide areas with RapidEye satellite imagery coverage. A methodology for image classification and landscape analysis was developed based on 20 LSU pilot sample units. Object-oriented classification using a process tree was adopted, through which the size of the segments between 1,000 and 500m² was defined, in order to detect the presence of small forest fragments. The classification of LULC was based on FAO protocols for Forest Resource Assessment (FRA) 2015: a) natural forests; b) planted forests; c) other wooded land; and d) other lands with trees, the only one that is located in non- forestlands, as agricultural or urban areas. This LULC class covers part of the so called "trees outside forests (TOF)" concept, as defined by FAO. Through the methodology and considering the sensor with spatial resolution of 5 meters, it was possible to detect that this class corresponds on average to 38 hectares of each pilot area, with an average frequency of 171 polygons per LSU. They can be also considered as stepping stones in the connectivity process of the forest landscape.

D8i: TROPICAL FOREST ECOSYSTEM RESTORATION FOR WATER RELATED ECOSYSTEM SERVICES

The carbon-water-energy-climate nexus and forest-water-people-climate systems

David Ellison¹

¹SLU, Umea, Sweden (ellisondl@gmail.com)

Rapid population growth, increasing agricultural production, mushrooming urban (and suburban) settlements and the continuous decline of forest cover bode ill for the delicate balance between carbon, water, energy and climate. People-forest-water-climate systems create ever more complex and potentially interactive feedbacks across the carbon-water-energy-climate nexus. Climate change can further exacerbate fundamental imbalances created by the anthropogenic modification of terrestrial landscapes. Globally warming temperatures and declining rainfall (in particular in the tropical and temperate regions), both compound and further aggravate an increasingly grim misuse of planetary resources. Where the forest-water debate is concerned, however, the scientific world remains divided into easily politicized camps, seemingly unable to observe and adequately understand what the other camp is up to. Despite this, as this presentation will demonstrate, many or most of the basic tools necessary for restoring at least a part of the delicate balance between the major ecosystem components of the carbon-water-energy-climate nexus are increasingly well understood and documented. Thus, an optimized ecosystem strategy could effectively use these tools to at least partially address the rapid advance of climate change and its increasingly threatening impacts on the availability of at-risk water resources, and on the million to billions of people and livelihoods who depend on them.

How good could be forest restoration to streamflow at Atlantic forest ecosystem?

Silvio Ferraz¹, Aline Fransozi¹, Carolina Rodrigues², Lara Garcia³, Katherine Vasquez¹, Matheus Ogasawara¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ²Pratica Socioambiental, Piracicaba, Brasil;

³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (silvio.ferraz@usp.br; aline.fransozi@usp.br; cabreuva@gmail.com; lara@ipef.br; katherinevasquezvasquez1@gmail.com; matheus.ogasawara@usp.br)

Following Brazilian restoration goals, more than 1 million of hectares will be restored at Atlantic Forest biome. Many sectors of society have high expectation about benefits on water provision and regulation by forest restoration, since there an association between native forest cover and quantity of clean water. Considering this context, it is necessary to increase understanding the effects of forest restoration on hydrological processes and, consequently, on water resources in tropical region. We used field data obtained at restored sites and forest catchments covered by on growing native vegetation and forest plantations (*Pinus* and *Eucalyptus*) to understand effects of active forest restoration at Atlantic Forest region. Effects of conversion to forest on hydrological dynamics vary according to forest growing rate, relative position of forest on topographic position and site resilience. Forest structure establishment is not directly linked to its hydrological processes' recovery, and the time lag depends on ecological condition of new forest, historical land-use and local natural physical characteristics. Positive effects of forest restoration on hydrological regime is expected on long term, when stream flow regulation is achieved, compensating the short-term effect of stream flow reduction. Based on current knowledge, a framework of forest restoration effects on streamflow is proposed and discussed.

Landscape characteristics and their implications to ecological restoration: observation and experience from Western China

Runsheng Yin¹, Daojun Zhang²

¹Michigan State University, East Lansing, USA; ²Northwest A&F University, Yangling, China (yinr@msu.edu; cugzdj@gmail.com)

So far, inadequate attention has been given to the design and implementation payments for ecosystem services and other ecological restoration programs in line with the characteristics of landscapes to be restored. Evidence from China's Sloping Land Conversion Program indicates that one family had only 1/3 ha of retired cropland in Sichuan and one ha in Shaanxi. Studying a watershed of 543.5 ha in Wuqi county of Shaanxi further reveals that it includes 491 plots, with an average size of only 1.1 ha, ranging from less than 0.01 ha to 27.2 ha. Also, these plots belong to > 50 households in three villages, with each household having 18 plots at the maximum and one at the minimum. Moreover, the slopes of these plots range from 3.7° to 37.5°, averaging 19.1°. Given the fragmented and tiny amount of the retired cropland, it is impossible to execute a contract bidding process at the household level; local- or landscape-level projects must be structured and bidding by community groups or intermediary aggregators be sought in order to achieve the functionality of the restored landscape on the one hand and market-based voluntary participation on the other. This is in contrast to the situations in some other countries. For instance, the restoration contract size in the U.S. averaged 30.4 ha and the mean sign-up amount was 44.8 ha per farm. It is thus more appropriate to construe ES provision and bidding contracts at the farm level in the U.S.

Recovering soil infiltration along a gradient of pasture to forest restoration in Atlantic Forest

Aline Fransozi¹, Marcia Sousa do Nascimento¹, Sílvio Frosini de Barros Ferraz¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (aline.fransozi@usp.br; marcia.sousa36@gmail.com; silvio.ferraz@usp.br)

Forest transition describes a landscape transformation where a huge decline of forest induced by human activities is followed by a partial recovery in the extent of new forests. Atlantic Forest is following this trend and after deforestation, exploitation and intensive soil use on this biome, many goals are been established for restoration of forest on previous agriculture landscapes. Most of these efforts occurs in pasture areas, sometimes actively with high investment costs, or passively, where the abandonment of areas less productive allows natural regeneration and create small forests in secondary succession processes. In most of Atlantic Forest biome, it is expected that these new forests support essential ecosystem functions related to soil and water protection. We assessed infiltration rates on new forests originated by natural regeneration on a pasture matrix landscape in two soil types: one loam and other sandy soil. It was used Beerkan Estimation of Soil Parameters through Infiltration Experiments, referred as BEST, to get the soil saturated hydraulic conductivity. After one decade, both soils at forest restoration sites presented infiltration rates around 10 times higher than pasture ones. Preliminary results from areas of active restoration coupled with management practices show that is possible to accelerate the recovery of infiltration rates on formerly pasture fields. A time framework to recovery soil infiltration capacity by forest restoration is discussed. FAPESP Process 2015/23719-6

Estimating the effects of restoration practices on controlling soil and water losses in China's Wei River Basin based on longitudinal observations and integrated methods

Yifei Wang¹, Runsheng Yin²

¹Northwest A&F University, Yangling, China; ²Michigan State University, East Lansing, USA (wangyifei1223@nwfau.edu.cn; yinr@msu.edu)

Understanding the soil and water processes and their interactions over time and space has attracted research and policy attention worldwide. But past studies have rarely adopted an interdisciplinary approach to integrating the primary natural and social forces in assessing the causes of soil and water loss or conservation. The purpose of this study is to evaluate the effects of restoring degraded cropland by means of reestablishing forest/vegetation covers and terracing on water and sediment control in the Wei River Basin, which was notorious for its high erosion rates but has witnessed tremendous improvement since the beginning of the new century. Based on a unique panel dataset covering 44 counties over 16 years (2000-2015), our simultaneous equations model was able to capture the structural linkages between water runoff, sediment concentration, and sediment transport. To highlight the crucial role of human interventions, a stepwise regression approach was undertaken. Our empirical results show that the reduction of sediment concentration has been driven largely by improved land cover, induced by implementing the Sloping Land Conversion Program, whereas terracing, as part of the Water and Soil Conservation Project, has played a positive role in mitigating runoff and sediment discharge.

Atlantic forest restoration and hydrological services: trade-off between water supply and protection services

Lara Gabrielle Garcia¹ , Silvio Frosini de Barros Ferraz²

¹Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ²Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Piracicaba, Brasil (lara.garcia@usp.br; silvio.ferraz@usp.br)

Water supply is the one the main objectives of forest restoration at Atlantic Forest biome, especially in critical regions like São Paulo State. Once forest has a direct influence on hydrologic processes, the increase of forest can affect hydrological services, however, effects could be positive or negative. In this context, our aim was to assess how forest restoration can affect hydrological services. The study area was an agricultural catchment located at southeast Brazil and simulations of forest cover increase were conducted using the physically based distributed hydrological model MIKE-SHE, previously calibrated. The scenarios used were 0% forest cover (FC) to 100% FC (nine scenarios between 10% and 90% FC). Hydrological services were analyzed through three water supply indicators (Q – annual flow, Q95 – minimum flow, and BFI - base flow index) and one protection indicator (Q5 – maximum flow). The results allowed us to affirm that the increase of forest cover resulted in a decrease of Q and Q95 values, and an increase of Q5 values. Therefore, our results indicate a water supply decrease and a protection increase following forest cover gain at catchment, which put in evidence a trade-off between hydrological services. The 50% FC scenario seems to be an important threshold for hydrological services since until this forest cover proportion simulations not show difference in water supply in relation to 0% FC, also this scenarios results in gain of water protection in relation to 40% FC. We discuss the tradeoff of hydrological services in relation to forest restoration strategies.

Modelling forest restoration to evaluate hydrology ecosystem services in the Cantareira System water supply context

Claudia Moster¹, Marcos Vinicius Folegatti², Jorge Eduardo Leon Sarmiento³

¹Universidade Federal Rural do Rio de Janeiro, Seropédica, Brazil; ²Universidade de São Paulo, Piracicaba, Brazil; ³The Nature Conservancy, Bogotá, Colombia (claudiamoster@usp.br; mvfolega@usp.br; jleon@inc.org)

The modeling of hydrological ecosystem services is an auxiliary tool in decision making for financial investment in land use practices and in forest restoration projects. Due to the need for improvement in the provision of these services at the lowest investment cost, this work aimed to evaluate scenarios for different methods of forest restoration in riparian areas and the transition of land use to hydrology ecosystem services. The study area comprises the Jaguari watershed, located in the head of water supply Cantareira System, which has the purpose of supplying water to the metropolitan region of São Paulo, Brazil. This study identified priority areas to transitions land use and land cover in RIOS model and evaluated export sediment and base flow production using the InVEST tool, to forest restoration assisted and unassisted in riparian areas and the transition to silvopasture in grassland. These scenarios were evaluated for the reduction of sediment exports in relation to the transition in the total drainage area, with unlimited financial resources initially, and the generation of base flow in second step. The priority area to transition resulted in 37.56% of Jaguari watershed, considering the agroforestry in the pasture land and restoration of riparian areas, could to reduce about 72% of sediment export and 9% of baseflow. The assisted restoration of riparian forest could improve the sediment retention but the reduction of baseflow would be significant. The modelling was effective to identify priority areas and simulate the effects of transition land use and cover to water supply.

Efficient water use in two forest species used for ecological restoration in a dry tropical forest in Colombia. Municipio del Agrado (Huila) / Uso eficiente del agua en dos especies forestales usadas para restauración ecológica en un bosque seco tropical de Colombia. Municipio del Agrado (Huila)

Miguel Eugenio Cadena Romero¹, Jaime Harley Gonzalez Cárdenas², Yaneth Sierra Carantón¹

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia; ²Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (cademielro@hotmail.com; harforest@gmail.com; ysierrac@gmail.com)

Este estudio se realizó en el departamento del Huila, municipio El Agrado; Sobre el área de compensación de la central hidroeléctrica del Quimbo en bosque seco tropical. El objetivo del estudio fue evaluar el uso eficiente del agua (WUE) de las especies, *Albizia guachapele* (Kunth) Dugand y *Enterolobium cyclocarpum* (Jacq.) Griseb. a la edad de un año y en tres estrategias de restauración ecológica (Nucleación, Nodrizas y Multinodrizas). Se caracterizaron física química y taxonómicamente los suelos, tomando registro micro climático del área y realizando análisis geoestadístico de las variables regionalizadas del suelo. Algunas propiedades físicas de los suelos varían de acuerdo al tipo de estrategia. Existe similitud en las propiedades químicas. El registro climático muestra que diciembre es más seca que abril y que esta condición influye significativamente en el WUE. El uso eficiente del agua analizado mediante el diseño experimental de bloques completos al azar en arreglo factorial 2 x 3 con submuestreo y en series de experimentos, empleando la prueba de comparaciones múltiples de Bonferroni determinó con una confiabilidad del 78% (Pr > 0.22) que la especie *A. guachapele* perteneciente al arreglo florístico de Nucleación y medido en época seca (interacción de segundo grado) registró el mayor WUE con un valor de 0.89 mmol CO₂ mol⁻¹ H₂O. En el análisis geoestadístico se evidencia que el mayor uso eficiente del agua instantáneo (WUE0) lo presentó la especie *E. cyclocarpum* con un índice de 3.3 mmol CO₂ mol⁻¹ H₂O, en la estrategia Nodrizas y en época húmeda.

Variable areas of affluence as priority areas for implementing ecosystem service programs: a proposal for application via river basin plans / Áreas Variáveis de Afluência como áreas prioritárias para implementação de programas de serviços ecossistêmicos: uma proposta de aplicação via planos de bacias hidrográficas

François Lopes Alves¹

¹Forestis Brasilis, Rio de Janeiro, Brazil (francois.eng@live.com)

A Política Nacional de Recursos Hídricos, instituída pela Lei federal nº 9433 de 1997, almeja a sustentabilidade e segurança hídrica através do gerenciamento eficaz das bacias hidrográficas brasileiras. Para tal estabelece que os planos de bacias hidrográficas são instrumentos que atuam como planos diretores de gerenciamento dos recursos hídricos. Um dos itens que devem conter nos planos de bacias são os programas voltados à proteção e conservação dos corpos hídricos e a definição de áreas sujeitas à restrição de uso, com vistas à proteção dos recursos hídricos através de áreas florestadas. Observando a realidade brasileira os planos de bacia visam em geral para a recuperação florestal às áreas previstas no Código Florestal, o que não significa proteger e conservar os recursos hídricos de maneira efetiva. O diploma legal não consegue garantir a conservação e preservação da zona ripária em sua totalidade, pois a delimitação da área variável de afluência de uma microbacia não está transcrita no texto jurídico, o que reflete diretamente na oferta hídrica e qualidade socioambiental da bacia hidrográfica. Partindo das bases de hidrologia florestal e com vistas a contribuir com o alcance de metas políticas à qualidade hídrica e ambiental o presente estudo propõe, fundamentado em uma sólida base bibliográfica, que as áreas variáveis de afluência sejam adotadas em conjuntos com as áreas de preservação permanente como áreas prioritárias para a execução de restauração florestal através de programas de serviços ecossistêmicos, como o pagamento de serviços ambientais, via plano de bacia hidrográfica.

D8k: FOREST MANAGEMENT AND BIODIVERSITY CONSERVATION

Genetic criteria and indicators for Brazilian *Araucaria* Forest conservation policies

Luciano Medina-Macedo¹ , Ailson Augusto Loper^{2,3} , Iain Davidson-Hunt⁴ , Juliana Vitoria Messias Bittencourt¹ , Alexandre Magno Sebbenn^{5,6,7,8} 

¹Universidade Tecnológica Federal do Paraná, Ponta Grossa, Brasil; ²Associação Paranaense de Empresas de Base Florestal, Curitiba, Brasil;

Paulista “Júlio de Mesquita Filho”, Ilha Solteira Brasil; ⁷Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Piracicaba,

Brazil; ⁸Thünen Institute, Braunschweig, Germany (medina.ppgebb@gmail.com; ailsonloper@apreflorestas.com.br; iain.davidson-hunt@ad.umanitoba.ca;

julianavitoria@utfpr.edu.br; alexandresebbenn@yahoo.com.br)

The objective of this study is to present how the genetic dataset from key-species can support conservation policies of endangered biomes. The *Araucaria* Forest is one of the most important subtropical biomes from Southern America covering near to 200.000 Km². However, the indiscriminate use leads in the 1990s to a dramatic reduction of mature forest stands to less than 2% of its original area. To avoid extinction, rules for sustainable management were established in the 1990s, but in 2000 four *Araucaria* Forest tree species were classified as vulnerable by IUCN. In 2001 the log of endangered species was forbidden in Brazil, and in 2006 the government selected areas to compose new conservation units. In the other hands, since 1998 more than 35 genetic studies with the emblematic *Araucaria angustifolia* species have been carried, looking for support conservation policies to *Araucaria* Forest biome. The most important results verified by different authors point that very well conserved areas have a low density of individuals; gene-flow is possible up to 2 Km distance; the pattern of seed dispersal leads to a significant spatial genetic structure, but genetic mechanisms avoid the mating among relatives; and in spite the diversity levels usually are relatively high anywhere, new alleles can be found at 5 Km distance. This evidence allows the adoption of integrative conservation policies to the farmers' owners of significant forest remnants areas, ensuring the creation of biodiversity corridor zones, able to promote the functional and ecologic connection among expressive *Araucaria* Forest fragments.

There are much more rare tree species in secondary subtropical Atlantic forests than it was thought: a tree rarity assessment using systematically gathered data

Laio Zimmermann Oliveira¹, André Luís de Gasper¹, Débora Vanessa Lingner¹, Lucia Sevegnani¹, Alexander Christian Vibrans¹

¹Fundação Universidade Regional de Blumenau, Blumenau, Brasil (laiozoliveira@gmail.com; algasper@furb.br; deboravanessa.ef@gmail.com;

luciasevegnani@gmail.com; acv@furb.br)

Biodiverse forests are usually composed of tree species with small abundance and/or narrow occurrence area. These rare species carry with them a sense of uniqueness and increased risk of extinction. Therefore, we sought to classify 646 tree species growing in three forest types within the Brazilian subtropical Atlantic Forest into seven rarity forms encompassing population size, habitat preference, and geographical distribution. In addition, we investigated the influence of sample size on the outcomes of rarity classification. We used data collected within 418 systematically distributed 0.4 ha plots. Among the 646 recorded species, 67.3% were classified into one of the seven rarity forms at least in one forest type; they represented less than 5% of the trees in each forest type. In turn, about 50% of the species observed in each forest type were rare. Myrtaceae was the family with the greatest number of rare species, followed by Fabaceae, Lauraceae, and Melastomataceae. Species with scarce populations (≤ 10 trees)—i.e., forms 1, 3 and 7—represented more than 40% of the total species richness recorded in each forest type. The sample plots located in old-growth stands, ecotone areas, or areas with particular environmental features (e.g., hydromorphic soils), often presented larger proportions of rare species. Quadratic plateau models suggested that the mean proportion of recorded rare species did not increase substantially in sample size classes greater than 70–80% of the reference sample. The rarity forms comprising scarce populations were particularly influenced by sample size if compared to other rarity forms.

Early successional bird community based clear-cut size modelling

Gediminas Brazaitis¹ , Rimgaile Pételytė-Brazaitienė¹, Kastytis Šimkevičius¹, Renata Špinkytė-Bačkaitienė¹

¹Institute of Forest Biology and Silviculture Vytautas Magnus university, Kaunas, Lithuania (gediminas.brazaitis@asu.lt; rimgaile@zoosodas.lt;

ksimkevičius@gmail.com; renata_shpy@yahoo.com)

We analyzed how local breeding bird communities are influenced by clear-cut spatial characteristics in hemi-boreal forest south-west Lithuania (54°24'–55°11'N, 23°17'–24°35'E). Birds studied by mapping method, surveyed during breeding season from April 15th to June 15th. Inventory covered 146 clear-cuts, totally 546 ha. New bird species colonized and local community density decreased significantly while clear-cut areas reached 2 ha. Bird communities were

almost stable in larger clear-cuts. We registered 55 bird species totally; 43 of them were sensitive to the minimum clear-cut size as habitat area. The size of minimum area up to 0.5 ha were typical for 18 bird species as well as 0.5-1.0 ha – 6 species; 1.1-2.0 ha – 9 species; 2.1-4.0 ha – 10 species. Increasing felled area proportion on landscape level affected positively the number of breeding bird species in clear-cut area. The highest density of bird communities was in landscapes of 11-35% felled area. Optimal shape coefficient of clear-cuts was 3.0-4.0 (for 1 ha area – 530-640 m of edge). For modeling optimal clear-cut size on landscape level we used real information on local bird communities. We compared bird community data from 100 ha clear-cut areas (clear-cuts of 0.5 ha v.s; 5.0 ha) and totally calculated: 18 vs; 43 inhabiting bird species and 950 vs; 650 bird pairs. Optimal clear-cut size distribution model must include various size clear-cuts in suggested proportions of (I) the number and/or (II) size. Forest types with dominating small-scale disturbance events can be based on equal size proportions as well as large-scale disturbance (e.g. fire) equal quantity of clear-cut proportions.

Does forest policy properly consider forest ecosystem services in decision making? An assessment from the Bangladesh Forest Inventory

Nikhil Chakma¹, Rajib Mahamud¹, Md. Akhter Hossain^{1,2} , Rashed Jalal¹, Purnata Chakma¹, Mondal Falgoonee Kumar¹, Kristofer Johnson¹, Matieu Henry¹
¹Food and Agriculture Organization of the United Nations, Dhaka, Bangladesh; ²Institute of Forestry and Environmental Sciences, University of Chittagong, Chittagong, Bangladesh (nikhil.chakma@fao.org; rajib.mahamud@fao.org; akhter.hossain@cu.ac.bd; rashed.jalal@fao.org; purnata.chakma@fao.org; mondal.falgooneekumar@fao.org; kristofer.johnson@fao.org; matieu.henry@fao.org)

Trees and forests provide numerous benefits to the humans in terms of income, foods, energy, environmental sustainability, mitigating climate change, water purification, soil protection and many more. While the role of forests to our society's welfare and provisioning ecosystem services are recognized in the national economy but other forest ecosystem services are neglected in that comparison. This paper aims to draw attention of policymakers to take into consideration for assessing the contribution of other forests ecosystem services for decision making in forestry and natural resources. National socioeconomic survey data conducted by Bangladesh Forest Department were considered to analyze the contribution of tree and forests to humans' activities and economic valuation of these services. From the survey data, the economic value of tree and forest products and net income were analyzed using specific mathematical formula at national level. The results showed that economic value of the collected products higher in non-forest (NF) areas than forests. Similarly, the annual net income of households from NF is also higher than forests. The economic value and net income increased at NF may be government policy restriction on collection of forests products from forests. However, the economic value of forest ecosystems would be higher than NF if cultural (tourism), regulating (i.e., pollution control) and supporting (i.e., nutrient cycling) services are considered in the survey assessment for economic valuation. Policies need to reflect the importance of forest ecosystem services in the economic assessment for effective decision making and investment in national resources management and improve livelihood.

Abundance and diversity of coleoptera beetles in areas of anthropized forests and forest remnants in the Southern sector of the Federal University of Amazonas / Abundância e diversidade de coleópteros em áreas de floresta antropizada e remanescente florestal no setor sul da Universidade Federal do Amazonas

Jekiston Silva¹, Norma Bustamante¹

¹Universidade Federal do Amazonas, Manaus, Brazil (jekistonandrade@gmail.com; ncbustamante@gmail.com)

A Ordem Coleóptera destaca-se devido sua enorme diversidade taxonômica e funcional. Estes insetos desempenham papel fundamental para o funcionamento dos ecossistemas e o entendimento da relação do ambiente alterado pela ação humana pode trazer dados relevantes, como bioindicadores ambientais. Com isso, este estudo teve por objetivo realizar um levantamento das famílias de Coleóptera para avaliação de sua diversidade e abundância em dois tipos de fragmentos florestais localizados no Campus da Manaus - AM. Os besouros foram coletados em dois períodos (chuvoso e seco) e em dois fragmentos (antropizado e remanescente florestal). Os besouros coletados foram transportados para o Laboratório de Preservação da Madeira – UFAM onde foram alfinetados, etiquetados e separados por fragmento e período coletado. Foi realizado a identificação em nível de família e a partir disto, análise estatística de dados para avaliar abundância, diversidade e similaridade. Foram coletados 308 indivíduos, representando 13 famílias nos dois fragmentos, sendo que as mais abundantes foram Scarabaeidae, Chrysomelidae e Cerambycidae. Para abundância, percebeu-se que no remanescente florestal foram coletados 191 indivíduos e no fragmento antropizado, 117 indivíduos da coleta total ($T=2,01$; $p<0,05$). Os valores de diversidade pelo índice de Shannon variaram entre 1,32 no fragmento antropizado/ período seco e 2,13 no remanescente florestal/período chuvoso. Correlacionando a diversidade dos dois fragmentos estudados pode-se observar diferença significativa ($T= 1.19$; $p<0,001$). Os resultados indicaram que os fragmentos revelam diferenças de abundância e diversidade para coleópteros, mostrando que a perturbação antrópica pode explicar o número reduzido de famílias amostradas em ambientes antropizados se comparado com ambientes remanescentes.

Springtails (*Collembola* spp) as soil bioindicators in remnants of native forests in the Colombian Orinoco region / Estudio de colémbolos como bioindicadores del suelo presentes en relictos de bosque natural en la Orinoquia colombiana

Dayssy Anyely Duarte Nuñez¹, Olga Patricia Pinzón Florián¹, Walter García Suabita¹

¹Universidad Distrital Francisco Jose de Caldas, Bogotá, Colombia (daduarten@correo.udistrital.edu.co; opatriciap@udistrital.edu.co; walter.suabita@gmail.com)

Los colémbolos (Hexapoda) contribuyen al ciclaje de nutrientes y a la estabilidad del suelo, de allí la gran importancia ecológica que representan en la productividad primaria de los bosques. Debido a su alta sensibilidad frente a cambios provocados en el ambiente, los colémbolos se consideran como bioindicadores frente a modificaciones relacionadas con cobertura vegetal y características físicas y químicas del suelo. Con el objeto de estimar la diversidad de colémbolos en relictos de bosque natural, se hicieron muestreos con trampas Pitfall instaladas en Villanueva (Casanare, Colombia) durante la época seca y húmeda en el año 2015. Se identificó la diversidad mediante el método de número efectivo y se explicó la composición de colémbolos mediante un análisis de redundancia integrando variables dasométricas y de suelos. La colembofauna estuvo compuesta por un total de 208 individuos clasificados en 17 géneros representados en las familias Entomobryomorpha (7), Poduromorpha (5) y Symphypleona (5). Se evidenció mayor presencia de colémbolos durante la época húmeda (133) que durante la época seca (75). No obstante, el registro de géneros indicadores para ambas épocas coincidió, destacando *Ptenothrix*, *Sphyrotheca* e *Isotoma*. La composición de especies se analizó teniendo en cuenta 14 variables ambientales evaluadas, de las cuales hubo mayor significancia en la variable de suelo Nitrógeno (N). Este trabajo resalta la importancia de relictos de bosques natural en la Orinoquia colombiana para la conservación de especies clave en los ecosistemas, y a su vez el gran valor que representa la diversidad de colémbolos para la provisión de servicios ecosistémicos.

Structure and composition vegetation in *Pinus caribaea* Morelet forests and their implication for the diversity of associated bird species / Estructura y composición de la vegetación de dos pinares de *Pinus caribaea* Morelet y su relación con la diversidad de las aves asociadas

Meily Arteaga Nuñez¹
¹INAF, Pinar del Rio, Cuba (disney.martinez96@nauta.cu)

La presente investigación se realizó en la Estación Experimental Agroforestal Viñales, con el objetivo de determinar la relación entre la diversidad de aves asociadas a dos áreas de pinar, con la composición y estructura de la vegetación. Para este fin se escogió un área natural de *Pinus caribaea* y una plantación de la misma especie con la finalidad de comparar ambas, se establecieron 4 parcelas circulares en cada una, con un radio fijo de 15 m. Se inventariaron las especies vegetales presentes en cada parcela y se midió la altura y el diámetro a los árboles, así como se inventariaron las aves presentes en cada parcela en los meses de enero y febrero 2018. Tanto para la vegetación como para las aves se determinó la diversidad alfa, la estratificación vertical. Se realizó la prueba de comparación de medias Kruskal-Wallis, para determinar si existían diferencias entre los valores de riqueza y abundancia de las aves detectadas, entre los estratos y los meses muestreados. Se realizó una matriz de correlación de Spearman para determinar la relación entre las aves y las variables de la vegetación medidas. Se identificaron un total de 18 especies de aves, las cuales se agruparon en 5 órdenes, 11 familias y 16 géneros. La mayoría de las especies fueron las residentes permanentes, no existiendo diferencias significativas en relación a la riqueza y abundancia de especies entre los meses y las parcelas, existiendo entre el estrato alto con el estrato medio y bajo. Existiendo poca relación entre las variables de la vegetación medidas y las especies de aves detectadas.

Fragmentation and changes in land use in the Del Valle del Magdalena Medio dry tropical forest in Tolima, Colombia / Fragmentación y cambio de uso del suelo en un bosque seco tropical del Valle del Magdalena Medio, Tolima Colombia

Fabian Hernandez¹, Angie Montañez¹
¹Universidad Distrital Francisco José de Caldas, Bogota, Colombia (faahernandez@correo.udistrital.edu.co; avmontanezs@correo.udistrital.edu.co)

Implementando tecnologías GIS y elementos de la ecología del paisaje, se estudiaron los patrones espaciales y factores determinantes en el cambio del paisaje de un bosque seco tropical ubicado en el valle del Magdalena en los municipios de Falán, Armero, Honda y Mariquita. Tomando datos de imágenes satelitales de los años 1988, 2003, 2014 y 2018, se utilizaron diferentes índices de composición y configuración de paisaje asociados a la cobertura de la tierra para analizar las características de pérdida de masa boscosa en esta zona. Los resultados muestran una disminución aproximada de 2600 hectáreas para la cobertura de bosque, evidenciando un cambio hacia una matriz de paisaje compuesta en su mayoría por mosaicos de pastos junto con cultivos de maíz y algodón. Se presentó una reducción de los parches de bosque seco en términos de tamaño, área núcleo y aumentó del efecto borde, lo que está generando alteraciones en las condiciones microclimáticas del bosque, la funcionalidad ecosistémica y servicios ecosistémicos. La pérdida de cobertura boscosa responde a las dinámicas naturales, económicas y sociales presentes en la zona de estudio, siendo la expansión de la frontera agrícola y el establecimiento de ganado los principales factores que han modificado la matriz original del paisaje y afectando la biodiversidad.

D8p: FOREST ENVIRONMENT

Aquatic macroinvertebrates: indicators of conservation and ecological restoration processes in a disturbed Andean watershed in Zapatoca, Colombia / Macroinvertebrados acuáticos: indicadores de procesos de conservación y restauración ecológica en una cuenca andina perturbada en Zapatoca (Colombia)

Vanesa Jaramillo Rodríguez¹, Jaime Polanía¹, Carolina Serna²
¹Universidad Nacional de Colombia, Medellín, Colombia; ²Universidad Nacional de Colombia sede Medellín, Medellín, Colombia (vjaramillor@unal.edu.co; jhpolaniav@unal.edu.co; csernac@unal.edu.co)

La restauración ecológica brinda servicios ecosistémicos, que incluyen la provisión de agua para consumo humano. Los macroinvertebrados acuáticos, sensibles a perturbaciones y contaminación antrópica, pueden revelar el estado de tal recurso; además, su presencia/ausencia y su consecuente abundancia y/o comportamiento reflejan diversos factores sobre su hábitat. En Zapatoca (Santander) varios cauces han sufrido durante décadas el impacto de la producción agrícola y ganadera. La cuenca El Poleo se ha integrado a la Reserva Natural de la Sociedad Civil "La Montaña Mágica-El Poleo", se encuentra desde hace más de un lustro en un proceso de restauración, por lo cual se propuso evaluar el grado de perturbación de dos afluentes mediante transectos de 100 m. Allí se midieron parámetros fisicoquímicos e hidrológicos y, con una red Surber, se tomaron muestras biológicas. El transecto en restauración mostró representantes de *Progomphus* (Odonata), *Phylloicus* y *Farrodus* (Ephemeroptera), y *Anacroneturia* (Plecoptera), así como la calidad de bosque de ribera (QBR=75) y diversidad de hábitats fluviales (IHF=67), representaron una calidad biológica aceptable. En contraste, el transecto del sitio perturbado mostró una vegetación de ribera disminuida (QBR=45), con presencia de familias del orden Diptera: Chironomidae, Tipulidae y Simuliidae, las cuales son tolerantes a la contaminación y típicas de zonas alteradas. Las actividades agrícolas persistentes impactan negativamente la diversidad y las interacciones bióticas de las comunidades bentónicas. El hábitat circundante determina la calidad biológica e hídrica de estas quebradas andinas, por lo cual acciones de restauración resultan importantes para alcanzar óptimos ecológicos.

Structure and successional dynamics in atlantic rainforest fragments with different disturbance histories in the South Central region of São Paulo State, Brazil

Deicy Carolina Lozano Sívicas¹, Celso Anibal Yaguana Puglla¹, Felipe Góes de Moraes¹, Renata Cristina Batista Fonseca¹, Iraê Amaral Guerrini¹
¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Botucatu, Brasil (caroladeicylo@hotmail.com; anibalya@hotmail.com; felipe.goes.de.moraes@gmail.com; rfonseca@fca.unesp.br; irae.guerrini@unesp.br)

The Atlantic Rainforest is one of the world hotspots and is under pressure from deforestation and fragmentation. The aim of the study was to characterize vegetation structure and natural regeneration in Atlantic Rainforest fragments with different disturbance histories. The sampling areas were: area A, B, E, G, selective logging of wood; area C, tree fall and landslides; area D, conserved and, area F, pasture until the 80s. In each area were allocated plots (5 x 5 m) to tree layer (DBH <5 cm) and the regenerating layer (5 x 1 m), totaling 90 plots in all seven areas. Phytosociological parameters, successional stage, dispersion syndromes and the Shannon-Wiener (H') diversity indexes, Jaccard similarity (Cj), and Pielou (J) fairness were calculated. The seven sampled areas are similar in relation to floristic composition of the tree and regenerating layer. There is greater similarity between areas D, E, G and A. The differences found were in the

forest structure (density and dominance). The families with the highest diversity were Fabaceae, Euphorbiaceae and Ochnaceae. The highest H' occurred in *area A* and *C*. *Area D* (lower degree of disturbance) showed low H' , indicating a higher equilibrium. Although *area F* has been pasture in the past, it is noticeable that it presented good recovery capacity when compared to *area D*. *Area A* presented the largest ecological group of species, such as *Trichilia elegans* and *Trichilia clausenii*. Zoocoria was the predominant dispersion syndrome for the species studied. This information can be used in planning programmes of conservation.

Integrated management of watersheds and ecosystem services: synergistic focuses of forest adaptation to climate change / Gestión integrada de cuencas hidrográficas y servicios eco-sistémicos: enfoques sinérgicos de adaptación forestal al cambio climático

Samuel Francke¹

¹Corporación Nacional Forestal Conaf, Santiago, Chile (samuel.francke@conaf.cl)

La gestión integrada cuencas hidrográficas representa un enfoque viable y sostenible, que contempla en lo central la potenciación de los servicios eco-sistémicos y servicios del bienestar humano, mediante medidas tipo buffer de amortiguación de impactos, medidas facilitadoras de la restauración de ecosistemas/cuencas hidrográficas y medidas complementarias adaptativas institucionales e instrumentales de tipo legal, reglamentarias y normativas. Las opciones de adaptación con medidas “buffering” (amortiguación) en cuencas hidrográficas y ecosistemas alterados medidas para “facilitadoras” (restauradoras de ecosistemas y cuencas hidrográficas) para re-direccionar la evolución de ecosistemas y cuencas hidrográficas hacia nuevos estadios y adaptables a las condiciones dinámicas cambiantes. Se necesitan enfoques flexibles y diversificados en función de la incertidumbre. El Modelo “ABE” de adaptación basada en ecosistemas implica el Manejo Sostenible de Recursos Naturales, la Gestión Integrada de Cuencas Hidrográficas, el manejo forestal sostenible, la Conservación en Áreas Silvestres, la Restauración de Ecosistemas, el Ordenamiento Territorial Sostenible, la Reducción de Riesgos de desastres y el mejoramiento del bienestar humano, entre otros aspectos. La implementación de los instrumentos del Ministerio de Agricultura (MINAGRI) por un monto de inversión anual del orden de US\$ 150 millones y su focalización debieran reorientarse en suelos y cuencas hidrográficas prioritarias, críticas y vulnerables conjuntamente con la aplicación de principios rectores como: la multisectorialidad, la integralidad, la transversalidad, la mancomunidad y participación de los actores, lo que permitirá enfrentar sosteniblemente los desafíos de la adaptación y mitigación frente a escenarios variables de cambio climático.

Planting trees in a rural area of the Cerrado: the impact on evapotranspiration / Influência do plantio de árvores em área rural do Cerrado sobre a evapotranspiração

Bruno Adorno¹ , Sybelle Barreira¹, Manuel Ferreira¹, Gabriel Veloso¹

¹Universidade Federal de Goiás, Goiânia, Brazil (brunoadorno@ufg.br; sybelle.barreira@gmail.com; mferreira.geo@gmail.com; gabrielveloso.geo@gmail.com)

O presente estudo buscou avaliar a influência do plantio de árvores em áreas rurais no Cerrado sobre a evapotranspiração, considerando seu papel como serviço ecossistêmico dentro do ciclo hidrológico. Definiu-se como área de estudos a fazenda Entre Rios, integrante do projeto Biomas no Distrito Federal, e sua vizinhança em dois períodos: antes e depois do plantio de árvores para fins comerciais ou de restauração. Utilizaram-se imagens Landsat dos dias 04/11/2008 e 21/09/2015 para o mapeamento da cobertura do solo da própria área da fazenda e de sua vizinhança. A partir disso regiões onde se detectaram mudanças de cobertura e uso do solo, ao se compararem os resultados para os dois períodos, foram selecionadas e avaliadas quanto o comportamento da evapotranspiração, calculada a partir do algoritmo SEBAL aplicado no sensoriamento remoto das imagens. Observou-se que áreas de agricultura e solo exposto convertidas em florestas plantadas sofreram aumento na evapotranspiração total. O contrário aconteceu em: áreas de florestas perenifólias ou semidecíduas convertidas em pastagens; áreas de savanas ou outras fitofisionomias de Cerrado convertidas em pastagens; e em qualquer tipo de cobertura do solo recém queimado. Na fazenda, os diversos plantios de árvores com apenas 2,5 anos de idade, onde antes se praticava agricultura, promoveram uma tendência no aumento da evapotranspiração. Confirmou-se, assim, a influência do plantio de árvores para o aumento da evapotranspiração local durante a estação seca e sugere-se mais estudos sobre até que ponto isso é benéfico ou não, considerando áreas originárias de diferentes fitofisionomias do bioma Cerrado.

Ecological analysis of bird fauna in the Pedro Antonio Pineda Tropical Forest Center in the lower Calima River Watershed in Buenaventura, Colombia / Análisis ecológico de la avifauna del Centro Forestal Tropical “Pedro Antonio Pineda”, en la cuenca baja del río Calima (Buenaventura, Colombia)

Stefany Patiño Forero¹ , Camila Martínez Páez¹ , Miguel Ángel Quimbayo Cardona¹ 

¹Universidad del Tolima, Ibagué, Colombia (spatinof@ut.edu.co; aquinadie23@gmail.com; miguelq@ut.edu.co)

El Centro Forestal Tropical (CFT) “Pedro Antonio Pineda” localizado en el municipio de Buenaventura (Valle del Cauca, Colombia), se caracteriza por la realización de estudios con participación directa de comunidades afrodescendientes orientadas al manejo sostenible del bosque secundario desde la Facultad de Ingeniería Forestal de la Universidad del Tolima desde hace más de 40 años. Entre los años 2013 y 2017 se realizaron observaciones de la avifauna, en los meses de abril y septiembre, durante ocho días. Se registró un total de 562 individuos, pertenecientes a 166 especies, 20 órdenes y 40 familias taxonómicas. Los órdenes más abundantes fueron Passeriformes (62.6%) y Apodiformes (8.3%). Las familias más abundantes fueron Thraupidae (17.3%), Tyrannidae (8.9%), Trochilidae (7.1%) y Thamnophilidae (6.5%). El 45% de las especies son insectívoras, 30% frugívoras y 8% granívoras y nectarívoras. El estrato de forrajeo más utilizado fue sotobosque (49%), seguido por dosel (26%); 89% presentan anidamiento individual y 11% presentaron apoyo entre individuos de la misma especie; 47% de las especies anduvo en bandadas (26% mixta y 21% monoespecífica), 42% comportamiento solitario, y 10% comportamiento de congregación. El 82% residentes y el 18% en estatus migratorio. Una especie está en LC, una especie en VU y tres especies en NT. El total de especies equivale al 8.6% de las aves de Colombia y 21.3% de las aves del Chocó biogeográfico. A pesar del bosque encontrarse en estado sucesión natural, actúa como hábitat para 22 especies casi endémicas y para especies que requieren de cavidades de árboles para anidación.

Accuracy of digital elevation models applied to mapping permanent preservation areas / Precisão de modelos digitais de elevação aplicados ao mapeamento de áreas de preservação permanente

Edézio Miranda¹, Bruno Mendonça¹

¹Universidade Federal Rural do Rio de Janeiro, Seropédica, Brazil (edezio.florestal@gmail.com; brunoafmendonca@gmail.com)

O uso de modelos digitais de elevação (MDE) de bases de dados de domínio público disponíveis não apresentam informações precisas para a delimitação de Áreas de Preservação Permanente (APP) em encostas, sendo necessário validá-los para serem utilizados no mapeamento de áreas com alta declividade. Deste modo, o objetivo desse trabalho foi criar uma estratégia de diferentes rotinas de pré-processamento para o mapeamento de APP maiores que 45° utilizando MDEs

disponíveis gratuitamente (IBGE, ASTER GDEM, SRTM e TOPODATA), validados com referência dos dados LIDAR. A área do estudo está localizada no assentamento São Pedro, município de Japeri - Rio de Janeiro sendo utilizado o softwares Notepad++ e Fusion para o processamento dos dados LIDAR e o ArcGIS 10.2 para as demais etapas. Foram reduzidos os tamanhos das células da resolução padrão dos modelos para 10 e 5 metros e comparado as áreas encontradas com a declividade de 45° e 30° para APP de encosta. Os resultados mostram uma área de 438 ha de APP considerada verdade de campo encontrada pelos dados de referência, seguida da redução da resolução dos pixels com a declividade do dados testados, sendo determinantes para representar a declividade do terreno. A validação dos dados ASTER GDEM apresentou o melhor resultado dentre as demais bases avaliadas, tendo sido encontrando uma área de 412,24ha com resolução de 10 m e 30° de declividade, representando 94% da área encontrada pela base de referência. Os dados IBGE apresentaram valores significativos encontrando 387,32 ha, dados SRTM e TOPODATA não apresentaram valores confiáveis.

Assessing the dynamics of flora composition in a forest fragment after fire in Viçosa, Minas Gerais, Brazil / Avaliação da dinâmica da composição florística em um fragmento florestal após ocorrência do fogo em Viçosa, MG (Brasil)

Fábia Maria dos Santos Souza¹, Cintia Virginia Mieko Souza Sekiya¹, Aldo Teixeira Lopes¹, Danusia Amorim Souto¹, Fillipe Tamiozzo Pereira Torres¹, Lydiane Lucia de Sousa Bastos¹

¹Universidade Federal de Viçosa, Viçosa, Brazil (fabiasantos93@hotmail.com; cintiasekiya@hotmail.com; aldo_uvf@hotmail.com; danusiasouto@gmail.com; torresftp2@gmail.com; lbastos@ufv.br)

A ocorrência do fogo pode influenciar na estrutura, composição da floresta e sucessão vegetal, tornando fundamental entender como as comunidades naturais se regeneram após sofrer esse tipo de perturbação. Esse estudo objetivou analisar as mudanças ocorridas em nível de composição florística e estrutura da comunidade vegetal de um fragmento de Floresta Estacional Semidecidual após quatro anos da ocorrência do fogo de baixa intensidade. Foi realizado o censo florestal de todos os indivíduos com Circunferência Altura do Peito ≥ 15 cm em uma área de 0,6 hectares, sendo 0,3 ha na área queimada (T1) e 0,3 ha na área não queimada (T2). A diversidade florística nas duas áreas foi considerada alta, revelada pelos índices de Shannon (1,00 T1 e 1,19 T2) e de concentração de Simpson (0,166 T1 e 0,129 T2). Além disso, o índice de Pielou (0,29 T1 e 0,31 T2) e de Jaccard (0,37) revelou alta uniformidade e similaridade nas duas áreas. A diversidade florística da regeneração natural nas duas áreas foi considerada média, revelada pelos índices de Shannon, (0,85 T1 e 0,65 T2) e de concentração de Simpson (0,33 T1 e 0,46 T2). O índice de Pielou (0,25 T1 e 0,21 T2) revelou que a uniformidade e equitabilidade nas duas áreas podem ter sido alteradas pelo fogo. O índice de Jaccard (0,20) indicou baixa similaridade. Portanto, a ocorrência do fogo de baixa intensidade não alterou a composição florística dos indivíduos adultos, porém a regeneração está acontecendo com importantes mudanças na sucessão.

The impact of fire on the soil seed bank in a fragment of semideciduous forest in Viçosa, Minas Gerais, Brazil / Impacto dos incêndios florestais sobre o banco de sementes do solo em um fragmento de Floresta Estacional Semidecidual em Viçosa, MG

Fábia Maria dos Santos Souza¹, Danusia Amorim Souto¹, Aldo Teixeira Lope's, Cintia Virginia Mieko Souza Sekiya¹, Fillipe Tamiozzo Pereira Torres¹, Lydiane Lucia de Sousa Bastos¹

¹Universidade Federal de Viçosa, Viçosa, Brazil (fabiasantos93@hotmail.com; danusiasouto@gmail.com; aldo_uvf@hotmail.com; cintiasekiya@hotmail.com; torresftp2@gmail.com; lbastos@ufv.br)

O banco de sementes do solo é um importante reservatório de sementes de espécies nativas, matéria orgânica, insetos, mesofauna e microfauna do solo, microrganismos e nutrientes. Em decorrência dos intensos impactos que vêm sofrendo os ecossistemas, aumentou-se o interesse em conhecer o papel do banco de sementes do solo na determinação da composição florística de áreas alteradas. Na área de estudo em que a presente pesquisa foi desenvolvida houve um incêndio de baixa intensidade, mesmo assim houve evidências de significativas diferenças na composição florística da comunidade de espécies lenhosas, com alta predominância de *Cecropia* sp. na área queimada em comparação com área não queimada. O objetivo deste trabalho foi verificar a influência do fogo sobre a estrutura do banco de sementes em um Fragmento Estacional Semidecidual Viçosa, MG. A germinação do banco do solo da área queimada há quatro anos não foi comprometida pelo incêndio de baixa intensidade, com número de sementes germinadas igual à da área não queimada.

Forest fires and resin tapping: anthropogenic factors affecting subtropical pine forests

Peter Fule¹, Satish Garkoti², Rajeev Semwal²

¹Northern Arizona University, Flagstaff, USA; ²Jawaharlal Nehru University, New Delhi, India (pete.fule@nau.edu; sgarkoti@yahoo.com; rajeevsem@gmail.com)

Tropical and subtropical coniferous forests provide critical ecosystem services but the effects of anthropogenic disturbance factors have not received sufficient scientific attention. We studied forest disturbance using tree-ring methods in a chir pine (*Pinus roxburghii*) forest of Uttarakhand, India. We developed a multi-century tree-ring chronology and crossdated fire scars from trees at three sites near rural villages. Fires were highly frequent but of low severity, so most mature trees of this thick-barked species survived numerous burns. However, intensive resin tapping interacted with surface fire by allowing fire to burn into the wood of tapped trees, damage the cambium, and weaken the structural integrity to the point of breakage and mortality. The effects of anthropogenic fire and resin-tapping merit further investigation at landscape to regional scales. We suggest developing a research network in Himalayan to East Asian coniferous forests to track interacting disturbances and their ecological and social implications.

Tree-related microhabitat co-occurrences: towards easier monitoring?

Laurent Larrieu^{1,2}, Alain Cabanettes¹, Benoit Courbaud³, Michel Goulard⁴, Daniel Kraus⁵, Thibault Lachat^{6,7}, Jörg Müller^{6,7}, Yoan Paillet⁸, Andreas Schuck⁹, Jonas Stillhard¹⁰, Miroslav Svoboda¹¹

Pesq. flor. bras., Colombo, v. 39, e201902043, Special issue, p. 1-768, 2019

A Tree related Microhabitat (TreM) is a distinct, well-delineated morphological singularity occurring on living or standing dead trees, that constitutes a crucial substrate or life site for species. TreMs are widely recognized as key features for biodiversity. The current TreM typology identifies 47 TreM types according to both to their morphology and associated taxa. These TreMs have been pooled into 15 groups then seven forms, in order to provide a range of accuracy and speed of use for different typology users. Thus, forest managers may use the form level during tree marking to ensure a TreM diversity at the stand scale while researchers should use the type level for recording TreMs in biodiversity assessment. Another approach to simplifying TreM recording in routine management job may be to use co-occurrence pattern to reduce the number of TreMs to be observed. From a large international TreM database, we evaluated both the significance and the magnitude of TreM co-occurrence on living trees for 11 TreM groups. We highlighted 33 non-random and positive co-occurrences for broadleaves while only nine for conifers. Bark loss, Rot-hole, Crack and Polypore showed the highest number of positive co-occurrences with the other TreMs for broadleaves (N=8) while bark loss (N=4) did for conifers. We found negative co-occurrences only for conifers: Exposed Heartwood with Dendrotelm and Sap run. Among a set of three variables tested for their positive contribution to significant co-occurrences, dbh was the most consistent.

The influence of riparian forests on surface water: a case in Southern Atlantic Forest biome, Parana, Brazil

Elenice Fritzsos¹, Luiz Eduardo Mantovani²

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (elenice.fritzsos@embrapa.br; lem@ufpr.br)

The stream water quality depends on the presence of riparian forest which acts as a filter to protect surface waters in watersheds. We have worked with 1,300 water samples and according with the following parameters: turbidity, color, pH, conductivity, dissolved solids, alkalinity, nitrate, chloride. Samples were collected in 33 field experiments over six contiguous hydrographic basins. These basins are located in the Southern Atlantic Forest biome, Humid Subtropical Climate of Altitude, ecosystem of Mixed Ombrophilous Forest, Parana, Brazil. The land use map and stream conflict map were drawn. The stream conflict map was drawn taking into account the fluvial PPAs (permanent preservation areas). This study has found 5 main land use typologies: natural forest, forestry, buildings, agriculture and pasture. Conflicts of PPAs were defined when natural riparian forest was absent and replaced by another typology, considering a 5-meter strip along the stream's banks, in compliance with the Brazilian law applied to this local situation. Multiple correlation analyses were performed taking into account water quality parameters, conflict over fluvial disputes, and land use. Our conclusion is that amount all streams studied, 51% of them, contain with the Brazilian law concerning fluvial PPAs. The water quality changes according to different seasons and also with the conflicts of fluvial PPAs in some typologies (agriculture, buildings and pasture). However, changes in water quality have not being found when taking to account different land uses, as well as precipitation events. This work confirms the close connection between occupation of riparian areas and surface water quality.

An assessment of the anthropic activities effects on canopy layer attributes in subtropical Atlantic Rainforest

Débora Lingner¹, Arthur Rodrigues², Laio Oliveira¹, André de Gasper¹, Alexander Christian Vibrans¹

¹Fundação Universidade Regional de Blumenau, Blumenau, Brasil; ²Universidade Federal do Rio Grande do Sul (UFRGS), Porto Alegre, Brasil (deboravanessa.ef@gmail.com; rodrigues.arthur.v@gmail.com; laiozoliveira@gmail.com; algasper@furb.br; acv@furb.br)

Subtropical forests are predominantly composed of second-growth remnants as a result of degradation processes caused by human-driven disturbances. We aimed to investigate the effects of anthropic disturbances on forest attributes of the canopy layer (DBH ≥ 10 cm), namely: aboveground biomass, rarefied species richness, and proportion of individuals of pioneer and threatened species. The study was carried out in the Brazilian subtropical Evergreen Rainforest and data from 186 systematically distributed 0.4 ha sample plots were used. The effects of anthropic disturbances on the forest attributes were modeled through ordinary least squares (OLS) and geographically weighted regression (GWR) models. Yet, a path analysis was applied to investigate if topographic heterogeneity (TH; standard deviation of altitude) influences indirectly the forest attributes via anthropic disturbances. The GWR models outperformed the OLS models in predicting the proportion of individuals of pioneer and threatened species. We showed that anthropic disturbances at different spatial scales – landscape, forest patch, and sample plot – may affect the forest attributes. Agriculture area was related to stands with greater biomass in landscapes with large forest remnants, while pasture area was related to stands with lesser species diversity and more exposed to proliferation of pioneer species. We identified stands with great proportion of threatened species exposed to risk factors, such as long road networks and selective logging. TH showed to limit the expansion of pasture areas over the landscape, affecting indirectly the species richness. Evidences were found regarding biotic homogenization and variation in forest productivity resulting from forest fragmentation and edge effects.

Human-induced edge influence on vegetation in boreonemoral forests

Līga Liepa¹, Inga Straupe¹

¹Latvian University of Life Sciences and Technology, Jelgava, Latvia (liga.liepa@llu.lv; inga.straupe@llu.lv)

During the last centuries European forest landscape has changed from mostly natural conditions of forest growth to the dominance of production forests. For forest management, it is important to understand the predictable influences on set-asides adjacent to post-harvesting areas. We studied temporal response on vegetation in black alder (*Alnus glutinosa*) swamp woods in boreonemoral forests in terms of the influence of edge after post-harvesting in adjacent forest stands. Forest edges have been well studied in nemoral and tropical forests, but less is known about the vegetation response toward human-induced edges in boreonemoral and boreal forests. We surveyed data on forest vegetation at black alder swamp woods adjacent to edges in a different age chronosequence (<10, 20–40 and ≥ 41 years post harvesting) was used to test how dynamics of edge effects changes during the time. We tested this by setting permanent sample plots from forest stand edge to interior, then vegetation survey at set distances from stand edge. The main results showed that even more than 41 years after harvesting the magnitude of edge influence persists on the herbaceous layer and rare epiphytic lichen species. This result highlights the need to consider edge effects in sustainable forest principles for set-asides where nature conservation has been prioritized.

A Belize forest landscape and its management

Nicholas Brokaw¹, Sheila Ward²

¹University of Puerto Rico, San Juan, Puerto Rico; ²Mahogany for the Future, Inc., San Juan, Puerto Rico (nvbrokaw@ites.upr.edu; sheila.emily.ward@gmail.com)

Permanent forest sample plots provide information on landscape patterns in space and time of tree composition, growth, and population and community dynamics. We present a 25-year study of trees ≥ 10 cm DBH in four 1-ha plots in old-growth, subtropical moist forest in Northwest Belize (Rio Bravo Conservation and Management Area, managed by Programme for Belize). The four plots are in *upland mesic* forest, *upland dry* forest, *palm/ hardwood* forest,

and riparian forest, respectively, and are within 12 km of each other. At the first census (1991) the number of stems ranged from 374 to 700 among the four plots, the number of species from 45 to 59. In each plot five to six species accounted for 50% of stems, while 15 to 19 species were represented by only one stem. Thirty-three species, of 118 total over all four plots, were represented by just one stem over all plots. Only 13 species were found in all plots. Growth and stem turnover were relatively high in riparian and palm/hardwood forests and low in upland forests. Parts of the upland forests were exceptionally slow growing and stable. This forest landscape is a mosaic of forest types differing in both composition and dynamics. Based on our results, and using a landscape perspective, we suggest actions for use and protection of this forest reserve.

D8r: FOREST BIODIVERSITY IN THE FRAMEWORK OF GLOBAL CHANGE AND THE ROLE OF LANDSCAPE

Saracá-Taquera National Forest: a case study of native terrestrial mammals in Pará, Brazil

Fabiano Melo^{1,2}, Analice Calaca², Michel Faria³, Diego Silva²

¹Universidade Federal de Viçosa, Viçosa, MG, Brasil; ²Universidade Federal de Goiás, Jataí, GO, Brasil; ³Universidade do Estado de Minas Gerais, Carangola, MG, Brasil (fmelo@ufv.br; analicecalaca@gmail.com; mchelfaria@uemg.br; diegoafonsosilva@gmail.com)

One of the most diverse mammal assemblage inhabits the Amazonian rainforest, not found anywhere around the World, therefore this species richness is still poorly understood. Many studies including inventories or monitoring are important for the comprehension of the ecology of many species and still provide basic data for conservation actions. During two decades of sampling in the Saracá-Taquera National Forest, we recorded at least 72 species of small - nonvolant, medium, and large mammals, considering 30 families in 10 orders. We also found 29 endemic species to the Amazon forest, some of them were classified as endangered. In summary, we found one of the most mammal species richness recorded in the Amazonian basin, probably greater than that already found in other sites elsewhere, indicating high levels of diversity in a biogeographic narrow scale. Our findings indicate the importance of this national forest for the maintenance of the mammalian fauna and highlight how important is the sustainable use of the forest, especially when we have to conciliate the rational exploitation and the protection of the biodiversity.

Changes in natural resources and the effect on landscapes in important tourist areas in Southern Chile / Alteración de los recursos naturales y su efecto en el paisaje en zonas de interés turístico al sur de Chile

Gastón Vergara¹, Miguel Ángel Herrera²

¹Universidad Austral de Chile, Valdivia, Chile; ²Universidad de Córdoba, Córdoba, Spain (gastonvergara@uach.cl; mc1hemam@uco.es)

El plan de acción propuesto al sur de Chile en el territorio de Panguipulli, Región de los Ríos, tiene como objetivo promover la actividad turística en la zona, diversificación de la economía local, generación de empleo y la valorización de los recursos naturales, a través de estrategias competitivas de tipo pública y privada, siguiendo las tendencias del mercado nacional e internacional. Sin embargo es necesario establecer que la intervención humana genera entropía que influye en el cambio climático y el calentamiento global, acciones que repercuten directamente en las características del territorio, generando transformación, alteración del paisaje y desaparición de recursos naturales indispensables para el desarrollo turístico. El objetivo de la presente investigación es revelar y cuantificar las transformaciones de los recursos naturales que ha sufrido la zona de interés turístico (ZOIT) de Panguipulli. Para el análisis de los cambios de uso del suelo en la zona, se utilizaron imágenes satelitales LANDSAT y técnicas geoestadísticas. Determinando alteraciones importantes en el cambio uso del suelo, principalmente el aumento de plantaciones forestales industriales, disminución de las praderas y del bosque nativo, de gran valor endémico que alberga sistemas de alta biodiversidad.

Exploring indicator species for evaluating forest degradation in Andean forests in Peru

It has been recognized that as well as deforestation, forest degradation has a great impact on forest ecosystems at global scale. However, the methodological approach is still not fully developed to appropriately evaluate the impact of forest degradation on forest structure and function. Utilizing indicator species has a potential to represent levels of forest degradation. We aimed to explore indicator species for forest degradation in relation to forest types (primary forest or secondary forest), forest structure and species composition. We conducted field survey to collect ground-based forest inventory data in Cusco region, Peru. Our study area covers upland tropical forest connecting to Amazon forest and Andean montane forest (ranged from 600 m to 3500 m a.s.l.). Using indicator species analysis, we found 12 tree species at low elevation sites (600 to 1000 m), four tree species at mid elevation sites (1000 to 2400 m) and one tree species at high elevation sites (> 2400 m). Not all, but some of the detected indicator species corresponded to primary/secondary forest classification of the stands based on field observation. Our results suggest that indicator species has a potential to evaluate current condition of forest degradation on a regional scale in the Andean region, but its availability might vary with elevation zone.

Tree strata structure in an ecotone among Amazon Forest types: a comparative study

Aline Canetti¹, Evaldo Muñoz Braz², Patricia Póvoa de Mattos², Afonso Figueiredo Filho³

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Universidade Estadual do Centro-Oeste do Paraná, Irati, Brasil (alinecanetti@gmail.com; evaldo.braz@embrapa.br; patricia.mattos@embrapa.br; afgfilho@gmail.com)

As it is an ecotone composed by two forest types, high composition complexity is expected in the Transitional Amazonian Forest. Thus, we aimed to describe the structural dynamics of the Transitional Amazonian Forest in Mato Grosso State, Brazil, and to evaluate whether the most abundant tree species present a structural pattern. Forest analysis occurred with six 100% inventories data considering all trees with 1.30 m diameter above the ground ≥ 40 cm, totalizing up to 5 thousand ha. The study areas were compared in terms of tree density, number of species and importance value of the most abundant species. The Morisita index and the cluster analysis tested the forests similarity. We also evaluated importance value of species in the upper and middle strata. Differences between study areas were detected regarding tree density and number of species. However, the forests presented more than 75% similarity and were grouped in 3

structural clusters. Some species showed alternations of dominance in the middle and upper strata. Although it is an ecotone, the trees had a structural pattern, where the same species dominate large areas, allowing us to apply results in a huge scale of approach.

Conservation of biodiversity in Boreonemoral Forests

Līga Liepa¹, Inga Straupe¹, Olga Mieziņa¹, Āris Jansons², Edgars Dubrovskis¹

¹Latvia University of Life Sciences and Technologies, Department of Silviculture, Jelgava, Latvia; ²Latvian State Forest Research Institute "Silava", Salaspils, Latvia (liga.liepa@llu.lv; inga.straupe@llu.lv; olga.mieziņa@llu.lv; aris.jansons@silava.lv; edgars.dubrovskis@llu.lv)

Boreonemoral forests have distinct floral and faunal communities and they provide multiple ecosystem services. Extensive tracts of boreonemoral forests are actively managed for timber production, but actions aimed at increasing timber yields may also affect other forest functions and services. An essential component of forest certification schemes (e.g. FSC) is that landowners should voluntarily set aside forest stands for biodiversity; maintain ecological quality in EU protected habitats and leave retention trees. It is now unclear how functional are all these conservation tools in the context of ecological quality and its linkage with land-use intensity. The aim of this study is to evaluate how existing forest conservation tools contribute to the conservation of biological diversity and the provision of ecosystem services. In order to investigate the relative roles of different types of conservation tools for sustainable forest management, field data were collected on ecological quality of 40 study areas in Latvia (including vegetation assessment, diversity of structural features and presence of rare species). The results allow developing cost-efficient tools, used in the sustainable management of forests in the boreonemoral biome. These preferences can be important knowledge to sustainable forest management complexity and policies balancing economic, ecological and social interests in the production forest landscape. Acknowledgments: This study was financially supported by the ERDF Post-doctoral Research Support Program (project nr.1.1.1.2/16/1/001) Research application "Balancing ecological interests with increasing demands for natural resources in production forests" (nr.1.1.1.2./VIAA/2/18/294).

Analysis of fragments of the Atlantic Forest biome in municipalities within the Recife micro-region: a focus on environmental management / Análise de fragmentos florestais do Bioma Mata Atlântica em municípios situados na Microrregião do Recife: um enfoque na gestão ambiental

Marília Regina Costa Castro Lyra¹, Felipe Pinto Guimarães^{2,1}, Jurandir Barbosa Cavalcanti Junior^{3,1}, José Antônio Aleixo da Silva⁴

¹Instituto Florestal de Pernambuco, Recife, Brasil; ²Embrapa Solos, Recife, Brasil; ³Adagro, Recife, Brasil; ⁴Universidade Federal Rural de Pernambuco, Recife, Brasil (mariliarcastro@uol.com.br; lipegui@yahoo.com.br; jbcengenharia@gmail.com; jaaleixo@uol.com.br)

A fragmentação da Mata Atlântica, motivada por um intenso processo de transformação da paisagem, tem tornado mais difícil a tarefa de preservar o bioma. Neste contexto, os instrumentos de gestão ambiental surgem como alternativa para viabilizar a conservação ambiental de fragmentos florestais em ambientes cujo uso antrópico predomina. A análise da paisagem apoiada com recursos do sistema de informações geográficas (SIG) é de suma importância na caracterização dos fragmentos florestais e respectivo planejamento ambiental. O trabalho baseou-se na análise de fragmentos florestais situados na Microrregião do Recife, para o ano de 2011 e de 2016. As métricas de ecologia utilizadas para caracterizar os fragmentos florestais e a verificação da significância estatística das diferenças observadas para as duas épocas propostas permitiu constatar que houve efetiva diminuição no tamanho dos fragmentos sem, contudo causar alteração expressiva mancha de vegetação geral. Sob o enfoque da gestão ambiental, os fragmentos florestais remanescentes mais expressivos estavam submetido a proteção legal. Fragmentos de supressão observados demandam ações de gestão ambiental orientada de acordo com a situação político-organizacional do município e o contexto socioeconômico do local. Fragmentos ligados a recomposição da vegetação indicaram práticas de gestão ambiental focadas na minimização do potencial degradador dos impactos antrópicos. Fragmentos ligados a recomposição da vegetação indicaram práticas de gestão ambiental focadas na minimização do potencial degradador dos impactos antrópicos.

Reflections on managing land for conservation / Reflexões sobre a gestão do território para a conservação

Mariana Beauclair¹, Paulo Fevrier¹, Marie Ikemoto¹, Barbara Schmidt^{1,2}, Vitória Araujo^{1,2}, Graziela Genovez^{1,3}

¹Instituto Estadual do Ambiente do Rio de Janeiro, Rio de Janeiro, Brazil; ²Universidade Federal Fluminense, Niterói, Brasil; ³Universidade Federal Rural do Rio de Janeiro, Seropédica, Brasil (maribo.inea@gmail.com; paulofevrier@gmail.com; ikemoto.inea@gmail.com; batrouche4@gmail.com; vitoriaaraujo@id.uff.br; grazielamartinsamoufrjr@gmail.com)

O planejamento para a conservação em geral se baseia em dados geobiofísicos e tem como objetivo o subsídio a ações predominantemente no espectro do comando e controle, como a criação de unidades de conservação ou outros instrumentos de ordenamento territorial. O custo (político, social e econômico) de implementação dessas ações é alto, o que limita sua adoção e dificulta o alcance dos objetivos pretendidos. A inclusão dos fatores políticos e sociais no planejamento – conjuntamente com os geobiofísicos – pode possibilitar o desenvolvimento de projetos, programas e ações cooperativas e de suporte, que conjuguem o atendimento a demandas coletivas (globais, nacionais ou regionais) com as demandas locais ou até individuais. Embora essas ações possam ter um custo semelhante ou até maior do que as de comando e controle no início, tem um potencial maior de se sustentarem ao longo do tempo e se difundirem no território sem a ação direta do Estado. A transição para esse novo paradigma – que não necessariamente substitui o existente, mas o complementa – ainda necessita de maior sustentação política, normativa e institucional para ser amplamente adotado como política de Estado. Essa questão será discutida com base na experiência do Projeto Conexão Mata Atlântica no Rio de Janeiro.

Deforestation and wildlife management: are elephants attracted by recently deforested areas?

Hugo Valls-Fox¹, Alessandro Fusari², Paola-Catalina Amaya-Corredor³, Marie Nourtier³, Frédérique Montfort³, Telina Randrianary⁴, Emmanuelle Richard⁵, Thomas Prin⁵, Philippe Chardonnet⁵

¹Centre de coopération internationale en recherche agronomique pour le développement (CIRAD), Montpellier, France; ²Fondation François SOMMER - Fondation Internationale pour la Gestion de la Faune, Maputo, Mozambique; ³Nitidae, Montpellier, France; ⁴Nitidae, Antananarivo, Madagascar;

⁵Fondation François SOMMER - Fondation Internationale pour la Gestion de la Faune, Paris, France (hugo.valls-fox@cirad.fr; alessandrofusari@yahoo.it; paola-catalina.amaya-corredor@etu.umontpellier.fr; m.nourtier@nitidae.org; f.montfort@nitidae.org; t.randrianary@nitidae.org; e.richard@chassenature.org; thomas.prin@chassenature.org; igf@fondation-igf.fr)

Deforestation is a major cause of wildlife decline in tropical ecosystems. The conversion of mature forest to fields by shifting cultivation leaves behind fallow lands with secondary vegetation. Paradoxically, secondary forest regrowth that provides abundant forage in comparison with mature forests can benefit some species as the African elephant (*Loxodonta africana*) but they are also attracted towards human communities and cultivations raising conservation issues. The

study was conducted in Gile National Reserve, Mozambique, an unfenced protected area composed of Miombo woodland. Among 60 elephants remaining in the Reserve, 5 individuals were equipped with GPS collars in 2014 in 2016. Deforestation was monitored by remote sensing from 1990 to 2016 and a map of forest productivity was built. To test our hypothesis, we modelled resource selection functions using the GPS data. Elephants spend about half of their time in the core area and half in the buffer zone where most of the deforestation occurs. Elephants neither prefer nor avoid pristine forest habitats and cleared between 1990 and 2005. They prefer areas cleared since 2005 where forest regrowth occurred since 2009. The areas the most selected were cleared between 2010 and 2013 and were in cultivation during the study. Shifting agriculture leads to the displacement elephants toward cultivated fields and regenerating forest vegetation thus increasing Human/Elephant conflicts. This resource selection strategy also raises conservation questions related to the Reserve management aiming at reducing deforestation. Diversity of habitats should be maintained and resource selection linked to vegetation dynamics should be further understood.

D8s: INVASIVE SPECIES IN FOREST ECOSYSTEMS, CAUSES, CONSEQUENCES, UTILIZATION AND MANAGEMENT OPTIONS

Leafcutter ants: impacts on herbaceous vegetation in South America's native temperate forests / *Hormigas cortadoras de hojas: impactos sobre la vegetación herbácea en bosques nativos templados de Sudamérica*

Julian Alberto Sabattini¹

¹Universidad Nacional de Entre Ríos, E3100AXD, Argentina (juliansabattini@hotmail.com)

Las hormigas cortadoras de hojas son consideradas consumidores dominantes de América en diferentes ambientes naturales. El objetivo fue cuantificar y evaluar la herbivoría anual de *Atta vollenweideri* sobre la vegetación en bosques nativos del Espinal Argentino. El trabajo se realizó en dos regiones de la provincia de Entre Ríos, Argentina. En ambos sitios, se seleccionaron 5 nidos, recolectándose material vegetal entre Mayo 2015 a Octubre 2017. La actividad forrajera se determinó recolectando fragmentos vegetales de hormigas cargadas en cada nido durante cinco minutos registrados cada dos horas. En laboratorio se identificaron cuatro fragmentos de material vegetal: a) monocotiledóneas graminiformes y ciperáceas, b) dicotiledóneas herbáceas y arbustivas, c) dicotiledóneas arbóreas y, d) material de desecho senescente. La biomasa total forrajada promedio por nido de *Atta vollenweideri* fue de 312 kg MS.nido⁻¹.año⁻¹. No se obtuvieron diferencias significativas entre sitios, registrando 282 kg MS.nido⁻¹.año⁻¹ en el Sitio I, mientras que en el Sitio II se obtuvo un total de 342 kg MS.nido⁻¹.año⁻¹. Los resultados globales indicaron que la tasa de forrajeo estaba conformada mayoritariamente por especies monocotiledóneas graminiformes y ciperáceas. Las colonias de *Atta vollenweideri* cosecha anualmente un 9,5% de la productividad primaria de un pastizal natural en bosques nativos del Espinal Argentino. Estacionalmente se observó una combinación de estrategias en el forrajeo para conformar su dieta mostrando gran plasticidad, que permite afirmar un comportamiento estrictamente selectivo sobre especies monocotiledóneas herbáceas graminiformes y ciperáceas cuando la abundancia relativa es alta, de lo contrario expresa un oportunismo muy marcado cortando otras especies vegetales.

Allelopathic effects of paper mulberry (*Broussonetia papyrifera* (L.) L'Hér. ex Vent.) extracts to the morpho-physiological characteristics of supa (*Sindora supa* Merr.) seedlings

Marilyn Combalicer¹, Mark Bryan Carayugan¹, Ma. Fatima Critica¹

¹Department of Forest Biological Sciences, College of Forestry and Natural Resource, University of the Philippines Los Baños, Los Baños, Philippines (mscombalicer@up.edu.ph; macarayugan@up.edu.ph; micritica@up.edu.ph)

The study investigated the allelopathic potential of leaves, stem and root aqueous extract of *Broussonetia papyrifera* using *Sindora supa* as a test plant for morpho-physiological implication. Parameters (height increment, root collar diameter increment, sturdiness quotient, leaf number increment, leaf area, chlorophyll content, net photosynthesis, transpiration, stomatal conductance, and water use efficiency (WUE), were tested at *B. papyrifera* extract concentration of 10%, 15%, 20% and 30%. Results indicated that stem and root extracts of *B. papyrifera* deterred the height of the test plant at 20% and 30%, respectively. Stem extract stimulated the root collar diameter growth of *S. supa* at 15% concentration. A stimulatory response is observed at low concentration levels, while deterrence transpires along increasing concentrations. This is similar to parameters of leaf area, chlorophyll count, net photosynthesis and WUE (stem extract). Transpiration, stomatal conductance and WUE (root extract) incurred variable response along increasing concentration levels. Seeds are more vulnerable to allelochemicals as compared to the 4-month old seedlings of *S. supa* (leaf extract). Therefore, increasing levels of *B. papyrifera* root and shoot extracts inhibit the growth of *S. supa*, indicating *B. papyrifera*'s allelopathic effect and dominance. Hence, this has implications in an effort to conserve native species and prevent the proliferation of invasive exotic species in the area. Further research on the allelopathic potential of the flowers and fruits of *B. papyrifera* is recommended, coupled with chemical characterization, to determine its full detrimental effect on natural forest areas, and to recognize the interplay of different chemicals affecting morpho-physiological dynamics of the affected plant.

Native plants recommended for cover of roadway slopes / *Plantas nativas indicadas para o recobrimento de taludes rodoviários*

Ana Cláudia Nogueira da Silva¹, Angeline Martini¹, Sebastião Venâncio Martins¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (anasilvanogueira@yahoo.com.br; martini@ufv.br; venancio@ufv.br)

Um dos principais impactos provocados pela construção de estradas é a criação de taludes, estes sofrem ação direta das intempéries possuindo alta taxa de erosão hídrica. A inserção de espécies vegetais é uma das técnicas mais recomendadas para a conservação de taludes. Espécies alóctones são as mais recomendadas devido à capacidade de recobrirem a área mais rapidamente e por possuírem maior resistência às condições climáticas. Contudo existem espécies autóctones que possuem comportamento semelhante às alóctones, porém não são comumente encontradas no mercado. Nessa premissa este estudo realizou um levantamento de plantas herbáceas e arbustivas nativas indicadas para a cobertura vegetal e/ou recuperação de taludes rodoviários. Espécies nativas com potencial ornamental foram priorizadas, uma vez que estas espécies são mais facilmente comercializadas. Foram listadas 62 espécies, sendo 48 de potencial ornamental. *Poaceae* foi a família com maior representatividade (9 espécies), seguida da *Fabaceae* (8 espécies). A Mata Atlântica foi o bioma com maior número de espécies (49), seguida do Cerrado (48), o Pampa foi o bioma que apresentou menor quantidade de espécies (16). *Andropogon bicornis*, *Andropogon leucostachyus*, *Axonopus siccus*, *Dolichandra unguis-cati*, *Ipomoea alba*, *Ipomoea carnea*, *Sphagnetocola trilobata*, *Stachytarpheta cayennensis*, *Stylosanthes guianensis* são espécies que podem ser utilizadas em todos os biomas brasileiros. Esta pesquisa corrobora com a Estratégia Nacional para Espécies Exóticas Invasoras enfatizando a importância da utilização de plantas nativas, diminuindo assim a introdução, dispersão de exóticas invasoras e selecionando espécies mais apropriadas para cada região, como também espécies adaptadas ao tipo de solo, clima e bem inseridas na paisagem.

Advancing understanding of invasion ecology with Pines

Susan Nuske¹, Paul Kardol¹, David Wardle², Marie-Charlotte Nilsson Hegethorn¹, Jane Smith³, Anibal Pauchard⁴, Alex Fajardo⁵, Duane Peltzer⁶, Martin Nuñez⁷, Michael Gundale¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²Nanyang Technological University, Singapore, Singapore; ³US Forestry Service, Corvallis, USA; ⁴Universidad de Concepción, Concepción, Chile; ⁵Centro de Investigación en Ecosistemas de la Patagonia, Coyhaique, Chile; ⁶Landcare Research, Lincoln, New Zealand; ⁷National University of Comahue, Neuquén, Argentina (susan.nuske@slu.se; paul.kardol@slu.se; david.wardle@ntu.edu.sg; marie-charlotte.nilsson@slu.se; jsmith01@fs.fed.us; pauchard@udec.cl; fajardo.alex@gmail.com; peltzer@landcareresearch.co.nz; nunezm@gmail.com; michael.gundale@slu.se)

Pine species have been introduced around the world for timber, soil stabilization and wind breaks. Selection for highly productive species and provenances has led to productive forestry but also to species that can readily spread and become invasive in otherwise productive pasture land, or biodiverse native grass- or shrub-land. Our research uses *Pinus contorta* as a model species to investigate mechanisms that underpin invasion ecology. Our international network of field sites enables us to compare native (USA and Canada), introduced and invaded ranges (New Zealand, Chile and Argentina). In order to disentangle the relative effects of genetics, abiotic nutrients and microbial community on seedling growth we performed an experiment that combined sterilization treatments, provenances and measurements of soil nutrients and fungal communities of soil and roots while keeping environmental conditions stable in a growth chamber 'home-versus-away' design. Our research allows us to compare multiple hypotheses at once, advancing understanding of invasion ecology.

So similar so different: evaluating the invasive potential of *Lymantria dispar* along the temperate South American

Stella Januario¹, Carmen Paz Silva², Sergio Estay²

¹Universidad San Sebastian, Valdivia, Chile; ²Universidad Austral de Chile, Valdivia, Chile (stella.mjs@gmail.com; carmenpazsilva@gmail.com; sergio.estay@gmail.com)

One of the most important species of the genus *Lymantria* is *Lymantria dispar*, commonly known as "gypsy moth". Highly polyphagous, the species feed on more than 500 species of trees and forest, fruit and ornamental shrubs. The gypsy moth is native to a wide region that ranges from Europe to Asia, currently distinguishing 3 subspecies: *Lymantria dispar dispar*; *Lymantria dispar asiatica*, *Lymantria dispar japonica*. This genus of moths is not present in Chile, however in 2012 some egg masses were intercepted from the port of San Antonio, corroborating the effective risk of entry of the species into the country and damage to plant resources. Here, we used occurrences from multiple invaded regions, statistical and GIS tools to model and validate the environmental conditions that might allow the 3 subspecies to persist and spread in Chile. Our results highlight that, by using portions of the habitat that are apparently distinguishable, the subspecies seem to be not only genetically distinct, but ecologically distinct as well. Understanding the relation of the distinct species with the surrounding environment provided valuable insights about probable routes of dispersion in Chile, especially into those areas considered suitable for the forest industry. We discuss the implications of our findings as a useful tool to anticipate the invasion of such harmful invasive species with regard to the most relevant environmental variables.

Effects of a native invasive species, *Magnolia kobus*, on the persistence of a rare species, *M. stellata*

Nobuhiro Tomaru¹, Naotaka Wadasaki¹, Kyohei Yukitoshi¹, Ichiro Tamaki², Suzuki Setsuko³, Kiyoshi Ishida⁴

¹Nagoya University, Nagoya, Japan; ²Gifu Academy of Forest Science and Culture, Mino, Japan; ³Forestry and Forest Products Research Institute, Tsukuba, Japan; ⁴Hirosaki University, Hirosaki, Japan (tomaru@agr.nagoya-u.ac.jp; www.wk.nk@gmail.com; kkkyohe1@yahoo.co.jp; ichiro@forest.ac.jp; setsukos@affrc.go.jp; ishidak@hirosaki-u.ac.jp)

Invasive species poses a serious threat to the native species genetically related to the invasive species through interspecific hybridization. *M. stellata* is a rare tree species, distributed only in Tokai region, Japan. In contrast, *M. kobus* is a common tree species, widely distributed mainly in Japan, but it is not distributed in the range of *M. stellata*. However, because *M. kobus* trees is well planted, the escaped trees that are their offspring are occasionally growing near the habitat of *M. stellata* and interspecific hybridization may occur. In this study, we evaluated the effects of a native invasive species, *M. kobus*, on the persistence of a rare species, *M. stellata*. First, we examined the genealogical classes of adult trees in two areas using nuclear and chloroplast microsatellite markers. We identified F1, F2 hybrids and backcrosses to *M. stellata* and *M. kobus*, indicating that the interspecific hybridization and the subsequent introgression can occur. Second, we conducted hand-pollination experiments. Interspecific crosses succeeded like intraspecific crosses. We also carried out pollination with mixed pollen from both species and determined pollen parents using paternity analysis with microsatellite markers, suggesting that reproductive interference between the two species can occur. Third, we examined the differences in survival and growth of adults and saplings (including seedlings) for four and two years, respectively, among the two species and hybrids. No significant differences appeared among them. Based on these findings, we discuss the effects of *M. kobus* on the persistence of *M. stellata*.

Influence of reproductive biology on the invasive capacity of Hymenoptera

Joséphine Queffelec¹, Jeremy Allison^{2,3}, Jaco Greeff⁴, Bernard Slippers¹

¹University of Pretoria, Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute, Pretoria, South Africa; ²University of Pretoria, Department of Zoology and Entomology, Forestry and Agricultural Biotechnology Institute, Pretoria, South Africa; ³Natural Resources Canada-Canadian Forest Service, Great Lakes Forestry Centre, Sault Ste. Marie, Canada; ⁴University of Pretoria, Department of Biochemistry, Genetics and Microbiology, Pretoria, South Africa (josephine.queffelec@fabi.up.ac.za; jeremy.allison@canada.ca; jaco.greeff@up.ac.za; bernard.slippers@fabi.up.ac.za)

Introduced species face numerous ecological barriers before they can establish in a new environment. Understanding how they overcome these barriers is crucial for the development of effective risk assessment, regulation and control strategies. Reproductive biology is known to influence invasive success in plants and is widely used for risk assessment. In the case of insects, this biological field should receive more attention as insects display a wide range of reproductive traits and have a great impact on the global economy and environment. Among insects, the order Hymenoptera is of interest for its diversity, both in terms of reproductive traits and introduction history, as invasive species and biological control agents. We review the main reproductive strategies of Hymenoptera and evaluate their effect on invasive potential. Thelytoky could decrease the strength of Allee effects while Arrhenotoky could increase adaptive potential. A species with complementary sex determination could be more affected by inbreeding than other species, while paternal genome elimination could lead to high levels of homozygosity. Finally, some reproductive behaviours could increase inbreeding, impede mate location or facilitate adaptation by encouraging admixture. The

invasive European Woodwasp, *Sirex noctilio*, is a pest of pine species causing losses for the industrial forestry of the southern hemisphere and is now threatening the forests of North America and China. This species serves as a case study to illustrate the influence of reproductive traits on the capacity of invasive species to establish in a new area, and their relevance to management.

D8t: FOREST ENVIRONMENT

The quality of forests located in springs in the Cascavel Sub-Plain area of the Paraná III Basin, Paraná, Brazil / A qualidade das florestas em nascentes do subplanalto de Cascavel, Bacia Hidrográfica Paraná III, Paraná, Brasil

Annete Bonnet¹, Gustavo Ribas Curcio¹, João Henrique Caviglione²

¹Embrapa Florestas, Colombo, Brasil; ²Instituto Agronômico do Paraná, Londrina, Brasil (annete.bonnet@embrapa.br; gustavo.curcio@embrapa.br; jhcaviglione@gmail.com)

As nascentes, como locais de descarga hídrica da paisagem, devem ser protegidas para garantir suas funcionalidades. São ambientes únicos que, no meio rural, compartilham espaço com os sistemas de produção. A vegetação que circunda as nascentes é protegida pela Lei 12.651/12, Código Florestal, em um raio de 50 m, denominada Área de Preservação Permanente. Como parte do projeto PronaSolos Paraná, estão sendo realizados levantamentos sistemáticos da vegetação em áreas de nascentes e de margens de rios, relacionando-se geomorfologia e solos. Os resultados demonstram que, de modo geral, a maioria dessas florestas se encontra simplificada em diversidade e estrutura e reduzida em tamanho de área ocupada, o que pode ser relacionado com a devastação causada pela colonização na região, que é recente (década de 30) e com a excelente aptidão dos solos para a agricultura. Pode-se citar como espécies arbóreas comuns branquilha (*Gymnanthes klotzschiana* Müll.Arg.), angico vermelho (*Parapiptadenia rigida* (Benth.) Brenan), vacum (*Allophylus edulis* (A.St.-Hil. et al.) Hieron. ex Niederl.), tapiá (*Alchornea triplinervia* (Spreng.) Müll.Arg.) e açoita-cavalo (*Luehea divaricata* Mart. & Zucc.). As espécies nativas ocorrem em baixa diversidade e com pequenas dimensões, denotando frequentemente estágios sucessionais iniciais de regeneração. Corroborando o quadro, registraram-se também várias espécies exóticas, como nêspera (*Eriobotrya japonica* (Thunb.) Lindl.), uva-do-Japão (*Hovenia dulcis* Thunb.), alfeneiro (*Ligustrum lucidum* W.T.Aiton), eucalipto (*Eucalyptus* spp.) e leucena (*Leucaena leucocephala* (Lam.) de Wit), por vezes, perfazendo a floresta que circunda a nascente. Finalmente, destaca-se a baixa ocorrência de epífitos vasculares e abundância de cipós cobrindo as árvores e prejudicando seu desenvolvimento.

Division of functional groups in Cerrado dry forest and seasonal semi-deciduous forests / Divisão de grupos funcionais em cerrado sentido restrito e floresta estacional semidecidual

Vanuza Pereira Garcia da Silva¹, Gabriel Venâncio Pereira Mariano¹, Vitor de Oliveira Santiago¹, Edla Lopes Silva¹, Vagner Santiago do Vale¹

¹Universidade Estadual de Goiás, Ipameri, Brasil (garciavp@outlook.com; gabrielvenancio_@outlook.com; vitoroliveiras@gmail.com; silvaedla2@gmail.com; vsvale@hotmail.com)

Grupos funcionais (GF) são agrupamentos de espécies vegetais com características semelhantes que desenvolvem o mesmo papel para a manutenção do ecossistema. O objetivo deste trabalho foi verificar se existem diferentes grupos funcionais entre as fitofisionomias cerrado sentido restrito e floresta estacional semidecidual e assim, analisar a influência das variáveis para o bom funcionamento do ecossistema. Foram amostradas 18 espécies consideradas entre as mais importantes de cada fitofisionomia. Foi elaborada uma matriz contendo as espécies e os atributos funcionais para grupos sucessionais, tolerância à luz e dessecação da semente, síndrome de dispersão e polinização, deciduidade, número de sementes por quilo, fenologia de floração e frutificação e cor da flor, e realizado um dendrograma de similaridade utilizando o método de agrupamento UPGMA e o método de Gower como medida de distância. Foram definidos 5 grupos funcionais. O grupo 1 foi formado por espécies de cerrado e de florestas cujas principais características foram a demanda de luz, dispersão por mamíferos e polinização por pequenos insetos; o grupo 2 foi formado por espécies de cerrado, demandantes de luz com dispersão anemocórica e polinização principal por abelhas; os grupos 3, 4 e 5 foram formados por espécies típicas das florestas, dispersas por aves ou mamíferos e polinizadas por insetos. Foi possível observar que a fitofisionomia inferior diretamente na divisão e apenas o grupo 1 foi formado por semelhante número de espécies de ambas as fitofisionomias. Houve mais grupos formados por espécies florestais do que de cerrado, refletindo a maior complexidade destes ambientes.

Edge effects on tree communities in semi-deciduous seasonal forests / Efeito de borda em comunidades arbóreas de florestas estacionais semidecíduais

Gabriel Venâncio Pereira Mariano¹, Vanuza Pereira Garcia da Silva¹, Lilian Cristina da Silva Santos¹, Joao Paulo Costa¹, Ana Carolina Ribeiro Vaz¹, Vagner Santiago do Vale¹

¹Universidade Estadual de Goiás, Ipameri, Brazil (gabrielvenancio_@outlook.com; garciavp@outlook.com; liliancristina_2011@hotmail.com; joaopaulo_mc@hotmail.com; anavazuegflorestal@gmail.com; vsvale@hotmail.com)

A borda é a região de contato entre a paisagem e o fragmento de comunidade arbórea natural. Efeito de borda são modificações nas estruturas e composição da vegetação marginal em uma floresta. O objetivo foi mensurar a distância abrangida pelo efeito de borda em dois fragmentos de Floresta Estacional Semidecidual. Em cada área foram alocadas três transectos com 10 parcelas de 10 x 10 m, da borda em direção ao interior da floresta, amostrando indivíduos com circunferência a 1,30 m \geq 15 cm. Foi elaborada a curva espécie-área, baseada na distância em relação a borda. Para cada área foram gerados dois dendrograma de similaridade, baseados na presença/ausência das espécies por parcela (índice de Sørensen) e no número de indivíduos por parcela (índice de Bray-Curtis). Em A1, a curva espécie-área demonstrou aumento expressivo de espécies a partir dos 40 m houve e na Área 2, a partir dos 70 m. Nos dendrogramas houve a divisão de grupos em ambos os índices e áreas analisados. Na Área 1 formaram-se grupos de parcelas mais próximas a borda (0 a 30 m) e interioranas (40 a 100 m) e na Área 2 os grupos foram de 0 a 60 m e 70 a 100 m. O efeito de borda na primeira área atingiu 30 m, já na segunda área, 70 m, ambos em direção ao interior da floresta. Assim, diferentes florestas podem ter diferentes tamanhos de borda, influenciadas de maneiras diferentes pelo efeito de borda e novos estudos devem demonstrar as razões destas distinções.

Spatial distribution of jatobá (*Hymenaea courbaril* L) / Distribuição espacial de jatobá (*Hymenaea courbaril* L)

Álef Solon Galdino¹, Hallefy Junio de Souza¹, Francieudes Pereira do Nascimento¹, Sybelle Barreira²

¹Universidade Federal de Goiás, Goiânia, Brasil; ²Universidade Federal de Goiás, Porangatu, Brasil (alefssolongaldinogomes10@gmail.com; hallefyj.souza@gmail.com; framurilo@gmail.com; sybelle.barreira@gmail.com)

O estudo da distribuição espacial de indivíduos arbóreos é uma importante ferramenta para se entender a estrutura populacional das espécies, pois determina como as espécies se encontram na floresta que nos ajuda com informação para manejo e aproveitamento da espécie. O objetivo deste trabalho foi avaliar a distribuição espacial de Jatobá (*Hymenaea Courbaril* L). A amostragem foi feita de forma aleatória com parcelas 20 x 20 m (400m²) sorteadas ao acaso no software arcgis, foram alocadas 25 parcelas, considerando-se todas as espécies arbóreas com DAP (diâmetro a altura do peito superior a 10 cm, foram coletados os seguintes dados: identificação da espécie vegetal (em campo), CAP (circunferência a altura do peito) e altura coletada com o auxílio de um clinômetro. Para tanto foi calculado o índice de Morisita para a espécie e o valor encontrado foi de 1,67, o que classifica a espécie como intermediária e por sua vez nos diz que a espécie possui uma distribuição aleatória dentro do espaço amostral. A distribuição aleatória dessa espécie é relacionada com as suas síndromes de dispersão, que são descritas como barocórica, devido a ocupação da espécie no extrato superior (porte superior a 20 m), e zoocórica, pois fruto é bastante atrativo para animais, essas sementes necessitam que ocorra sua facilitação para sua germinação, e essa interação entre as sementes e o trato digestivo desses animais, auxilia na sua germinação devido a quebra de dormência. A interação com esses animais justifica a dispersão dessas espécies por toda área e justifica sua distribuição aleatória da espécie.

CO2 emissions patterns in a small municipality in Paraná, Brazil / Padrão de emissão de CO2 em um município de pequeno porte do estado do Paraná, Brasil

Dianafaz Eloiza Canan¹, Natália Maria Venciguerra Aires¹, Felipe Spina Vieira¹, Ana Leticia de Campos¹, Jaqueline de Moraes¹, Cristian Medrado Canonico¹, Flávia Gizele König Brun¹, Eleandro José Brun¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brazil (dianafaz_eloiza@hotmail.com; natalia.maria.venciguerra@hotmail.com; felipespina@outlook.com; analeticacampos95@hotmail.com; jaquemoraesinha@gmail.com; cristianc@alunos.utfpr.edu.br; flaviag@utfpr.edu.br; eleandrobrun@utfpr.edu.br)

O Painel Intergovernamental de Mudanças Climáticas cita que 95% das mudanças climáticas sejam devido aos gases antrópicos do efeito estufa. O CO₂ é um dos principais gases atmosféricos causadores do efeito estufa em 2018 segundo a Organização Meteorológica Mundial com valores de 403,3 ppm, ultrapassando o nível proposto pelo Acordo de Paris 2015 (400 ppm). Estudou-se, em Dois Vizinhos/Paraná/Brasil, em 2018, em três setores: industrial (sem arborização), residencial (arborizado em um lado da via) e centro (sem arborização) por três dias nos horários das 09:00; 15:00 e 18:00h. Os locais e horários avaliados apresentaram diferença significativa ao nível 5,0% (Teste Duncan) entre locais e horários, sendo os níveis de poluentes mais elevados no centro (436,67 ppm), área residencial (421,13 ppm) e industrial (416,49 ppm), o que se deve a fatores econômicos/culturais como presença de veículos automotores por habitante (0,7 veículos/hab. (Jornal de Beltrão 2018)), sistema deficitário de transporte público e baixo estímulo a outras formas de mobilidade, falta de fiscalização de emissões locais (frota veicular, setor industrial e emissões domésticas), baixa arborização. Os valores obtidos estão acima dos estabelecidos em acordos nacionais e globais. Assim, recomenda-se que as políticas nacionais de redução de emissões (Lei 12.187/2009) devem ser trabalhadas não somente em grandes centros urbanos, mas também em cidades pequenas, para que estas consigam se adequar e contribuir para o alcance das metas previstas para 2020, que visa 36,1% de redução de emissões de CO₂.

Forest dynamics and detecting permanent preservation and legal reserve areas in municipalities in São Paulo, Brazil / Dinâmica florestal e detecção de áreas de preservação permanente e reserva legal em municípios paulistas

Carlos Ronquim¹, Ivan Alvarez¹, Cristina Rodrigues¹, Marcelo Fonseca¹, Edlene Garçon¹

¹Embrapa Territorial, Campinas, Brazil (carlos.ronquim@embrapa.br; ivan.alvarez@embrapa.br; cristina.rodrigues@embrapa.br; marcelo.fonseca@embrapa.br; edlene.garcon@embrapa.br)

Por meio do uso de geotecnologias avaliou-se a dinâmica florestal e a adequação ambiental de dois municípios delimitando-se as Áreas de Preservação Permanente (APPs) e estimando as áreas de Reserva Legal (RL). A área das florestas nativas de São Carlos em 2016 representou 28,4 % do território ante 19,4% em 1988, crescendo de 22,1 mil para 32,5 mil ha, ou 9,0%. A área total de APP é de 6,4 mil ha estando 3,5 mil ha preservados o que dá um total 64,9% regularizados. A área de RL em função da área cultivável é de 19,9 mil ha sendo que há um total de mata nativa em 27,0 mil ha. Há uma área florestal vegetada maior que a determinada por lei, porém essa área não está distribuída perfeitamente pelas propriedades. Em Ribeirão Preto houve diminuição de 0,7% das florestas nativas que perderam 481,2 ha passando de 8,1 mil para 7,7 mil ha. A área total de APP cobertas por mata é de 913 ha, ou seja, apenas 37,7% das APPs estão regularizadas. Os 20% de área florestal nativa fora das APPs foi de 4,1 mil ha, havendo um passivo ambiental de RL de 2.972,2 ha. Seriam necessários trabalhos de campo para verificar o local exato das nascentes e um levantamento detalhado dos corpos d'água segundo sua situação (naturais ou artificiais) para determinação com exatidão das APPs, além da verificação dos limites das propriedades por meio do Cadastro Ambiental Rural (CAR) para determinação exata dos passivos de RL em cada propriedade.

Water quality in a reservoir located in a small municipality in the State of Paraná, Brazil / Qualidade de águas em reservatório de um parque municipal em município de pequeno porte no Paraná, Brasil

Natália Maria Venciguerra Aires¹, Dianafaz Eloiza Canan¹, Gabriel Mancini Antunes¹, Nathielly Alice Luiz Carvalho¹, Paulo Afonso Vieira Pastori¹, Gabriela Lovison¹, Flavia Gizele König Brun¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brazil (natalia.maria.venciguerra@hotmail.com; dianafaz_eloiza@hotmail.com; twilight.mancini@hotmail.com; nathiellycarvalho@outlook.com; pauloavp2@yahoo.com.br; gabrielalovison@gmail.com; flaviagbrun@gmail.com)

A análise da qualidade hídrica é essencial, os compostos químicos estão presentes na água contaminada por resíduos podem fazer mal ao organismo humano. Portanto, objetivou-se analisar a qualidade hídrica de um reservatório para o consumo e banho. O lago está localizado no município de Dois Vizinhos, situado na região Sudoeste do estado do Paraná, Brasil. Possui 40.234 habitantes e contém 8 áreas verdes, sendo 2 parques municipais e 6 praças. Para determinação da qualidade da água foram realizadas análises *in loco* com o uso do termômetro digital e Phmetro. Os resultados obtidos mostraram que o pH da água encontrado variam de 6,5 a 9, sendo parâmetros recomendados pela portaria 2914/2011 do Ministério da Saúde, para que a água adquira características de potabilidade de consumo e banho, apesar das condições visuais apresentar grande quantidade de gordura na superfície, turvamento da água, causando a redução de oxigênio na

água, causado pela destruição da mata ciliar ao entorno. As temperaturas máximas e mínimas tiveram valores elevados a 29°C, pelo pouco sombreamento no lago, resultando numa água básica e bastante contaminada por poluentes provenientes de empresas e dos dejetos humanos. A educação ambiental, a fiscalização e a revitalização do lago, são medidas fundamentais para a resolução de tal problemática, além da desintoxicação da água tanto para consumo, quanto para banho, isso seria um fator que atuaria principalmente para redução da fila do SUS, pois as pessoas poderiam usufruir desse recurso hídrico sem ter medo de contaminação.

Associations of tree species within a miombo woodland ecosystem in Quirimbas National Park, Mozambique, and implications for their conservation / Associações de espécies arbóreas em um ecossistema de Miombo no Parque Nacional das Quirimbas (PNQ), Moçambique e implicações para a sua conservação

Nocy Bila^{1,2}, Roman Carlos Rios¹, Alessandro Camargo Angelo¹, Salomao Olinda Bandeira²

¹Universidade Federal do Paraná, Setor de Ciências Agrárias - CIFLOMA, Curitiba, Brasil; ²Universidade Eduardo Mondlane, Maputo, Mozambique (nocybila@gmail.com; rioselvas@gmail.com; alessandroangelo@gmail.com; salomao.bandeira4@gmail.com)

Decorreu um estudo fitossociológico no PNQ com 1358 indivíduos arbóreos (331 em áreas de baixa altitude (0 - 200 m), 728 em áreas de média altitude (200 - 400 m) e 299 em áreas declivosas e longo dos *Inselbegs* (400 - 700 m). Identificou-se 116 espécies, 68 gêneros e 32 famílias. Fabaceae-Caesalpinioideae (15), Mimosoideae (12), Papilionoideae (10), Combretaceae (8), Anacardiaceae (7), Sterculiaceae (6), Bignoniaceae (5) e Burseraceae (5 espécies). Entre 200 - 400 m, os indivíduos são mais diversificados, melhor distribuídos e estruturalmente mais conservados. As principais essências florestais *Brenaniodedron carvalhoi*, *Millettia stuhlmannii*, *Pteleopsis myrtifolia*, *Brackystegia allenii* e *Terminalia sericea*. Existem 154 aldeias, estas populações vivem dentro e entorno do PNQ e dependem dos recursos (florestais e faunísticos). As atividades humanas constituem formas de pressão sobre os recursos, sendo queimadas descontroladas usadas para limpeza de áreas agrícolas, caça e corte ilegal de madeira valiosa; geradores de grandes conflitos entre autoridades do PNQ, populações e empresas privadas madeireira. A exploração madeireira ilegal reduziu consideravelmente devido incursões do Governo e entidades do PNQ, no entanto, existem algumas dificuldades para controlar esta situação na Zona Tampão devido à sua vastidão e existência de vários pontos de acesso. As populações locais necessitam de pequenas quantidades de madeira para construir habitações tradicionais e carpintaria, embora estas atividades não representem grande problema para a conservação. Foi desenvolvido um projecto de Gestão e Conservação produzido no Plano de Maneio do PNQ (2012-2021), que regulamenta a exploração com base em licenças simples para comunidades locais em áreas apropriadas no PNQ.

D8u: FOREST ENVIRONMENT

Ecosystem decay: influence of 'edge effect' on forest structure, tree species diversity and above-ground carbon stock in fragmented forest patches of Taita Hills, Kenya

Chemuku Wekesa¹, Bernard Kirui², Elias Maranga², Gabriel Muturi³

¹Kenya Forestry Research Institute, Wundanyi, Kenya; ²Egerton University, Nakuru, Kenya; ³Kenya Forestry Research Institute, Nairobi, Kenya (chemukufri@gmail.com; bkkirui@egerton.ac.ke; ekmaranga@yahoo.com; gabrielmuturia2012@gmail.com)

Comparative studies were undertaken in five forest fragments of varying sizes to determine the effects of forest edge on the forest structure, species diversity and richness and above-ground carbon stock along forest edge-interior gradient, and the relationship between pioneer and late successional tree species. Belt transects proportional to the forest area were established for data collection. Within each belt transect, plots of 10.0x10.0 m were systematically established and replicated three times in a stratum at an interval of between 10.0 and 50.0 m along forest edge-interior gradient depending on the size of the forest fragment. Results showed that there was no significant edge effect on tree species diversity in *Chawia* ($p=0.564$), *Fururu* ($p=0.689$), *Mbololo* ($p=0.369$), *Ngangao* ($p=0.576$) and *Vuria* ($p=0.338$), although species diversity was higher in the forest interior than in the intermediate forest and on the forest edge. Similarly, there was no significant edge effect on species richness in *Chawia* ($p=0.490$), *Fururu* ($p=0.507$), *Mbololo* ($p=0.303$), *Ngangao* ($p=0.886$) and *Vuria* ($p=0.090$). Above-ground carbon stocks were not significantly affected by edge effect in *Chawia* ($p=0.704$), *Fururu* ($p=0.908$), *Mbololo* ($p=0.544$), *Ngangao* ($p=0.991$) and *Vuria* ($p=0.590$). *Tabernaemontana stapfiana* and *M. lanceolata* co-existed with 45.5% and 18.2% of the late successional tree species respectively while 9.1% of the late successional tree species co-existed with each of the following pioneer tree species: *A. gummifera*, *M. conglomerata*, *S. guineense* and *X. monospora*. These results could be used to develop conservation strategies that may minimize forest degradation, and biodiversity erosion and loss in fragmented forest ecosystems.

Effects of seed size and leaf litter depth on early settlement in Major Korean Trees

EuiJoo Kim¹, SooIn Lee², YoungHo Jung², SeungYeon Lee¹, YongSik Hong¹, EungPill Lee¹, JiEun Kim¹, MinJoo Kim¹, YoungHan You¹

¹Kongju National University, Gongju-si, Korea, Republic of; ²Baekdudaegan National Arboreum, Bonghwa-gun, Korea, Republic of (euijoo@kongju.ac.kr; ecolove093@kongju.ac.kr; jyh5250@kongju.ac.kr; ecollee21@kongju.ac.kr; hongfin@smail.kongju.ac.kr; lyp2279@kongju.ac.kr; jekim64@kongju.ac.kr; minjoo1164@naver.com; youeco21@kongju.ac.kr)

The forests in Korea are getting thicker and the litter layers are getting higher. Also, It is now progressing succession from pine forests to oak ones. In this study, we investigated the difference of response of tree seeds to the leaf litter in order to verify autogenic influential factor that causes the forest succession in Korea. Seeds used in the experiment were six species such as succession early species (*Pinus densiflora*), and the later species (*P. koraiensis*, *Abies holophylla*) and oak's three species. The seed of these trees were sown at the above and below in litter depth of 5cm and 10cm or on the bare ground, and germination rate was measured and initial survival rate was counted. To determine the effect of drying, the survival rate was surveyed after stopping the water supply. As a result, germination rate of oaks were higher on the bare ground. And regardless of the depth of litter, germination rate of the pines were higher than oaks. Under the litter, germination rate of Oaks were 100%. Germination rate was highest *Q. acutissima* among the oak trees and *P. densiflora* among the pine trees. And *Q. acutissima* than *P. densiflora* was highest the survival rate relation to the drying stress. Therefore, *Q. acutissima* in Korea will be advantageous for early settlement. This work was supported by the National Research Foundation of Korea(NRF) grant funded by the Korea government(MSIT)(No. NRF-2018R1A2B5A01021358)

Interaction network of *Quercus humboldtii* honeydew: possible ecological dynamics of an NTFP in Colombia

Hugo Alexander Benjumea Ochoa¹, Jaime Polanía¹, Carolina Serna¹

¹Universidad Nacional de Colombia, Medellín, Colombia (habenjumeao@unal.edu.co; jhpolanaiav@unal.edu.co; csernac@unal.edu.co)

Honeydew is a sugary solution coming from the anal projection of *Stigmacoccus asper* (Hemiptera: Stigmacoccidae) in interaction with oak forests (*Quercus humboldtii*, a ‘vulnerable’ species, whose use is legally restricted) and a sooty mold, growing over the tree’s bark. Honeydew is used by hummingbirds (Trochilidae), Meliponin bees and *Apis mellifera* (Hymenoptera: Apidae). The latter take it to produce honey of international quality. Here, we deepen in the understanding of, and we differentiated between interaction types (e.g., parasitism or commensalism) in oak forests of the Colombian Cordillera Oriental (municipality of Zapatoca, Santander). Furthermore, we determine the infestation degree on oak specimens in the Natural Reserve of the Civilian Society “El Páramo-La Floresta”. In 2015, four permanent 400 m² plots were set up inside the oak forest, at 2,500 masl, and two years later DAPs were measured again. The infestation was estimated at ~80% of the trunks. Using R and a Kruskal test, significant differences were found for DBH growth compared to a neighboring oak grove lacking the hemiptera. However, the mean growth was higher in the infested oak forest. Here we suggest guidelines for assessing the sustainability of honeydew as a potential NTFP for neighboring communities, and as food for hummingbirds. This study emphasizes the articulating role of Colombian oak in the ecology of mountain forests. In addition, we show the set of chain reactions that can be generated around a parasitism, and speculate about the possible effects that oak groves will have in the light of continuous monitoring.

Forest landscape characteristics of *Prionailurus bengalensis*’s habitat in Rural area, South of Korea

HoSeung Choi¹, EuiJoo Kim¹, JeongGeun Yun¹, DaeHee Kim¹, HaeIn Yu¹, SeungJun Lee¹, KiHwan Lim¹, YongSik Hong¹, EungPill Lee¹, SeungYeon Lee¹, YoungHan You¹

¹Kongju National University, Gongju-si, Republic of Korea (rhrorchl@hanmail.net; euijoo@kongju.ac.kr; yuntery26@naver.com;

daehee1999@naver.com; feline27@daum.net; gudwp98@hanmail.net; feverfew79@kongju.ac.kr; hongfin@smail.kongju.ac.kr; lyp2279@kongju.ac.kr; ecolee21@kongju.ac.kr; youeco21@kongju.ac.kr)

In order to find out about the characteristics of the preferred habitat in the forest area of *Prionailurus bengalensis*, authors analyzed the relationship between the area where *Prionailurus bengalensis* appeared from August 2016 to May 2017 and the environment factors such as forest landscape element, elevation element, slope element, Age-class element, DBH-class element, density, etc. using ArcGis, AutoCad, Photoshop, etc. As a result, the share of environmental factors in the research area and the share of distribution areas by environmental factors in the research area were relatively high, with the appearance of *Prionailurus bengalensis* in areas with a slope ranging from 15-20 ° to 35-40 °. These results indicate that the research area is feeding in grassland areas, the area extending to the north is used as a transportation route, and that the slope is slower than the slope of the slopes of the forest or the valley. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education(NRF-2018R1D1A1B07050269)

Estimating the density and productive potential of Brazil nuts (*Bertholletia excelsa* H.B.K.) based on environmental variables in Madre de Dios / Estimación de densidad y el potencial productivo de castaña (*Bertholletia excelsa* H.B.K.) en base a variables ambientales – Madre de Dios

Jheyson Jerzel Valdivia Gómez^{1,2}

¹Universidad Nacional Amazónica de Madre de Dios, Puerto Maldonado, Peru. ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brazil (jheyson540@gmail.com)

El objetivo de este proyecto fue, estimar la densidad y el potencial productivo de la castaña (*Bertholletia excelsa* H.B.K.), en base a variables ambientales en más de 400 concesiones ubicadas en el departamento de Madre de Dios, con un total de 135528 individuos, así como entrevistas realizadas a 32 concesionarios. Además, se realizó un inventario del 10% de la población dentro de éstas concesiones, para corroborar los datos obtenidos entre el primer y segundo quinquenio. Los resultados demuestran que, a mayores temperaturas, la producción es menor, mientras que con las precipitaciones sucede lo contrario; se encontró una productividad mayor a la misma, antes de la estación seca (mayo-septiembre). También se observó mayor productividad en suelos con pH<5, y con mayor contenido de arcilla, limo y carbono (lo inverso al contenido de arena). Las altitudes entre 250-350 m.s.n.m., favorecen la densidad y productividad, con pendientes no mayores de 10°. *B. excelsa*, tiene una alta densidad y productividad a medida que se aleja de los cuerpos de agua, distinto con respecto a los caminos, ya que cercano a ellos se obtuvo una alta densidad y productividad. Así mismo, se evidenció que la productividad también depende de las condiciones fitosanitarias y estructurales de esta especie. Se lograron hallar valores de mayor productividad en individuos con presencia de termitas y menor en aquellos con presencia de lianas, exudación, ramas rotas y huecos en la estructura del árbol. La presencia de tumores y la presencia de árboles cercanos no tienen influencia en la productividad.

Alpha diversity indexes for woody species in the departments of Glass and Alberdi, Santiago del Estero, Argentina / Índices de diversidad alfa de especies leñosas en los departamentos Copo y Alberdi, Santiago del Estero, Argentina

Constanza Josefina Garnica¹, Maria de los Angeles Basualdo¹, Franco Diaz², Walter Cassino³

¹Facultad de Ciencias Forestales, Universidad Nacional de Santiago del Estero, Santiago del Estero, Argentina; ²Dirección General de Bosque y Fauna, Ministerio de Producción, Santiago del Estero, Argentina; ³Nodo Regional Parque Chaqueño, Santiago del Estero, Argentina (garnicaconstanza@gmail.com; mbasualdo@agro.uba.ar; francodiaz.sgo@gmail.com; walter.cassino@gmail.com)

Los inventarios forestales proporcionan información valiosa para el conocimiento cuali y cuantitativo del recurso bosque; además de la determinación del volumen de madera y su crecimiento podemos estimar biodiversidad. El objetivo del trabajo es generar información sobre diversidad local y regional de especies leñosas de los bosques de Copo y Alberdi pertenecientes a la Región Chaqueña Semiárida. Se trabajó con datos provenientes del muestreo piloto del Segundo Inventario Forestal de Bosques Nativos (MAyDS, 2015- 2016). El diseño de muestreo fue sistemático, se relevaron 169 unidades muestrales, cada una conformada por un conglomerado de 3 parcelas circulares de 1000 m² (tamaño de la UM 3000 m²). La estimación de diversidad regional se realizó a través de Riqueza (R), la diversidad local a partir de los índices Shannon-Wiener (H) y Simpson (D). Los resultados muestran para Copo un índice H de 1,49 y un índice D de 0,30; para Alberdi de 1,44 y 0,32 respectivamente. El valor R promedio para Copo y Alberdi es 39. Concluimos que los resultados obtenidos se asemejan a los reportados por otros autores para la región. Valores de H varían generalmente entre 1,5 y 3,5 (Magurran, 1988). Valores de 1-D varían entre 0,80 y 0,93 (Gimenez et al, 2008). En un bosque primario del Parque Nacional Copo se encontró un R de 31 especies (Torrela et al, 2011). Debido a las altas tasas de deforestación destacamos la importancia de promover el conocimiento y valoración de la región chaqueña; considerada una de las ecorregiones con alta prioridad de conservación según la SAyD.

Conservation and use of *Gossypium mustelinum* in restoration of degraded areas / *Conservação e uso do Gossypium mustelinum na restauração de áreas degradadas*

Rafaela Gonçalves da Silva^{1,2}, Lucia Vieira Hoffmann², Amanda Moreira Siqueira¹, Alessandra da Cunha Moraes³

¹Universidade Federal de Goiás, Goiânia, Brasil; ²Embrapa Algodão, Goiânia, Brasil; ³Embrapa Arroz e Feijão, Goiânia, Brasil (rafaelags05@gmail.com; lucia.hoffmann@embrapa.br; amandamoreira-s@hotmail.com; alessandra.moraes@embrapa.br)

Gossypium mustelinum é uma espécie de algodão nativo do Brasil. A espécie arbórea ocorre naturalmente nos estados da Bahia, Pernambuco e Paraíba e Rio Grande do Norte, mais frequentemente próxima a leitos de rios que não são perenes e, quando na mata, parece ter preferência por clareiras. O uso do *Gossypium mustelinum* poderia ser uma opção de espécie utilizada na restauração de áreas degradadas, seja em áreas de preservação permanente (APP) ou reserva legal, como uma espécie que não seja para fins lucrativos, ainda que possua características favoráveis para tal finalidade, o objetivo é restaurar a forma e a funcionalidade do local. A Embrapa promove a conservação em banco de germoplasma. Ainda são poucos indivíduos de *G. mustelinum* encontrados no país, alguns foram encontrados em Áreas de Proteção Ambiental como a APA Santa Cruz, e poucas sementes já foram coletadas, para a restauração é necessário plantar as sementes existentes, e assim formar uma área de coleta de sementes-ACS e/ou área de produção de semente-APS, o ambiente tem que ser semelhante aos locais de plantio, por isso sugere-se parcerias com prefeituras para implantação das mesmas. Neste sentido, sugere-se alternativas para aumentar a população de indivíduos de *Gossypium mustelinum* nas regiões de ocorrência. Contudo, a conscientização da comunidade local é essencial, sendo esta realizada por diversos meios de comunicação, como Jornais e a ação de guardiões, pois a principal ameaça é a interferência humana, garantindo que o desenvolvimento socioambiental se faça com a conservação de seu patrimônio natural, histórico e cultural.

Challenges of forest governance related to paying for environmental services, directed at subsistence farms in Costa Rica / *Desafios de la gobernanza forestal para atender la nueva modalidad de PSA dirigido a fincas de subsistencia en Costa Rica*

Víctor Meza¹, Monserrat Romero¹, Kevin Alfaro¹

¹UNA, Heredia, Costa Rica (victor.meza.picado@una.cr; mariamonse01@gmail.com; kevin15aj@gmail.com)

Se crea en el año 2018 una nueva modalidad de PSA que busca reconocer los servicios ambientales que se generan en fincas de menos de 10 ha. Con la intención de evaluar la efectividad de la nueva modalidad se trabajó en tres proyectos pilotos en diferentes regiones del país. Uno de estos ha sido desarrollado por la UNA en un asentamiento llamado Asarias María ubicado en la Región Huetar Norte, con un promedio de tamaño de finca de tres hectáreas. La finalidad principal es contribuir al mejoramiento de la economía de pequeños productores mediante el cultivo de clones superiores de caoba (*Swietenia macrophylla*) en sistemas agroforestales (SAF); apoyado con el PSA. Se observó que los productores están dispuestos a plantar en promedio un 30% más de árboles en sus fincas con tal de acceder al PSA. No obstante, se ha dado una baja respuesta de las instituciones encargadas en certificar requisitos de los productores que son solicitados por el FONAFIFO. Las organizaciones no muestran interés por fomentar esta nueva modalidad debido al bajo ingreso que les significa. Se mantuvieron requisitos que se presentan en los otros esquemas de PSA que son más rentables para implementar por las organizaciones, por tal motivo le resta competitividad al nuevo esquema de PSA. En consecuencia, existe un gran desafío para que las actuales instituciones cambien sus estructuras rígidas hacia estructuras más adaptativas que puedan promover la implementación del nuevo esquema reconociendo las particularidades de los pequeños productores.

D9a: CONSERVATION ECONOMICS: PROSPECTS AND CHALLENGES

Prevented degradation of payments for forest conservation: an empirical analysis of the Socio Bosque Program

Francisco Aguilar¹, Philip Mohebalian²

¹Swedish University of Agricultural Sciences, Umea, Sweden; ²US Census, Washington, USA (francisco.aguilar@slu.se; philip.m.mohebalian@census.gov)

Payments for forest conservation programs financially compensate forest owners to maintain and increase the provision of ecosystem services. We examined the additionality of the Socio Bosque Program (SPB) in prevented deforestation based on the establishment of field-level plots within the Ecuadorian Amazon basin region. Forest inventories were complemented with face-to-face landowner surveys to elicit preferences for various conservation contractual arrangements. Inventory data suggest that forests within SPB-enrolled areas exhibited less evidence of degradation. The likelihood of finding a tree species at risk of extinction within forests enrolled in the SPB was 1.8 times that of non-enrolled forests. An experiment conducted with 200 forest owners suggests that opportunities for greater conservation impacts remain if participants were allowed to harvest timber under a strict management plan. Moreover, contracts managed by local municipalities or international NGOs showed stronger preferences over those managed by centralized institutions. Taking risk of deforestation into consideration and based on stated landowner preferences, greater conservation benefits might be attainable if sustainable timber harvesting is allowed along with long-term conservation agreements.

A cost-effective way to increase revenue and reduce illegal deforestation in Amazon forestlands

Vivian Ribeiro¹, Paulo Moutinho¹, Claudia Azevedo-Ramos², Ane Alencar¹, Raissa Guerra¹, Isabel Castro¹, Daniel Silva¹, Marcelo de Castro Chaves Stabile¹, André Loubet Guimarães¹

¹Amazon Environmental Research Institute, Brasília, Brazil; ²Center for Higher Amazonian Studies, Federal University of Para, Belém, Brazil (vivian.ribeiro.bio@gmail.com; moutinho@ipam.org.br; claudia.azevedoramos@gmail.com; ane@ipam.org.br; raissa.guerra@ipam.org.br; isabelcastro@ipam.org.br; daniel.silva@ipam.org.br; marcelo.stabile@ipam.org.br; a.guimaraes@ipam.org.br)

The Brazilian Amazon has over 60 million ha of public forests not allocated for any specific use. These areas have been register by the Brazilian National Cadaster of Public Forest. However, the lack of allocation of these public forest under some protect area category threatens their integrity. The weak enforcement and governance associated with the availability of these undesignated forest leads to land grabbing and illegal deforestation. The deforestation in these areas represents around 25% of the total annual deforestation in the region. Since these areas are key to maintaining ecosystem services and carbon stock, contributing to climate change mitigation, we applied a prioritization methodology considering environmental, social and economic variables, to identify which of these areas should be allocated as integral protection or sustainable use conservation units. Furthermore, we also estimated the cumulative costs over a 12 year period to allocate all of the public forests to conservation units as been BRL 4.49 billion (approximately USD 1.28 billion). On the other hand, this investment may have a financial return of BRL 5.85 billion (approximately USD 1.67 billion) as result of tourism and harvesting of timber and non-timber products. Additionally it can preserve a carbon stock of 0.4 Gt CO₂, which would be at risk during the period. By allocating these areas as Conservation Units, we could reduce potential deforestation by 88% in the allocated area.

Assessment of the World's largest afforestation program "Three North Protective Forest Program": success, failure and future

Jiaojun Zhu¹, Xiao Zheng¹, Yirong Sun¹, Qiaoling Yan¹, Lining Song¹, Kai Yang¹, Tian Gao¹, Jinxin Zhang¹

¹CAS Key Laboratory of Forest Ecology and Management, Qingyuan Forest CERN, Institute of Applied Ecology, Chinese Academy of Sciences, Shenyang, China (jiaojunzhu@iae.ac.cn; xiaozheng@iae.ac.cn; yirongsun@iae.ac.cn; qlyan@iae.ac.cn; liningsong@iae.ac.cn; kyang@iae.ac.cn; tiangao@iae.ac.cn; zhangjinxin@iae.ac.cn)

Large-scale afforestation programs have been attempted worldwide to help improve environmental conditions. Most of these attempts have been unsuccessful for social-political, technical, and/or ecological reasons. However, China's Three-North Protective Forest Program, the World's Largest Afforestation Program (TNAP), is still ongoing (1978 to 2050). TNAP was designed to improve environmental conditions over an area of ≈ 4 million km² (42% of China). Although US \$35.2 billion were invested in TNAP during its first 40 years (1978–2017), its rationale and success are still being debated among scientists and in the media. To provide an objective evaluation of TNAP, we systematically conducted a range-wide assessment of it based on remote sensing, field surveys, and statistics. TNAP has produced significant ecological and socio-economic benefits: 71.5% increase in forest coverage, 1.4% improvement in crop yield, 61.0% and 14.9% reduction in areas of soil erosion and desertification, respectively between 1978 and 2017. TNAP helped 15 million persons out of poverty, provided the jobs for 300 million people, and enhanced the people's awareness of ecological protection. Challenges for TNAP include limited success in desertification control (the 14.9% total reduction almost exclusively limited to light desertification areas), and low coverage of shelterbelts (the ratio of shelterbelt area to farmland area was only 2.4%). Overcoming these challenges during the next 32 years will further enhance the contribution of TNAP, and profoundly influence the policy and practice of environmental protection and improvement in China and worldwide.

Promoting socio-economic development and cultural wellbeing in protected Atlantic forest areas: the potential and limitations of ecological fiscal transfers

Gracie Verde Selva¹ , Milena Kiatkoski Kim² 

¹Instituto Brasileiro de Desenvolvimento e Sustentabilidade, Brasília, Brasil; ²The University of Western Australia, Perth, Australia (gracieselva@gmail.com; milena.kim@uwa.edu.au)

Protected areas are an important component of Brazilian environmental policy to preserve forests. Protected areas require community support in order to achieve optimal outcomes, which can be facilitated through a number of policy approaches. Pioneered in Paraná in the early 1990s and then adopted by other states, the Ecological ICMS (ICMS-E) is an example of an ecological fiscal transfer (EFT) policy which attempts to address the trade-offs and opportunity costs associated with protected area regulation. In this presentation we examine versions of the ICMS-E from two states; Paraná and São Paulo. In both cases the ICMS-E provides monetary compensation to local governments that host protected areas within their municipal area of jurisdiction, whilst in Paraná the ICMS-E also promotes and rewards local conservation initiatives. We interviewed 51 state and local stakeholders from Brazilian municipalities located within relatively intact areas of Atlantic rainforest. We show the opportunities and obstacles municipalities have encountered in using the ICMS-E to (1) support local economic development that is aligned with environmental restrictions and (2) promote the cultural wellbeing of traditional communities. The results highlight the importance of the institutional arrangement underpinning the implementation of EFTs, and the necessity to engage with local institutions and communities in order for social, economic and environmental benefits to be realised. As the ICMS-E is now being widely adopted within Brazil and EFTs are being implemented elsewhere, the lessons learned in this case study have wider relevance for policy makers internationally.

Economics of wildlife conservation: the case of Chitwan National Park in Nepal

Ram Pandit¹

¹University of Western Australia, Perth, Australia (ram.pandit@uwa.edu.au)

Wildlife conservation involves various direct and indirect benefits and costs. The benefits of conservation are often shared by both local and global communities, while most of the direct costs are often borne by local communities. Conservation policies and economic instruments intend to balance such benefits and costs to achieve optimal conservation outcomes. Considering the conservation policies used over-time, this paper aims to examine an array of benefits and costs of conserving wildlife at Nepal's Chitwan National Park. The paper further draws on aspects of policy evolution and conservation status of targeted species in enhancing conservation benefits while minimising conservation costs. It also highlights the prospects and challenges associated with species conservation where private costs and public benefits are involved.

Real Options theory to value a forest restoration project in Legal Reserve

Rafaele Almeida Munis¹ , Maria Jose Brito Zakia¹ , Silvana Ribeiro Nobre² , Mariana Aparecida Carvalhaes³ , Danilo Simões¹ 

¹São Paulo State University (Unesp), School of Agriculture, Botucatu, Botucatu, Brazil; ²Universidad Politécnica de Madrid (UPM), Madrid, Spain; ³Embrapa Produtos e Mercado, Campinas, Brazil (rafaele.munis@gmail.com; zeze.zakia@uol.com.br; silvana.rnobre@gmail.com; mariana.carvalhaes@embrapa.br; danilo.simoese@unesp.br)

The obligation of an area located in a property is called Legal Reserve (LR) and in Brazil is given by the Law 12.651 / 2012 which provides for the protection of native vegetation to landowners holding areas greater than four fiscal modules. The main purposes of Legal Reserve are the conservation and restoration of the native flora, in addition the sustainable forest management. In this sense, the objective of this study was to value a forest restoration project destined to LR, with phytocology of Seasonal Semideciduous Forest, through the approach of pricing of discrete time multiplicative binomial options. The forest assets investment project, located in Botucatu city, State of São Paulo, Brazil, included species of native occurrence that generated income from timber and non-timber products. The cash flow planning horizon was 20 years, time required for RL recovery, discounted by CAPM. Due to uncertain commercial prospects, the forest producer may wait two years to realize the investment. Furthermore, if the investment is executed in the fifteenth year, the forest producer may expand the restored area by 30%. The results show that the probability of the investments being executed after two years was 100%. Moreover, the expansion at the end of the fifteenth year has a 7% probability of being exercised. Considering the options jointly exercised, the project added 90.04% of value to the forest producer, resulting in an expanded net present value of USD4,004.95, corroborating the economic feasibility of the restoration of native flora.

Framing woodland key habitats: how has the debate in media evolved over time?

Isabella Hallberg-Sramek¹, Therese Bjärstig², Annika Nordin¹

¹Swedish University of Agricultural Sciences (SLU), Department of Forest Genetics and Plant Physiology, Umeå, Sweden; ²Umeå University, Department of Political Science, Umeå, Sweden (isabella.hallberg.sramek@slu.se; therese.bjarstig@umu.se; annika.nordin@slu.se)

Woodland key habitats (WKHs), is a well-used concept in northern Europe, denoting sites in the forest landscape with particularly high nature conservation values. In Sweden WKHs on private forestland have been inventoried by the governmental Forest Agency since the early 1990ies in order to inform forest owners of valuable biotopes. Recently, various actors have started to question the WKH concept and its policy implications. To investigate how framing of the WKH concept has changed over time we conducted a media analysis based on *collective action frames*-theories, which states that actors who wants to promote a change often points out (1) who/what is *causing* a problem?, (2) who/what is *solving* a problem?, and (3) who/what is *suffering* from a problem?. In total, the analysis covered the period 1991-2018 and 294 articles in daily newspaper media framing WKHs. Our results showed that over time WKHs have mostly been framed by governmental agencies and by newspaper journalists as suffering from various forestry practices. However, during the most recent period, WKHs have also been framed as causing problems to private forest owners. This indicates a more polarized debate than previously between actors supporting forests' biodiversity vs economic values. We conclude that the WKH concept has changed from being a tool informing forest owners of their forest's biodiversity values to a highly politicized concept frequently debated in media. To fully understand the rationale behind this development, further studies are necessary.

From constrain to opportunity: win-win public-private partnership for financing sustainable poplar plantations and biodiversity conservation in Lombardy (Northern Italy)

Alex Pra^{1,2}, Alessandro Leonardi², Giulia Amato³, Mauro Masiero¹, Paola Gatto³

¹TESAF Dept. University of Padova, Padova, Italy; ²ETIFOR, Padova, Italy; ³TESAF Dept. University of Padova, Padova, Italy (alex.pra@etifor.com; alessandro.leonardi@etifor.com; giulia.amato@etifor.com; mauro.masiero@unipd.it; paola.gatto@unipd.it)

Financing the creation and maintenance of biodiversity conservation areas is a major challenge in times of constraints in public spending. In this context, Payment for Ecosystem Services are considered innovative and effective market approaches to conservation finance. We analyzed the objectives, the contents of the negotiated agreement, and the main outcomes of a Payment for Biodiversity Conservation Scheme (ECOPAY Connect) in the Lombardy Region in northern Italy, which brings together Regional Park authorities, timber industry, and private poplar growers as partners involved in complying with the requirements connected to an FSC® (Forest Stewardship Council) certification initiative. This scheme represents a win-win solution and transforms a certification compliance requirement, i.e. the set-aside of the 10% of the productive area for ecological restoration, into an opportunity, where a public-private partnership led to reduction of costs for both partners, and more functional restoration interventions within the park. The scheme now runs by its own, making ECOPAY Connect one of the few functioning PES schemes in Italy and in EU. The scheme was launched with a grant from the Bank Foundation and this partnership is now used as a best practice in many EU projects such as Gestire 2020, an integrated LIFE project by Lombardy Region, and Sincere, a Horizon 2020 project.

Social and spatial approach in constructing biodiversity indicators / Abordagem social e espacial na construção de indicadores de biodiversidade

Maria Luiza Almeida Luz¹

¹Universidade de Brasília, Brasília, Brazil (marialuizaluz@gmail.com)

A conservação da biodiversidade necessita ser ampliada sem prejudicar a economia e o seu crescimento. Isso poderá ser realizado pelos economistas se eles incorporarem indicadores de biodiversidade apropriados em seus modelos. Adicionalmente, os países devem assegurar que tais indicadores sejam metodologicamente robustos, que as necessidades dos diferentes grupos sociais estejam representadas e que os indicadores sejam os instrumentos ideais para avaliar a política à qual estão atrelados. Este trabalho propôs que a construção de indicadores de diversidade biológica incorpore os aspectos social (*stakeholders*) e espacial (escala). Foram analisados qualitativamente as metas e indicadores brasileiros de biodiversidade apresentados nos relatórios nacionais para a Convenção sobre Diversidade Biológica (anos 2011 e 2015), e o conjunto nacional de indicadores do PainelBio (2016). Os resultados apontam que o Brasil não adotou uma boa metodologia para as metas de 2011, com mais da metade das 51 metas não cumpridas, mas vem tentando incorporar as metodologias recomendadas pela CDB a partir do relatório de 2015 e do PainelBio. O avanço é frágil e o país ainda pauta o acompanhamento das metas de maneira qualitativa, carecendo de uma abordagem quantitativa. Outro gargalo identificado foi quanto à rastreabilidade das informações apresentadas nos documentos oficiais. Dessa forma, é preciso avançar para que o processo metodológico de elaboração dessas metas e indicadores seja registrado, compartilhado e disponibilizado de maneira mais transparente e acessível para toda a comunidade, para garantir que a metodologia empregada corresponda às expectativas científicas que se desejam alcançar com os instrumentos de avaliação da biodiversidade.

D9b: INTEGRATED APPROACHES TO SUPPORT EFFECTIVE IMPLEMENTATION OF FOREST LANDSCAPE RESTORATION

Who are stakeholders in forest landscape restoration?

Stephanie Mansourian¹

¹Mansourian.org, Gingins, Switzerland. University of Geneva, Geneva, Switzerland (smansourian@infomaniak.ch)

Understanding the diversity of stakeholders involved in large scale forest restoration is essential to success as they are at the core of any forest restoration effort. Stakeholders may be categorised in many different ways, recognising that categories hide unique differences. The purpose of this contribution is to better understand why it is important to identify stakeholders, present ways of categorising stakeholders in forest landscape restoration (FLR) and understanding what motivates them to engage in restoration. When dealing with landscapes or large scales, stakeholders can be found at many different spatial scales, and those involved in the restoration action may not necessarily be the ones benefitting or losing the most from restoration. Over time stakeholders evolve and change. Power dynamics are also an essential component in decision-making related to large scale forest restoration. Integrating different stakeholder characteristics, needs and values in FLR helps to secure long term buy in and success. Exploring some of the specificities of FLR also helps to better understand the full range of issues associated with stakeholders. I outline the diversity of stakeholders, at different scales, and highlight some of the reasons different stakeholders engage in restoration.

Integration for restoration: reflecting on lessons learned from the silos of the past

Rachel Carmenta¹, Bhaskar Vira¹

¹University of Cambridge, Cambridge, United Kingdom (rc730@cam.ac.uk; bv101@cam.ac.uk)

Momentum for forest and landscape restoration (FLR) is building and holds the potential to make a positive contribution to local livelihoods, wellbeing and the ecological integrity of forest landscapes. Yet FLR is operating amid multiple and competing demands for land and resources, which are too often acting in parallel rather than in unison. Silo-style approaches in which ecologists produce narrow restoration guidelines, foresters plant trees for production, companies invest in tree planting for carbon credits, and so on must be exchanged for new models of governance, management and knowledge production. This talk will draw on evidence that elaborates the shortfalls of approaching sustainable forest management through sectoral approaches. We focus in particular on the challenges that impact the management and governance of FLR interventions and those which confound and constrain the knowledge creation and the intellectual back-drop informing interventions and their implementation. These two issues are relevant to the fundamental questions that surround all forms of FLR: notably, FLR for what, pursued where and measured how. We focus on the tropics, drawing on the literature and specific case studies which illustrate how a lack of integration can undermine initiatives. We stress, in particular, the previous pot-holes on the road to forest restoration in order to highlight the need to incorporate these lessons in the current and emergent FLR agenda. We argue that without such reflection, the FLR momentum risks adopting an ahistorical and apolitical technocratic approach to the challenges of forest and land management.

Integration of traditional and western knowledge in forest landscape restoration

John Parrotta¹, Frank K. Lake², Christian P. Giardina³, Iain Davidson-Hunt⁴, Yadav Uprety⁵

¹USDA Forest Service, Research & Development, Washington, DC, USA; ²USDA Forest Service, Research & Development, Arcata, CA, USA; ³USDA Forest Service, Research & Development, Hilo, HI, USA; ⁴University of Manitoba, Winnipeg, Canada; ⁵Tribhuvan University, Kathmandu, Nepal (jparrotta@fs.fed.us; franklake@fs.fed.us; cgiardina@fs.fed.us; iain.davidson-hunt@umanitoba.ca; yadavuprety@gmail.com)

The diversity of environmental, historical, social, economic and cultural contexts in which forest landscapes (and their degradation) occur requires that restoration efforts effectively engage and mobilize the social and cultural capital that exists within these socio-ecological systems. In many parts of the world, the importance of incorporating local and indigenous knowledge, into land management decision-making is increasingly recognized, particularly to align management with the varied needs and place-based objectives of diverse stakeholders and the historical ecological realities of forest landscapes. In this presentation, we explore the process of integrating multiple knowledge systems in FLR, with a primary focus on experiences in North America. We will first examine the values and world views underlying Western and Traditional knowledge systems, as well as specific efforts to integrate knowledge systems in restoration and management at landscape scales in a variety of ecological and socio-cultural contexts. We consider the challenges - and opportunities - involved with integrating Traditional and Western knowledge systems at various stages of the FLR planning and implementation process, and how these challenges have been met, through case studies in Canada and the US.

Reconciling biodiversity conservation with livelihoods of vulnerable value chain actors through land degradation neutrality: shaping an enabling environment for sustainable and inclusive resource and market access in Brazil

Marcelo Inacio da Cunha¹

¹United Nations Convention to Combat Desertification, Bonn, Germany (mcunha@unccd.int)

This study analyses value chains of non-wood forest products (NWFP) – which occur in areas of high biodiversity and low human development indices – such as the Brazil nut chain in the Amazon. Such food chain actors are embedded in landscapes characterised by the lack of an enabling environment for achieving land degradation neutrality (LDN). Yet, ensuring no net loss of land-based natural capital depends on an enabling environment – particularly inclusive governance structures – for balancing socioeconomic and environmental trade-offs. Qualitative and quantitative data were collected from 2012–2015 to understand how institutions affect the resource and market access by vulnerable rural dwellers in Brazil. Household interviews (N=185) and key informant interviews, as well as problem-centered and narrative interviews (N=89) were conducted from community to national level – *inter alia* with the Brazilian Ministry of Environment. Results demonstrate that 15.5% of overall household income comes from forests, including 13.1% from Brazil nut gathering and marketing in the Lower Amazon basin. Environmentally sound resource and market access as well as inclusive sustainable development of the Brazil nut value chain is found to mainly depend on local democratic participation in decision-making by transforming the governance structures of councils for managing inhabited protected areas from consultative to deliberative ones. Results illustrate the importance of NWFP and the relevance of inclusive governance for reconciling environmental conservation and local livelihoods, while avoiding unsustainable land uses. Evidence is offered for shaping an enabling institutional and policy environment towards inclusive governance for sustainable integrated landscape planning.

Forest stewardship for restoration: integrating grassroots initiatives into landscape approaches

Andre Eduardo Biscaia de Lacerda¹, Maria Izabel Radomski^{1*}, , Julio R C Tymus²

¹Embrapa Florestas, Colombo, Brasil; ^{*}in memoriam; ²TNC do Brasil, Curitiba, Brazil (andre.biscaia@embrapa.br; maria.radomski@embrapa.br; jtymus@tnc.org)

In Southern Brazil, we have been developing and testing models of forest restoration that are economically viable and enable farmers to move away from monocultures, reduce their use of pesticides, and maintain the forest cover that is critical for local and regional ecosystem services. These models have been developed in collaboration with small-scale erva-mate (*Ilex paraguariensis*) producers and based on traditional knowledge of the forest. Forest products are key aspects of these models, including trees for wood production, erva-mate and other native fruit tree species; but they must adhere to Brazil's restrictive Forest Code. Avenues of agricultural innovation are needed to ensure that restoration approaches value the knowledge and important role farmers play in forest stewardship. The rationale of our restoration model is to rapidly establish a forest cover using fast-growing native pioneer species, especially *Mimosa scabrella* (bracatinga), which provides an appropriate shaded environment for erva-mate to thrive and direct economic return. After a forested environment is established (~3 years), natural regeneration is managed for species and product diversification while maintaining erva-mate production for a period of > 30 years. Additionally, we seek to value and document the voices and knowledge of traditional erva-mate producers not only to ensure that their products and culture is valued by society, but also that their important role in rural and urban ecological well-being is recognized and appreciated.

Forest Landscape Restoration (FLR) in Chile: how far are we?Rodrigo Mujica¹, Andrés Meza², Daniel Alvarez³, Constanza Troppa²¹Instituto Forestal (INFOR), Ministry of Agriculture, Valdivia, Chile; ²Corporación Nacional Forestal (CONAF), Ministry of Agriculture, Santiago, Chile; ³División de Recursos Naturales y Biodiversidad, Ministry of Environment, Santiago, Chile (rmujica@infor.cl; andres.meza@conaf.cl; dalvarezl@mma.gob.cl; constanza.troppa@conaf.cl)

In the last decades, Chile has made significant efforts to stop deforestation, recover soils through exotic forest plantations and conserve native forest ecosystems in protected areas. Likewise, in recent years sustainable management of native forests has been promoted through new regulations with the purpose of reversing their degradation. Although these processes are well valued by sector actors, they are increasingly criticized for their excessive centralism, which does not adequately account for the ecosystem and socio-cultural diversity of the territories in Chile. This aspect is one of the main motivations to promote the elaboration of the National Forest Landscape Restoration Plan, initiated in 2018 jointly by the Ministries of Agriculture and Environment. There is consensus in recognizing that the deterioration of ecosystems and their impact on the provision of ecosystem services diminish the current and potential future economy of the country and the well-being of the population. Likewise, it is recognized that Forest Landscape Restoration allows the search of common objectives by the different actors in the territories, which facilitates directing more effectively the public-private efforts to advance towards a socio-ecological development in balance with the local economies. In Chile, this process is considered a national strategic challenge of high relevance, which should specify and modify aspects of governance, financing, associativity, innovation, market, among others. A first version of the National Forest Landscape Restoration Plan will be presented at the next United Nations Climate Change conference, COP25, in Chile.

Systematizing experiences and analysis related to the processes of landscape degradation and restoration in Puriscal, Costa Rica / Sistematización de experiencias y análisis del proceso de degradación y restauración del paisaje en el Cantón de Puriscal, Costa RicaLizbeth Perea¹, Róger Villalobos²¹CATIE, ustín Metzquitlán, Mexico; ²CATIE, Turrialba, Costa Rica (lizp.badillo@gmail.com; rvillalo@catie.ac.cr)

Puriscal es el cuarto cantón de la provincia de San José. Tiene una extensión de 55 366 ha y se encuentra ubicado en el Pacífico Central de Costa Rica, se caracteriza por poseer una gran biodiversidad, se destaca la presencia de especies endémicas; sin embargo, una gran área presenta altos niveles de degradación, por lo que en la zona se han implementado diversas acciones para detener este proceso, mejorar la productividad de las tierras, y con ello, mejorar la calidad de vida de la población. Esto ha sido posible por medio de proyectos locales, nacionales o internacionales. Los procesos de degradación y restauración en el cantón de Puriscal se han dado como respuesta de la sociedad ante las pautas establecidas por los convenios internacionales a través de financiamiento y acompañamiento técnico, las tendencias políticas, principalmente las relacionadas con el sector agropecuario y ambiental y las demandas del mercado nacional e internacional. La identificación de los factores sociales, ecológicos, económicos que impulsaron la degradación y la restauración en parte del paisaje del cantón de Puriscal, dejan ver la influencia que han tenido las políticas de desarrollo económico y las demandas de los mercados de productos agropecuarios principalmente a nivel internacional o nacional y como la suma de todos estos factores ha moldeado el paisaje de este territorio, sin dejar de señalar que existe entre la población un sentimiento de apego al territorio y una ya formada conciencia ambiental que va favoreciendo a los cambios.

THEME E: FORESTS, SOIL AND WATER INTERACTIONS**E1a: AN INTEGRATED APPROACH FOR AFRICAN FOREST LANDSCAPE MANAGEMENT: WATER, ENERGY AND FOOD (WEF) NEXUS****Tropical montane forests are a critical resource for water and food security in East Africa**Mariana Rufino¹, Paolo Cerutti², Jan Gräff³, Suzanne Jacobs³, Naomi Karimi Njue⁴, Christopher Martius⁵, Anne Marie Ran⁶, John Quinton¹, Jaqueline Stenfert-Kroese⁷, Lutz Breuer³¹Lancaster University, Lancaster, United Kingdom; ²CIFOR, Nairobi, Kenya; ³Justus Liebig University, Giessen, Germany; ⁴Kabianga University, Kabianga, Kenya; ⁵CIFOR, Bogor, Indonesia; ⁶GIZ, Nairobi, Kenya; ⁷Lancaster University, Lancaster, Kenya (m.rufino1@lancaster.ac.uk; p.cerutti@cgiar.org; jan.graef@umwelt.uni-giessen.de; suzanne.r.jacobs@zeu.uni-giessen.de; kariminaomi@gmail.com; c.martius@cgiar.org; annemarie.ran@giz.de; j.quinton@lancaster.ac.uk; j.stenfertkroese@lancaster.ac.uk; lutz.breuer@umwelt.uni-giessen.de)

Tropical forests are critical for the water cycle and for water provisioning. In East Africa, increasing human population, rising incomes and competing demands on the land have led to massive forest loss. In Kenya, the forests of the 'water towers' are the headwaters of rivers delivering drinking water to most towns in the country. These forests are hotspots for biodiversity, and important carbon sinks, facing increasing pressure of human encroachment. Since 2014, we quantify the importance for water provisioning of the Mau forest, the largest montane forest in Kenya. Water is a critical currency for most people: it can be a blessing and a curse evidenced by the impacts of drought and floods. Excess water can cause crop and infrastructure damage and soil loss leading to community conflicts. Understanding of the dynamics of water flows, water quality and land use is required to improve land management. Our research shows that the largest concerns related to forest cover loss are the large amount of sediments in rivers and streams. The loss of fertile top-soil has direct impacts on food security with consequences for future generations, reducing the amount of crop harvests and their quality. Lack of forest cover undermines water and food security and therefore supporting communities to monitor their water resources is critical to create awareness and empower local decision-making. Our research used a citizen-science approach and demonstrated that communities can monitor their resources and use this information to implement sound management plans for forests, water and landscapes.

Anthropogenic influence on the floristic composition and water quality of a watershed ecosystem in three ecological zones of Nigeria: a need for integrated watershed managementSamuel Olajuyigbe¹, Israel Asinwa², Adebola Adegeye¹¹University of Ibadan, Ibadan, Nigeria; ²Forestry Research Institute of Nigeria, Ibadan, Nigeria (lekito2001@yahoo.com; israelasinwa@gmail.com; badegeye2005@yahoo.com)

Watershed forests protect rivers that provide water for agriculture, domestic and industrial uses, while ensuring biodiversity conservation and ecosystem sustenance. Thus, understanding the influence of land use change on the floristic composition and water quality are pertinent. Ogun River meanders through a

riparian ecosystem in three ecological zones in Nigeria. Using a stratified sampling technique, plant community diversity indices, water quality and soil physico-chemical characteristics were evaluated in the three land use types (primary-forest, degraded-forest and farmland) of the savanna, rainforest and swamp-forest ecosystems. Land use significantly influenced the vegetation cover, species diversity, soil properties and water quality. For instance, ground flora increased with land disturbance $266.55 \pm 20.2/m^2$ to $972.4 \pm 51.3/m^2$ with invasive herb species (*Chromolaena odorata* and *Petiveria alliacea*) dominating the disturbed ecosystems. Tree population and canopy cover increased with reduced disturbance of the ecosystem with 145 plant species (56 families) identified. Species diversity indices were inversely proportional to the degree of degradation and indicator species dominated each ecological zone e.g. *Daniella oliveri* (19.4%), *Adansonia digitata* (20.7%), *Parkia biglobosa* (41.1%). Soil physical and chemical properties improved with reduced disturbance of the land use types. For example, nitrogen and organic matter ranged from 0.88 ± 0.01 g/kg - 4.79 ± 0.05 g/kg and 1.48 ± 0.01 g/kg - 13.12 ± 0.21 g/kg, respectively. Undisturbed forest had the richest forest structure and diversity with a corresponding increase in the water quality of the river, irrespective of the ecological zone. There is need for an integrated approach to watershed management and restoration of the forest cover.

Forests and freshwater fish consumption in Nigeria

Amy Ickowitz¹, Michaela Lo¹, Sari Narulita¹, Terry Sunderland¹

¹Center for International Forestry Research (CIFOR), Bogor, Indonesia (a.ickowitz@cgiar.org; m.lo@cgiar.org; s.narulita@cgiar.org)

Nigerians depend on fish for maintaining diverse and healthy diets. Fish are a key source of protein and micronutrients, both of which are important for healthy diets. Some research has shown that forests provide important ecosystem functions that support the productive capacity and sustainability of inland fisheries. Our study aims to empirically assess the relationship between forest cover around rivers and fish consumption. We use data from the Living Standards Measurement Survey (LSMS) and spatially merge household and village data with forest cover and river maps. We estimate the relationship between forest cover around rivers and average village fresh fish consumption, whilst also accounting for other socio-economic and geographical determinants. We find that the density of forest cover around rivers is positively and significantly correlated with village consumption of fresh fish. Our results suggest that forests influence the consumption of fresh fish by improving the productivity of inland fisheries and increasing the availability of fish. Thus clearing forests for agriculture in order to produce more agricultural crops, might have the unintended consequence of reducing another important food source.

The conservation of the forest of *Acacia etbaica* located in Tigray region, Northern Ethiopia for the sustainable utilization

Masazumi Kayama¹, Koichi Takenaka², Kazuhisa Koda², Toru Sakai², Shunji Oniki², Masahiro Hirata³, Ryunosuke Ogawa³, Buruh Abebe⁴, Gebreyohannes Girmay⁴, Melaku Berhe⁴, Birhane Gebreanenia⁴, Emiru Birhane⁴

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Japan International Research Institute for Agricultural Sciences, Tsukuba, Japan;

³Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan; ⁴Mekelle University, Mekelle, Ethiopia (kayama@affrc.go.jp;

koichitk@affrc.go.jp; kodakazu@affrc.go.jp; torus@affrc.go.jp; oniki.shunji@affrc.go.jp; masa@obihiro.ac.jp; ryunosuke0225@gmail.com;

buruhetemek@gmail.com; gebreyohannes.girmay@gmail.com; melakuberhe@gmail.com; birhane.gebre12@gmail.com; emiru.birhane@mu.edu.et)

Acacia etbaica is a main woody species in the highland of Tigray region located in Northern Ethiopia. In this forest, deforestation due to expanding farmland and harvesting of fuelwood has been continuing. Longstanding deforestation causes soil erosion in rainy season. To conserve forest vegetation, we started up the integrated project in 2016. The contents of our project were divided into forest-ecology and socio-ecology. To estimate basic productivity of *A. etbaica*, we measured the biomass and growth. We also investigated the actual situation on the utilization of timber of *A. etbaica* by the residents. The annual productivity of *A. etbaica* in the research site was 63.6 kg ha⁻¹. Meanwhile, residents at the research site collect branches of *A. etbaica* for the fuelwood, and their consumption were markedly exceeded by their production. Therefore, forest of *A. etbaica* could not conserve because of large consumption of timbers. We should promote to plant the seedlings of *A. etbaica* for the sustainable utilization of fuelwood. However, seedling is easy to die by the long period of dry season. Biochar have a role to increase survival and growth of seedlings, and use of biochar produced by *A. etbaica* can contribute sustainable utilization by circulation of resource. We conducted the experiment to examine the effects of biochar. We planted the seedlings of *A. etbaica* adding 1 kg of biochar of *A. etbaica* in July 2017. After 14 months, we confirmed that addition of biochar increased leaf biomass of *A. etbaica*.

Determining Leaf Area Index threshold for obtaining an expected water yield for *Pinus radiata* plantations

Carlos Gonzalez-Benecke¹, M. Paulina Fernandez², Horacio Bown³, Oscar Mardones⁴

¹Oregon State University, Corvallis, USA; ²Pontificia Universidad Catolica de Chile, Santiago, Chile; ³Universidad de Chile, Santiago, Chile; ⁴Forestal Mininco, Los Angeles, Chile (carlos.gonzalez@oregonstate.edu; pfernan@uc.cl; hbown@uchile.cl; oscar.mardones@cmpc.cl)

Intensive forest management of *Pinus radiata* plantations in Chile has been focused on increasing stem volume production and maximizing revenue. Nevertheless, increasing drought, in addition to emerging conflicts with neighbor communities regarding water use in the watersheds, have opened the discussion about the sustainability of pine plantations, with emphasis in the general water balance. Base on that, in this study we explored the inclusion of critical Leaf Area Index (LAI) needed to attain a desirable water yield (WY) as an alternative decision variable for managing planted *P. radiata*. The 3-PG model was parameterized and validated for *P. radiata* plantations using the approach proposed by Gonzalez-Benecke et al. (2014 and 2015), including a new module that allows for thinning based on threshold upper and residual LAI. We tested the use of LAI in terms of WY and volume production. Thirty site conditions were selected, including different soils and climate across the distribution of planted forests in Chile. Using the newly parameterized 3-PG model, yearly LAI, WY and stem volume yield were computed for each site. Then, a range of critical or desired values of water yield were tested, and the mean LAI that can support this WY were obtained for each site. We determined the relationship between mean annual LAI and WY on sites with different water deficit. We also determined the trade-off between WY and stand volume yield at age 22 years. We demonstrated that LAI and water yield can be considered in future management for *P. radiata* plantations.

Modelling the impacts of Wattle (*Acacia mearnsii*) plantations on Ecosystem Services in South Africa

Dennis Junior Choruma^{1,2}, Stephan A. Pietsch³

¹Institute for Water Research, Rhodes University, Grahamstown, South Africa; ²Southern African Systems Analysis Centre, Stellenbosch, South Africa; ³IIASA – International Institute of Applied Systems Analysis, Laxenburg, Austria (denychor@gmail.com; pietsch@iiasa.ac.at)

Commercial forestry in South Africa is based on plantations of fast growing alien timber species like *Pine*, *Eucalyptus* and *Acacia* (Wattle). Besides the potential problem of species invasion towards sites outside of plantations, these exotic species exert a strong impact on ecosystem services delivery at the local, catchment level and regional scale. Among the best studied areas in South Africa, the case of the two streams catchment area is exceptionally rich in data collected over the last two decades. Data collected include tree growth, stand transpiration, above canopy eddy covariance fluxes, stream flow and soil water profiles. As such the

two streams catchment area is an ideal test case for the application of biogeochemical (BGC) vegetation models to complement ongoing soil water atmosphere transport (SWAT) modeling. Within this research we will assess the possible benefits of detailed process based vegetation modelling using field data from wattle plantations within the Two-Streams catchment area, BioGeoChemical ecosystem modelling to assess best options in terms of timber yield, catchment hydrology and their respective temporal dynamics.

E1b: SILVICULTURAL CHALLENGES UNDER ABIOTIC AND BIOTIC STRESSES AND ADAPTATIONS TO CLIMATIC ABNORMALITIES

Silvicultural production under climatic conditions of high-water deficit

Ben du Toit¹, Keith M Little², Dean da Costa^{1,3}, Paul W M Viero³, Jonathan Sheppard⁴, Anton Kunneke¹, Hugo A Lambrechts¹, Werner Mbongo¹, Gideon F Malherbe¹

¹Stellenbosch University, Stellenbosch, South Africa; ²Nelson Mandela University, George, South Africa; ³Mondi Limited, Hilton, South Africa; ⁴Albert-Ludwigs-University, Freiburg, Germany (ben@sun.ac.za; keith.little@mandela.ac.za; dean.dacosta@mondigroup.com; paul.viero@mondigroup.com; jonathan.sheppard@iwu.unifreiburg.de)

Several forested regions of the world experience high water deficits for protracted time periods. This limits productivity and poses significant environmental and economic risks to sustainability. We draw most examples from African landscapes where planted forest systems have been established to supplement production from (usually sparse and slow growing) natural forest enclaves. Under high water stress conditions, adaptations to conventional silvicultural systems may increase ecosystem resilience and profitability, and these adaptations apply at three different scales: (1) At the landscape scale, it is necessary to match the chosen silvicultural system(s) with a strategic risk management plan, to cater for stream flow impacts, fire and biotic risks. Case studies where tree planting is confined to specific terrain positions in the landscape (in combination with risk-averse silvicultural systems) are evaluated. We discuss landscape-scale wildfire buffer zones combined with intensified fuel management. Silvicultural systems in semi-arid zones may need multiple or enhanced income sources (such as non-timber forest products for high-end markets, combined with ecosystem benefits) to remain economically viable. (2) At the farm level, selection of silvicultural regimes that match site capability with viable wood product and market options are essential for system resilience. This may involve changes to conventional silvicultural regimes with respect to the species composition, stand density, thinning operations and rotation length. (3) Adaptation of operations at the forest compartment level (e.g. enhanced site preparation and residue management, intensive establishment and vegetation management techniques, as well as robust, vigorous transplant material) may increase survival and early tree growth.

Drought effect on root architecture and non-structural carbohydrate of *Cunninghamia lanceolata*

Zhenya Yang¹, Benzhi Zhou¹, Xiaogai Ge¹, Yonghui Cao¹

¹Research Institute of Subtropical Forestry Chinese Academy of Forestry, Hangzhou, China (yangzhenya1234@163.com; benzhi_zhou@126.com; gexiaogai2006@163.com; fjcyh77@sina.com)

The drought is a main abiotic stressor, which significantly impacts the eco-physiological processes of forest plants. Plant root is the first receiver of the soil drought, therefore, its response and adaptability is of great significance to forest silviculture under the climate change scenario. In this study, the root architecture and total non-structural carbohydrate (TNC) composition were investigated of one-year-old potted seedlings of *Cunninghamia lanceolata*, one of the most important timber tree species in subtropical area in China, under medium-level (50-55% maximum field capacity, MFC) and severe-level (30-35% MFC) drought stress. The dry weight, length, surface area and volume of root were all significantly lower under drought treatments than those under CK, and the differences significantly increased as the drought duration expanded. The drought significantly decreased the root fractal dimension, root tip number and root branching angle, turning the root systems more simplifiedly-constructed and developing downward into the deeper soil. The content of soluble sugar and TNC under medium-level drought was significantly higher than that under CK at the 30th day of this experiment, and declined over time, with no significant difference at the 60th day, and a significant decrease at the 90th day. *C. lanceolata* tends to invest more carbon to root system at the early stage of drought, and as the stress proceeds, it could simplify its root architecture at limited cost, and reduced root branching angle to facilitate the water absorption from deeper soil.

Water availability effects on growth and phenology of 11 poplar cultivars growing in semiarid areas in Turkey

Akkin Semerci¹, Claudio Guevara², Carlos Gonzalez-Benecke²

¹Gaziosmanpaşa University, Tokat, Turkey; ²Oregon State University, Corvallis, USA (aksemerci@gmail.com; guevarac@oregonstate.edu; carlos.gonzalez@oregonstate.edu)

In Turkey, current wood production does not meet the demand of wood-products, and that gap is expected to be larger in the near future. It is necessary to increase the productivity and growth efficiency of current forests and to expand the extension of forest plantations, including areas where drought is the main climatic constraint. Fast-growing species, such as poplars, are an effective way to obtain large volume yield. Even though Turkish researches have been working in hybridization programs to improve the quality and productivity of poplars cultivars, there are still large gaps in the understanding of the effects of drought on the performance and physiology of these cultivars. In this study, we analyzed the effects of water stress on growth and phenology of eight cultivars of black poplar (*Populus nigra*), two cultivars of Canadian poplar (the hybrid *P. x canadensis*), and one cultivar of eastern cottonwood (*P. deltoides*). The objective was to identify the cultivars better adapted to dry conditions in semiarid areas of Turkey. Seedlings of the eleven cultivars were grown under two contrasting watering regimes (well-watered and water stress). Seedling height, ground line diameter, and biomass were registered along with phenological traits such as bud break, leaf loss, and infection by *Cytospora chrysosperma*, a common fungal disease in Turkey. Significant interactions in the response of cultivars to water availability were observed for most of the traits assessed. Results obtained from this study provide valuable information for forest managers for selecting better adapted poplar cultivars for semiarid conditions.

A potential approach to restore inland salinity with *Eucalyptus* hybrids in Thailand

Nisa Leksungnoen¹

¹Kasetsart University, Chatuchak, Thailand (ffornsl@ku.ac.th)

Salinity is an ongoing abiotic stress problem, in the northeastern part of Thailand, due to the presence of salt in the parent rock material together with salt mining and deforestation. It leads to the reduction in the agricultural and plantation area, especially of the *Eucalyptus* plantation. Salinity varies with soil depth and seasons, ranging from 3 to 120 dS/m from the surface to a depth of 100 cm. During the dry season, the highest salinity is found in the top soil, while it is evenly distributed throughout the soil profile during the rainy season. Therefore, in the field, planting *Eucalyptus* seedlings, at a spacing of 3.5 m × 3.5 m, at a depth of 30 – 50 cm soil during the rainy season, is suggested to ensure survival at high salinity levels. Apart from the technique, the selection of high salt tolerant *Eucalyptus* species is equally important. Due to a similar drought and salt response, a *Eucalyptus* hybrid between *E. camaldulensis* × *E. urophylla* (H4), identified as drought tolerant, was selected to test for its salt tolerance and found that it could tolerate a salinity of up to 16 dS/m. Therefore, exogenous chemicals were applied to improve the salt tolerance. Selenium can enhance salt tolerance in the *Eucalyptus* seedlings at levels up to 40 dS/m with a 60% survival rate and a lower cell damage when compared to salicylic acid and proline. We recommend to treat *Eucalyptus* seedlings with selenium before planting with the suggested technique to improve the survival in the field.

Closing the forest hydrology loop: surface water and groundwater interaction within a South African Pine plantation and indigenous afrotemperate forest

Tatenda Mapeto¹, Mark Gush², Richard Bugan², Nangamso Tuswa³, Josua Louw¹

¹Nelson Mandela University George Campus, George, South Africa; ²Council for Scientific and Industrial Research, Stellenbosch, South Africa; ³University of Western Cape, Cape Town, South Africa (tatendamapeto@gmail.com; mgush@csiro.co.za; rbugan@csir.co.za; 3137233@myuwc.ac.za; josua.louw@mandela.ac.za)

In water scarce South Africa, natural forests are limited in extent and the country is reliant on plantations of introduced tree species for its fibre and timber requirements. These highly productive tree systems replaced lower leaf area vegetation such as grassland and scrub, causing increases in evapotranspiration with resultant changes in hydrological dynamics of afforested catchments. Paired catchment experiments and later process measurements, combined with modelling have allowed for quantification and regulation of stream flow reductions associated with tree plantations. However, aligning plantation hydrological impacts with only stream flow reduction represents a “black box” approach to understanding groundwater and surface water interaction. In this study, the hydrological processes in a catchment characterised by a mosaic of two Pine species plantations and indigenous afrotemperate forest, and generally a fractured rock aquifer environment were monitored over four years. The catchment is located in the southern Cape region of South Africa. A novel combination of sap flow, eddy covariance, groundwater, weather, and soil water monitoring, was combined with modelling. The mean annual precipitation over the monitoring period was 835 mm, including a dry 2016/17 total of 639.6 mm. Annual transpiration totals for the *Pinus radiata* and *Pinus elliotii* stands were 640 mm and 575 mm respectively in 2016/17, while mean evapotranspiration totals for the two stands over the entire monitoring period were 712 mm and 868 mm respectively. Modelling indicated significantly higher potential groundwater recharge in the indigenous forest compared to the Pine plantation stands.

Effect of planting density and irrigation in growth and CO₂ uptake of *Gmelina arborea* in Colombian dry tropical forests / Efecto de la densidad de plantación y la irrigación en el crecimiento y la captura de CO₂ de *Gmelina arborea* en el bosque seco tropical colombiano

Omar Melo¹, Carolina Betancourt¹

¹Universidad del Tolima, Ibagué, Colombia (omelo@ut.edu.co; acetancourt@ut.edu.co)

La investigación se realizó en áreas de bosque seco tropical del valle geográfico del río Cauca, en la región central colombiana (precipitación promedio= 1266 mm.año⁻¹., temperatura media anual de 25,5 °C. altitud= 595 m). Se estableció un experimento con seis densidades de plantación (3000, 2000, 1300, 900, 600 y 400 árboles.ha⁻¹) y dos condiciones de agua en el suelo (irrigación y no irrigación). Se evaluó el cociente de forma base (QB), el volumen del fuste, la biomasa total y la actividad fotosintética. Las evaluaciones se realizaron durante 4 años. Árboles establecidos en alta densidad (3000, 2000 árboles.ha⁻¹), presentaron volúmenes entre 0,05 a 0,07 m³. La forma del fuste fue cilíndrica (QB=0,72) y con ramas delgadas (18,4 a 22,3 mm). El factor de expansión de biomasa fue de 1,12. La dominancia apical del fuste se mantuvo en más del 90% de los individuos. Los árboles establecidos en baja densidad de plantación (600 y 400 árboles.ha⁻¹), alcanzaron volúmenes de 0,28 y 0,42 m³. La forma del fuste fue ahusada (QB=0,43) y con ramas gruesas (75,5 a 82,5 mm). El factor de expansión de biomasa fue de 1,94. La dominancia apical fue menor al 54%. La irrigación impidió la defoliación de los árboles en el periodo de sequía y la productividad se incrementó en más del 57% en comparación con el tratamiento de no irrigación. La asimilación neta con irrigación fue 28, 9 μmol.m⁻².s⁻¹, y de 17,5 μmol.m⁻².s⁻¹, sin irrigación. Estos resultados permiten entender el efecto de los factores limitantes y la competencia.

Modeling the effects of competing vegetation on soil moisture dynamics and planted conifer seedling water stress, growth and mortality in the U.S. Pacific Northwest

Claudio Guevara¹, Carlos Gonzalez-Benecke¹, Maxwell Wightman¹

¹Oregon State University, Corvallis, USA (guevarac@oregonstate.edu; carlos.gonzalez@oregonstate.edu; maxwell.wightman@oregonstate.edu)

Competition between newly established seedlings and competing vegetation can restrict seedling growth resulting in significant growth reductions. Forest vegetation management (FVM) reduces the cover of non-desired vegetation allowing seedlings to more effectively capture site resources and has been shown to increase the survival and growth of numerous conifer species, including Douglas-fir and western hemlock. However, there are still large gaps in the understanding of competition dynamics and resources usage, which could be addressed by studying the ecophysiology of these species. The Competition and Site Interactions Experiment (CoSiNE) being conducted by the Vegetation Management Research Cooperative (VMRC) at Oregon State University is investigating the influence of a common set of FVM treatments on planted conifer seedling survival, growth and ecophysiological responses across a range of climatic and soil conditions in the Pacific Northwest. The VMRC currently has 2 intensively measured CoSiNE research sites, one for western hemlock and one for Douglas-fir. Measurements being conducted at these sites include: soil moisture and weather dynamics, seedling growth, seedling predawn and midday water potential, and understory vegetation growth dynamics (cover, height and biomass). The data being collected at these study sites is being used to develop a process-based model to predict planted seedling growth and survival using site-specific weather, soils, and vegetation community information. This presentation will provide an overview of the CoSiNE project and share preliminary results on the water use of competing vegetation and the impact of competing vegetation on seedling drought stress and mortality.

Measurements of leaf water potential for three *Eucalyptus* species in Brazil

Amanda de Castro Segtowich¹, José Leonardo de Moraes Gonçalves¹, Alexandre de Vicente Ferraz²

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (amandasegtowich@usp.br; jlmgonca@usp.br; alexandre@ipef.br)

Leaf water potential (LWP) is an important physiological attribute of the plant water status. In this study, LWP was measured monthly during pre-dawn and midday in three *Eucalyptus* species (*E. grandis*, *E. urophylla* and *E. camaldulensis*). The experiment was carried out at the Experimental Station of Forest Sciences in Itatinga/SP, Brazil. Measurements were performed using the Scholander pressure chamber during a six-month period. Sixteen leaves per species (four per tree) were used in each campaign. The leaves were collected from the upper third of the canopy. *E. urophylla* had the lowest mean value of LWP throughout the whole period of study, both during pre-dawn and midday, reaching its lowest (-1.98 MPa) in the driest month (July 2018), when the gross rainfall was of 14.3 mm. *E. grandis* had the highest mean value of LWP in most of the measurements. Although *E. camaldulensis* is considered a tolerant species to water deficit, this species had a similar behavior to *E. grandis*, which showed lower water stress during most of the study period, including the driest month (July 2018) during midday. The results obtained for *E. urophylla* in this site suggest that this species has another type of mechanism in relation to water stress, one that shows it can grow under lower water potentials without having its growth and vital processes being affected. The high values of LWP measured during pre-dawn, however, suggest that there are hardly any water-related issues in the study site.

Production of carbohydrates, lignin, and flavonoids in *Eucalyptus urophylla* plants with B, Cu, and Zn deficiency / Produção de carboidratos, lignina e flavonoides em plantas de *Eucalyptus urophylla* sob carência de B, Cu e Zn

Liamara Masullo¹, José Leonardo de Moraes Gonçalves¹, Alexandre de Vicente Ferraz², Gislene Roberta Manarim¹, Patrícia Andressa de Ávila¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo Piracicaba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (liamaramasullo@usp.br; jlmgonca@usp.br; alexandre@ipef.br; gislene.manarim@usp.br; andressapa@yahoo.com.br)

Os micronutrientes são necessários em diversas rotas metabólicas que atuam na defesa das plantas contra o ataque de pragas e patógenos, tais como a produção de lignina, fenóis e fitoalexinas. Neste estudo, avaliou-se os impactos da deficiência de boro (B), cobre (Cu) e zinco (Zn) sobre a produção de carboidratos, lignina e flavonoides em folhas de *Eucalyptus urophylla*. O experimento foi conduzido em casa de vegetação. Mudanças clonais de *Eucalyptus urophylla* com seis meses de idade foram cultivadas em vasos com solução nutritiva por 120 dias. Foram avaliados os tratamentos: fertilização completa (FC) e omissões de B, Cu e Zn na solução nutritiva de cultivo. A carência de Cu e Zn elevou a concentração de carboidratos nas folhas em cerca de 10% (774 para 834 mg g⁻¹). A omissão de Cu desfavoreceu em 10% o processo de lignificação quando comparado à fertilização completa. A produção de flavonoides foi de 8,05 mgRE g⁻¹ nas plantas com fertilização completa, entre 45 e 75% maior do que nas plantas que ficaram sob omissões de B, Cu e Zn. O aumento do teor de carboidratos e as reduções dos teores de lignina e flavonoides nas folhas podem tornar as plantas de *E. urophylla* mais susceptíveis ao ataque de pragas e patógenos, além de reduzir sua resiliência (ex. cicatrização dos tecidos danificados).

E1p: SILVICULTURE AND HEALTH IN PLANTATION FORESTS

Adaptive capacity of different Norway spruce populations to lethal drought

Andreas Bolte¹, Tomasz Czajkowski¹, Tamalika Chakraborty¹, Tanja Sanders¹, Marco Natkhin¹

¹Thünen Institute of Forest Ecosystems, Eberswalde, Germany (andreas.bolte@thuenen.de; tomasz.czajkowski@thuenen.de; tamalika.chakraborty@thuenen.de; tanja.sanders@thuenen.de; marco.natkhin@thuenen.de)

Climate change is affecting forest ecosystems in particular by more frequent and severe extreme weather events like heat waves and droughts. This poses a specific risk for the drought sensitive Norway spruce (*Picea abies*), one of the most important commercial tree species in Europe. Thus it is assumed that maintaining a forest structure with spruce will increase the risk of forest damage. Here different populations of Norway spruce from its European range were studied in their response to extreme drought. In a greenhouse pot experiment lethal drought was simulated on spruce seedlings of eight provenances. Drought was applied until plants' death; during the experiment soil water availability (SWA, percentage proportion of available water AW), gas exchange, plant water status (pre-dawn water potential), and survival rate for each provenance were recorded. Based on survival rates, survival functions for the different populations were fitted. Results show varying responses of the provenances to drought, with the critical mortality rate of 50% (LD50) reached at a remaining soil water availability (SWA) ranging from 7% for a lowland population with low yearly precipitation to 8.3% for a mountainous population with considerably higher yearly precipitation. These outcomes demonstrate the general possibility to increase drought resistance of Norway spruce regeneration by using more drought-tolerant spruce provenances. Based on the results for spruce and those found in previous experiments with European beech (*Fagus sylvatica*) we will discuss the options and limitations of the use of rear-edge provenances of native species to improve forests' adaptive capacity in Central Europe.

Nutritional diagnosis of clonal *Eucalyptus* plantations in different climate zones in Brazil

Alvaro Andres Ramirez Palacio¹, José Leonardo de Moraes Gonçalves¹, Alexandre de Vicente Ferraz²

¹Universidade de São Paulo. Escola Superior de Agricultura Luiz de Queiroz., Piracicaba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (aramirez@usp.br; jlmgonca@usp.br; alexandre@ipef.br)

To maintain a high and sustainable productivity in forest plantations it is necessary to monitor the nutritional status of trees based on foliar analysis. The accuracy of the nutritional diagnosis of plants depends on the leaf concentrations that are used as reference values. For Brazilian conditions, with a large climatic gradient, establishing specific nutritional reference values for climate zones would contribute to a more accurate nutritional diagnosis, improving fertilizer recommendations as well as avoiding productivity losses. Considering the lack of specific nutrient reference values for different regions and genotypes, in this study we determined the nutritional sufficiency ranges in three different climate zones for the most planted *Eucalyptus urophylla* clone in Brazil. We used data of foliar nutrient content and tree growth from 454 sites (10,100 ha) with 1 to 2 years old stands of I144 clone, located in regions with different Köppen's climate types: Cfa (Paraná), Cwa (São Paulo) and Aw (Minas Gerais). There were differences in sufficiency ranges and in the nutrient limitation order among the climate zones. The differences were associated with water availability and soil attributes, mainly clay and soil organic matter levels. We conclude that the use of specific sufficiency ranges by climate zones could contribute to improve the accuracy of the nutritional diagnosis, providing a greater optimization of fertilizer use in forestry.

Fine-root distribution in *Eucalyptus pellita* F. Muell plantations in response to fertilizing with dolomitic lime, P₂O₅, and K₂O, in Puerto López, Colombian Orinoco region / Distribución de raíces finas, en plantación de *Eucalyptus pellita* F. Muell, en respuesta a fertilización con Cal dolomita, P₂O₅ y K₂O, en Puerto López, Orinoquía colombiana

Sandra Milena Díaz-López^{1,2}, Cristian Alexander Vega Marin³, Miguel Eugenio Cadena Romero²

¹Instituto de Proyección Regional y Educación a Distancia. Universidad Industrial de Santander, Málaga, Colombia; ²Universidad Distrital Francisco José de Caldas, Bogotá, Colombia; ³Corporación Colombiana de Investigación Agropecuaria – AGROSAVIA, Rionegro, Colombia (smdiazl09@gmail.com; cavcid@gmail.com; cademiello@hotmail.com)

En plantación de *Eucalyptus pellita* F. Muell, sometida a fertilización, con Cal dolomita (t/ha), P₂O₅ (Kg/ha) y K₂O (Kg/ha), localizada en la Orinoquía colombiana, zona de clima tropical, con distribución de precipitación monomodal, suelos muy pobres en nutrientes y alta acidez. Se instalaron cilindros de crecimiento interno a profundidad de 0 a 15 cm, en 4 distancias definidas desde el árbol, en diseño de bloques completos al azar 3x3x3 en la modalidad de serie de experimentos con diferente sitio e igual época, para conocer la incidencia de la fertilización en la distribución de raíces. Las muestras se recolectaron cada tres meses durante un año. Se obtuvo diámetro, área y longitud de raíz, analizadas junto con propiedades físicas y químicas del suelo. La interacción de los tres fertilizantes es preponderante y afecta la resistencia tangencial al corte; los tratamientos con mayor desarrollo radicular se encuentran en zonas de baja y media resistencia a la penetración, entre 18 – 25 kpa/cm y dosis medias y altas de P₂O₅ (75 y 120 Kg/ha). Para la longitud (m) en las localizaciones desde el árbol, la interacción en segundo grado fue significativa para los cilindros más cercanos (37.5 cm) y más alejados del árbol (150 cm). La forma de aplicación de los fertilizantes afecta la distribución de las raíces. Se confirma mayor concentración radicular con las dosis altas de P₂O₅ y la tendencia de las especies que crecen en suelo con texturas gruesas de tener más raíces laterales que buscan explorar mayores volúmenes de suelo.

Quality of *Eucalyptus* clonal seedlings produced in Ellepot and tube systems / Qualidade de mudas clonais de eucalyptus produzidas nos sistemas Ellepot e tubetes

Renan Santos¹, Adalberto Novaes¹, Nilton Sousa²

¹Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista, Brazil; ²Universidade Federal do Paraná, Curitiba, Brasil (renanalves93@hotmail.com; adalberto.brito@globo.com; nilton.ufpr@gmail.com)

Esta pesquisa foi desenvolvida no sul da Bahia, Brasil e analisou a viabilidade do uso de uma nova metodologia para a produção de mudas clonais de *Eucalyptus* spp., comparando a eficiência de recipientes biodegradáveis (Ellepot®), por meio de parâmetros morfo-fisiológicos, com mudas produzidas no sistema de tubetes. O experimento foi instalado em esquema fatorial 3x3, sendo três recipientes (Ellepot® 76,9 cm³ e Ellepot® 115,5 cm³); tubetes plásticos (55,0 cm³); e três clones de *Eucalyptus*: VCC-865, CO-1407 e AEC-144). No viveiro e casa de vegetação avaliou-se os parâmetros morfo-fisiológicos: a) altura da parte aérea (H); b) diâmetro de colo (D); c) relação H/D; d) biomassa fresca e seca aérea, radicular e total; e) potencial de regeneração de raízes-P.R.R. No campo avaliou-se: a) sobrevivência; b) altura da parte aérea; c) diâmetro ao nível do solo; d) comprimento e profundidade da raiz principal; e) deformações radiciais. A análise estatística consistiu de análises de variância, teste de médias (Tukey 95%) e análise de regressão. O sistema de produção de mudas em recipientes biodegradáveis (Ellepot®), com adequada formação e distribuição de raízes, foi superior em todas as fases de avaliação no viveiro e campo, quando comparado ao sistema convencional em tubetes (55 cm³). O P.R.R. foi considerado um parâmetro fisiológico confiável na determinação da qualidade das mudas e na predição de seu desempenho no campo. O clone VCC-865 apresentou a maior taxa de crescimento em altura e diâmetro no campo, 120 dias após o plantio.

Dynamics of growth of *Eucalyptus* clonal stands under wide edaphoclimatic and nutritional variations

Andréa V. A. Wenzel¹, José Leonardo de Moraes Gonçalves¹, Eduardo A. S. C. Melo², José Henrique T. Rocha³, Clayton Alcarde Alves⁴,

José Carlos Arthur Junior⁵, Rodrigo E. Hakamada⁶, Cristiane C. Z. Lemos⁷, Jarbas S. Borges⁸, Rogério R. Malheiros⁹
¹Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ²Sinarum Forestry, Perawang, Indonesia; ³Faculdade de Ensino Superior e Formação Integral, Agriculture and Forest Engineering College, Garça, Brasil; ⁴Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ⁵Universidade Federal Rural do Rio de Janeiro, Departamento de Silvicultura, Seropédica, Brasil; ⁶Universidade Federal Rural de Pernambuco, Departamento de Ciências Florestais, Recife, Brasil; ⁷International Paper do Brasil, Mogi Guaçu, Brasil; ⁸Duratex, Agudos, Brasil; ⁹Ramires Refortec, Ribas do Rio Pardo, Brasil (andrea.wenzel@gmail.com; jlmgonca@usp.br; eascmelo@yahoo.com.br; rocha.jht@gmail.com; caalvares@yahoo.com.br; josecarlosarthurjunior@gmail.com; rodrigo_hakamada@yahoo.com.br; cristiane.lemos@ipaper.com; jarbas.borges@duratex.com.br; rogerio@ramires.com.br)

Despite the adaptation of the genus *Eucalyptus* to the edaphoclimatic conditions of Brazil, reaching high productivity, the rhythm of increment in sectional area of the trunk and leaf area are influenced by abiotic agents, being soil fertility and water availability the most limiting for growth. Since the majority of soils destined for these plantations are highly weathered and with low nutritional content, the objective of this study was to evaluate over the course of 12 months the growth patterns of clonal stands between 48 and 60 months of age, established under omission of fertilization with N, P, K, complete omission and complete fertilization. This study was conducted in 4 forest sites, 3 in the State of São Paulo and 1 in Mato Grosso do Sul, differing as genetic material (*E. grandis* x *urophylla* and *E. urophylla* x *globulus* híbridos), soil class and climatic classifications (Aw and Cwa). The experiment consisted of 5 treatments, being the increase in the trunk of the trees evaluated by means of permanent dendrometers measures and, the canopy, by hemispheric photographs. It can be verified that the atypical climate of 2014 significantly influenced tree growth, being the water restriction the most limiting factor, between 18 and 40%. The dynamics of growth (gain and contraction of the trunk) varied between forest sites and class of trees, which can be explained by up to 66% by the rainfall, mean temperature and thermal amplitude. The treatments with the lowest accumulated increment were the omission of K and complete fertilization.

Potentially toxic elements in tropical soil under long-term effect of sewage sludge applied in *Eucalyptus* plantation

Antonio Leite Florentino¹, José L.M. Gonçalves¹, Alexandre de Vicente Ferraz², Cassio Hamilton Abreu-Junior³

¹Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ³Centro de Energia Nuclear na Agricultura, Universidade de São Paulo, Piracicaba, Brasil (antonio.florentino@usp.br; jlmgonca@usp.br; alexandre@ipef.br; cahabreu@cena.usp.br)

Studies about long-term effects of sewage sludge (SS) application are still scarce, especially in tropical areas under forestry management. Normally, the SS application in forestry plantations increase soil fertility, plant growth and nutrient cycling. However, there is a risk of contamination by potentially toxic

elements (PTE). We aimed to evaluate the long-term effects of SS application in tropical soil in terms of PTE (As, Ba, Cd, Co, Cr, Cu, Mo, Ni, Pb, Se and Zn) concentration in soil and their stock in Eucalyptus plantations. The measurements were after 12.2 years of the SS application on the soil, in Eucalyptus plantation with 45 months old, in Brazil. The long-term effect of SS increased PTE levels in soil and plants. There was a positive relationship between dose of sludge and concentration PTE in soil, mainly in superficial layers (0-20 cm). Notwithstanding, the PTE concentrations in soil were generally lower than the prevention values according the Environmental Company of São Paulo State (CETESB). In the same time, the aerial biomass production was favored by SS doses at 12.2 years ago, compared with control treatment. Consequently, we observed higher PTE stock in the stem, bark, branch and leaf compartments, respectively. The concentrations of As, Ba, Cd, Co, Cr, Cu, Mo, Ni, Pb, Se and Zn in soil didn't cause soil contamination or plant toxicity. Studies on long-term SS effects should be done to monitoring the pedoenvironment and serve for guidelines to ensure best practices when applying SS in forest plantings.

Forest performance of *Eucalyptus grandis* x *E. camaldulensis* hybrids in different planting spacing arrangements in the Chapada do Araripe, Araripina, Pernambuco, Brazil / Desempenho silvicultural do híbrido de *Eucalyptus grandis* x *E. camaldulensis*, sob diferentes espaçamentos de plantio na Chapada do Araripe, Araripina-PE

Marcos Drumond¹, Viseldo Oliveira¹, José Gomes Chaves², Jorge Ribaski³

¹Embrapa Semiárido, Petrolina, Brasil; ²Universidade Federal de Alagoas, Maceió, Brasil; ³Embrapa Florestas, Colombo, Brasil (marcos.drumond@embrapa.br; viseldo.oliveira@embrapa.br; jgomeschaves@hotmail.com; jorge.ribaski@embrapa.br)

O presente trabalho teve por objetivo avaliar efeitos de diferentes espaçamentos de plantio no desempenho silvicultural do híbrido *Eucalyptus grandis* x *E. camaldulensis*, na Chapada do Araripe. O ensaio foi instalado na Estação Experimental do IPA no município de Araripina-PE, (Latitude: 7°27'50"S, Longitude: 40°24'38"W, Altitude de 828 m), com temperatura média anual de 24 °C. A precipitação média anual é de 750 mm concentrados entre os meses de fevereiro e abril. O delineamento experimental adotado foi blocos ao acaso com cinco espaçamentos: 3,0 x 2,0 m; 3,0 x 2,5 m; 3,0 x 3,0 m; 3,0 x 3,5m e 3,0 x 4,0m, e quatro repetições. Cada parcela foi constituída de 64 plantas, com áreas úteis variáveis de 216 a 432 m², totalizando 11.520 m² de ensaio. Para efeito de análise foram consideradas apenas as 36 plantas centrais de cada parcela. O plantio foi feito no início do período chuvoso, após a aplicação de 2 toneladas por hectares de calcário dolomítico. Aos três anos de idade o híbrido *Eucalyptus grandis* x *E. camaldulensis* apresentou a menor sobrevivência (94%) para o espaçamento mais amplo, diferindo estatisticamente, dos demais, sendo 100% para os espaçamentos 3,0 x 2,0 m e 3,0 x 3,0 m. A altura variou de 12,5 a 13,2 m sem diferença significativa. Os dois espaçamentos mais amplos, apresentaram diâmetros superiores a 11,0 cm, diferindo dos demais. Quanto ao volume, o espaçamento de 3,0 x 2,0 m foi de 45,5 m³ha⁻¹, sendo superior aos demais, porém, sem diferença significativa do valor apresentado no espaçamento de 3,0 x 3,5 m, (38,4 m³ha⁻¹).

Effects of different spacing arrangements on forest performance of *Eucalyptus urophylla* x *E. brassiana* hybrids in the Chapada do Araripe, Araripina, Pernambuco, Brazil / Efeitos de diferentes espaçamentos de plantio sob o desempenho silvicultural do híbrido de *Eucalyptus brassiana* x *E. urophylla*, na Chapada do Araripe, Araripina-PE

Marcos Drumond¹, Viseldo Oliveira¹, João Calixto Junior², Jorge Ribaski³

O trabalho teve por objetivo avaliar desempenho silvicultural do híbrido *Eucalyptus brassiana* x *E. urophylla* submetido a diferentes espaçamentos de plantio, na Chapada do Araripe. O ensaio foi instalado na Estação Experimental do IPA no município de Araripina-PE, (Latitude: 7°27'50"S, Longitude: 40°24'38"W, Altitude de 828 m), com temperatura média anual de 24 °C. A precipitação média anual é de 750 mm concentrados entre os meses de fevereiro e abril. O delineamento experimental foi blocos ao acaso com cinco espaçamentos: 3,0 x 2,0 m; 3,0 x 2,5 m; 3,0 x 3,0 m; 3,0 x 3,5 m e 3,0 x 4,0 m, com quatro repetições. Cada parcela foi constituída de 64 plantas, com áreas úteis variáveis de 216 a 432 m², totalizando 11.520m². Para efeito de análise foram consideradas apenas as 36 plantas centrais de cada parcela. O plantio foi feito no início do período chuvoso, após a aplicação de 2 toneladas por hectares de calcário dolomítico. Aos três anos de idade, observou-se a sobrevivência do híbrido *Eucalyptus brassiana* x *E. urophylla* diferiu estatisticamente entre os diferentes espaçamentos, sendo inferior (83,3%) para o menor espaçamento (3,0 x 2,0 m), e superior (97,7%) para o espaçamento de 3,0 x 3,5 m. Para as demais variáveis os espaçamentos não influenciaram significativamente entre si, entretanto o espaçamento de 3,0 x 2,0 m em valores absolutos apresentou a maior produção volumétrica de madeira (49,0 m³ha⁻¹) enquanto que no espaçamento de 3,0 x 3,0 m a menor produção volumétrica foi de 30,0 m³ha⁻¹, evidenciando não existir competição entre as plantas nesta fase de desenvolvimento.

E4b: MANAGING INDUSTRIAL PLANTATION FORESTS FOR MULTIPLE OBJECTIVES

Review: productivity, economics and environmental impacts of short-rotation forest plantations in Northern Europe

Hardi Tullus¹, Reimo Lutter¹, Tea Tullus¹, Heiki Hepner¹, Arvo Tullus²

¹Estonian University of Life Sciences, Tartu, Estonia; ²University of Tartu, Tartu, Estonia (hardi.tullus@emu.ee; reimo.lutter@emu.ee; tea.tullus@emu.ee; heiki.hepner@kohila.ee; arvo.tullus@ut.ee)

Short-rotation forest (SRF) plantations have steadily expanded from southern regions to Northern Europe (NE). Poplars, aspens, birches are regarded as potentially suitable species for SRF in the region. SRF plantations could satisfy an increasing demand for renewable energy resources, reduce harvest pressure in natural forests, mitigate climate change and support biodiversity conservation. Hereby, we review the recent research progress concerning SRF in NE during the last decade and point out the future research needs. Research conducted during the last decade has proven that SRF plantations have a very high production potential compared to traditional long-rotation forestry. Besides that, the depletion of soil nutrient reserves is negligible and the need for additional fertilisation has not occurred, at least in short term. However, long-term understanding about nutrient dynamics is still needed. The testing of new plant material from breeding programmes is showing promising results; however, more attention should be paid to the adaptation with climate change. The studies about SRF plantations carbon (C) balance are reporting C sequestration effect but dynamics of soil C pools needs a longer observation time. The nature conservation studies are showing that SRF plantations can improve biodiversity in the landscape and offer a temporal habitat for forest species. SRF is probably an inevitable reality in NE in order to satisfy the increasing demand for wood-based products and mitigate climate change. The larger expansion of SRF plantations is currently mainly restricted by political boundaries such as lack of stable subsidies and uncertainties about certification.

A framework for assessing ecosystem goods and services from planted forests

Himal Baral¹, Manuel Guariguata¹, Rodney John Keenan²

¹Center for International Forestry Research, Bogor, Indonesia; ²The University of Melbourne, Melbourne, Australia (h.baral@cgiar.org; m.guariguata@cgiar.org; rjkeenan@unimelb.edu.au)

Recent research highlights the essential role of planted forests in providing multiple ecosystem goods and services (EGS) to human society. However, there has been little assessment of these EGS due to the lack of an appropriate framework, and knowledge of the tools to make EGS assessments. Researchers, policymakers and society at large have shown considerable enthusiasm and called appropriate approaches, classification and tools to be developed for assessment of EGS from planted forests. Drawing on lessons derived from EGS assessments around the world and consultations with a variety of stakeholders, we propose an easy-to-apply framework to assess EGS from planted forests that will be useful for various plantation types around the world. We recognise that the diverse characteristics of planted forests such as location, purpose, choice of species, rotation, management intensity, local demand and supply situation can influence the provision of EGS from planted forests. We anticipate this framework will be tested in various settings and will provide an important avenue to assess EGS from planted forests.

From acacia to eucalypt: productivity and fertility implications of plantations species shift in Indonesia

Johannes Pirker^{1,2}, Stephan A. Pietsch¹, Dmitry Schepaschenko¹, Sidiq Pambudi³, Subekti Rahayu³, Florian Kraxner¹

¹International Institute for Applied Systems Analysis (IIASA), Laxenburg, Austria; ²KU Leuven - Catholic University Leuven, Leuven, Belgium; ³World Agroforestry Center (ICRAF), Bogor, Indonesia (pirker@iiasa.ac.at; pietsch@iiasa.ac.at; schepd@iiasa.ac.at; s.pambudi@cgiar.org; s.rahayu@cgiar.org; kraxner@iiasa.ac.at)

The plantation forestry sector in Indonesia has seen a change in species from *Acacia mangium* to *Eucalyptus pellita*. This change, forced by diseases spreads, has affected more than 90% of the plantation area in Indonesia and it is unprecedented in its scale in the history of plantation forestry (Nambiar et al., 2018). It is also a change of tree species with very different eco-physiological patterns: *Acacias* – in contrast to eucalypts - are leguminous trees and therefore self-sufficient in nitrogen supply and capable of building significant stocks of nitrogen and carbon in the soil, two main determinants of plantation productivity. The large-scale species shift therefore raises questions about the sustainability of the pulp and paper sector in Indonesia in the coming decades as well as the role of past land use and site quality in Indonesia's forest restoration pledge. The proposed contribution therefore aims at analyzing the sustainability in terms of productivity of the Indonesian plantation forestry sector under the new eucalypts regime. To that end, we will deploy the BioGeoChemistry Management Model (BGC-MAN; Pietsch, 2014) which is capable of representing the carbon, water and nitrogen cycles in great detail. Expected results will include a reconstruction of the rise and fall of *A. mangium* and shift to *E. pellita* as well as forecasts of plantation productivity and soil fertility over the next decades; it will notably answer the question for how long soil N-stock accumulated by acacias will be able to feed eucalypts.

Discussion on sustainable management strategy of *Eucalyptus* plantation in China

Yaojian Xie¹

¹China Eucalypt Research Centre, Chinese Academy of Forestry, Zhanjiang, China (cercxiejy@163.com)

Eucalyptus was introduced to China as early as 1890s. After successful development of some larger plantations in western Guangdong and southern Guangxi in 1950s, *Eucalyptus* gradually came to be recognized as one of key plantation tree species in southern China. Since the beginning of 1990s *Eucalyptus* plantations have developed particularly rapidly, and their plantation area reached 4.5 million m² in 2015. The annual production of wood from this *Eucalyptus* plantation resource have reached over 30.0 million m³, accounting for 26.9% of China's entire domestic timber production and making significant contributions to the security of the country's wood and fibre supply. China's *Eucalyptus* industry now comprises a complete industrial chain that includes nurseries and seedling production, fertilizers, saw-timber, pulp and papermaking, artificial board, biomass and forest by-products with a total annual outputs of around RMB ¥300 billion. The key to future successful development of *Eucalyptus* plantations is scientifically sustainable management. Firstly, the government should have a good planning for *Eucalyptus* development. Secondly, we must revise industry's concept of management from that purely for timber production to management that combines timber production with environment protection. At the same time, following technical measures of sustainable management need to be achieved: (1) Planting tree species and varieties properly matched with sites; (2) establishing mixed species plantations; (3) Scientific management of all vegetation; (4) improving site preparation and planting techniques; and, (5) scientific management of plant diseases and pests.

Precision forestry in zoning the productive potential of *Pinus taeda* L. in Midwestern Santa Catarina, Brazil / Silvicultura de precisão no zoneamento do potencial produtivo de *Pinus taeda* L. na região Centro-Oeste do Estado de Santa Catarina, Brasil

Edison Rogério Perrando¹, Sérgio Luiz Bostelmann², Vlademir Martarello², Bruno Conte², Juliana Tramontina^{2,3}, Rudinei De Marco⁴, Maio Boff Burgin⁵

¹Universidade Federal de Santa Maria, Frederico Westphalen, Brazil; ²Adami S/A Madeiras, Caçador, Brazil; ³Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; ⁴Universidade Federal de Pelotas, Pelotas, Brazil; ⁵Klabim, Telêmaco Borba, Brazil (edison.perrando@ufsm.br; sergio.bostelmann@adami.com.br; vlademir.martarello@adami.com.br; bruno.conte@adami.com.br; tramontina.ju@gmail.com; rudineidemarco@hotmail.com; marioboffburgin@hotmail.com)

As florestas plantadas ocupam 7,84 milhões de hectares e são responsáveis por mais de 90% de toda a madeira utilizada para fins produtivos. A perspectiva para os próximos anos aponta um desequilíbrio entre oferta e demanda de madeira, com risco de déficit no fornecimento. O planejamento e a gestão florestal possuem o desafio e a responsabilidade de tomar ações que preconizam a otimização dos recursos e atividades, garantindo aumento de produtividade e maximização dos lucros. A silvicultura de precisão, no âmbito das geotecnologias, é uma ferramenta útil à decisão e implementação de intervenções eficazes e economicamente sustentáveis no manejo dos povoamentos. O presente estudo objetivou mapear a variabilidade espacial da capacidade produtiva em povoamentos de *Pinus taeda* L., bem como avaliar e identificar os principais fatores limitantes de sua produtividade florestal. A abrangência do estudo foi equivalente a 17.200 hectares, na área de manejo florestal da empresa Adami S/A, localizada na região Centro Oeste de Santa Catarina, e contou com o apoio da Universidade Federal de Santa Maria Campus Frederico Westphalen. Uma base de dados com 2.308 pontos de coleta de campo permitiu, em ambiente SIG (Sistema de Informações Geográficas), a caracterização fisiográfica do meio e dos atributos físico/químicos do solo. A análise integrada de mapas temáticos de produtividade em relação aos atributos do meio físico, assim como uma análise hierárquica "multicritérios" (AHP) possibilitou identificar as variáveis condicionantes à produtividade de *Pinus taeda* e, por conseguinte, embasar a tomada de decisão em nível de Unidades de Manejo Florestal.

Effects of site preparation and fertilization on early growth of *Gmelina arborea* growing under environmental conditions of the tropical dry forest in Colombia

Ana M. López¹, Alonso Barrios¹, Alvaro Davila¹

¹Universidad del Tolima, Ibagué, Colombia (amlopeza@ut.edu.co; abarriost@ut.edu.co; aadavilag@ut.edu.co)

Site preparation and fertilization applied in the first years of development of a forest plantation allow the maximization of economic benefits of the crop with increased yield in volume. Quantifying the response to these intensive silvicultural practices is essential to develop environmentally sustainable and cost-effective systems. *Gmelina arborea* is one of the main species used in reforestation programs in Colombia because of its adaptability to different site conditions and its growth rates. The aim of the study is to evaluate the effect of site preparation and fertilization on the early growth of *G. arborea* growing under edaphic and climatic conditions of the upper Magdalena river basin, Colombia. The experimental design used is a randomized complete block design with arrangement in split plots. The treatment arrangement has two factors: site preparation (two levels) and fertilization (eight levels) and three replications. The evaluated response variables are growth in diameter, height, basal area and volume. After 20 months of evaluation it was found that site preparation and fertilization had a significant effect on growth in height, diameter, basal area and volume. The mechanized site preparation showed increases of up to 34% compared to the manual site preparation. The combination of fertilization with N+P+K and subsoiling showed to be the best combination of treatments reaching mean annual increments of up to 54 m³/ha/year. These results allow to identify practices that contribute to increase yields and decrease rotation times for the species.

Strengthening forest productivity through diffusion and transfer of alternative forest species, promoting innovation and competitiveness among forest owners and companies in Chile / Fortalecimiento de la productividad forestal a través de la difusión y transferencia de especies forestales alternativas, promoviendo la innovación y competitividad de propietarios forestales y empresas en Chile

Juan Carlos Pinilla Suárez¹, Karina Luengo Vergara¹, Mauricio Navarrete Torres¹

Instituto Forestal de Chile, San Pedro de la Paz, Concepción, Chile (jpinilla@infor.cl; kluengo@infor.cl; mnavarre@infor.c)

El Instituto Forestal de Chile desarrolla programas de investigación sobre especies forestales, con el propósito de ofrecer al sector nuevas opciones productivas, generando información acerca de ellas y sus mejores técnicas de establecimiento y manejo de plantaciones, en estrecha colaboración con empresas forestales, servicios públicos y asociaciones de medianos y pequeños propietarios. El artículo se enfoca en el potencial de desarrollo y aporte de bosques con especies de *Acacia* a la comunidad rural y sector productivo, el cual a través de la difusión de los resultados y el trabajo directo con los propietarios, ha permitido la adopción de adecuadas herramientas de gestión forestal, con mejoras en la productividad de bienes económicos y sociales proporcionados por este tipo de bosques, lo que se asocia a mejoras en las condiciones de habitabilidad de las comunidades rurales y emprendimientos locales, con un incremento de la calidad de vida, además de externalidades positivas referidas a la protección de los suelos, su aporte a la mitigación de los efectos de los gases de efecto invernadero y del cambio climático. Las especies del Género *Acacia* en Chile, presentan crecimientos y productividad que permiten alcanzar retornos económicos a temprana edad, asociado a adecuadas propiedades de la madera, permitiendo optar a opciones de negocio a propietarios y productores. Se presenta el proyecto y sus resultados, centrado en fomentar la utilización eficiente de especies de *Acacia* en procesos de producción, industria de la madera y energía, apoyando a productores locales y el bienestar de los habitantes rurales y urbanos.

E4c: TROPICAL WETLANDS, CLIMATE, AND LAND-USE CHANGE: CHALLENGES AND OPPORTUNITIES

The Sustainable Wetlands Adaptation and Mitigation Program (SWAMP) as a model program for integrating science with international development

Randy Kolka¹

¹USDA Forest Service Northern Research Station, Grand Rapids, MN, USA (kolka003@umn.edu)

Carbon-rich tropical wetlands (mangroves and peatlands) are important in climate change adaptation and mitigation strategies and provide numerous ecosystem services such as storm protection, nursery areas for fish, habitat for rare species, long-term storage of carbon, and food, fiber, and fuel for humans. Because of their importance we developed the Sustainable Wetlands Adaptation and Mitigation Program (SWAMP) to assist countries with their accounting and conservation of tropical wetlands. SWAMP is a collaborative effort between the Center for International Forestry Research and the USDA Forest Service through support from the US Agency for International Development. The goal of SWAMP is to provide policy makers and natural resource professionals with credible information and training to make sound decisions regarding the role of tropical wetlands in climate change adaptation and mitigation. The SWAMP objectives are to: (1) Quantify greenhouse gas emissions from intact and disturbed wetlands; (2) Quantify carbon stocks of representative tropical wetlands; (3) Develop carbon modeling tools and scaling approaches using remote sensing; (4) Define roles for tropical wetlands in climate change adaptation strategies; and (5) Promote capacity building and outreach as integral parts of all activities. Through integrating research, outreach and policy, SWAMP has led to many leveraged efforts both within and across participating countries leading to more accurate tropical wetland greenhouse gas accounting and governmental responses to changing climate.

Carbon burial in mangrove forests: implications for mangrove restoration

Richard MacKenzie¹, Sahadev Sharma², Sigiti Sasmito^{3,4}, Daniel Murdiyarsa⁴, Joko Purbospito⁵, Alan Castillo⁶

¹US Forest Service, Hilo, USA; ²University of Malaya, Kuala Lumpur, Malaysia; ³Charles Darwin University, Darwin, Australia; ⁴Center for International Forestry, Bogor, Indonesia; ⁵Sam Ratulangi University, Manado, Indonesia; ⁶Department of Environment and Natural Resources, Los Banos, Philippines (rmackenzie@fs.fed.us; sahaddev.isro@gmail.com; sigitdeni.sasmito@cdu.edu.au; d.murdiyarsa@cgiar.org; jpurbobop@gmail.com; allan536@yahoo.com)

Mangrove forests remove and store massive amounts of C from the atmosphere. This occurs through C burial in waterlogged and anoxic sediments that preserve C stocks, increasing mangroves importance in climate change mitigation and adaptation strategies. Despite their importance, mangroves continue to be cleared for charcoal, salt pannes, aquaculture ponds, and rice fields. This has resulted in an average loss of 516 Mg C/ha, most of which has come from mangrove sediments. Despite recent mangrove restoration efforts to offset C losses, it has been suggested that it could take ~300 years to restore mangrove C stocks that have been lost. This estimate is based off of a global average C burial rate of 1.74 Mg C ha⁻¹ yr⁻¹. More recent studies comparing C stocks across different aged restored sites have found that C stocks of restored mangrove can approach baseline levels of intact systems in as little as 30-70 years. This is likely due to higher

C burial rates in younger forests through greater root production. Using the naturally occurring radionuclide ^{210}Pb and the Constant Rate of Supply model, we tested this idea by quantifying C burial rates from sediment cores collected across different aged restored mangrove sites in Southeast Asia. Preliminary results revealed that C burial in restored sites can range from 2.85-14.25 Mg C ha⁻¹ yr⁻¹, much greater than the global average. This suggests that C stocks of younger restored sites may approach C stocks of intact forests much faster than previously suggested.

Evaluation of large-scale mangrove plantations in the Philippines and its policy and management implications

John Benrich Zuniga^{1,2}, Carmelita Villamor¹, Alvin Gestada¹, Diana Riza Africa¹

¹Ecosystems Research and Development Bureau, Los Banos, Laguna, Philippines; ²University of the Philippines, Los Banos, Laguna, Philippines (johnbenrichzuniga@gmail.com; villamor321@gmail.com; alvingestada@yahoo.com.ph; diane.africa@gmail.com)

In the Philippines, ecosystem damages from strong typhoons has prompted the government to rehabilitate mangroves to increase coastal resiliency. However, various environmental and management factors affect mangrove plantation success. The study evaluated the survival rate of 30 selected large-scale plantations across the Philippines as affected by different environmental parameters. The average survival rates were found to be highly variable across the sites which ranges from 24%-84% and an average of 56% to 48% in 2016 and 2017 respectively. Survival rate was found to be related to distance from shoreline/mangrove forest edge ($p=0.002$), planting of correct species ($p=0.025$), land-use type ($p=0.025$) and negatively correlated with average wind speed ($p=0.029$). Multiple Regression Analysis ($R^2=0.56$, $p<0.001$) was done to determine the corresponding regression weights of significant factors. Results further show that mortality were attributed to climatic phenomenon such as frequency and strength of storms in combination with species-site mismatch. In response, there have been several initiatives by the Philippine government to improve mangrove rehabilitation initiatives which includes nationwide capacity building and technical assistance on mangrove conservation and rehabilitation projects. It is further recommended to strengthen science-based mangrove planting and interagency convergence particularly in rehabilitating former mangrove areas such as abandoned brackish water fishponds which was also shown to have higher survival rate compared to other habitat types. Science-based policy recommendations from this study may be applied to improve the effectiveness of future mangrove rehabilitation projects for coastal protection in the Philippines.

Opportunities and challenges for effective, efficient and equitable mangroves management: lessons learnt Vietnam

Thuy Pham Thu¹, Phuong Vu Tan², Chien Pham Duc², Truong Nguyen Van², Trang Dao Le Huyen², Hoa Hoang Nguyen Viet², Long Hoang Tuan¹, Chi Dao Thi Linh¹, Tien Nguyen Dinh¹

¹Center for International Forestry Research (CIFOR), Hanoi, Vietnam; ²Vietnamese Academy of Forest Sciences (VAFS), Hanoi, Vietnam (t.pham@cgiar.org; phuong.vt@vafs.gov.vn; p.d.chien@vafs.gov.vn; truong.nv@vafs.gov.vn; huyentrang0804@gmail.com; hoa.hnv@vafs.gov.vn; bberviet@gmail.com; chi.daolinh161194@gmail.com; ndtien.up@gmail.com)

The area of mangrove loss in Vietnam has been increased for the last 20 years. This study aims to analyses both opportunities and constraints for mangrove protection and management in Vietnam and draws out lessons learnt for more effective, efficient and equitable policies. We collected data from focus group discussion, household survey, semi-structure interviews and consultation workshops with more than 1000 people. We found that a large number of policies and projects in place to promote mangrove conservation activities has helped to enhance stakeholders capacity, provide additional funding for mangrove protection, raise local awareness of the role and importance of maintaining mangrove. However, drivers of mangrove deforestation and degradation are complex, and often associated with national economic development strategies. Current mangrove protection policies and projects are impeded by insecure tenure, land grabbing, elite capture, and inequitable benefit-sharing mechanism. Institution setting for mangrove protection is also constrained by overlapping and unclear responsibilities amongst government agencies and weak monitoring and evaluation system. The current policies and projects gave a strong emphasis and create incentives to replant mangrove forests but not to maintain and conserve existing mangrove. Incentives are also designed to compensate local labor costs to reforest mangrove or carry out patrolling activities rather than addressing direct drivers of mangrove loss. Protecting existing mangrove area requires a policy shift in land use planning to address drivers of mangrove deforestation and degradations, accountable and transparent benefit sharing mechanism, inclusive decision-making process and a combination of both in-kind and in-cash payments

Enhancing NDC ambitions of countries with carbon-rich peatlands in the tropics: a preliminary account

Daniel Murdiyoso¹, Christopher Martius¹, Kristell Hergoualch², Stephen Leonard¹

¹Center for International Forestry Research, Bogor, Indonesia; ²Center for International Forestry Research, Lima, Peru (d.murdiyoso@cgiar.org; c.martius@cgiar.org; k.hergoualch@cgiar.org; s.leonard@cgiar.org)

The recent IPCC report confirmed that an average global temperature increase of 2 °C above pre-industrial levels poses greater risks than previously believed. Limiting warming to 1.5 °C can substantially lower these risks – but requires dramatic emission reductions by 2030 and carbon neutrality by around 2050. The Paris Agreement requires Parties to the United Nations Framework Convention on Climate Change to contribute their emission reduction target through Nationally Determined Contributions (NDCs). Southeast Asia and the Amazon are among the regions with great opportunities to transform their NDC ambitions through peatlands. Indonesia's first NDC with emission reduction target of 29% would bring the emission level to 2,034 Mt CO₂-e in 2030 from 1,334 Mt CO₂-e in the base year of 2010. Meanwhile, Peru's first NDC with emission reduction target of 20% would bring down its emission level to 298 Mt CO₂-e in 2030 from 171 Mt CO₂-e in the base year of 2010. Provided the current strong policy on peatland conservation and restoration is sustained, Indonesia could further lower its emissions by 11 to 110 Mt CO₂-e annually depending on how peatland fires prevention can be imposed. Since Peru has no peatland-related policy in place, the opportunity from emission avoidance of around 30% due to drainage might be missed. The only factor that sustain Peruvian peatlands is their remoteness and lack of road network.

Tropical peatland degradation and restoration of Indonesia: inclusive evidence-based diagnostics and planning

Sonya Dewi¹, Andree Ekadinata¹, Arga Pandiwijaya¹, Ping Yowargana²

¹ICRAF, Bogor, Indonesia; ²IIASA, Laxenburg, Austria (s.dewi@cgiar.org; a.ekadinata@cgiar.org; a.pandiwijaya@cgiar.org; yowargan@iiasa.ac.at)

Land use changes have been imposing major pressures to peatland ecosystems of Indonesia, being the largest in the tropics, and causing extensive and severe degradation. Climate changes, through extreme weather, especially droughts, exacerbate the impacts of peat draining on fire and GHG emissions. The government have made commitments to restore peat ecosystems. Planning, implementation and impact monitoring have been initiated, supported by policies and fiscal instruments. In supporting this aspiration, we conduct the analysis of land use/cover changes on peat ecosystems throughout Indonesia over the past

25 years, teasing apart the large-scale plantation-driven and smallholder-driven conversion of land and forest across various designated functions, including production and protection forest land and agricultural land. We then delve deeper in South Sumatra province, which in 2015 had experienced the worst fire incidence throughout Indonesia. The paper describes the process and discuss the results of the technical analysis that serve as diagnosis of driver-pressure-state-impacts of peat degradation, followed by the strategy development to restore the degraded peat ecosystems. We conclude that the interaction between large-scale operations, namely oil palm and pulp forest plantations, with the smallholder agricultural practices have been the primary activities that causes unprecedented rate and extent of peat degradation in the relatively recent years. In restoring peat ecosystems, system-wide diagnosis, broad solution space, coherent policies and strong partnerships need to be in place. Economic-based scenario modelling at the national level combined with spatially explicit modelling at the local level are instrumental to support the evidence-based planning of peat restoration.

Carbon dioxide and methane budgets of a palm swamp peatland in Iquitos, Peru

Timothy Griffith¹, Daniel Roman², Lizardo Fachin Malaverri³, Randall Kolka², Jhon Rengifo Marin³, Dennis del Castillo Torres³, Erik Lilleskov⁴, Rodney Chimner⁵, Craig Wayson⁶

¹University of Minnesota, Saint Paul, USA; ²USDA Forest Service, Grand Rapids, USA; ³Instituto de Investigaciones de la Amazonia Peruana, Iquitos, Peru; ⁴USDA Forest Service, Houghton, USA; ⁵USDA Forest Service, Washington D.C., USA; ⁶International Programs, Washington D.C., USA (timgriffis@umn.edu; danielroman@fs.fed.us; lfachin@iiaip.org.pe; rkolka@fs.fed.us; jhevrema@gmail.com; ddcastillo@iiaip.org.pe; elilleskov@fs.fed.us; rchimner@mtu.edu; cwayson.silvacarbon@gmail.com)

Tropical peatlands have been identified as a major biophysical feedback factor on the atmospheric greenhouse effect. The largest expanses of tropical peatlands are located in lowland areas of Southeast Asia and the Amazon basin. The Loreto Province of Amazonian Peru is comprised of ~36,000 km² of peatlands. However, little is known about these peatlands and their carbon dioxide and methane budgets and their response to hydrometeorological forcing. To address these knowledge gaps we established an eddy covariance flux tower in a palm swamp peatland in Iquitos, Peru. Here, we report on energy balance, carbon dioxide, and methane flux observations over the period January 2017 to present. The seasonal variation in hydrometeorology had a strong control on evaporation and carbon dioxide fluxes. Evaporation was most pronounced in November through December, while the net ecosystem carbon dioxide exchange revealed large uptake from November through April. The cumulative net ecosystem carbon dioxide exchange for 2018 indicated that the peatland was a significant carbon sink of 330 g C m⁻² y⁻¹ and was substantially larger than that reported for other tropical peatlands. The annual methane emissions were on the order of 20 g C m⁻² y⁻¹ and were comparable with other tropical and temperate peatlands. Thus, the annual carbon budget of this tropical palm swamp peatland appears to be a major carbon sink given the current hydrometeorological conditions. Our ongoing research is assessing the major controls on these fluxes including satellite-based sun-induced fluorescence measurements to help verify the large photosynthetic uptake of carbon dioxide.

Degradation of palm swamp peatlands in the Peruvian Amazon severely raises emissions of greenhouse gases

Kristell Hergoualc'h¹, Jeffrey van Lent¹, Rupesh K Bhomia¹, Nelda Dezzee¹, Julio Grandez¹, Mariela Lopez¹, Louis Vincent Verchot²

¹CIFOR, Lima, Peru; ²CIAT, Cali, Colombia (k.hergoualc'h@cgiar.org; vanlent.jeffrey@gmail.com; r.bhomia@cgiar.org; ndezzee@gmail.com; jmgr_19@hotmail.com; m.lopez@cgiar.org; l.verchot@cgiar.org)

Palm swamp peatlands of the Amazonia have barely been the subject of biogeochemical investigation despite their large extent and potential to mitigate climate change. In Peru, these ecosystems are suffering recurrent degradation due to slashing of palms for harvesting their fruits. We conducted long-term research to evaluate how this practice affects carbon and nitrogen dynamics across a gradient of degradation that comprised an intact site, a moderately and a heavily degraded site. Site properties and fluxes of above and below-ground litter, soil heterotrophic respiration, and CH₄ and N₂O were monitored monthly for 1–4 years. Degradation altered the hummock-hollow micro-topography of the forest floor, the structure and composition of the vegetation and properties of the soil. Inputs of organic matter to the peat decreased by twofold while outputs increased by 40% as a result of heavy degradation. The net CO₂ balance indicated that the peat at the intact and moderately degraded sites was neutral (0.5 ± 5.3 and 2.8 ± 3.6 Mg CO₂ ha⁻¹ y⁻¹) but it was a source at the heavily degraded site (25.9 ± 3.4 Mg CO₂ ha⁻¹ y⁻¹). Soil CH₄ emissions were high (200 kg C ha⁻¹ yr⁻¹) and not affected by degradation. Small site-differences in N₂O emissions seemed driven by spatial heterogeneity of soil water-filled pore space. Palm swamp peatlands in their natural state constitute a net source of greenhouse gas (27 ± 8 Mg CO₂-equivalent ha⁻¹ y⁻¹). Their degradation leads to increased emission rate by 70% highlighting the urgency to develop sustainable management practices.

Quantifying carbon sink and source activities in Amazonian peatlands under a changing climate

Qianlai Zhuang¹, Sirui Wang¹, Outi Lähteenoja², Frederick Draper², Hinsby Cadillo-Quiroz²

¹Purdue University, West Lafayette, USA; ²Arizona State University, Tempe, USA (qzhuang@purdue.edu; wang2381@purdue.edu; outitulikki.lahteenoja@asu.edu; freddie.draper@gmail.com; hinsby@asu.edu)

Amazonian peatlands store a large amount of soil organic carbon (SOC) and its fate under a future changing climate is unknown. Here we use a process-based peatland biogeochemistry model to quantify the carbon accumulation for peatland and non-peatland ecosystems in the Pastaza-Marañon foreland basin (PMFB) in the Peruvian Amazon from 12,000 years before present to 2100 AD. Model simulations indicate that warming accelerates peat SOC loss while increasing precipitation accelerates peat SOC accumulation at millennial time scales. The uncertain parameters and spatial variation of climate are significant sources of uncertainty to modeled peat carbon accumulation. Under warmer and wetter conditions over the 21st century, SOC accumulation rate in the PMFB slows down to 7.9 from the current rate of 16.1 and the region may turn into a carbon source to the atmosphere at -53.3 (negative values indicate a source), depending on the level of warming. Peatlands show higher sensitivity than flooded forests. Peatland and non-peatland soils in the PMFB may lose up to 0.4 Pg C by 2100 AD with the largest loss from palm swamp. The carbon-dense Amazonian peatland area may switch from a current carbon sink into a source in the 21st century.

E8a: FOREST MANAGEMENT PRACTICES AND THE RESPONSES OF SOIL CARBON, WATER, NUTRIENTS AND THEIR INTERACTIONS

The effects of post-mountain pine beetle infestation vegetation recovery on carbon and water interactions at the watershed scale

Krysta Giles-Hansen¹, Xiaohua (Adam) Wei¹

¹University of British Columbia, Kelowna, Canada (krysta.gh@gmail.com; adam.wei@ubc.ca)

Mountain pine beetle (MPB) infestation and associated salvage logging mainly occurred 10 years ago had caused destructive impacts on carbon and many other ecological functions over a very large scale of forested landscapes in western Canada. For example, it was found that forests in British Columbia was switched from carbon sinks to carbon sources as a result of the MPB infestation. A big question now is: what would happen to forest carbon and water after 10 year or long-term vegetation recovery. This presentation will provide a critical assessment on the long-term effects of post-MPB infestation recovery on forest carbon and water interactions at the watershed scale using the modelling approach (CBM-CFS3 for forest carbon). Our analysis demonstrated that forest recovery mainly through understory vegetation has rapidly increased forest carbon sequestration. However, the increase of total forest carbon storage is not as much as we expected due to high respiration from dead materials. Annual water yields are greatly decreased due to ET increasing as a result of rapid recovery of understory vegetation and natural regeneration of lodgepole pine trees. Clearly, there are trade-offs between forest carbon storage and annual water yield. The dynamic interactions between forest carbon and water yields during the recovery period and their management implications are discussed.

Effect of adaptive forest management on the soil carbon pool in Central Europe

Robert Jandl¹, Georg Kindermann¹

¹Bundesforschungszentrum für Wald, Vienna, Austria (robert.jandl@bfw.gv.at; georg.kindermann@bfw.gv.at)

Adaptive forest management is required in order to cope with climate change effects. Emerging problems with current forests call for the investigation of alternatives. The management of forest stands has immediate and lasting effects on the soil carbon pool because the quantity and chemical quality of the aboveground and belowground litterfall is altered. In a simulation exercise we used the data of the Austrian Forest Inventory as starting point and ran scenarios for (i) business as usual forest management, (ii) replacement of conifer stands with deciduous stands, (iii) shorter rotation periods of conifer stands, and (iv) non-management. The chosen scenarios are currently discussed as potential remedies. We used 150-years climate scenarios (RCP 4.5, RCP 8.5), a climate sensitive forest growth model (Caldias vatis), and the soil carbon model YASSO15. Preliminary results show a slight decrease in the soil carbon pool in the business-as-usual scenario. A climate-change effect is likely, but the signal over-ridden by management effects. A shorter rotation period from previously approx 100 years to 70 years leads to a decline in the soil carbon pool. The analysis of the change to deciduous-tree dominated forests is in progress. We put the management effects on the soil carbon pool in perspective with the change in carbon in the aboveground biomass and the carbon that is retained in harvested wood products.

Forest management practices for maintaining and increasing soil organic carbon

Cindy Prescott¹

¹University of British Columbia, Vancouver, Canada (cindy.prescott@ubc.ca)

Globally, more than 40% of the total organic C in terrestrial ecosystems is stored in forest soil. Sustaining or increasing stocks of soil organic carbon has many benefits in addition to C sequestration, such as increased soil fertility and water-holding capacity, increasing potential site productivity, and fostering belowground biodiversity. As the manner in which forests are managed can influence SOC stocks, there is potential to consider this factor when planning management activities. Recognizing the need for action toward preserving and enhancing stocks of SOC, the FAO requested syntheses of current scientific evidence. In this talk I present ten forest management practices that could be employed to sustain or increase C stocks in forest soils.

Manage temperate forest for soil carbon: lessons from natural forests

Junwei Luan¹, Shirong Liu²

¹International Centre for bamboo and Rattan, Beijing, China; ²Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China (junweiluan@icbr.ac.cn; liusr@caf.ac.cn)

Temperate forests have large potential in sequestering carbon (C), especially to soil, and reasonable management practices can reduce the release of C from soils. Here we are synthesizing around ten years study on temperate forests of middle China, focusing particularly on soil C stability and soil CO₂ fluxes, in order to feed insights in managing temperate forests for soil C sequestration, and cope with climate change such as warming and drought. We evaluated the effect of 1) natural succession; 2) restoration strategies (natural versus artificial regeneration); 3) tree species (broad-leaved versus coniferous) and diversity; and 4) manipulated warming and drought on soil organic C quality, stability and CO₂ fluxes. Our results illustrated the mechanisms of higher soil C stability of natural regeneration versus artificial regeneration, and long-term forest succession in soil C sequestration; Also, we reveal that higher tree species diversity will benefit the soil C stability but different mechanisms may prevail the underlying mechanisms between broadleaf mixed and broadleaf and coniferous mixed. We point out the vulnerability of soil C to climate change such as warming and drought in temperate forests, and future study should focus on mechanisms of plant soil feedbacks, in clarifying relationships between tree species diversity, soil biota functional diversity, and soil C sequestration, especially under the threat of climate change, to feed insights of management strategies of soil C sequestration in temperate forests.

Response of N losses from the boreal forest soil to logging residue piles of different tree species

Tiina Törmänen¹, Veikko Kitunen², Antti-Jussi Lindroos¹, Juha Heikkinen¹, Aino Smolander¹

¹Natural Resources Institute Finland, Helsinki, Finland; ²Natural Resources Institute Finland, Espoo, Finland (tiina.tormanen@luke.fi; veikko.kitunen@luke.fi; anti.lindroos@luke.fi; juha.heikkinen@luke.fi; aino.smolander@luke.fi)

With current harvesting practices piles of logging residues are left on the forest floor. As a result on clear cut area under the piles, soil nitrogen (N) cycling processes can be accelerated, especially net nitrification. When N is transformed to more mobile form, the risk for N losses via leaching or nitrous oxide (N₂O) emissions from the forest floor may increase. The aim of this study was to understand how logging residues of Norway spruce (*Picea abies*), Scots pine (*Pinus sylvestris*) and silver birch (*Betula pendula*) affect N losses in forest soil after clear-cutting. A spruce-dominated stand was clear-cut. Plots with fresh

logging residue piles of different tree species, and control plots without logging residues, were subsequently established. Effects of logging residue piles were monitored; leaching as N concentrations in soil percolating water, and N₂O emissions with closed chamber technique over two growing seasons. Soil denitrification activity and the contribution of nitrification and denitrification to N₂O production were determined in laboratory experiment, as well as nitrogenase activity in the logging residues. Logging residue piles increased nitrate (NO₃-N) concentrations in soil percolating water. In addition logging residues piles tended to stimulate N₂O fluxes although in general the fluxes were low. Logging residues showed some nitrogenase activity. Currently we study the effects of large logging residue storage piles on N mobilization and losses.

Nitrogen addition to nitrogen rich forests: effects on soil nitrogen content

Lars Högbom¹, Ulf Sikström²

¹The Forestry Research Institute of Sweden, Uppsala, Sweden; ²The Forestry Research Institute of Sweden, Uppsala, Sweden (lars.hogbom@skogforsk.se; ulf.sikstrom@skogforsk.se)

Human activities have altered the pools and fluxes of nitrogen (N) in the forest soil. In southern Sweden, a substantial deposition of air-borne N pollution has been going on for several decades. During the most recent decades up to 15–25 kg ha⁻¹ yr⁻¹ of N has been deposited in forested areas. At present the major part of deposited N is retained in the soil. However, there are concerns that the input of N into forest ecosystems will lead to so called N-saturation. Generally, the N cycle in Swedish forests is closed and the small amount of leaching that occurs is mainly of organic N. However, quite high leaching of inorganic N has occasionally been observed in some areas, especially in southwestern Sweden. In order to simulate effects of an elevated N deposition a series of experiments was established in forest in the southern part of Sweden including annual addition of low N doses (20 kg ha⁻¹ yr⁻¹). The experiments were established in stands of two different site productivity classes within two regions with differences in N deposition. The main aim of the project is to study effects on several forest ecosystem properties of low N dose addition as well as of conventional practical forest N fertilization. Here we report on changes in soil N content in the upper soil layer following addition of low-dose N application by a series of soil samplings, in order to estimate how much of the added N is retained there.

Is there a niche complementarity for nitrate uptake among savannah shrub and tree species in a very deep Brazilian soil?

Rafael Pinheiro¹, Jean-Paul Laclau^{2,3}, Iraê Guerrini², Livia Alô², Jean-Pierre Bouillet^{3,4}

¹Faculdade de Ciências Agrônomicas de Botucatu/UNESP, Montpellier, Brasil; ²Faculdade de Ciências Agrônomicas de Botucatu/UNESP, Botucatu, Brasil; ³UMR Eco&Sols - CIRAD, Montpellier, France; ⁴Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (rafamic_10@hotmail.com; laclau@cirad.fr; iguerrini@fca.unesp.br; livialanzi@yahoo.com.br; jpbouillet@cirad.fr)

Belowground niche complementarity between deep-rooted and shallow-rooted species in mixed forests may result in a more complete exploitation of soil resources than in monocultures. Our study aimed to assess 1) the maximum distance (horizontally and vertically) where the fine roots from common Cerrado species take up mobile nutrients in deep Ferralsols, and 2) whether there is a niche complementarity in nitrate uptake between some Cerrado species. Our study was carried out in a closed-canopy forest with dense woody understorey (cerradão) at Bauru (Sao Paulo State); 15N-NO₃⁻ was injected at the onset of dry and rainy seasons at 6 depths (0.1, 1.5, 3, 6, 9 and 12 m) with 3 plots per depth and a distance > 50 m between each injection depth. Leaves were sampled 4 months after tracer injection in 3 frequent species in each plot located at 4 intervals of distance from the tracer injection point (0-2 m; 3-6 m; 7-10 m; ≥ 12 m) and 15N atom% was determined. Great differences in 15N tracer uptake between the studied species showed a niche complementarity in this native savannah. *Xylopia aromatica* exhibited a strong 15N uptake at 6 m of depth, irrespective of the season. This species seems to exploit a much larger soil volume than the others, both vertically and horizontally (15N taken up at 5 m from the injection point). *Miconia albicans* and *Coussarea hydrangeifolia* showed similar behaviours, with a strong 15N uptake in the topsoil and down to 1.5 m depth, within 2 m from the injection point.

Litterfall production and litter decomposition at several forests considering climate and litter quality in South Korea

Byung Bae Park^{1,2}, Si Ho Han¹, Afroja Rahman¹, Huong Thi Thuy Dao¹, Jeong Min Seo¹, Woo Bin Youn¹, Aung Aung¹, Ji Young An^{3,1}, Hwa Ja Hyun⁴, Hyung-Soon Choi⁵

¹Chungnam National University, Daejeon, Korea, Republic of; ²Korean Society of Forest Science, Seoul, Republic of Korea; ³Kyoto University, Kyoto, Japan; ⁴Warm Temperate and Subtropical Forest Research Center, Seogwipo, Republic of Korea; ⁵Forest Conservation Department, Seoul, Republic of Korea (bbpark@cnu.ac.kr; bupleumhan@cnu.ac.kr; afroja.r10@gmail.com; thuyhuong.150495@gmail.com; jmseo3@naver.com; dbsdnlqs95@naver.com; baganaung777@gmail.com; an.jyoung.2e@kyoto-u.ac.jp; viola1974@korea.kr; forgene@korea.kr)

We investigated litterfall production and litter decomposition, which are the major pathway for carbon and nutrients in forest ecosystem, at a couple of different forests considering climate and litter quality. Litterfall production has been observed at several deciduous or evergreen forests for about ten years across temperate and sub-tropical region in Korea. Leaf litter translocation experiments have been carried out covering 14 °C – 17 °C range of mean annual temperature and 1,200 mm - 1,400 mm range of mean annual precipitation. The results showed that total litterfall was much higher at evergreen broadleaf forest (903 gm⁻² yr⁻¹) than others (698 gm⁻² yr⁻¹), but was annually fluctuated. Litterfall production in evergreen forest was the highest at spring season, but for deciduous forest fall season was the maximum. Litter decomposition follows the similar decomposition trend, but decomposition was much faster in forests which has higher temperature during winter season. Litter decomposition was diverse by litter quality and average temperature during winter season. Although the effect of forest type, climate, and litter quality on litter production and litter decomposition is complex, this experiment will give an overview how these factors influence on carbon and nutrient cycling by modifying litterfall production and litter decomposition.

Post-logging management and soil type can affect litter layers in Amazon tropical forest?

Fernando Cesário¹, Fabiano Balieiro², Lucas Mazzei³

¹Universidade Federal Fluminense, Rio de Janeiro, Brasil; ²Embrapa Solos, Rio de Janeiro, Brasi; ³Embrapa Amazônia Ocidental, Pará, Brasil (fernandovieiracesario@gmail.com; fabiano.balieiro@embrapa.br; lucas.mazzei@embrapa.br)

Litter is one of the main carbon and nutrient pools in the terrestrial ecosystem. However, the litter structural organization and the characteristics of its horizons, especially in humus forms perspective, that enables us to understand the topsoil processes of tropical forest ecosystem functioning are not well understood. We hypothesize that the soil class affects the soil macro and microbial activity and fertility, and thus the humus forms horizons. Likewise, the logging practices and the producer-decomposer forest processes altering the decomposition rates and litter input was evaluated. We used morpho-functional approach (Zanella et al., 2017) to describe the humus forms horizons on two different soil types (Ferralsols and Gleysols), under two post-logging practices of management (with

and without crown removal). The fine roots, the Ai horizon, the presence of fungi and the aggregates were variables most important to the separation of soil types and post-logging management. While the presence of fungi suggests interference of the post-logging on the humus forms horizons, the root thickness was related to soil type indicating two different strategies for nutrient retention. The presence of fungi seems to be related to the presence of more recalcitrant material associated with loamy soils and to the development of the Ai thickness. Soils with superficial sandy layer and restricted drainage (as Gleysols) favored the formation of superficial root mantle; nevertheless, they inhibited the formation of the Ai horizon.

Phloem sap analysis: a novel diagnostic tool to determine forest growth performance

Nirmol Kumar Halder^{1,2}, David Fuentes¹, Malcolm Possell¹, Benjamin Bradshaw³, Andrew Merchant¹

¹Center for Carbon, Water and Food, Faculty of Science, The University of Sydney, Camden, Australia; ²Ministry of Planning, Government of Bangladesh, Dhaka, Bangladesh; ³Australian Blue Gum Plantations, Victoria, Australia (nhal6573@uni.sydney.edu.au; david.fuentes@sydney.edu.au; malcolm.possell@sydney.edu.au; ben.bradshaw@austgum.com.au; andrew.merchant@sydney.edu.au)

Improving the efficiency of fertiliser application is paramount to both sustainability and profitability in forest plantations. Developing reliable, cost-effective tools to assess tree nutritional status is therefore of great interest. This investigation sought to assess the use of phloem sap derived metabolites as an indicator of nutritional status on a background of seasonal (hence water) availability of *E. globulus* trees grown under field conditions. Phloem derived amino acids were found to vary in accordance with N supply, however, this response was lost in the concurrent addition of P. Significant seasonal variation in all measured parameters was also detected highlighting the need for caution in making quantitative relationships with growth. Broader implications of the interactive effects of both water supply and multi-nutrient additions and relationships with growth are discussed.

Nitrogen transfer from *Acacia mangium* to *Eucalyptus* appears to controls the decomposition of *Eucalyptus* litter under mixed plantation

Fabiano Balieiro¹, Caio Rachid², Guilherme Chaer³, Etevlino Novotny¹, Felipe Santos⁴, Raquel Peixoto³, Alexandre Rosado³

¹Embrapa Solos, Rio de Janeiro, Brasil; ²Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brasil; ³Embrapa Agrobiologia, Seropédica, Brasil; ⁴Universidade Federal Rural do Rio de Janeiro, Seropédica, Brasil (fabiano.balieiro@embrapa.br; caiorachid@micro.ufrrj.br; guilherme.chaer@embrapa.br; etevlino.novotny@embrapa.br; martinisantos@gmail.com; raquelpeixoto@micro.ufrrj.br; asrosado@micro.ufrrj.br)

Litter decomposition is a key process for the sustainability of planted forest since it determines the magnitude of organic matter transformations and nutrient cycling. Although N deposition is high in *Acacia mangium* (acacia) plantations, the high internal cycling of P, provides reduced inputs of P to soil. The litter decomposition of *Eucalyptus urograndis* (eucalyptus) and *acacia* under tropical climate in Brazil was studied from the perspective of the Domestic Advantage Theory. To test this hypothesis, we used the mass loss of reciprocal translocated litterbags, the changes in fungi communities structure (pyrosequencing) using litter samples with different ages and structural alterations in litter composition using spectroscopy and factor analysis. Was observed a distinct HFA for decomposition litter from acacia and eucalyptus, with acacia decomposing in home stand faster than under eucalyptus stand and in contrast, litter from eucalyptus decomposed faster under acacia stands. Additionally, litter of each material showed a very distinct fungal and change very little in function of time, besides the local of incubation did not influence the microbial community. Higher diversity and lower dominance of fungi were observed in litter from acacia and mixed plantations during the decomposition period (180d), independently of the local that they decompose. Eucalyptus litter during the decomposition under acacia stand be more proteinaceous than the initial residue. Migration of N to eucalyptus litter is speculated. In contrast, the acacia litter did not change in terms of chemical composition during the incubation. Our results demonstrate the importance of biological N fixed to the eucalyptus litter decomposition.

E8b: HYDROLOGICAL AND BIOLOGICAL RESPONSES OF AQUATIC ECOSYSTEMS TO CONTEMPORARY FOREST PRACTICES AROUND THE WORLD

Saturation excess overland flow generation in a catchment covered by forest plantation of *Pinus* spp.

Carla Riovane Chiles¹, Mariane Bueno de Camargo², Fábio Vale Scarpere³, Quirijn de Jong van Lier³, Sílvia Frosini de Barros Ferraz¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brazil; ²Klabin, Telêmaco Borba, Brazil; ³Universidade de São Paulo, Centro de Energia Nuclear na Agricultura, Piracicaba, Brazil (carla.chiles@usp.br; maricamargo@klabin.com.br; fabioscarpere@hotmail.com; qdvlierv@usp.br; silvia.ferraz@usp.br)

Native forest plays important role in regulation and provision of water, however, land-use change can affect the original hydrological functions, such as the overland flow mechanism. The saturation excess overland flow occurs at Variable Source Area (VSA), which have high probability of saturation during a storm event, varying over time according to lateral flow and water table. Thereby, since VSA has different hydrological characteristics than other areas along hillslope gradient, its mapping is essential to guide management practices and to preserve its ecosystem functions. The objective of this study was to use a method to delineation the VSA in a catchment covered by forest plantation of *Pinus* spp. The VSA delimitation was done using a modified wetness index calculated from a high-resolution Digital Elevation Model (1 m) and the validation was made by data collected of soil water potential in a transect along topographic gradient. The soil with topographic index (>7) remained saturated more than 30% of the time in the two catchments, contributing with overland flow generation. The VSA occur in 18,5% of the catchment area, which 86% of the VSA are in areas covered by forest plantation of *Pinus* spp., 12,7% are in areas with native forest, and 1,3% are in roads. The VSA mapping identified sensitive areas that are not restricted to areas with native forest, so this demonstrate the importance of identification and mapping to be used in the forest management and roads, reducing risks of soil loss, stream contaminations and modify streamflow regulation.

Infiltration capacity of dense woods, a key to hydraulic sustainability in watersheds / Capacidad de infiltración bajo bosques, una clave para la sostenibilidad hídrica de cuencas

Carlos Francisco García Olmos¹, Diana Constanza García Rincón²

¹Universidad Distrital Francisco José de Caldas, Bogotá D.C., Colombia; ²Universidad de Sao Paulo, Sao Paulo, Brazil (cfcgarciao@gmail.com; dianinat4@gmail.com)

Se estudió la capacidad de infiltración bajo bosques maduros de *Cupressus lusitanica*, *Eucalyptus globulus* y bosque natural en la cuenca del río San Cristóbal al sureste de Bogotá. Se hizo la caracterización de los bosques y se escogieron al azar tres áreas circulares de nueve metros de diámetro y con centro en cada una de ellas se realizaron mediciones de capacidad de infiltración según diseño de ensayos. Con las curvas de la capacidad de infiltración obtenidas se obtuvieron las curvas características de la capacidad de infiltración según los modelos de Horton, Philip, Kostiakov y Kostiakov modificado. Las curvas más representativas fueron las de Horton. Se pudo establecer que el bosque de *Cupressus lusitanica* presenta las curvas características con los mayores valores de la capacidad de infiltración, y luego el de *Eucalyptus globulus*, ambos por sus sistemas radiculares más robustos y profundos. Estos resultados fueron validados estadísticamente, y se estableció que las diferencias halladas son significativas. Este estudio permite conocer las bondades de estos bosques maduros en la recarga de las aguas subterráneas, y son una guía sobre los criterios a establecer en la selección de especies arbóreas que fomenten la capacidad de regulación y la sostenibilidad hídrica de las cuencas.

Comparative analysis of international legislation on buffer zones, with an emphasis on Latin America / Análisis comparado de la legislación internacional de zonas buffer con énfasis en América Latina

Samuel Francke¹, Celso Carnieletto¹

¹Corporación Nacional Forestal Conaf, Santiago, Chile (samuel.francke@conaf.cl; celso.carnieletto@conaf.cl)

Las zonas amortiguación vegetacionales (buffer) resultan fundamentales para la protección contra la erosión, la sedimentación, contaminación y eutroficación de los cauces y cuerpos de agua en función de factores edáficos, vegetacionales, hidrológicos, topográficos, climáticos y paisajísticos. Se presentan diversos esquemas de protección vegetal para cursos hídricos según legislación: Sistemas Buffer, EE.UU. Forest Service, Se establecen recomendaciones técnicas que varían desde 16,5 m a 50 m y se incrementa 1,5 m en función de cada 1% de pendiente, para anchos medios que varían de 25 m a 50 m; Matas Ciliares Brasil (1965); En el Código Forestal de Brasil establece fajas de protección vegetal de cursos hídricos que aumentan con el ancho y que varían de 30m a 500m de cada margen de ríos, lagos, embalses, represas o nacientes, respecto del espejo de agua. Fajas Hidroreguladoras, Cuba (1988); En la legislación forestal de Cuba, se establece el concepto de "Fajas Hidroreguladoras" para la protección de ríos y embalses. En relación al orden de los ríos varían de 10m. a 20m.; Legislación comparada en Chile en relación a fajas de protección vegetal cursos hídricos y cuerpos de agua Ley de Bosques 1931, Ley de Bosque Nativo 2007, Protocolo de plantaciones forestales. Se establecen anchos mínimos como zonas de protección en función de la pendiente. Se incluyen medidas de protección en humedales, manantiales, cuerpos de agua y microcuencas abastecedoras de agua potable. El presente trabajo analiza y compara la normativa legal para mejorar y garantizar los servicios eco sistémicos a nivel de cuencas hidrográficas.

Effects of Eucalyptus forest plantation on stream water quality: what we know in Brazil?

Lara Gabrielle Garcia¹, Carolina Bozetti Rodrigues¹, Arthur Vrech¹, Silvio Frosini de Barros Ferraz²

¹Forestry Science and Research Institute, Piracicaba, Brazil; ²Luiz de Queiroz College of Agriculture, Piracicaba, Brazil (lara@ipef.br; cabreuva@gmail.com; arthur@geplant.com.br; silvio.frosini@usp.br)

Forest plantations in Brazil are reaching about 7.8 million of hectares, more than 5 million are occupied by Eucalyptus, which is characterized as a fast-growing forest (6 to 8 years rotation). These characteristics require forest intensive management operations (e.g. clearcutting and application of fertilizers) that could affect water quality. The aim of this study was to assess stream water quality from Eucalyptus forest plantation in relation to the concentration of nitrate (NO₃) and total suspended solids (TSS). The catchments are monitored by Program of experimental catchments monitoring and modeling (PROMAB) in different regions of Brazil. PROMAB was created with the objective of understanding forest management effects on hydrological resources and it is based on continuous monitoring of discharge and water quality at the catchment scale. We analyzed a data set of water sample collected at nine catchments mainly covered by Eucalyptus forest (namely Eucalyptus total – ET). Furthermore, we assessed differences in NO₃ and TSS concentrations among catchments. The median concentration of NO₃ (n=2878) was 0.6 mg L⁻¹ and the median concentration of TSS (n=3011) was 6.0 mg L⁻¹ in the ET data set. Our results showed that the most part of the nine catchments present differences in both parameters analyzed, thus the same land cover results in distinct water quality. Therefore, others catchments features (e.g. soil type, etc.) have impacted on NO₃ and TSS concentration and could influence water quality at catchment scale. We discuss the contribution of local physical variables and management on observed differences on water quality.

Effect of deforestation of different genesis on seasonal changes in water chemistry in the Carpathians: a Beskid Śląski and Western Tatra case study

Amanda Kosmowska¹, Mirosław Żelazny¹, Stanisław Malek², Tomasz Stańczyk³, Mateusz Żelazny⁴

¹Department of Hydrology, Institute of Geography and Spatial Management, Jagiellonian University in Kraków, Gronostajowa 7, 30-387 Krakow, Poland, Krakow, Poland; ²Department of Forest Ecology and Reclamation, Institute of Ecology and Silviculture, Forest Faculty, University of Agriculture in Kraków, al. 29-go Listopada 46, 31-425 Krakow, Poland, Krakow, Poland; ³Department of Environmental Improvement, Faculty of Civil and Environmental Engineering, Warsaw University of Life Sciences – SGGW, Nowoursynowska 166, 02-787 Warsaw, Poland, Warsaw, Poland; ⁴Faculty of Mining Surveying and Environmental Engineering AGH UST, Mickiewicza 30, 30-059 Krakow, Poland, Krakow, Poland (amanda.kosmowska@doctoral.uj.edu.pl; miroslaw.zelazny@uj.edu.pl; rlmalek@urk.edu.pl; tomasz_stanczyk@sggw.pl; miroslaw.zelazny@gmail.com)

The purpose of the study was to determine the effects of deforestation caused by a set of different factors on water chemistry. The study occurred in catchments of the Skrzyczne Massif in the Beskid Śląski Range (anthropogenic impact) and in the Kościeliska Valley in Tatras (windfall, bark beetle degradation). Changes in chemistry water were assessed using 180 water samples collected in the field on a monthly basis in 15 catchments deforested to a varying degree. Ion chromatograph was used to determine the presence of ions: Ca²⁺, Mg²⁺, Na⁺, K⁺, NH₄⁺, Li⁺, HCO₃⁻, SO₄²⁻, Cl⁻, NO₂⁻, NO₃⁻, PO₄³⁻, Br⁻, F⁻. The research showed the variable effect of different types of deforestation on water chemistry. Hillslope deforestation caused changes in water chemistry, especially in relationships between anions. An increase of several hundred percent in the NO₃⁻ concentration and increase in its share of the total anion content (4,3% mval·dm⁻³) were observed in the Tatras in catchments affected by wind-driven deforestation. A significant increase in the SO₄²⁻ content (31,6 % mval·dm⁻³) was observed along

with a marked decrease in HCO_3^- ($5,2 \text{ \% mval}\cdot\text{dm}^{-3}$) in total anion content in water in catchments deforested due to air pollution in the Beskid Śląski. Sulfate ions play a dominating role in the water chemistry of deforested catchments. Research has shown the key role of forests covering mountain slopes in the hydrochemistry of a catchment. The spatial context includes an atypical phenomenon known as hydrochemical mosaics, as manifested in the occurrence of different relationships between bicarbonate, sulfate, nitrate.

Do contemporary forest harvesting practices return sediment fluxes to pre-settlement levels in oregon forests?

Jeff Hatten¹

¹Oregon State University, Corvallis, USA (jeff.hatten@oregonstate.edu)

Forest harvesting practices can expose mineral soils, decrease infiltration capacities of soils, disturb the stream bank and channel, and increase erosion and fine sediment supply to stream channels. To reduce nonpoint source sediment pollution associated with forest management activities and to maintain the high water quality typically provided from forests, contemporary harvesting practices employed forestry regulations and best management practices (BMPs), which were developed and implemented in the 1970s in the Oregon Coast Range. We examined the impact that these improved management practices had in 2 studies 1) a 10-year long study in the Alsea Paired Watershed Study and 2) a 1500-year long sediment core from an Oregon Coast Range Lake. In both cases, we found that contemporary harvesting practices were associated with lower sediment concentrations/fluxes and sedimentation rates, respectively. While we found that annual sedimentation rates appear to have returned to pre-settlement levels, sedimentation rates during rare, large events with low frequency still appear to be elevated. We will discuss recent research that attempts to pin the source of this elevated event associated sedimentation to hill-slope processes (e.g. harvesting) or in-channel processes (e.g. ditches and channel alterations) and the implications for forest management.

Changes in water quality and primary producers after forest harvest in the Trask Watershed, Oregon, USA

Alba Argerich¹, Sherri L. Johnson², Linda Ashkenas³

¹University of Missouri, Columbia, MO, USA; ²US Forest Service Pacific Northwest Research Station Forest Service, Corvallis, OR, USA; ³Oregon State University, Corvallis, OR, USA (argericha@missouri.edu; sherrijohnson@fs.fed.us; linda.ashkenas@oregonstate.edu)

Forest harvest and its associated land changes have the potential to increase nutrient delivery to streams, alter water temperature, and affect the physiology and distribution of benthic algae. Although the impacts of forest harvest to streams have been significantly reduced because of Best Management Practices (BMPs), there is still concern about their potential effects on water quality and the aquatic organisms. Here we present results from the Trask Watershed Study, a multi-disciplinary research project located in the Coastal Range of Oregon, designed to evaluate the effectiveness of BMPs in protecting aquatic ecosystems during forest management in headwater basins. We have examined algae and water quality parameters during eight years (four before and four after forest harvest) in eleven headwater basins subjected to different treatments (existence of a riparian buffer/ no buffer/ no harvest). Water chemical composition changed after harvest, with a 6 to 40-fold increase in nitrate concentration in relation to pre-harvest levels. However, the increased availability in nitrogen did not reflect on the amount of algal biomass, which remained relatively constant throughout the study.

E8c: NEXUS: FOREST, WATER AND CLIMATE

The forest-water nexus: an international perspective

Elaine Springgay¹

¹FAO, Rome, Italy (elaine.springgay@fao.org)

Water security is one of the greatest challenges we face to ensure a sustainable future. Trees and forests are imperative for quality water supply. Integrating natural solutions in land-water management, including the strategic management of forests and landscapes with water considerations, will be crucial for a resilient water supply in the future. The MEA (2005) estimates that 75 percent of available freshwater resources comes from forested watersheds. Despite the importance of forests for water, only 25 percent of forests globally are managed with water considerations (FAO, 2015). An international perspective on forests and water will be presented, taking a closer look at the status of forest management for water, and the extent to which the forest-water nexus is considered in climate change based on a review of the (Intended) National Determined Contributions ((I)NDCs). The objective is to identify and discuss the gaps and opportunities where the forest-water-climate nexus can be addressed globally, regionally and nationally; in particular, where science and practice could support and shape the political agenda.

On the concept of hydrologic space

David Ellison¹

¹SLU, Umea, Sweden (ellisond@gmail.com)

Forests provide many important water-related, ecosystem services including water purification and flood mitigation. We illustrate that the forest role in precipitation recycling and the regulation of the hydrologic cycle must also be clearly recognized as an ecosystem service. Deforestation leads to more local runoff and reduced precipitation. However, the importance of reforestation in supporting the flow of atmospheric moisture and promoting precipitation recycling is underappreciated. Since the evapotranspiration from forests falls again as precipitation, the terrestrial, forest-based production of atmospheric moisture has important consequences, both for local and downwind precipitation and water availability. We emphasize the importance of atmospheric inter-basin connectivity. This spatial interconnectedness is rarely reflected in the study of land-atmosphere interactions and their contribution to the hydrologic regime. Focusing on the *supply-side* characteristics of rainfall, we define and formalize the concept of hydrologic space and apply the concept to the derivation of the catchment basin water balance. Conventional approaches to the c-basin water balance typically fail to consider the import and export of atmospheric moisture as a principal determinant of locally and regionally available water supply. Land use modification has important implications for the production of atmospheric moisture and downwind precipitation, as well as for the re-export of local moisture and the availability of runoff: the total amount of water available for productive and consumptive purposes. These consequences are not adequately reflected in most policy efforts at multiple levels and scales of governance.

A spatial pattern of water and carbon tradeoff among China's natural forests and planted forests

Shirong Liu¹, Zhen Yu², Jingxin Wang³

¹Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China; ²Department of Ecology, Evolution, and Organismal Biology, Iowa State University, Ames, USA; ³Division of Forestry and Natural Resources, West Virginia University, Morgantown, USA (liusr@caf.ac.cn; zyu@iastate.edu; jingxin.wang@mail.wvu.edu)

The area of planted forests in China has been expanding rapidly and ranked first of the world. However, the benefits of large-scale afforestation in carbon sequestration in relation to water consumption is unclear. We know little about carbon sequestration and water consumption among natural forests and planted forests across different climate zones. How does climate change affect this spatial pattern? We compare carbon sequestration and water consumption in plantation forest (PF) and natural forest (NF) across China using combination of remote sensing and field inventory. We found NF consumed 6.8% (37.5 mm per growing season) less water but sequestered 1.1% (12.5 g C m⁻² growing season⁻¹) more carbon than PF in the period of 2000–2012. While there was no significant difference in water consumption in energy-limited areas (dryness index [DI] < 1), water consumption was significantly ($p < 0.001$) higher in PF than that in NF in water-limited regions (DI > 1). Moreover, a distinct and larger shift of water yield was identified in PF than in NF from the 1980s to the 2000s, indicating that PF were more sensitive to climate change, leading to a higher water consumption when compared with NF. Our results suggest NF should be properly valued in terms of maximizing the benefits of carbon sequestration and water yield. Future forest plantation projects should be planned with caution, particularly in water-limited regions where they might have less positive effect on carbon sequestration but lead to significant water yield reduction.

Ecological restoration and conservation of soil and water towards water resources, forestry and climate change policies in Brazil

Marcos Airton De Sousa Freitas¹, Sandra Regina Afonso²

¹National Water Agency, Brasilia, Brazil; ²Serviço Florestal Brasileiro, Brasilia, Brazil (masfreitas@ana.gov.br; sandra.afonso@florestal.gov.br)

The article deals with the discussion of ecological restoration and conservation of soil and water in relation to the integration and implementation of three important Public Policies in Brazil: National Policy of Water Resources, National Policy on Climate Change and Forest Policies. National Water Resources Policy, created by Law 9.433/1997, has been implemented through its instruments: grants, charges, watershed plans. National Policy on Climate Change (Law 12.187/2009) has tools, such as the National Plan and the National Fund on Climate Change. The main policy that regulates Brazilian forests is the Forest Code (Law 12.651 /2012), which presents several instruments, such as: Environmental Rural Registry (ERR), Environmental Regularization Program (ERP) and Environmental Reserve Quota (ERQ) and Program of Support and Incentive to the Preservation and Recovery of the Environment. This last program presents as a line of action the payment or incentive to environmental services as monetary retribution to the activities of conservation and improvement of ecosystems. This scope includes the Water Producer Program, implemented by the National Water Agency and partners. In analyzing the implementation of the various instruments and programs established in these three policies, there is a need for greater integration between them in order to ensure the participation of society in decision-making processes. In addition, these policies need to ensure ecological restoration and soil and water conservation, as well as mitigate the adverse effects of climate change.

Forest and water relations in a changing environment, increased human activities and complex watershed conditions

Zhiqiang Zhang¹

¹Beijing Forestry University, Beijing, China (zqzhang@bjfu.edu.cn)

Understanding forest water relations is becoming a more challenging issue under the changing environment, increased human activities and complex watershed conditions. Here we present an evolving framework shifted from traditional forest water studies to the current forest eco-hydrological studies and beyond. Our recent studies from tree and stand water use to watershed stream-flow responses to land use/ human activities and climate variability will be presented to illustrate the critical needs for understanding forest water relations in the future. In doing this, a couple of methods were used including sap-flow measurement and eddy covariance system at ecosystem scale while elasticity differential analysis and physically-based MIKESHE model at watershed scale. We concluded that to identify forest water relations in future will heavily dependent on the novel and robust methodological innovations to excluding many factors influencing eco-hydrological processes at multiple spatial and temporal scales.

Forest disturbance thresholds on hydrology: concept, quantification and variation

Xiaohua (Adam) Wei¹

¹University of British Columbia, Kelowna, Canada (adam.wei@ubc.ca)

Forest disturbance including both human and natural disturbance can significantly affect various ecological processes. However, forest disturbance is often cumulative over space and time, particularly for any large landscapes or watersheds. Forest disturbance thresholds are commonly defined as levels of disturbance at or above which ecological processes are significantly altered. Thus, determination of forest disturbance thresholds can be useful and important to guide forest planning and management. In terms of hydrological changes caused by forest disturbance, 20–30% disturbance thresholds in a given watershed are commonly used. However, those are unlikely accurate as they do not address variability in climate and watershed property, which are also key drivers for hydrological responses. In addition, they are likely varied with choice of hydrological variables. This presentation will describe the concepts of forest disturbance thresholds, and provide in-depth discussion on quantification methods using some examples, and highlight possible uncertainties or variations.

Forests for water security in a changing climate

Juliana Baladelli Ribeiro¹, Fabio Scarano², Aliny Pires³, Rafael Barbieri⁴

¹Boticario Group Foundation, Curitiba, Brazil; ²Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES), Rio de Janeiro, Brazil; ³Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services, Rio de Janeiro, Brazil; ⁴The World Resources Institute, São Paulo, Brazil (ribeiroj@grupoboticario.com.br; fscarano@gmail.com; alinyppires@gmail.com; rafael.barbieri@wri.org)

The Boticario Group Foundation, the World Resources Institute (WRI), the Brazilian Foundation for Sustainable Development (FBDS) and the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) have been working on assessments to understand the best strategies for improving Return on Investment in natural areas (for both restoration and protection) and compliance with environmental laws, such as the Native Vegetation Protection Act (NVPL). Natural infrastructure investment opportunities have been evaluated to reduce sediment management costs and ensuring water flows, considering

climate change. Cases conducted in 4 Brazilian Metropolitan Regions (Cantareira-Sao Paulo, Guandu-Rio de Janeiro, Jucu-Vitoria and São Bento do Sul, Santa Catarina), showed that forest restoration could boost sedimentation avoidance, provide cleaner water, and reduce turbidity levels. Regional benefits such as avoided costs of flood damages and global benefits (carbon sequestration) were also evaluated. Law enforcement also has the potential to improve several water-related ecosystem services provided by forests, but such effect can depend on the land use and climate context. The NVPL aims for the Atlantic Forest the restoration of 10 million ha of riparian vegetation, which will contribute to the achievement of the Brazilian NDC. In Cerrado, the restoration of riparian areas near reservoirs returns the investment in less than 5 years. These results show that it is worth it to invest in natural infrastructure and to consider restoration and nature conservation as part of the solution.

Forest cover, windspeed and precipitation recycling

Emory Ellis¹, Robin Sears², David Ellison³

¹Hampshire College, Amherst, USA; ²Harvard Forest, Petersham, USA; ³SLU, Umea, Sweden (ece16@hampshire.edu; robin.sears@aya.yale.edu; ellisondl@gmail.com)

Within the broader scope of forest-water interactions, there is a clear gap in our comprehension of how forest cover potentially alters and sustains regional precipitation cycles across continental scales. We analyze high resolution data on forest cover, annual average wind speed and total annual precipitation amounts in order to better understand how forest cover and forest density impact windspeed, and how the forest impact on windspeed can influence the transport and potential re-deposition of atmospheric moisture as downwind rainfall. Our global analysis of these interactions indicates that forests slow wind speeds, providing more opportunity for the accumulation and aggregation of incoming atmospheric moisture and local evapotranspiration, thereby contributing to its potential re-deposition as rainfall. Our findings suggest that greater forest cover intensifies the hydrologic cycle by providing more opportunities for atmospheric moisture and evapotranspiration to condense, precipitate, re-evaporate and re-transpire back to the atmosphere, thereby optimizing terrestrial rainfall and water availability across continental surfaces. With an improved understanding of how forest, wind, and water interact, the scientific community will be able to develop a more rigorous approach to hydrological preservation through forest landscape restoration.

Projecting the climate change and its impact on the hydrology of a watershed in Northern China

Wenxu Cao¹, Zhiqiang Zhang¹

¹Beijing Forestry University, Beijing, China (caocaowenxu@163.com; zhqzhang@bjfu.edu.cn)

Climate change, especially global warming and uneven precipitation distribution, is expected to intensify the earth's hydrological cycle and increase flood/drought risks. This study aims to project the impact of climate change under different scenarios on streamflow. The Regional Hydro-Ecological Simulation System (RHESys) and Statistical Downscaling Method were coupled to investigate future streamflow variation and extreme events over the 21st century in the Chaohe watershed, northern China, based on climate change scenarios generated by three GCMs. The results indicated that future temperature over the Chaohe watershed will continually increase: annual maximum temperature T_{max} and minimum temperature T_{min} are forecast to increase by 1.51 to 2.39 °C and 0.44 to 1.21 °C under RCP2.6, 1.91 to 3.64 °C and 0.62 to 2.14 °C under RCP4.5, 2.19 to 7.12 °C and 1.15 to 3.87 °C under RCP8.5, respectively. Increasing trends in annual precipitation were projected by different GCMs under different RCP scenarios with different rates and fluctuations. Consistent with future precipitation, streamflow is forecast to increase in general in the 21st century. It was worth noting that streamflow predicted by CanESM2 and CNRM-CM5 showed an increase in monthly dispersion coefficient in July and August, indicating that future streamflow could be expected to be highly unstable in those months. Moreover, most GCMs indicated that high-streamflow (95th percentile) would increase over the 21st century with the potential for intensifying flood hazard. Similarly, influenced by increased precipitation, low-streamflow (5th percentile) will increase in the future, suggesting that drought risk will alleviate in the 21st century.

Effects of climate change on water yield and water quality of forested watersheds in Southeastern Brazil

Matheus Ogasawara¹, Marina Otto¹, Eduardo Mattos², Humberto Rocha³, Ricardo Figueiredo³, Silvio Ferraz¹

¹Universidade de São Paulo, Piracicaba, Brasil; ²Geplanta Tecnologia Florestal, Piracicaba, Brasil; ³Embrapa Meio Ambiente, Jaguariúna, Brasil (matheus.ogasawara@usp.br; msgentil@usp.br; eduardo@geplanta.com.br; humberto.rocha@iag.usp.br; ricardo.figueiredo@embrapa.br; silvio.ferraz@usp.br)

Climate change effects on water resources are one of the most concerns of public authorities, and such impacts can be predicted through hydrological simulation, considering climate change scenarios and models calibrated using a historical climatic data from a given region. We considered that watersheds have different responsiveness to climate change due to their physical characteristics. Therefore, effects of these changes will cause different levels of impact on water flow and quality, depending on the region in which the basin is located. The objective of this study is use the hydrological model of Fu adapted, calibrated and validated for a series of climatic data from 29 watersheds in the Southeastern region of Brazil. Model was used to simulate and predict the climate change effects and identify critical factors for the stability of water yield and water quality in watershed. At studied watersheds, forest cover varied from 5% to 80%, mean annual precipitation ranged from 1200 to 1800 mm and the annual runoff represented 20% to 50% of the annual precipitation across all sites. The model proposed was able to capture the differences among watersheds, enabling simulations under climate change scenarios. Simulations showed high variation on sensitiveness to climate change. Regional mapping of sensitiveness was created, critical areas for stability of water yield and water quality were identified in the watersheds. Results provide subsidies to guide the planning of public policies and propose ways of managing and conserving forest on watersheds.

Planted forests: an alternative for natural maintenance of flying rivers and ecological corridors, mitigation of climate change, and prevention of natural disasters related to extreme rainfall / Florestas plantadas: uma alternativa para a manutenção natural dos rios voadores e corredores ecológicos e mitigação das mudanças climáticas e medida de prevenção de desastres naturais relacionados às precipitações extremas

Vania Santos¹

¹Viveiro Florestal de Taubaté, Instituto Florestal, Secretaria do Meio Ambiente, Taubaté, Brasil (vas.vania1@gmail.com)

Nos últimos anos o Brasil sofre com desastres naturais relacionados às precipitações extremas, ao mesmo tempo em que vivencia uma crise hídrica generalizada. Longas secas no campo acarretam perdas econômicas, contribuem para a migração rural-urbana e colocam em risco a segurança alimentar. Eventos climatológicos, hidrológicos, geofísicos e meteorológicos como estiagem e chuvas de granizo; alagamentos e enchentes; movimentação de massa e deslizamentos; tornados e vendavais decorrentes das mudanças climáticas acarretam perda de vidas, proliferação de doenças e danos econômicos. A diminuição da cobertura florestal

impacta diretamente no clima e na sobrevivência de espécies que ficam isoladas em pequenas áreas, como acontece na mata Atlântica, correndo o risco de extinção. A Floresta amazônica, por exemplo, além de manter a umidade do ar para si mesma também exporta rios aéreos de vapor, conhecidos como rios voadores que possibilitam as chuvas fartas por todo o hemisfério, sua diminuição dá causa as estiagens vivenciadas no sudeste brasileiro. A floresta é recicladora de umidade e o desmatamento impede que o fluxo de umidade transcurse do norte ao sul do país, acarretando escassez hídrica. A recomposição florestal possibilita reverter o uso do solo de extensas áreas ocupadas e por meio da transpiração, restabelecer dentro de 10 a 15 anos as funções exercidas pelas matas e os rios voadores. Como medida preventiva de desastres naturais vinculados a precipitações extremas, a pesquisa propõe reflorestar terras desmatadas ao longo do curso dos “rios voadores” e a criação de um novo modal de Unidades de Conservação específico de Florestas Plantadas.

Converting native deciduous hardwoods to evergreen conifers reduces water yield in the Southeastern United States

Ge Sun¹, Johnny Boggs¹, Steven McNulty¹

¹Southern Research Station, USDA Forest Service, Research Triangle Park, USA (gesunmail@gmail.com; jboggs@fs.fed.us; smcnulty@fs.fed.us)

The compositions of forests in the southeastern United States are changing as result of changes in forest management objectives, climate patterns, fire regimes, and urbanization. Consequently, there are concerns about how these biophysical changes in forests may impact watershed hydrology and water availability through altered evapotranspiration processes in forests. The paper reports a long-term paired watershed study that aims at understanding the hydrological effects of converting naturally-generated hardwoods to pines. The study used two paired mixed-pine hardwood watersheds located in two distinct geological regions (i.e., Carolina Slate Belt, (CSB) and Triassic Basin, (TB)) that have different soil characteristics. In 2010, loblolly pines (*Pinus taeda*) were planted in the CSB watershed and shortleaf pine (*Pinus echinata*) were planted in the TB. Water yield increased by 263% in the CSB and 248% in the TB one year after the clearcut. Yield decreased in subsequent years following a rapid regrowth of planted pines and vegetation. By 2017, the TB watershed annual water yield was 5.5% less than what yield would have been if the hardwood trees were not cut (i.e., 171 mm vs 181 mm). Flow from the CSB watershed was lower than precut levels by the end of 2018. This study links basal area changes and water yield and soil conditions to expand our ability to effectively sustain forest and water resources using innovative silvicultural practices. Results are being integrated to modeling tools to predict hydrological changes in vegetation on water supply in the southeastern U.S. and beyond.

E8d: PLANT: SOIL INTERACTIONS IN FORESTS

Factors affecting rhizospheric soil carbon stability in nitrogen-fixing plants and non-nitrogen-fixing plants in rainforests of southern China

Huai Yang¹, Shirong Liu²

¹International Center for Bamboo and Rattan, Beijing, China; ²Chinese Academy of Forestry, Beijing, China (yanghuai@icbr.ac.cn; liusr@caf.ac.cn)

In this study, we examined the influence factors of the rhizosphere soil C stability such as selected functional traits of leaf, root and soil nutrient characteristics for both N-fixing and non-N-fixing plants in southern China. The results show that: (1) N-fixing plants have significantly lower specific leaf areas, and higher leaf carbon, leaf nitrogen, and leaf phosphorus content relative to non-N-fixing plants; (2) N-fixing plants have significantly lower rhizosphere soil nitrogen, soil phosphorus, and higher light fraction carbon and heavy fraction carbon relative to non-N-fixing plants; (3) The diameters of N-fixing plants are relatively large and the specific root length (SRL) values of these roots are low relative to non-N-fixing plants; (4) The influence patterns of regulating rhizosphere soils C stability was contrary between N-fixing and non-N-fixing plants; (5) The spatial distribution of rhizosphere soil C stability demonstrated different environmental influence factors among different N-fixing types and different orders roots.

Tree species effects on stocks and vertical distribution of soil carbon: links to mycorrhizal association, soil fauna and soil microbial characteristics

Lars Vesterdal¹, Yan Peng¹, Christina Steffens², Haifeng Zheng¹, Petr Hedenec¹, Luciana Bachege^{1,3}, Bingru Wang¹, Inger K. Schmidt¹, Cindy E. Prescott⁴

¹University of Copenhagen, Frederiksberg C, Denmark; ²University of Hamburg, Hamburg, Germany; ³Federal University of São Carlos, São Paulo, Brazil; ⁴University of British Columbia, Vancouver, Canada (lv@jgn.ku.dk; yape@jgn.ku.dk; christina.steffens@uni-hamburg.de; hazh@jgn.ku.dk; peh@jgn.ku.dk; bachegeal@gmail.com; biw@jgn.ku.dk; iks@jgn.ku.dk; cindy.prescott@ubc.ca)

Tree species with leaf litter traits driving slow rates of leaf litter decomposition have traditionally been associated with accumulation of higher SOC stocks than tree species with fast litter decomposition rates. This hypothesis has mainly been based on observations of thick C-rich forest floors under tree species associated with ectomycorrhizae (ECM). However, a recent hypothesis suggested that tree species with foliar litter traits conducive to fast decomposition will lead to more pronounced microbial transformation and stabilization of litter C. The latter tree species are often associated with arbuscular mycorrhizae (AM) and may enhance deeper incorporation of C by more active soil fauna communities and by higher belowground rates of litter input. The Danish common garden tree species experiments include ECM and AM tree species that differ widely in traits such as foliar litter chemistry. Six common European tree species formed distinct groups that largely reflected their mycorrhizal association. Forest floor C stocks were consistent with the traditional perception of slowly decomposing ECM species being conducive to high SOC stocks, but an intriguing pattern of more C in the mineral soil in AM tree species supported the recent microbial stabilization hypothesis and suggested deeper incorporation of C in more stable forms. Based on new results on microbial, macro- and mesofauna communities, fine root dynamics and repeated soil sampling, this talk will revisit Danish common garden tree species experiments for a synthesis of processes and patterns in organic matter formation that may explain observed patterns in SOC stocks and vertical SOC distribution.

Regulation mechanism of vegetation on slope runoff, sediment yield and soil water infiltration

Xiao Li¹, Zhiqiang Zhang¹

¹College of Soil and Water Conservation, Beijing Forestry University, Beijing, China (lxsdau@yeah.net; zhqzhang@bjfu.edu.cn)

Vegetation is the main component of ecosystem and plays an important role in controlling soil erosion. The relationships between precipitation, vegetation and erosion are important yet unresolved issues in the field of earth surface processes. Through indoor simulated rainfall experiments, we analyzed the characteristics, regulation of, and correlation among the slope rainfall-infiltration-runoff, erosion and sediment under different vegetation conditions, and the process mechanism of soil and water loss on slopes was revealed from the viewpoint of hydrodynamics and physical mechanics. The results showed that vegetation had a strong role in regulating runoff and sediment, and its spatial structure (canopy, root, etc.) can effectively reduce runoff and flow velocity and

increase infiltration, then achieved water storage and sediment reduction. Vegetation reduced the velocity of slope flow by increasing the slope roughness, affected the hydraulic parameters of slope shallow open channel flows, and effectively increased slope resistance coefficient and soil anti-scourability. At the same time, vegetation had a significant role in enhancing soil shear strength. Under different conditions, soil cohesion had a significant negative correlation with runoff and sediment yield. The change characteristics of soil cohesion and internal friction angle were affected by both cover conditions and water content of vegetation slope. Based on this, vegetation had a good role in soil and water conservation. The research results would help us to quantitatively evaluate the effects of water storage and erosion reduction of vegetation and deepen the understanding of soil erosion mechanics process.

Do Norway spruce, Douglas fir and European larch stands differ in litter decomposition and belowground carbon storage?

Lisa Bischofer¹, Torsten W. Berger¹, Douglas L. Godbold¹, Mathias Mayer¹

¹University of Life Sciences and Natural Resources, Institute of Forest Ecology, Vienna, Austria (bischofer.l@gmail.com; torsten.berger@boku.ac.at; douglas.godbold@boku.ac.at; mathias.mayer@boku.ac.at)

An increase in droughts and insect infestations threatens Norway spruce (*Picea abies*) stands across European forests. With a higher drought tolerance, Douglas fir (*Pseudotsuga menziesii*) and European larch (*Larix decidua*) became a suitable non-native and a native silvicultural alternative to Norway spruce. How tree species selection affects litter decomposition and belowground carbon (C) storage is, however, still not fully understood. Here, we want to 1) answer if Norway spruce, Douglas fir and European larch differ with regard to litter mass loss partitioning into leaching of dissolved organic C (DOC) and CO₂ efflux during decomposition, 2) to link mass loss partitioning to litter biochemical properties and 3) to relate mass loss partitioning to belowground C stocks. It is hypothesized that tree species with a higher partitioning into leaching of DOC have higher belowground C stocks. The study took place in Austria and measurements were conducted over the course of one year. Litter CO₂ efflux and leaching of dissolved organic C was measured *in situ* by means of respiration chambers and lysimeters. Litter bags were used to study mass loss and biochemical litter processes/properties. The results of this study will help to improve our understanding of tree species effects on the forest belowground C cycle. In order to lower the uncertainties of C sequestration estimates for the forestry sector, this information is very important. Furthermore, new insights into the complex process of litter break down will be provided. First results of the study will be presented at the conference.

Use of arbuscular mycorrhizal fungi (AMF) in ecological restoration projects for the Atlantic Forest / Uso de fungos micorrízicos arbusculares (FMA) em projetos de restauração ecológica da Mata Atlântica

Girlei Cunha^{1,2}, Susane Rasesa^{3,2}, Frederico Miranda^{1,2}, Eduardo Gusson^{1,2}, Flávio Mendes³, Alexandre Astorino⁴

¹Biodentro Consultoria Florestal, Piracicaba, Brazil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brazil; ³Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brazil; ⁴AES TIETÊ, Bauru, Brazil (girlei.cunha@gmail.com; susanerasera@yahoo.com; fredtsmiranda@gmail.com; eduardogusson@gmail.com; fgandara@usp.br; alexandre.astorino@aes.com)

A maioria das plantas superiores associa-se a fungos micorrízicos arbusculares (FMA). A simbiose promove efeitos positivos para a nutrição e sobrevivência das plantas. A pesquisa está inserida no P&D da ANEEL realizado pela AES-Tietê e IPEF. O experimento de campo está na Estação Experimental de Genética de Anhumas, ESALQ/USP, em Piracicaba, SP. As espécies avaliadas foram: *Mabea fistulifera*, *Lafoensia pacari*, *Psidium myrtiloides*, *Esenbeckia leiocarpa*, *Gallesia integrifolia* e *Maclura tinctoria*. Os FMA foram: *Glomus intraradices* e *G. etunicatum*. Delineamento experimental de blocos ao acaso, com cinco tratamentos: 1) Mudanças não inoculadas em viveiro (MNIV), recebendo fertilizantes na quantidade recomendada por análise de solo (FR); 2) Mudanças inoculadas em viveiro (MIV) e FR; 3) MIV, com fertilização recomendada para N e K e redução de P para 1/3 do indicado (P1/3); 4) MNIV e FR, com adição de FMA na cova (MIC); 5) MIV, P1/3 e MIC. Aos 24 meses foi realizado inventário com medição das plantas. *E. leiocarpa* apresentou alta mortalidade em todas as situações; *M. fistulifera* apresentou maior sobrevivência nos tratamentos com FMA; *L. pacari*, *P. myrtiloides*, *G. integrifolia* e *M. tinctoria* apresentaram alta sobrevivência em todos os tratamentos. A redução de P em plantas com FMA não afetou o crescimento, exceto *G. integrifolia* que apresentou altura significativamente superior quando inoculado com FMA no viveiro ou no campo e recebendo fertilização da quantidade recomendada. O efeito da adição de FMA variou conforme a espécie mas, de uma maneira geral, pode ser considerado vantajoso na restauração ecológica da Mata Atlântica.

Plant responses to belowground variations along elevational gradients in temperate and tropical climates

Monique Weemstra^{1,2}, Alexia Stokes¹, Leonore Jimenez³, Nereyda Cruz⁴, Fabien Anthelme⁵, Luis Merino-Martin^{2,1}, Manon Bounous¹, Beatriz Marin-Castro⁶, Hervé Rey⁷, Awaz Mohamed⁸, Zhun Mao¹, Stéphane Fournier¹, Marco Morales-Martinez⁹, Grégoire Freschet², Katrin Sieron⁹, Guillermo Angeles³, Catherine Roumet²

Soil is a hyper-heterogeneous environment, and how plants respond to changes in belowground variations in soil properties and microclimate is poorly understood. Environmental gradients are useful for examining how root traits mediate plant responses to soil heterogeneity. We measured soil/air temperature, soil water potential and physical/chemical properties in 30 plots along elevational gradients located in France and Mexico, both above- and below the treeline. High elevations were colder than lower elevations at both sites, but in Mexico, precipitation decreased at high elevations, whereas in France, higher elevations were wetter than lower altitudes. Soil properties were more idiosyncratic along both gradients. We selected 11 (France) and 14 (Mexico) woody and herbaceous species based on their abundance along the gradients. A range of root and leaf functional traits were measured. Data showed that trends in root traits along gradients were often masked by the hyper-heterogeneous belowground environment, whereas patterns in leaf traits were more evident. Results will be discussed with regard to the effect of elevation as an environmental filter on plant traits.

Epidaphic springtails (Collembola) in commercial forests and savanna regions of the Colombian Orinoco region / *Colémbolos epiedáficos en forestaciones comerciales y sabanas en la orinoquia Colombiana*

Adriana Ramos Díaz¹, José G. Palacios Vargas², Olga Patricia Pinzón Florián³

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia; ²Departamento de Ecología y Recursos Naturales, Facultad de Ciencias, Universidad Nacional Autónoma de México, 04510, México D.F., Mexico; ³Laboratorio de Sanidad Forestal, Universidad Distrital Francisco José de Caldas., Bogotá, Colombia (adriramdi@gmail.com; troglolaphysa@hotmail.com; opatriciap@udistrital.edu.co)

Los colémbolos desempeñan un rol ecológico clave en la descomposición de la materia orgánica y ciclaje de nutrientes y son considerados indicadores del cambio de uso del suelo. Con el fin de estimar cambios en la diversidad de colémbolos luego del establecimiento de plantaciones de *Acacia mangium* en sabanas, se muestrearon plantaciones de tres edades y áreas de sabana en el municipio de Puerto Gaitán (Meta, Colombia) durante un periodo húmedo y seco. Para estimar y comparar la diversidad efectiva de colémbolos epiedáficos (diversidad q_0 , q_1 , q_2), se realizó un muestreo utilizando trampas de caída. Con el objeto de explicar el ensamblaje de los colémbolos, se midieron variables fisicoquímicas del suelo y estructurales de las plantaciones que se correlacionaron con la diversidad mediante un análisis de redundancia (RDA). Las plantaciones favorecieron la diversidad y abundancia de los colémbolos epiedáficos en los primeros 5 años desde el establecimiento de la plantación. La época seca tuvo un efecto más limitante en la abundancia y diversidad de colémbolos en los suelos de sabana, que el mismo establecimiento de las plantaciones. La temperatura y contenido de humedad del suelo, desarrollo de la plantación (altura), contenido de arcilla, carbono orgánico y compactación están relacionados con la abundancia y/o riqueza de colémbolos en las áreas estudiadas. Se concluye que estados tempranos de la forestación de sabanas con *A. mangium* favorecen la diversidad de colémbolos pero se requieren más estudios para entender los efectos en el suelo, a largo plazo de este tipo de actividad.

Mycorrhizal association in *Plathymentia reticulata* and *Dalbergia nigra* plantations in Southeast of Brazil

David Pessanha Siqueira¹, Andréia Francisca Riter Netto¹, Juliana Müller Freire², Deborah Guerra Barroso¹

¹Universidade Estadual do Norte Fluminense Darcy Ribeiro, Campos dos Goytacazes, Brazil; ²Embrapa Agrobiologia, Seropédica, Brazil (dps@pq.uenf.br; afrancis@uenf.br; juliana.muller@embrapa.br; deborah@uenf.br)

The Brazilian forestry species plantations are alternatives to reduce the deforestation as well to degraded areas recovery. In this context, the association with arbuscular mycorrhizal fungi can enhance the host plant growth, improving nutrients absorption. Our work aimed to verify mycorrhizal colonization in *P. reticulata* and *D. nigra* homogeneous plantations, five years after planting. Soil sampling were collected nearby the trees and fine roots were selected. To determine the mycorrhizal colonization, the fine roots were washed and clared in 10% KOH at 85°C for 10 minutes and after in H₂O₂ for 1 hour. Next, the roots were placed in 5% HCl for 5 minutes and then in 0.05% trypan blue for 15 minutes at 90°C. After coloring, root segments were distributed on slides, under a coverslip and carried out to a microscope to observe fungi structures. Spore counting were assessed by wet sieving and centrifugation and sucrose flotation techniques. The spore quantification was performed on acrylic plates with concentric rings under a microscope (50x). Both in *P. reticulata* or *D. nigra* roots we found fungal structures (vesicles and hyphae) that confirm the mycorrhizal colonization. In 50cm³ of soil under younger stands we found 4,913 and 8,123 spores in *P. reticulata* and *D. nigra* plantations, respectively. Have been identified *Glomus macrocarpum* and *Ambispora leptoticha*, in soil under *P. reticulata* and *G. macrocarpum*; *G. aggregatum*, and *Claroideoglomus etunicatum* in soil under *D. nigra*, suggesting that there are different fungi colonizing the roots in both studied species.

E8f: CURRENT UNDERSTANDING AND FUTURE CHALLENGES FOR FOREST RESEARCH AFTER THE TWO NUCLEAR ACCIDENTS OF CHERNOBYL AND FUKUSHIMA - I

Radioactivity in forests: research, importance and risk

Brenda J Howard¹

¹University of Nottingham, Nottingham, United Kingdom (bjho@ceh.ac.uk)

Widespread contamination of forests by radionuclides occurred due to the atmospheric releases from two major nuclear accidents, at Chernobyl in the Ukraine in 1986 and Fukushima Daiichi in Japan in 2011. In both countries, large areas of forests were contaminated by long-lived radionuclides, notably isotopes of radiocaesium, strontium and plutonium. The impact of contamination was diverse and lasted for many years after deposition of fallout occurred. In both the USSR and Japan, the utilisation of the forest for forestry, extensive animal production, harvesting of wild plants and mushrooms and hunting of wild animals was severely curtailed. Extensive research studies were conducted on the dynamic behaviour of radionuclides in different types of forest, the effects of exposure to radiation on biota, the transfer of radionuclides to edible products and the vertical and lateral movement of radionuclides. The outcome of these studies has been recently summarised in the International Atomic Energy Agency's MODARIA II programme and will be briefly summarised. The importance of such studies for our understanding of the ecological behaviour of contaminants in forests and the diversity encountered between different types of forests, landscapes and climate will be outlined. The consequent impact in terms of both external and internal routes of exposure to radiation for both humans and wildlife, and the impact of remediation activities on communities, will also be considered. Lessons learned from the research response needs to be made readily available to other countries to ensure appropriate responses to future similar events.

Introduction to radiation session of forests - current understanding and future challenges for forest research after the two nuclear accidents of Chernobyl and Fukushima

Satoru Miura¹ 

¹Forestry and Forest Products Research Institute, Tsukuba, Japan (miura@ffpri.affrc.go.jp)

Technical session about radioactive contamination of forests was first held in IUFRO World Conference 2014. Now, in 2019, 33 years from Chernobyl accident and 8 years from Fukushima Daiichi accident, this session aims to review current knowledge of the environmental behavior of radioactive substances in various forest areas after the both accidents. Exchange idea between experiences in Chernobyl and in Fukushima must be meaningful for deepening understanding radiation contamination. It consists of a short keynote and seven overview/synthesis papers (E8f) combined with technical oral (E8h) and poster (E8fp) presentations. The scope covers the distribution of radioactive contamination in components of forest ecosystems, the changes with time that have occurred and may occur in the future, the technological or management-based remediation options that were applied and developed and the long-term social consequences

for the affected communities. Challenging studies of the biogeochemical behavior of both radio- and stable- cesium in forest vegetation are also addressed. And, through this session, I would like to lay the foundation for a gradual international network of radiation protection and radiation ecology over forests. Countries with nuclear power plants and countries adjacent to them could be learned from experiences in Chernobyl and Fukushima and should be prepared for the worst possible accidents. Forests are ecosystems located on land and very close to human society and strongly utilized. However, we should be aware that once a severe accident occurs at a nuclear power plant, radioactive contamination of the forest will last for a very long time.

Iodine and uranium isotopes in forest soils around Chernobyl, 30 years after deposition

George Shaw¹, Liz Bailey¹, Neil Crout¹, Maria Izquierdo², Scott Young¹

¹University of Nottingham, Nottingham, United Kingdom; ²Institute of Environmental Assessment and Water Research, Barcelona, Spain (george.shaw@nottingham.ac.uk; liz.bailey@nottingham.ac.uk; neil.crout@nottingham.ac.uk; maria.izquierdo@idaea.csic.es; scott.young@nottingham.ac.uk)

At the time of the Chernobyl accident in 1986, 40-50% of the area surrounding the power plant was covered by forest. Since then, forests have expanded and encroached on highly contaminated land which has now been abandoned for over 30 years. The forest soils within the 30 km Chernobyl Exclusion Zone (CEZ) contain a complex mixture of radionuclides, some of which are so long-lived that the area will probably never be rehabilitated for public access. The CEZ now provides a unique natural laboratory for the long-term measurement of radionuclides such as I-129, U-238 and U-235, which have been relatively poorly studied compared to the shorter-lived radionuclides Cs-137 and Sr-90. Of particular interest is the rate and degree to which I-129 and uranium isotopes equilibrate with the natural biogeochemical cycles within the forest soils. Measurements of soil samples taken from the CEZ almost 30 years after the Chernobyl accident show that neither I-129 nor the two uranium isotopes, U-238 and U-235, have reached equilibrium with native I-127 or naturally-occurring uranium isotopes, respectively. This is important information when considering the long-term impacts of severe nuclear accidents and radioactive waste disposal on forest ecosystems. In both cases, safety assessments must account for the fate of radionuclides including I-129 and uranium isotopes, for which a reliable understanding of their biogeochemical fate is needed, based as much as possible on 'real world' measurements.

Radiological situation in forests of Ukraine on late phase of the Chernobyl disaster

Dmytrii Holiaka¹, Valerii Kashparov¹, Svyatoslav Levchuk¹, Sergiy Zibitsev²

¹Ukrainian Institute of Agriculture Radiology, National University of Life and Environmental Sciences of Ukraine, Kyiv, Ukraine; ²National University of Life and Environmental Sciences of Ukraine, Institute of Forestry and Landscape-Park Management, Kyiv, Ukraine (george.shaw@nottingham.ac.uk; liz.bailey@nottingham.ac.uk; neil.crout@nottingham.ac.uk; maria.izquierdo@idaea.csic.es; scott.young@nottingham.ac.uk)

Chernobyl accident (1986) led to contamination with ¹³⁷Cs of more than 1 million hectares of forests in Ukraine (density >40 kBq·m⁻²). During first two decades, milk and meat were major source for internal doses of population. Currently, more than half of cases of excess of permissible levels (PL) (¹³⁷Cs) derived from forest products - wild mushrooms, berries, meat. Activity concentration of ¹³⁷Cs in dried mushrooms outside the Chernobyl Exclusion Zone (ChEZ) can be two-three orders of magnitude (up to 3MBq·kg⁻¹) higher than PL (2.5 kBq·kg⁻¹). ChEZ and its vicinity contaminated with ⁹⁰Sr with a density of more than 5.5 kBq·m⁻², where ⁹⁰Sr activity concentration in fuelwood may exceed PL (60 Bq·kg⁻¹). The radiological threat of wildfires in ChEZ for firefighters and population has been evaluated. Distribution, depots and fluxes of ⁹⁰Sr and ¹³⁷Cs in forest ecosystems were studied. Currently, up to 10% of ¹³⁷Cs located in biomass of pine forests and up to 40% in litter. Due to high mobility of ⁹⁰Sr in sandy soils, its content in 20-cm root layer of pine forests has decreased up to 20% of total amount in ecosystem because of intensive root uptake (> 50%) and vertical migration in soil (> 20%) so TF of ⁹⁰Sr increased of more than order of magnitude over the last 20-30 years. Radionuclides have lower bioavailability in deciduous forests compared to coniferous. The data on the non-uniform distribution of ⁹⁰Sr and ¹³⁷Cs in wood of pine and birch trees for typical forest stands presented.

Forests in Fukushima: radiocesium dynamics and their ecological and social impacts

Shoji Hashimoto^{1,2}, Masabumi Komatsu¹, Shinta Ohashi¹, Naohiro Imamura¹, Toshiya Matsuura¹, Satoru Miura¹

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²The University of Tokyo, Tokyo, Japan (shojih@ffpri.affrc.go.jp; kopine@ffpri.affrc.go.jp; shinta0084@ffpri.affrc.go.jp; nimamura@ffpri.affrc.go.jp; matsuu50@ffpri.affrc.go.jp; miura@ffpri.affrc.go.jp)

The majority of the land contaminated by the Fukushima Daiichi Nuclear Power Plant accident is forested (approx; 70 %). Since the accident, many scientists have been devoted to researching the resulting contamination and tracking radionuclides in Fukushima forest ecosystems. Studies of the Chernobyl accident revealed that trees efficiently captured radioactive deposition and the deposited radionuclides migrated within forests; similar dynamics have been observed in Fukushima forests. Furthermore, after the Chernobyl accident, radioactive contamination damaged the economy, communities, and livelihoods of local people. The Japanese government has taken several measures to mitigate damage from the contamination; however, effective countermeasures for forest ecosystems are limited, and the forests remain contaminated. Some parts of contaminated forests have been established as exclusion zones, but people still worry about the contaminated forests and their products. In this presentation, we compiled research on Fukushima forests and report 1) the uncovered and predicted dynamics of radiocesium, the major radionuclide, in contaminated Japanese forests, 2) how radioactive contamination has affected the livelihoods of local people, and 3) what countermeasures have been taken in Fukushima.

Decline and future recovery of wild plant/mushroom gathering in rural communities in Fukushima

Toshiya Matsuura¹, Ken Sugimura²

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Nagasaki University, Nagasaki, Japan (matsuu50@affrc.go.jp; k-sugimura@nagasaki-u.ac.jp)

Radioactive contamination due to the Fukushima Dai-ichi Nuclear Power Plant accident had deteriorated provisioning and cultural ecosystem services in eastern Japan. Wild plant/mushroom gathering is one of such services for rural residents as their food culture and outdoor recreation. In this study, we elucidated a drastic decline in the gathering frequency after the accident using household questionnaire surveys in rural communities in Fukushima. We then delineated former potential gathering areas of common edible wild plants/mushrooms with specific environmental conditions, e.g., vegetation, topography, and proximity to roads, using multicriteria evaluation and geographic information system. We also estimated external radiation dose using different scenarios of frequency, species, and areas of gathering, under the physical decay trend of radiocesium. By overlaying maps of potential gathering areas and external radiation dose, we estimated the future recovery of gathering under different scenarios. We found that it was difficult to recover the former gathering sites due to high external radiation dose, particularly in highly contaminated areas. However, we also saw some possibility of recovery by reducing the gathering frequency or by

gathering only within areas with less contamination since radiocesium deposition is spatially heterogeneous even in a community or a municipality. Selection of gathering species is also useful for further reduction of internal radiation dose because radiocesium absorption differs widely among species.

How knowledge on K and ^{133}Cs biocycling can be used to estimate ^{137}Cs root uptake in Japanese cedar stands contaminated by the Fukushima fallouts

Pierre Hurtevent¹, Frederic Coppin¹, Marc-André Gonze¹, Philippe Calmon¹, Kenji Nanba², Yuichi Onda³, Yves Thiry⁴

¹IRSN, Saint-Paul-Lez-Durance, France; ²IER/Fukushima University, Fukushima, Japan; ³CRIED/University of Tsukuba, Tsukuba, Japan; ⁴ANDRA, Chatenay-Malabry, France (pierre.hurtevent@irsn.fr; frederic.coppin@irsn.fr; marc-andre.gonze@irsn.fr; philippe.calmon@irsn.fr; nanba@sss.fukushima-u.ac.jp; onda@geoenv.tsukuba.ac.jp; yves.thiry@andra.fr)

The radiocesium (rCs) deposited onto forests of the Fukushima region was incorporated into the biogeochemical cycle of elements leading to its persistence within these ecosystems. To date, rCs partitioning has not reached an apparent steady state and its root uptake flux must still be accurately determined for long-term predictions of rCs behavior. Using its stable analogs (K and ^{133}Cs) is a relevant approach to quantify this flux. Data were obtained from monitored even-aged Japanese cedar stands sampled in November 2013, 2014 and 2016. A mass balance approach was used for the determination of rCs, K and ^{133}Cs annual recycling fluxes. Part of the results obtained in this study was used for parameterizing a dynamic rCs transfer model (cf. Gonze et al, IUFRO 2019). As expected, K and ^{133}Cs concentrations remained constant over the 4-year period in all tree compartments. By contrast, rCs concentrations slowly decreased in all tree compartments over the same period. The measured $[^{133}\text{Cs}]/[\text{K}]$ ratios significantly varied between the biomass compartments, the discrimination between those elements being especially pronounced between living and corresponding senescing organs (e.g. outer and inner bark). It was also demonstrated that the root uptake fluxes of K and ^{133}Cs were higher than internal translocation fluxes in both stands. We estimated the root uptake of ^{133}Cs by applying the observed discrimination factors to each K apparent flux. This approach allows the use of K instead of ^{133}Cs measurements that are poorly available for the calculation of rCs root uptake. Its efficiency will be discussed.

Process-based modelling of the short and long-term dynamics of radiocesium in Fukushima coniferous forests

Marc-André Gonze¹, Philippe Calmon¹, Pierre Hurtevent¹, Frédéric Coppin¹, Valérie Nicoulaud¹

¹IRSN, Saint-Paul lez Durance, France (marc-andre.gonze@irsn.fr; philippe.calmon@irsn.fr; pierre.hurtevent@irsn.fr; frederic.coppin@irsn.fr; valerie.nicoulaud@irsn.fr)

Since Fukushima accident, numerous surveys have been conducted by Japanese researchers in a variety of forest stands contaminated by atmospheric radiocesium (rCs) fallouts. The thousands of observations acquired offer a genuine opportunity to improve models for predicting rCs transfers in the soil-vegetation system, even though there are still relatively few studies on this subject (Hashimoto et al; 2013, Calmon et al; 2015, Nishina and Hayashi 2015, Ota et al; 2016, Nishina et al; 2018). To benefit from this new knowledge, significant improvements have been made to a simple model developed after Chernobyl (in RODOS project). Major efforts were invested in: the refinement of the conceptual approach, the quantification of the hydrological/eco-physiological functioning of the forest stand and the parameterization of tree transfer processes based on K/biomass cycling. This process-based dynamic model (TREE4) was tested against a comprehensive set of time observations over 2011-2017 in Japanese cedar & cypress stands. This dataset was established by extending the meta-analysis by Gonze et al (2017) to field studies conducted throughout Japan after 2013. While most of the model parameters could be estimated from the literature, including their ranges of variability, a few of them could not be otherwise than by calibrating outputs (with a Bayesian technique). We then conducted SA/UA to evaluate the predictive accuracy of the model over this 7-year period, quantify the respective contributions of root/foliar pathways and evaluate sensitivity of the outputs to forest specificities and atmospheric deposition conditions. Further, prognostic simulations until 2041 will be discussed.

E8g: PLANT: SOIL INTERACTIONS IN FORESTS - II

Forest conversion to conifers induces a regime shift in acidic soils that affects soil carbon stability

Ellen Desie¹, Karen Vancampenhout², Kathleen Heyens², Jakub Hlava³, Kris Verheyen⁴, Bart Muys¹

¹KU Leuven, Leuven, Belgium; ²KU Leuven Campus Geel, Geel, Belgium; ³Czech University of Life Sciences, Prague, Czech Republic; ⁴Ghent University, Ghent, Belgium (ellen.desie@kuleuven.be; karen.vancampenhout@kuleuven.be; kathleen.heyens@kuleuven.be; hlava@af.czu.cz; kris.verheyen@ugent.be; bart.muys@kuleuven.be)

A substantial part of forests worldwide is located on acidic soils. In such soils, processes are typically characterized by non-linear responses to external drivers. Acid buffer ranges and thresholds in soils are widely acknowledged, yet these non-linearities are rarely incorporated into our understanding of soil carbon dynamics. We studied the effect of conversion of broadleaved mixed forest to Norway spruce monocultures on different functional compartments of the belowground carbon cycle, i.e. litter layers, soil fauna and soil micro-organisms. We have examined how they affect soil biochemical characteristics and ultimately, soil carbon stability. By studying these effects along a soil buffering gradient we were able to evaluate the relative significance of forest management and edaphic constraints on soil carbon processing. Our findings show that effects of conversion are more dramatic for forests that shifted from one buffering domain to another upon conversion. This indicates that changes in forest composition can, depending on the initial acid buffering capacity, cascade through different compartments of the soil carbon cycle and eventually alter the way carbon is stored. Although increased carbon concentrations were observed in stands converted to conifers, this carbon is stored in less protected pools. In these pools, carbon is not occluded in aggregates or bound to soil minerals and thus more vulnerable to disturbance. As the vast majority of the world's forest soils are acidic, considering non-linearities in the belowground ecosystem is crucial to optimize carbon sequestration and climate smart forest management.

Soil and tree regeneration relationships in an old growth urban forest, Philadelphia, Pennsylvania

Robert Loeb¹ 

¹Pennsylvania State University, DuBois, Pennsylvania, USA (rxl5@psu.edu)

One focus of urban foresters is to increase the urban forest by planting trees in the streets and parks of cities. A valuable alternative to plantings in urban parks is enabling natural tree regeneration to become reestablished which is particularly important for the long-term survival of natural old growth urban forests. A key limiting factor for tree regeneration is depauperate forest soils in urban parks. Understanding which nutrients are needed to reestablish natural regeneration of

existing canopy trees is key to ensuring the long-term survival of old growth urban forests. Haddington Woods in Cobbs Creek Park, Philadelphia, Pennsylvania, USA contains a 2.2 ha natural old growth urban forest. The canopy dominants *Carya glabra*, *Liriodendron tulipifera*, *Prunus serotina*, *Quercus alba*, and *Quercus rubra* are the typical canopy species found in natural old growth urban forests in the eastern United States. The atypical aspect is that parts of the forest contain extensive populations of seedlings and saplings of the canopy dominants, which is in sharp contrast to the dearth of natural regeneration in other natural old growth urban forests in the eastern United States. The natural regeneration occurs despite the presence of white-tailed deer which over browse other urban forests and open public access permitting trampling that kills seedlings. This presentation will provide the statistical analysis of relationships between forest regeneration and measures of soil fertility including pH, phosphate, potash, magnesium, calcium, exchangeable cation capacity, organic matter, soluble salts, nitrogen, and aluminum stress to examine the limiting factors for natural tree regeneration.

Comparison of soil fertility in artificial and natural stands of Persian oak (*Quercus brantii*)

Mehrdad Zarafshar^{1,2}, Mohammad Matinzadeh¹, Yahya Kooch³, Kokab Enayati¹, Alireza Abbasi¹, Mohammad Reza Negahdarsaber¹, Mohammad Javad Rosta¹, Seyed Kazem Bordbar¹

¹Fars Agricultural and Natural Resources Research and Education Center, AREEO, Shiraz, Islamic Republic of Iran; ²Research institute of forests and rangelands, Iran, Tehran, Islamic Republic of Iran; ³Tarbiat Modare University, Tehran, Islamic Republic of Iran (mehrdadzarafshar@gmail.com; yahya.kooch@yahoo.com; enayatik@yahoo.com; a.abasi@areeo.ac.ir; sabersiamak@gmail.com; m.roosta@areeo.ac.ir; sbordbar86@gmail.com)

In Zagros forest, Persian oak is an important species that grows along southern parts of forests. This current research was aimed to study the effect of Persian oak plantation on the soil chemical and biological parameters to compare the obtained results with a natural stand of the species. We tested the hypothesis that afforestation with Persian oak can improve soil fertility in the long-term when compare with natural forests of the species. For this purpose, three afforested oak plots (11×11 m) with 50 years old, beside a natural forest, were selected and soil samples were taken from two depths (0-10 and 10-20 cm) and their physicochemical, biological, and enzymatic properties were assessed. The obtained data demonstrated that artificial stands could considerably improve of the soil fertility. The higher values of soil moisture, organic carbon and magnesium and potassium concentrations were observed at natural stand while higher concentration of phosphorous was belong to the planted stand. pH, EC, N, C/N, Na, Fe, Mg+Ca, Zn and N and C stock did not show any considerable difference between the stands. activity of Acid and Alkaline phosphates and Dehydrogenase and Urease were slightly higher in planted plots. On the other hand, soil microbial parameters including soil microbial respiration and microbial biomass of N and C were at the same level for both the stands. Our finding clearly show that plantation with Persian oak could be considered to rehabilitate degraded natural forests of the species along Zagros region through improving soil quality.

Trees, soil chemistry and microbiota interactions: driving forces and feedback processes in a Mediterranean remediated ecosystem

Teodoro Marañón¹, Marta Gil-Martínez¹, Cristina Aponte², Álvaro López-García³, Paula Madejón¹, Carmen M. Navarro-Fernández¹, María T. Domínguez⁴

¹IRNAS, CSIC, Seville, Spain; ²University of Melbourne, Melbourne, Australia; ³EEZ, CSIC, Granada, Spain; ⁴University of Seville, Seville, Spain (teodoro@irnase.csic.es <https://orcid.org/0000-0002-7751-9316>; marta-gil@irnase.csic.es; caponte@unimelb.edu.au; lopez.garcia.alvaro@gmail.com; pmadejon@irnase.csic.es; nfcarmen@gmail.com; mdominguez23@us.es)

Trees are ecosystem engineers able to generate effects on soil properties and microbiota that could lead to a feedback effect (Aponte et al; 2013). We present here several evidences of interactions between different tree species with soil chemistry and microbiota, in the Guadiamar Green Corridor (SW Spain); 1) We have analysed the potential of seven tree species for phytoremediation of soils contaminated by trace elements. Some of the studied tree species showed a positive effect on soil phytoremediation: increase soil pH underneath the trees and high phytostabilisation of trace elements in the rhizosphere (Madejón et al; 2018); 2) Tree species identity was a driving factor for the activities of four soil enzymes involved in C, N and P cycles. For example, beta-glucosidase activity tended to be higher in soils under white poplar (*Populus alba*) trees (Gil-Martínez et al., unpublished); 3) Composition of soil fungal communities, determined by next generation sequencing (NGS) techniques, differed in relation to the tree species (Gil-Martínez et al., unpublished); 4) Ectomycorrhizal fungal communities and their functional traits affected holm oak (*Quercus ilex*) performance in contrasted soil conditions. For example, As, Mn and Zn translocation from soil to roots was best explained by the composition of mycorrhizal fungal communities rather than by toxic elements concentrations (Gil-Martínez et al; 2018). A synthesis of tree-soil-microbiota interactions in a Mediterranean remediated ecosystem is presented.

Effect of uniformity and fertilizing on wood production in one clone of *Pinus taeda* in Paraná, Brazil / Efeito da uniformidade e fertilização na produção de madeira de um clone de *Pinus taeda* no Paraná

Isabel Deliberati¹, Mauro Valdir Schumacher², Marco Aurélio Figura³, James Stahl³, Monique Pimentel Lagemann², Rodrigo Toledo Coutinho⁴, Reinaldo Hoinacki da Costa⁵

¹IPEF – Forestry Science and Research Institute, Piracicaba, Brazil; ²Universidade Federal de Santa Maria, Santa Maria, Brazil; ³Klabin S.A., Telêmaco Borba, Brazil; ⁴Arauco do Brasil, Curitiba, Brazil; ⁵Juliana Florestal Ltda, Caçador, Brazil (isabel@ipef.br; mauro.schumacher@ufsm.br; mafigura@klabin.com.br; jstahl@klabin.com.br; moniquelagemann@gmail.com; rcoutinho@arauco.com.br; reinaldo@frameport.com.br)

A uniformidade do povoamento é afetada pelo material genético e pelo manejo silvicultural utilizado, principalmente no estabelecimento do plantio. Estudos mostram que povoamentos com estrutura mais uniforme resultam em maiores produtividades devido ao aumento na captura e eficiência de uso dos recursos. Deste modo, este trabalho busca avaliar o comportamento da uniformidade e da fertilização na produção de madeira de um clone de *Pinus taeda* em Telêmaco Borba – PR. O delineamento experimental utilizado foi fatorial com 2 níveis de nutrição (com e sem fertilização) e 2 níveis de uniformidade (uniforme e heterogêneo – replantio tardio), com 3 repetições. O estoque de biomassa de tronco aos 11 anos foi significativamente maior no tratamento uniforme (ganho de 8%) e no tratamento fertilizado (ganho de 44%), não havendo interação entre estes fatores. O índice de área foliar (m² m⁻²) não apresentou diferenças significativas entre os tratamentos, porém foi 2% superior nos uniformes e 9% no fertilizado. As diferenças de produtividade nas parcelas fertilizadas podem ser explicadas em parte por apresentarem o dobro da eficiência de uso da luz (0,41 g MJ⁻¹) do que as parcelas sem fertilização (0,16 g MJ⁻¹), sendo que para o fator uniformidade não houve diferença. Também se deve considerar os padrões de alocação de carbono, fator não avaliado. Portanto, estes resultados mostram que a qualidade das atividades silviculturais realizadas no estabelecimento da floresta são de grande importância para o resultado final da produtividade, pois o fato das árvores serem geneticamente idênticas não garante elevadas taxas de crescimento.

Climate and fire influence fine root traits of tropical forests across Ghana

Shalom Addo-Danso¹, Lucy Amissah¹, Mark Appiah¹, Ernest Foli¹, Daniel Ofori¹, George Ametsitsi¹, Reginald Guuroh¹, Gloria Djagbletey¹, Stephen Adu-Bredu¹

¹CSIR-Forestry Research Institute of Ghana, Kumasi, Ghana (sadaniso@csir-forig.org.gh; lamissah@csir-forig.org.gh; mappiah@csir-forig.org.gh; efoli@csir-forig.org.gh; dofori@csir-forig.org.gh; gametsitsi@csir-forig.org.gh; rguuroh@csir-forig.org.gh; gddjagbletey@csir-forig.org.gh; sabredu@csir-forig.org.gh)

Fine root traits offer insights into root exploitation strategies, and how ecosystems respond to environmental changes. However, our knowledge of fine-root trait distribution, and the driving factors in the tropical forest biome is limited by the lack of data, particularly from Africa. Here, we assessed fine (< 0.6 mm in diameter) root architectural (branching intensity and biomass) and morphological (root diameter, specific root length and root tissue density) traits in forest ecosystems ranging from dry through moist to wet evergreen across Ghana. We further correlated root trait estimates with mean annual precipitation (MAP) mean annual temperature (MAT). Overall, specific root length and branching intensity were highest in forests in dry sites compared to those in moist and wet sites. On the other hand, root diameter and root biomass were highest in wet sites, and correlated with MAP and MAT. Specifically, root biomass correlated strongly and positively with MAP, but was negatively correlated with MAT. Root diameter correlated negatively with MAT. Additionally, when the data were separated into fire-prone and non-fire dominated forests, fine-root biomass was significantly lower in the fire-prone forests. Our study suggests that there is diversity of belowground strategies in these tropical forests, depending on climatic conditions and fire disturbances. Hence, future changes in climate, and resultant influence on wildfires could modify root traits, with consequences for resource acquisition and biogeochemical cycling in tropical forests.

Influence of vegetation in hydraulic conductivity in three types of forests in the San Cristóbal River Watershed in Bogotá, Colombia / Influencia de la vegetación en la conductividad hidráulica en tres tipos de bosque en la cuenca del Río San Cristóbal, Bogotá, Colombia

Tatiana Bermejo¹, Angela Bibiana García¹, Luis Fernando Soler¹

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (tbermejoc@correo.udistrital.edu.co; abgarciah@correo.udistrital.edu.co; lfsoleru@correo.udistrital.edu.co)

La conductividad hidráulica saturada (Ks) es la propiedad que determina el movimiento del agua en el suelo en condiciones de saturación, su estudio resulta fundamental para entender dinámicas que confluyen en el ciclo hidrológico y la compleja interacción entre suelo-vegetación, por tanto permite evidenciar la incidencia de las alteraciones que han sufrido los ecosistemas, para este caso de carácter estratégico en la regulación hídrica producto de cambio de coberturas vegetales y la ausencia de éstas. El objeto de investigación fue evaluar la incidencia de la cobertura vegetal en la (Ks) en tres bosques: Bosque-natural (BN) dominado por *Weinmannia tomentosa* L.f., Bosque *Hesperocyparis lusitanica* (Mill.) Bartel (C) y Bosque *Eucalyptus globulus* Labill (E), ubicados en la cuenca del Río San Cristóbal (Bogotá-Colombia) a partir de factores como la densidad, cobertura de la vegetación arbórea y de sotobosque además de características físicas del suelo determinadas para el área de estudio. Los valores de (Ks) en cada uno de los bosques evaluados presentó diferencias en las tasas de infiltración: 4,21 a 0,89 mm/h; 8,06 a 1,50 mm/h y 1,84 a 0,72 mm/h, respectivamente. En relación, se encontró que no hay diferencias significativas de la vegetación arbórea que incida en la (Ks), sin embargo sí las hay en el sotobosque en cuanto al porcentaje de cobertura y densidad presentando una correlación positiva con la (Ks) en C y BN, no obsta resaltar las propiedades del suelo evaluadas obteniendo relación entre la (Ks), el grado de compactación y la cantidad de materia orgánica.

Does hydrochar-amended nursery substrate improve growth of pine seedlings?

Samieh Eskandari¹, Ali Mohammadi¹, Maria Sandberg¹, Karin Granström¹

¹Karlstad University, Karlstad, Sweden (samieh.eskandari@kau.se; ali.mohammadi@kau.se; maria.sandberg@kau.se; karin.granstrom@kau.se)

Sweden is the world's second largest exporter of pulp, paper and wood products. There is about 28 million hectares of forest land in Sweden where pine trees constitute 40% of the total standing volume. The forest land is annually restocked with container-grown tree seedlings dominantly produced in peat and peat-based growing media. Nutrient-rich growing media alternatives, especially biochar, have become an interest area for researchers as growing global demand for wood will end in further degradation of forest soils in a near future. Biochar and hydrochar have been proposed as novel materials for providing soilless growth media. However, research to date has not yet determined the potential benefits of hydrochar for producing pine seedlings at nurseries. Hydrochar is characterised by numerous good properties to be used as a soil amendment, however, properties of hydrochar depend on the feedstock and the production procedure. Treatment plant sludge and ash are rich in nutrients and cations such as K, Ca and Mg and therefore can be a great feedstock for hydrochar. This study aimed to investigate whether adding enriched hydrochar (mixed with wood ash) from biosludge, in either forms of powder or pellets, improves the growth of pine seedlings. Therefore, we amended raw peat with 10% and 20% hydrochar-ash composites with no added fertilizers, and fertilizers added in 50% and 100% of recommended rates for pine seedlings. This study reports for the first time the effects of hydrochar-ash powder and pellets, when used as a growing media component, on pine seedling growth.

E8h: CURRENT UNDERSTANDING AND FUTURE CHALLENGES FOR FOREST RESEARCH AFTER THE TWO NUCLEAR ACCIDENTS OF CHERNOBYL AND FUKUSHIMA - II

¹³⁷Cs circulation in plants of forest ecosystems on the territory of the Chernobyl exclusion zone

Nataliia Zarubina¹

¹Institute for Nuclear Research of NAS of Ukraine, Kiev, Ukraine (nataliia.zarubina@gmail.com)

Research was carried out on the territory of two sampling areas in Chernobyl exclusion zone. We investigated changes of ¹³⁷Cs specific activity levels in plants of the forest ecosystems throughout the year. Sampling of one- and two-year-old needles and branches, and wood of *Pinus sylvestris* L. (the main forest-forming species) was carry out from 25 model trees with a frequency of one time per two weeks during 2013-2015. The content of ¹³⁷Cs in the researched organs of *P. sylvestris* was defined by method of gamma spectrometry. The specific activity levels of ¹³⁷Cs change in the needles, branches and wood during the year. The maximum of ¹³⁷Cs content in the needles and branches is noted in summer. The opposite effect is observed in wood - the maximum concentration of ¹³⁷Cs is fixed in the middle of winter. The presence of a correlation (0.67) ¹³⁷Cs specific activity in one-year needles, one-year branches and two-year branches indicates the similarity of the processes of radiocaesium intake and elimination in this organs of *P. sylvestris*. The correlation between the content of ¹³⁷Cs in wood and other organs is practically absent (r<0.24). This evidences about distinction of the redistribution mechanisms of ¹³⁷Cs in organs of *P. sylvestris* with different

physiological activities. Periodic changes in the content of ^{137}Cs in investigated organs of *P. sylvestris* evidence that the radionuclide fallen after the accident in forest ecosystems is in a constant circulation; ^{137}Cs intakes to the plants and it eliminates from plants during a year.

Tracing radiocesium in stem wood after the FDNPP accident

Shinta Ohashi¹, Katsushi Kuroda¹, Takeshi Fujiwara², Tsutomu Takano¹

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Forest Bio-Research Center, Forestry and Forest Products Research Institute, Hitachi, Japan (shinta0084@ffpri.affrc.go.jp; kurodak@affrc.go.jp; fujiwara@ffpri.affrc.go.jp; ttakano@ffpri.affrc.go.jp)

To understand situations of radioactive cesium (^{137}Cs) contamination in tree stem wood after the Fukushima Nuclear Power Plant accident, ^{137}Cs concentration distributions in the radial and vertical directions of the stem were investigated. In addition, to clarify whether the ^{137}Cs distributions differ from distributions of stable isotope cesium (^{133}Cs), which has been transferred into the tree stem only by root uptake since before the accident, ^{133}Cs concentration distributions of some samples were also analyzed. About 3 years after the accident, 6 cedars (*Cryptomeria japonica*), 3 cypresses (*Chamaecyparis obtusa*) and 2 larches (*Larix kaempferi*) (around 50 years old) were cut down and disks were collected from different heights of the tree stem. The disk was divided every 2 cm in the radial direction, and the ^{137}Cs concentration was determined using a Ge detector and the ^{133}Cs concentration using ICP-MS. In many individuals, both ^{137}Cs and ^{133}Cs concentrations in the heartwood tended to be higher at the upper part of the stem. In the cedar and cypress, the ^{137}Cs concentration was typically higher in heartwood than in sapwood; however, depending on the individual and stem height, there was also a case that the ^{137}Cs concentration was higher in sapwood than in heartwood. In the larch, the higher ^{137}Cs concentration in sapwood than in heartwood was found in all individuals and stem heights. The radial distribution of $^{137}\text{Cs}/^{133}\text{Cs}$ concentration ratio differed among the individuals and species, indicating a variety of ^{137}Cs transfer processes into the tree stems.

Reduction of radio cesium uptake by Japanese cypress seedlings with potassium fertilization

Keizo Hirai¹, Masabumi Komatsu¹, Junko Nagakura¹, Kyotaro Noguchi²

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Tohoku Research Center, Forestry and Forest Products Research Institute, Morioka, Japan (hirai@ffpri.affrc.go.jp; kopine@ffpri.affrc.go.jp; kurya@ffpri.affrc.go.jp; kyotaro@ffpri.affrc.go.jp)

We investigated effects of potassium (K) fertilization on root uptake of radio cesium (^{137}Cs) by hinoki cypress (*Chamaecyparis obtusa*) seedlings from soils contaminated after the Fukushima accident. During June–July 2014, three-year-old seedlings without contamination were planted in a clear-cut forest and potassium chloride fertilizer (83 kg K ha⁻¹) was applied three times (August 2014, April 2015 and 2016); ^{137}Cs concentrations in the needles in the fertilized plots were one-fifth of those in the unfertilized plots at the end of the third growing season (November 2016). Our results clearly indicated that K fertilization reduced radio cesium transfer from soil to planted cypress seedlings. A linear mixed model analysis revealed that ^{137}Cs concentrations in the needles were significantly affected by ^{137}Cs inventory in the soil (Bq m⁻²), exchangeable K in surface mineral soils (0–5 cm) and fertilization. These results suggested that the levels of exchangeable K in the soil would increase by fertilization during the growing season, and radio cesium uptake by tree roots was suppressed.

Six-year trends in exchangeable and organic matter-bound radiocesium in Fukushima forest soils

Takuya Manaka¹, Naohiro Imamura¹, Shinji Kaneko², Satoru Miura³, Hitomi Furusawa¹, Tsutomu Kanasashi¹

¹Department of Forest Soils, Forestry and Forest Products Research Institute, Tsukuba, Ibaraki, Japan; ²Kansai Research Center, Forestry and Forest Products Research Institute, Fushimi, Kyoto, Japan; ³Center for Forest Restoration and Radioecology, Forestry and Forest Products Research Institute, Tsukuba, Ibaraki, Japan (manaka@affrc.go.jp; nimamura@ffpri.affrc.go.jp; kanekos@ffpri.affrc.go.jp; miura@ffpri.affrc.go.jp; fu1103@ffpri.affrc.go.jp; tkanasashi00@ffpri.affrc.go.jp)

A large amount of cesium-137 (^{137}Cs) was released into the atmosphere after the Fukushima Dai-ichi Nuclear Power Plant (FDNPP) accident and deposited in forests in Fukushima prefecture. We investigated the changes of exchangeable ^{137}Cs in soils of contaminated forest ecosystems until 6 years after the Fukushima radioactive atmospheric deposits; to do so we performed chemical extractions of ^{137}Cs by using ammonium acetate, from both organic and mineral soil layer sampled in two forest stands, one Japanese cedar and one broadleaf deciduous, located 26–27 km southwest from FDNPP. The exchangeable ^{137}Cs as a proportion of the total ^{137}Cs inventory was only 10% in the organic layer and 6.1% in the mineral soil layer about 5 months after the accident. We observed an exponential decrease in the exchangeable ^{137}Cs proportion in both organic and mineral soil layer samples over the 6-years observation period at both sites. The pronounced decrease within 2–4 years after the accident is attributed to (1) the decreasing transfers of ^{137}Cs from the canopy to the organic layer and from the organic layer to the mineral soil layer, and (2) the rapid fixation of ^{137}Cs by frayed edge sites of clay minerals. The exchangeable ^{137}Cs was almost constant after that. Those results support the interpretation that contaminated forests have entered in a steady-state phase of the ^{137}Cs cycling. We will also report the changes of ^{137}Cs which was bound to various contents of organic matters, such as acid-insoluble lignin, in the organic layer samples.

Uptake of radio- or stable-cesium and potassium by hardwood forests

Satoru Miura¹, Tsutomu Kanasashi¹, Hiroki Itô², Junko Nagakura¹, Keizo Hirai¹

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Forestry and Forest Products Research Institute, Hokkaido, Sapporo, Japan (miura@ffpri.affrc.go.jp; tkanasashi00@ffpri.affrc.go.jp; hiroki@ffpri.affrc.go.jp; kurya@ffpri.affrc.go.jp; hirai@ffpri.affrc.go.jp)

Reducing incorporation of radio-cesium by hardwood coppice forests is one of the most concerns for local forestry people in Fukushima after nuclear accident in March, 2011. Because Abukuma Mountains was a famous major production area of mushroom logs, for which the allowable radiation limit was determined to 50 Bq/kg by Forestry Agency of Japan. We investigated the relationship of ^{137}Cs , ^{133}Cs and K concentrations in current shoots of major hardwood species for mushroom logs and exchangeable those elements in soils at 40 hardwood forests in Miyakoji, Tamura, Fukushima. We detected clear nonlinear inverse correlation between ^{137}Cs in current shoots and mass of K⁺ in 0–5 cm soils. We observed a hundred folds increase of ^{137}Cs in current shoots against a ten folds decrease of K⁺ (100 to 10 kg/ha) in the soils. This relationship was by far stronger than that of ^{137}Cs in current shoots and ^{137}Cs inventory in soils. We also found almost the similar relationship about ^{133}Cs in current shoots and $^{133}\text{Cs}^+$ in the soils for the same dataset. However, K concentrations in current shoots were almost constant irrespective of variable K⁺ in the soils. We led two suggestions from these findings. One is that incorporation of ^{137}Cs is controlled by incorporation property of ^{133}Cs because of 4–6 orders larger atomic ratio of $^{133}\text{Cs}^+$ to $^{137}\text{Cs}^+$. The other one is that the observation of Cs incorporation by current hardwood trees in forest ecosystems may reflect competition between K⁺ and Cs⁺ for ion influx to root cells.

Radiocesium concentrations in edible wild mushrooms in eastern Japan

Masabumi Komatsu¹

¹Forestry and Forest Products Research Institute, Tsukuba, Ibaraki, Japan (kopine@ffpri.affrc.go.jp)

Wild mushrooms tend to absorb large amounts of radioactive cesium. The commercial shipping of wild mushrooms has been restricted across eastern Japan (spanning across more than one hundred municipalities) as a result of the Fukushima Daiichi Nuclear Power Plant accident. The concentrations of radioactive cesium in wild mushroom species after the Chernobyl accident have been shown to vary greatly, depending on the species. Detailed information on these concentrations could be very important when considering the criteria for safe collection. However, the absorption concentrations for each species in Japan have not been investigated thoroughly. Therefore, we analyzed the data from radioactivity monitoring of wild edible mushrooms that were collected by the local governments in eastern Japan. In the analysis, the radioactivity deposition data from aircraft monitoring was used to standardize the mushroom radiocesium concentrations with the contamination levels of the sampled area. Our results showed that there was a large difference of up to 100 times within each species. As in previous studies, the concentration of mycorrhizal species tended to have higher concentrations of radiocesium. Some saprophytic species also had high concentrations. For the mushroom species that were also evaluated in the post-Chernobyl studies, we found that the same species had similar levels of absorption and a positive correlation was found. Moreover, the estimation of radiocesium concentration was much improved by the use of information from the municipalities of mushroom collection. We observed regional bias from the municipality effect.

Temporal changes in spatial distributions of radiocesium in forest floors in Fukushima, Japan

Naohiro Imamura¹, Toshiya Matsuura¹, Akio Akama¹, Yoshiki Shinomiya¹, Masahiro Kobayashi¹, Satoru Miura¹, Shinji Kaneko²

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Forestry and Forest Products Research Institute, Kyoto, Japan

(nimamura@ffpri.affrc.go.jp; matsuu50@affrc.go.jp; akama@affrc.go.jp; shinomiya@ffpri.affrc.go.jp; kbmasa@affrc.go.jp; miura@affrc.go.jp; kanekos@affrc.go.jp)

Due to the Fukushima Dai-ichi Nuclear Power Plant accident, the majority of areas of East Japan forests were contaminated by radiocesium. Estimation of the spatial distributions of radiocesium within the forest would help in devising strategies both for reducing exposure for forest workers and for decontamination in the forest. In this study, the spatial distribution of radiocesium and its temporal change were estimated at both observed plot (2 m × 2 m) and forest (0.12–0.24 ha) scales. Radiocesium inventories of the litter and mineral soil layers (0–5 cm) were collected in 12 observed plots in each of four forest with various topographies in Fukushima Prefecture. The ambient dose rate at a height of 10 cm was measured in 20–36 points in the same forests. These observations were conducted in summer from 2012 to 2016. Results showed temporal change in the radiocesium inventories accumulated in the litter and mineral soil layers collected at the observed plot scale. However, the distribution pattern of the ambient dose rate did not change significantly over time at the forest scale. These findings suggested that the spatial variation at the observed plot scale could be affected by the initial distribution or local migration of radiocesium in the litter and mineral soil layers. However, there was no significant migration of radiocesium that could affect the ambient dose rate in the forest. This study also indicated that topographic characteristics had no effect on the spatial distributions of the ambient dose rate.

A rechargeable increment borer for radiocesium monitoring

Akira Kagawa¹, Takeshi Fujiwara¹, Shinta Ohashi¹

¹Forestry and Forest Products Research Institute, Tsukuba, Japan (akagawa@ffpri.affrc.go.jp; fujiwara@ffpri.affrc.go.jp; shinta0084@ffpri.affrc.go.jp)

Radioactive cesium analysis requires large amount of wood (Kagawa *et al.*; 2002, Journal of Environmental Quality 31(6):2001-2007). Initially, in our Fukushima project, we have felled trees to obtain stem disks for the analysis. In recent years, we have explored the possibility of using increment cores (12-mm diameter) for radio-cesium analysis as a substitute of wood disks. Increment core sampling has advantages over disk sampling because it does not kill the trees and therefore enables continual monitoring of radio-cesium levels within an individual tree over many years. Disk sampling may cause significant disturbance that may affect dynamics of radio-cesium movement within a forest ecosystem. We developed an automated increment-core sampling device, “Smartborer”, to increase the sample throughput (Kagawa and Fujiwara 2018, Journal of Wood Science 64(1):52-58; www.smartborer.com). The lightweight, portable device employs a battery-powered electric wrench and the complete system to drive the boring operation weighs less than 10 kg. It is capable of taking both 5- and 12-mm diameter cores of more than 800-mm length, even from hardwood. Compared to equipment used in previously published articles, Smartborer enables more rapid sampling and demonstrates a superior torque output/total weight ratio. Overall, averaged radio-cesium concentrations over the two increment cores sampled from two opposing directions of a stem showed a good match to the values obtained from the stem disk. However, the radio-cesium concentrations of heartwood based on increment-core measurement showed a little less accuracy than those based on disk measurement.

E8p: FOREST MANAGEMENT PRACTICES AND THE RESPONSES OF SOIL CARBON, WATER, NUTRIENTS AND THEIR INTERACTIONS

Dendrometric aspects of the biochar application in *Eucalyptus urograndis*

Ricardo Trippia dos Guimarães Peixoto¹, Claudia Maria Branco de Freitas Maia¹, Leticia Machado dos Santos², Lucilia Maria Parron¹

¹Embrapa Florestas, Colombo, Brasil; ²Pontifícia Universidade Católica do Paraná, Curitiba, Brasil

(ricardo.trippia@embrapa.br; claudia.maia@embrapa.br; leticia.agronomiapucpr@gmail.com; lucilia.parron@embrapa.br)

Biochar application aims to improve the soil properties and increase its carbon stable reservoir. The aim was to evaluate the effect of the use of biochar in soils with *Eucalyptus urograndis*, under different fertilization rates in tree growth. The experiment is in São Jerônimo da Serra (Paraná, Brazil), in a Red-Yellow Latosol, as a factorial in 4 randomized blocks with subdivided plots, with and without biochar in plots, and 3 fertilization rates in subplots. The treatments were: T1 - without biochar and without fertilizer; T2 - without biochar and fertilizer rate reduced by 20%; T3 - without biochar and commercial fertilizer rate; T4 - with biochar and without fertilizer; T5 - with biochar and fertilizer rate reduced by 20%; and T6 - with biochar and commercial fertilizer rate. Each plot comprised of 36 trees spaced of 3 m × 3 m. It was applied 9 kg of biochar (1 kg/tree or 3.21 t ha⁻¹) in strip with 1 m of width and incorporated 15 cm with a grid. The commercial fertilization (NPK at planting 4:42:6 and second dose 15:05:30) were of 166 g/tree. The tree height (AP) and stem basal diameter (DC) were measured in 20 trees/plot at the 3, 6, 9, 12 and 18 months age. The AP and DC at each age varied between treatments with and without fertilization. However, there were no effect reducing the fertilizer rate neither with the biochar application until 18 months old. The effect of biochar on soil quality attributes and carbon storage are being evaluated.

A broadleaf species alters and evenly distributes soil organic carbon chemical composition in a *Pinus massoniana* planted forest in southern China

Hui Wang¹, Shirong Liu¹, Jingxin Wang², Zuomin Shi¹, Daoxiong Cai³, Lihua Lu³, Angang Ming³

¹Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China; ²Division of Forestry and Natural Resources, West Virginia University, Morgantown, USA; ³Experimental Center of Tropical Forestry, Chinese Academy of Forestry, Pingxiang, China (wanghui@caf.ac.cn; liusr@caf.ac.cn; jxwang@wvu.edu; shizm@caf.ac.cn; rlxcxdx@126.com; kjc8526136@163.com; mingangang0111@163.com)

There are potential effects of planted forest type conversions from conifer to broadleaf or mixed-species on the soil organic carbon (SOC) chemical composition, and the evenness of its distribution remains uncertain. An afforestation experiment with different tree species (*Pinus massoniana*, *Erythrophleum fordii*, and mixed *P. massoniana* and *E. fordii*) was conducted in a clear-cutting site of *P. massoniana* planted forests in a subtropical region. Topsoil organic C quality and microbial diversity were assessed after eight years of afforestation. The proportions of alkyl C and carbonyl C in SOC, as well as alkyl C/O-alkyl C ratios and the evenness of the SOC chemical composition distributions were higher in monospecific *E. fordii* and mixed-species planted forests than the monospecific *P. massoniana* planted forest. The positive relationship of SOC chemical composition distribution with litter as well as fine root C quality was observed. Microbial biomass C was positively correlated with the labile SOC. Fine root C had a closer correlation with the chemical composition of SOC than litter. The present results are not consistent with our previous findings in a 25-year afforestation site, in which soil microbial community composition rather than litter quality was linked with SOC chemical composition, suggesting plant C chemical composition would better predict belowground C sequestration functioning in the early afforestation system. These results highlight that mixing native N fixing broadleaf species into conifer forests probably enhance the SOC chemical stability and resistance to climate change by increasing the recalcitrant C components and the evenness of SOC distribution.

Allometric models to estimate biomass aboveground in forest recovery areas

Anani Morilha Zanini¹, Rafaella Mayrinck², Bruna Santos Lopes¹, Simone Aparecida Vieira³, Ricardo Ribeiro Rodrigues¹

¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Piracicaba, Brazil; ²University of Saskatchewan, Saskatoon, Canada;

³Universidade Estadual de Campinas, Campinas, Brazil (ananizanini@hotmail.com; rafamk@hotmail.com; bruna.santos.lopes@usp.br; savieira08@gmail.com; rresalq@usp.br)

Quantify carbon stock on forest restoration areas is a global interest, since this area provide the important environmental service of mitigating climate change. It is crucial have more studies on allometry to help on predicting biomass and carbon stocking for those areas. Thus, the objective of this study was to quantify forest biomass and carbon content to a 5-year-old region under restoration process, so models could be fitted to the area and also used to similar sites. Three sites nearby Itu city, SP, Brazil, were studied, 5 years after the restoration process was implemented. In each site, three 900 m²-plots were installed, and a forest inventory was done, measuring tree height and circumference at breast height. Sub-plots (25 m²) were randomly selected in each 900 m²-plots and all trees inside it were cut and had its volume measured, stratified into foliage, roots and stem pools. Carbon content was determined on the Isotopic Ecology Laboratory for each species and pool. This data was used to fit models to estimate biomass. The best model was selected using the adjusted coefficient of determination (R²), residual charts and Akaike's information criterion (AIC). Mean biomass for the area was 20.19±0.146 Mg ha⁻¹, mean Carbon stock was 9.73 Mg C ha⁻¹, and average carbon content was 45.3%.

N₂ fixing trees (*Acacia mangium*) introduce in eucalypt plantations modify rapidly the pools of organic P and low-molecular-weight organic acids (LMWOAs) in tropical soils contrasted for their C/P stoichiometry

Kittima Waithaisong^{1,2}, Agnès Robin^{3,4}, Louis Mareschal³, Jean-Pierre Bouillet³, Jean-Paul Laclau³, José Leonardo de Moraes Gonçalves⁴, Manon Villeneuve⁵, Philippe Deleporte³, Claude Plassard¹

¹INRA/ UMR Eco&Sols, Montpellier, France; ²Department of Microbiology, Faculty of Science Silpakorn University-Sanam Chandra Palace Campus, Nakhon Pathom, Thailand; ³CIRAD, UMR Eco&Sols, Montpellier, France; ⁴Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Piracicaba, Brasil; ⁵IRD, UMR Eco&Sols, Montpellier, France (kittima2214@gmail.com; agnes.robin@cirad.fr; louis.mareschal@cirad.fr; jean-pierre.bouillet@cirad.fr; laclau@cirad.fr; jlmgonca@usp.br; manon.villeneuve@ird.fr; philippe.deleporte@cirad.fr; plassard@supagro.inra.fr)

In this study, soil organic P (Po) and low-molecular-weight organic acids (LMWOAs) were quantified under different land uses in order to investigate the effect of N₂ fixing tree introduction on phosphorus cycle. Soils were collected from plantations of pure acacia (Ac), pure eucalyptus (Euc) or both species (50/50) and original savannahs (S) that were located in Brazil (low P, high N and high C soil) and in Congo (high P, low N and low C soil). Po and LMWOAs were identified in sodium hydroxide soil extracts with ion chromatography (IC). Phosphate monoesters as AMP and glucose-6-phosphate (G6P) were the main Po forms in both sites. Phytate, ATP and fructose-bisphosphate (FrucbisP) were also present as well as the mineral form of pyrophosphate (PrP). Malate, oxalate and malonate were the major components of LMWOA fraction in the two soils. Citrate was also present at low concentrations. Interestingly, phytate concentrations were always decreased under acacia plantations. This could result from a better mineralisation or lower inputs into these soils. In mixed stands, the effect of acacia introduction on Po and LMWOAs composition is more pronounced in high P than in low P soil, due to a much better N₂ fixation. Our results highlight that the introduction of a legume tree is able to strongly modify the composition of Po and LMWOAs in soil even after a first short-time rotation, especially when the rate of N₂ fixation is high.

Microbial enzymatic activities and community-level physiological profiles (CLPP) in subsoil layers are altered by harvest residue management practices in a tropical *Eucalyptus grandis* plantation

François Maillard¹, Valentin Leduc¹, Cyrille Bach¹, José Leonardo de Moraes Gonçalves², Fernando Dini Andreote², Laurent Saint-André³, Jean-Paul Laclau⁴, Marc Bueé¹, Agnès Robin^{3,4}

¹Université de Lorraine, INRA, LAM, Nancy, France; ²Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Piracicaba, Brasil;

³INRA UR 1138 Biogéochimie des Ecosystèmes Forestiers, Nancy, France; ⁴CIRAD, UMR Eco&Sols, Montpellier, France (francois.maillard@inra.fr; valentineduc@hotmail.fr; cyrille.bach@inra.fr; jlmgonca@usp.br; fdandreo@gmail.com; laurent.saint-andre@inra.fr; laclau@cirad.fr; marc.buee@inra.fr; agnes.robin@cirad.fr)

Harvest residue management is a key issue for the sustainability of Eucalyptus plantations established on poor soils. Soil microbial communities contribute to soil fertility by the decomposition of the organic matter (OM), but little is known about the effect of whole-tree harvesting (WTH) in comparison to stem only harvesting (SOH) on soil microbial functional diversity in Eucalyptus plantations. We studied the effects of harvest residue management (branches, leaves, bark) of *Eucalyptus grandis* trees on soil enzymatic activities and community-level physiological profiles in a Brazilian plantation. We measured soil microbial

enzymatic activities involved in OM decomposition and we compared the community level physiological profiles (CLPP) of the soil microbes in WTH and SOH plots. WTH decreased enzyme activities and catabolic potential of the soil microbial community. Furthermore, these negative effects on soil functional diversity were mainly observed below the 0-5 cm layer (5-10 and 10-20 cm), suggesting that WTH can be harmful to the soil health in these plantations.

Carbon sequestration and soil fertility in dryland *Acacia senegal* plantations of varying age in Sudan

Wafa Abaker¹, Frank Berninger², Gustavo Saiz³, Mike Starr⁴

¹University of Khartoum, Khartoum, Sudan; ²University of Eastern Finland, Kuopio, Finland; ³Imperial College London, Ascot, United Kingdom; ⁴University of Helsinki, Helsinki, Finland (wafaadam59@yahoo.com; frank.berninger@uef.fi; g.saiz@imperial.ac.uk; mike.starr@helsinki.fi)

African drylands are extensively degraded as indicated by reduced soil organic carbon (SOC) contents. Restoration through management practices that increase tree cover can be expected to increase SOC contents and soil fertility. We investigated the potential of *Acacia senegal* trees for increasing SOC and improving soil fertility at two sites in Sudan. Biomass C and SOC stocks, contribution of trees and herbs to SOC, soil nutrient (N, P, available P, K, exchangeable K) contents and potential N₂ fixation by *A. senegal* in plantations of varying age (7 to 24 years) and in adjacent grasslands were determined. Total biomass C stocks increased with plantation age. While most of this increase was due to the trees, the ground vegetation C stock also increased (facilitation effect). SOC stocks (0-50 cm) increased with plantation age and were greater than in the grasslands. $\delta^{13}C$ partitioning values indicated that the age-related increase in SOC stocks was derived not only from the acacia trees but also from an increase in ground vegetation biomass. While soil concentrations of the studied nutrients were relatively low, they were positively correlated to SOC concentrations, highest in the topsoil (0-10 cm) and increased with plantation age – all indicating the importance of SOC to soil fertility. High acacia foliage $\delta^{15}N$ values indicated that N₂ fixation was not an important contributor to soil N. Our findings showed that increasing tree cover in African drylands can increase SOC stocks and thereby improve soil fertility for the benefit of local communities besides sequestering atmospheric CO₂.

Role of nitrogen availability on enhancing soil carbon sequestration in typical subtropical planted forests in Southern China

Shirong Liu¹, Hui Wang²

¹Chinese Academy of Forestry, Beijing, China; ²Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China (liusr@caf.ac.cn; wanghui@caf.ac.cn)

Planted forest ecosystem is becoming a key component of the China's forest resources and timber storage and plays a key role in the context of potential carbon (C) sequestration and sustainable forest management. Information on the effects of tree species composition and diversity on soil nitrogen (N) availability and organic carbon (C) sequestration remains limited. The investigation and long-term manipulation experiment were carried out in typical subtropical planted forests. Soil under Eucalyptus mixed with N₂-fixer accumulated more soil organic C and N, and had lower CO₂ emission than in pure stands by increasing total organic C and microbial biomass C, as well as through increased soil microbial community diversity and abundance. SOC and N stocks in the *Pinus massoniana* and *Castanopsis hystrix* mixed plantation were higher than in *P. massoniana* monospecific plantation. The admixing with the higher-quality *C. hystrix* litter hastened mass loss for recalcitrant C chemical compositions and nutrient return of conifer litter. Our results also showed that tree species mixture significantly altered the soil bacterial community composition and structure, compared with single-species plantations. The C/N ratios of soil and litterfall, TOC, NH₄-N, litterfall mass and NO₃-N were key factors affecting the soil microbial community. There was a negative relationship between SOC mineralization rates and the abundance of K strategists and a positive relationship for r-strategists. These results indicated that N availability plays an important role on enhancing SOC sequestration through changing soil microbial community composition in subtropical plantations.

Forest management strategies to safeguard water supply in karst regions under climate change

Klaus Katzensteiner¹

¹Institute of Forest Ecology, University of Natural Resources and Life Sciences, Vienna (BOKU), Vienna, Austria (klaus.katzensteiner@boku.ac.at)

Worldwide, karst aquifers developed on calcareous bedrock are important sources of drinking water. Large karst areas of the montane and subalpine vegetation belts in the Calcareous Alps are dominated by forests. The increasing frequencies and intensities of disturbances, partly a consequence of climate change, may alter the water storage, filtering and buffering capacity of forest ecosystems, thereby threatening the continuous provision of pristine water. Safeguarding water supply from karst regions therefore requires the adaptation of forest management strategies. In the presentation, forest management and disturbance effects upon soil condition and water quality in karst regions are discussed based on case studies from the Alps. Stability- and vulnerability- indicators of karst systems and its subsystems, from tree species, the vadose zone, in particular soils, to karst water, are incorporated in a conceptual framework for adaptive forest management strategies in view of water protection.

E8q: EFFECTS OF FOREST MANAGEMENT PRACTICES ON SOIL PROPERTIES AND ECOSYSTEM PROCESSES

Teor de carbono e nitrogênio no solo em função da adubação em um sistema de integração Lavoura-Pecuária-Floresta e Plantio Direto

Luciane Cristina Lazzarin¹, Juliano Coruli Corulli Corrêa², Iraê Amaral Guerrini¹, Paulo Hentz³

¹Unesp, Botucatu, Brazil; ²Embrapa Suínos e Aves, Concórdia, Brazil; ³IFC, Concórdia, Brazil (lucianelazzarin@unc.br; juliano.correa@embrapa.br; iguerrini@fca.unesp.br; paulo.hentz@ifc.edu.br)

A prática de adubação, quando necessário, promove ganho de produtividade até três vezes maior em comparação a sua não adoção. O uso de fertilizantes orgânicos pode resultar em ganhos econômicos e ambientais, potencializando a diversidade do sistema. Este trabalho objetivou avaliar o teor de carbono e nitrogênio no solo no sistema de produção integração lavoura-pecuária-floresta (iLPF) e plantio direto (PD) após 3 anos com fertilizantes orgânicos ou minerais. O experimento foi conduzido no município de Concórdia-SC, onde o delineamento experimental foi blocos casualizados, com 3 repetições, em fatorial 2 x 4, sendo dois tipos de sistemas de produção (iLPF e PD) em interação com três tipos de fertilizantes (dejeito de suínos, cama de aves e mineral) e o controle (sem adubação). As amostras de solo foram coletadas até 100 cm, e analisadas através do analisador elementar (CNHOS). Não houve efeito da adubação sob o teor de carbono nas diferentes camadas para o sistema iLPF, enquanto que para o PD houve diferença para a adubação cama de aves e mineral nas camadas superficiais.

Soil net N mineralization in responses to forest type conversion in a subalpine region of the Eastern Qinghai-Tibetan Plateau

Zuomin Shi¹

¹Institute of Forest Ecology, Environment and Protection, CAF, Beijing, China (shizm@caf.ac.cn)

Soil nitrogen (N) availability and cycling are crucial in regulating the dynamics of ecosystem functions. Subalpine areas of the Eastern Qinghai-Tibetan Plateau have experienced different forest re-establishment methods after primary forest clear-cutting. We investigated soil net N mineralization and microbial community compositions in four forest types, i.e. *Abies faxoniana* primary forest (AF), *Picea asperata* broadleaved mixed forest (natural regeneration after artificial planting, MF) composed of planted *P. asperata* and naturally regenerated native broadleaved species, natural secondary forest (natural without assisted regeneration, NF) and *Picea asperata* plantation (artificial planting, PF) from June to November. Forest type had a significant effect on soil net ammonification rate, but not on net nitrification rate. The cumulative ammonified N value was significantly higher in NF (11.40 g kg⁻¹) and lower in PF (4.79 g kg⁻¹), and the cumulative nitrified N value ranged from 17.75 (in AF) to 27.98 g kg⁻¹ (in MF) with no significant difference among forest types. However, average net N mineralization varied smoothly among the four forest types with generally negative values of net ammonification rate for MF and NF. These results indicate that NF might consume larger ammonium N by plant uptake and microbial immobilization relative to other forests. The net ammonification and nitrification rates exhibited different monthly patterns with the higher values at the end and the middle of the period, respectively. The net N mineralization rates could be well described by soil properties and the ratio of fungal to bacterial PLFAs.

Why fine-root decomposition rates of 13 tree species differ between mixed- and monospecific forest stands: a search for mechanisms across European forests

Janna Wambsganss¹, Friderike Beyer¹, Gregoire Freschet², Jürgen Bauhus¹, Michael Scherer-Lorenzen³

¹Chair of Silviculture, University of Freiburg, Freiburg, Germany; ²Centre d'Ecologie Fonctionnelle et Evolutive, Montpellier, France; ³Institute of Geobotany, University of Freiburg, Freiburg, Germany (janna.wambsganss@waldbau.uni-freiburg.de; friderike.beyer@waldbau.uni-freiburg.de; gregoire.freschet@cefe.cnrs.fr; juergen.bauhus@waldbau.uni-freiburg.de; michael.scherer@biologie.uni-freiburg.de)

Decomposition is one of the key processes determining carbon and nutrient cycling and thereby crucial for overall ecosystem functioning. To which extent the management for mixed-species forests affects litter decomposition has mainly been investigated for above-ground plant organs, despite the fact that fine roots contribute substantially to the soil organic matter pool. The objective of this study was therefore to determine fine-root decomposition rates in relation to tree species diversity, fine-root traits and environmental conditions. We hypothesized that decomposition rates (1) are higher for mixed-species stands than for monospecific stands; (2) are related to morphological, architectural and chemical traits as well as microbial associations; (3) are largely explained by fine-root traits, more than climate or tree species diversity. Fine-root litter bags containing absorptive fine roots of 13 different tree species were incubated for 12 months in the field in mixed-forest stands consisting of three tree species and in the corresponding monospecific stands in the frame of a large-scale pan-European project. The four study sites represented major European forest types along an environmental gradient across Europe ranging from boreal to thermophilous forests. Fine-roots of the 13 species were analyzed for morphological, architectural and chemical traits as well as microbial associations. The results of this study will provide new insights in the dynamics and controls of fine-root decomposition of 13 significant European tree species and thereby could eventually be used for forest management recommendations.

Microbe-mediated attenuation of soil respiration in response to soil warming in a temperate oak forest

Yi Wang¹, Junwei Luan¹, Shirong Liu^{1,2}

¹Institute for Resources and Environment, ICBR, Beijing, China; ²Institute of Forest Ecology, Environment and Protection, CAF, Beijing, China (wangyi@icbr.ac.cn; junweiluan@icbr.ac.cn; liusr@caf.ac.cn)

Soil respiration (Rs) in response to climate warming received wide concerns thank to its role in terrestrial ecosystem carbon (C) cycling. But the warming induced effects of soil microbes on soil respiration are still less understood, especially over time. Our study aims to understand the long-term warming induced effects of soil microbes on Rs. A field soil warming experiment was conducted in a naturally regenerated oak forest (*Quercus aliena*) in central China from 2011 to 2015. Our results showed that soil temperature was a main factor in regulating Rs in a temperate oak forest, but soil water content only determined Rs in natural dry year. The positive effect of soil warming on Rs that was observed with the significant increase (i.e. 37.5 to 42.0% in the first two years) gradually diminished in the following three years (i.e., 0.9-15.4% in the last three years). Significant positive warming effect on temperature sensitivity of Rs (Q₁₀) only occurred in the second year. Continuous soil warming caused the decline in nitrogen (N) availability, but with the significant increase in microbial biomass-specific enzyme activities for N-acquiring. The attenuation of microbial biomass increment and the deceased ratio of enzymatic C:N acquisition contributed to the diminished warming effect on Rs over time. Our study suggests that microbe-mediated attenuation of Rs accompanied by the concomitant decline in soil N availability in response to warming should be taken into consideration in global C cycle modeling.

Effects of different natural secondary *Quercus mongolica* forest management models on leaf functional traits and soil physical and chemical properties

Youjun He¹, Gao Yue¹, Chaofan Chen¹, Qin Lin¹

¹Chinese Academy Of Forestry, Beijing, China (hyjun163@163.com; ziguang_yue@163.com; 494634999@qq.com; nilniq@163.com)

Plant functional traits is a bridge between plants and environment. In this paper, effects of natural secondary forest of *Quercus mongolica* under three management modes on the leaf functional traits and soil physical and chemical properties was studied at Danqinghe forest farm in Harbin, Heilongjiang province, China. The results showed that: (1) in addition to the total soil potassium, available potassium and organic carbon content, there were no significant difference in soil physical and chemical properties between different management modes. (2) the functional traits of natural secondary *Quercus mongolica* forest under different management modes were obviously different, the individual leaf area of target tree management model was significantly higher than ecosystem management model and no interference ($P < 0.01$), and the leaf organic carbon content and leaf nitrogen content of target tree management model were significantly lower than ecosystem management model and no interference ($P < 0.01$); there were significant negative correlation between leaf area, leaf nitrogen content and leaf organic carbon content ($P < 0.01$). (3) soil organic carbon had significant influence on the individual leaf area, leaf nitrogen content, leaf phosphorus content and leaf organic carbon content. Soil organic carbon was the main factor affecting the variation of leaf functional traits. The natural secondary *Quercus mongolica* forest communities adapted to the environment through the coupling or combination of functional traits. The response of plant functional traits on soil physicochemical properties is a long process, we need to strengthen the long-term monitoring and study more.

The influence of different nutrients solutions at *Eucalyptus benthamii* adventitious rooting

Leticia Miranda¹, Regiane Abjaud Estopa¹, Marco Aurélio Figura¹

¹Klabin S/A, Telêmaco Borba, Brazil (lemiranda@klabin.com.br; restopa@klabin.com.br; mafigura@klabin.com.br)

The clonal propagation of Eucalyptus by mini-garden system is a technique already elucidated in the Brazilian forest sector. However, subtropical Eucalyptus species, such as *Eucalyptus benthamii*, are recalcitrant to adventitious rooting, which causes a reduction in the rooting rate of the mini-cuttings produced in this system. The nutrition of mini-stumps is one of the most important factors in clonal mini-gardens, and affects the mini-cuttings production as well as their rooting. In this context, this work evaluated the influence of five mini-garden nutrient solutions in the production of shoots and rooting of mini-cuttings of two *E. benthamii* clones. The treatment solutions had different concentrations of nitrogen (N), iron (Fe) and zinc (Zn). The reference solution was denominated T1, and the other treatments had the following differences: 45% of N reduction in T2 and T3 treatments, and 27% of N reduction in T4 and T5; Fe increase of 2.5x in T2 and T3 and of 1.9x in T4 and T5; Zn increase of 20x on T2 and T4, and of 40x on T3 and T5. Different formulations of nutrient solutions influenced the rooting rates of the two clones at 1% statistical significance. Clone K1100 solutions T2 and T3 had the highest rooting rates and did not have differences between them. For clone K1101, only the T3 solution had the rooting rates higher than the other treatments. These findings make T3 solutions the most recommended for these clones, and potential ones for this specie.

Initial decomposition of forest litter in different levels of coverage in a forest of *Nothofagus obliqua* within a silvopasture management system / Descomposición inicial de hojarasca en diferentes niveles de cobertura en bosque de *Nothofagus obliqua* bajo manejo silvopastoril

Mariela Alfaro¹, Francis Dube², Erick Zagal²

¹Universidad de Costa Rica, San José, Costa Rica; ²Universidad de Concepción, Concepción, Chile (marriela.alfaro@ucr.ac.cr; fdube@udec.cl; ezagal@udec.cl)

La hojarasca constituye la vía de entrada principal de los nutrientes en el suelo y es uno de los puntos clave del reciclado de la materia orgánica y de los nutrientes. Se realizaron experimentos de descomposición de hojarasca en un sistema silvopastoril con pradera mejorada en un bosque de *Nothofagus obliqua*, bajo tres diferentes niveles de cobertura arbórea: abierta, parcialmente abierta, y parcialmente cerrada. Se utilizó la técnica de "bolsas de litera", y se evaluó las pérdidas de peso de hojarasca y liberación de nutrientes inicial a los 6 meses de descomposición. La combinación de cobertura arbórea abierta y el sistema silvopastoril con pradera mejorada presentó una pérdida de peso por descomposición de hojarasca significativamente más elevada. Las coberturas parcialmente abierta y parcialmente cerrada no presentaron diferencias. Se registraron pérdidas de peso de 29,67; 23,12; y 24,43% para las coberturas abierta, parcialmente abierta y parcialmente cerrada, respectivamente. Las constantes de descomposición k asociadas a esas pérdidas de peso fueron 0,71; 0,53; y 0,56; respectivamente. Los contenidos de carbono, potasio, magnesio, hierro, manganeso, se establecieron como los primeros elementos en ser liberados en las etapas iniciales de descomposición de la hojarasca en las tres coberturas arbóreas evaluadas. El crecimiento de pastos pudo influenciar en el comportamiento de las temperaturas sobre y del suelo y su contenido de humedad en las diferentes coberturas arbóreas, y la adición de nitrógeno con la implementación del sistema silvopastoril pudo influenciar aumentando las tasas iniciales de descomposición de la hojarasca.

Fertilizer distribution and its influence on initial growth and uniformity of *Eucalyptus* plantations

Ana Rosaria Sclifo Zucon¹, Guilherme Batistuzzo², José Henrique Bazani³, José Leonardo de Moraes Gonçalves³, Rodrigo Eiji Hakamada⁴, Cristiane Lemos⁵, Brandon Hawkes⁵, Clayton Alcarde Alvares⁶, Guilherme Rodrigues de Pontes², Thiago Ubiratan de Freitas², José Carlos Arthur Junior⁷

Eucalyptus clonal plantations commonly present variations on tree growth within stands, being often related to quality of forest operations. In order to improve efficiency and precision of it, the precision silviculture concept has been adopted among forest companies. It consists on a technology frequently used on forest fertilization operation which enables uniform application of fertilizers. However, the quality of application should be verified as well as its effects on plants initial growth uniformity. Thus, the objectives of this study were to validate this technology and to verify the relation between quality of fertilizer distribution and initial growth uniformity of Eucalyptus in stands in the countryside of São Paulo. The validation of this technology was based on observed and estimated data (at the dosage of 220 kg.ha⁻¹) provided by the application system. The initial growth of the trees was quantified using measures of plant crown area from images taken from an Unmanned Aerial Vehicle and fieldwork. The Pvar50 was used as uniformity index for crown areas. The relationship between variation of fertilizer dosage applied by the system and the initial plant growth uniformity measures was checked. The application system was validated presenting 82% of the data within 10% of recommended dosage tolerance. The stand presented high fail index (10% in average), which may indicate lapses in forest operations or due to the hydric deficit occurred after planting in 2014. The 10% variation of recommended dosage did not explain the variation found in the uniformity of Eucalyptus crown area of this study.

E8r: FOREST MANAGEMENT PRACTICES, WATER SUPPLY, WATER QUALITY AND SOIL EROSION

Impacts of reducing permanent preservation areas (APP) in urban areas on water quality: the case of the Irurá Watershed in Santarém, Pará, Brazil / Influência da diminuição das áreas de preservação permanente-APP em áreas urbanas, sobre a qualidade da água: Estudo de Caso Microbacia do Irurá, em Santarém-PA

Thiago Nascimento¹, Christiane Monte¹, Edinelson Saldanha¹

¹Universidade Federal do Oeste do Pará, Santarém, Brasil (shinaigger@gmail.com; christiane.monte@yahoo.com.br; edinelson_saldanha@hotmail.com)

As ações antrópicas provocam uma diversidade de impactos ambientais, entre estas, sobre os recursos hídricos, nas últimas décadas vem sofrendo alterações significativas, como no caso do córrego do Irurá, localizado em Santarém-Pará, região Amazônica. Sobre o contexto em que o poder público, não consegue sanar necessidades básicas, como esgotos, habitação, drenagem, ou seja, componentes mínimos para o saneamento, o que traria mitigação dos danos sobre as florestas e nos recursos hídricos. Mesmo considerando a capacidade de autodepuração do corpo córrego do Irurá, a conservação da mata ciliar é um fator importante sobre a qualidade da água. Desta forma este tem como objetivo monitorar a qualidade da água do córrego que o igarapé, as relacionando com a diminuição da área das matas ciliares. Para isso foram realizadas coletas de 2015 à 2018 no períodos sazonais, em cinco pontos da nascente até sua foz, realizando análises físicas, químicas e bacteriológicas, os quais foram utilizados no cálculo do índice de qualidade de água (IQA), para se conhecer os impactos que vem sofrendo no decorrer dos últimos anos, para a definição da área de drenagem, foi realizada com uso do modelo digital de elevação (MDE), uma classificação supervisionada de imagens spots definirão o monitoramento das APP, no período do estudo. Desta forma pode-se observar que a expansão urbana desordenada, provocou diminuição das APP, isso refletiu sobre a qualidade das águas ao longo dos três anos de monitoramento, embora ainda tenham se mantido dentro dos valores limitantes pelo CONAMA 357, para rios de classe II.

Suspended sediments discharge before and after thinning related to construction of spur roads

Yoshiki Shinomiya¹, Masahiro Kobayashi¹, Tatsuya Tsurita¹, Yoshio Tsuboyama¹, Shinji Sawano¹, Yuko Itoh¹, Yasuhiro Ohnuki², Koji Shichi³

¹FFPRI, Tsukuba, Japan; ²FFPRI, Tohoku, Morioka, Japan; ³FFPRI, Shikoku, Kochi, Japan (sinomiya@affrc.go.jp; kbmasa@affrc.go.jp; tatsuya@affrc.go.jp; tsubo@affrc.go.jp; ssawano@affrc.go.jp; yuko106@affrc.go.jp; bchankan@affrc.go.jp; shichi@affrc.go.jp)

We investigated suspended sediment (SS) discharges before and after line thinning in a forested watershed located in a national forest in Ibaraki Prefecture, Japan. Line thinning was conducted at a thinning rate of 35% across 17% of the watershed area in 2012 and at same rate for the rest of the watershed in 2013. Spur roads were constructed along all streams. The lower slopes of the watershed were covered with conifer plantations of Japanese cedar, whereas the upper slopes were covered with deciduous trees. Line thinning has not conducted in the upper slopes. Stream water samples of about 1-2 L were collected hourly using an automatic water sampler and filtered through glass fiber filters (0.5 µm) to measure SS concentrations. Comparison between the same ranges of runoff showed higher SS concentrations in flood flow after thinning (October 2013–December 2014) than before thinning (June 2010–August 2012). Higher SS concentrations were not found in the second and third years after implementation of thinning, compared with levels observed before thinning. Although SS increased once, it tended to decrease because bared areas (mainly spur road) were covered with litterfall and vegetation regrowth within a few years after thinning. Results indicated that SS discharges in stream water increased after thinning, but that it eventually returned to the initial condition.

Hydraulic status and carbon buildup in ecological restoration systems depend on functional diversity, not taxonomic diversity / O status hídrico e acúmulo de carbono de sistemas de restauração ecológica dependem da diversidade funcional e não da diversidade taxonômica

Angelo Bertholdi, Vera Engel, Luiz Fernando Almeida

¹UNESP, Botucatu, Brazil (angelobertoldi@gmail.com; vera.lex@unesp.br; luiz.rolim@unesp.br)

Espera-se que sistemas de restauração com alta diversidade de espécies alcancem melhor performance e estabilidade. Por exemplo, a combinação de espécies de crescimento rápido e lento possibilita uma rápida estratificação vertical, maior sombreamento e estabilidade do microclima no interior dos plantios. Entretanto, não se sabe se essas combinações seriam mais eficientes quanto ao uso da água e sequestro de carbono dos sistemas, questões relevantes num contexto de mudanças climáticas. Nosso objetivo foi avaliar se a capacidade de perda e recarga hídrica e acúmulo de carbono de espécies com ritmos de crescimento contrastantes favorecem as trajetórias de sistemas de restauração, e se a estrutura e diversidade dos mesmos afetam a performance das espécies. Avaliamos variáveis relacionadas à disponibilidade de água no solo e ambiente, relações hídricas e acúmulo de carbono em 6 espécies, com crescimento rápido e lento, em três sistemas de plantio: alta diversidade (40 espécies), sistema agroflorestal (20 espécies) e consórcio de espécies comerciais para madeira e lenha (25 espécies), em dois solos com fertilidade contrastante. As espécies de crescimento rápido mostraram melhor quanto ao status hídrico e acúmulo de carbono, principalmente no sistema agroflorestal e consórcio madeira e lenha, implantados com menor riqueza de espécies. Além disso, estes sistemas, embora com menor riqueza taxonômica e complexidade, apresentaram maior diversidade funcional. A eficiência fisiológica de determinados sistemas de restauração dependeu da diversidade funcional e não da diversidade taxonômica. Os resultados são importantes para orientar a escolha de espécies e de sistemas mais resilientes, num contexto de mudanças climáticas.

Effects of natural disasters (wind damage, beetle damage) on nitrate concentrations in water in high mountain areas (Southern Poland, Tatras)

Mirosław Żelazny¹, Monika Sajdak¹, Agnieszka Rutkowska², Marta Pufelska¹, Tomasz Zwijacz-Kozica³

¹Institute of Geography and Spatial Management, Jagiellonian University in Kraków, Kraków, Poland; ²Department of Applied Mathematics, University of Agriculture in Kraków, Kraków, Poland; ³Tatra National Park, Zakopane, Poland (miroslaw.zelazny@uj.edu.pl; monika.sajdak@doctoral.uj.edu.pl; rnrutkow@cyfkr.edu.pl; marta.pufelska@doctoral.uj.edu.pl; tzwijacz@tpn.pl)

Tree stand decline has been observed in recent years due to beetle damage and wind damage in the high mountain areas of the Tatra Mountains in Poland. The aim of the study was to identify spatial and temporal differences in the concentration of nitrate in spring and stream water in the woodland zone of the Tatras (Poland). The Polish Tatras (area: 211.6 km², woodland: 70%) are located in Central Europe and are characterized by the presence of climate and vegetation zones. The mountain range is an environmentally unique area and remains protected by law in the form of a national park and an International Biosphere Reserve (UNESCO). Two hydrologic and chemical surveys were conducted for a total of 1,397 spring and stream water samples including 529 samples in 2007 and 868 samples in 2017. Water chemistry was determined at IGIGIP in Kraków using ion chromatography (DIONEX 2000) for the following ions: Ca²⁺, Mg²⁺, Na⁺, K⁺, NH₄⁺, Li⁺, HCO₃⁻, SO₄²⁻, Cl⁻, NO₃⁻, NO₂⁻, PO₄³⁻. The concentration of nitrate in water has increased rapidly due to tree stand decline caused by beetle damage and wind damage from 2.37 mg/L in 2007 to 3.27 mg/L in 2017 or a 42% increase. The maximum concentration in 2007 was 7.91 mg/L, while in 2018 it was

21.3 mg/L or roughly a 260% increase. The increase in the concentration of nitrate is observable also at the D90 level, which has risen roughly 160% (2007 $D_{90} = 3.84$ mg/L, 2018 $D_{90} = 6.16$ mg/L).

Superficial runoff in initial remediation after bauxite mining / Escoamento superficial na reabilitação inicial após mineração de bauxita

Aline Gonçalves Spletozer¹, Lucas Jesus Silveira¹, Herly Carlos Teixeira Dias¹

¹Universidade Federal de Viçosa, Viçosa, Brazil (alinespletozer_afmt@hotmail.com; ljsfloresta@hotmail.com; herly@ufv.br)

A mineração de superfície altera os processos hidrológicos e as características do solo e o escoamento superficial é um parâmetro que pode ser utilizado para monitorar a eficiência da reabilitação após a mineração. Neste trabalho, comparamos o escoamento superficial gerado na reabilitação inicial, após a mineração de bauxita, com o escoamento de antes da mineração. Sete parcelas, em área de mina de bauxita em Minas Gerais, Brasil, foram alocadas para coleta de escoamento superficial e monitoradas antes da mineração (janeiro a maio de 2017) e durante a reabilitação inicial (janeiro a maio de 2018). Os fatores físico-ambientais que interferem no escoamento superficial foram caracterizados nos dois períodos e submetidos à análise de componentes principais (ACP). O escoamento superficial diminuiu de 0,76 para 0,30% da precipitação na reabilitação inicial em relação à área de referência. A inclinação do terreno e rugosidade da superfície foram os fatores determinantes na ACP, pois restringem a velocidade e o volume das perdas de água. A cobertura de vegetação nas parcelas antes e na reabilitação inicial foi de 100 e 64%, respectivamente. A densidade e o teor de silte do solo aumentaram e a porosidade total, macroporosidade e matéria orgânica diminuíram na reabilitação inicial. As taxas de infiltração foram iguais nos períodos, provavelmente devido a presença de fissuras e fendas no substrato da reabilitação inicial que se assemelha aos caminhos biológicos de antes da mineração. A reabilitação após a mineração reduziu o escoamento superficial, sendo a inclinação e rugosidade da superfície os fatores determinantes.

Comparative analysis of maintenance models to improve efficiency and sustainability in forest operations in Parana, Brazil

Carlos Diniz¹, Claudio Guevara², Eduardo Lopes³, Gabriel Miranda³, Henrique Koehler⁴

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Oregon State University, Corvallis, USA; ³Universidade Estadual do Centro-Oeste, Irati, Brasil;

⁴Universidade Federal do Paraná, Corvallis, Brasil (carlos.diniz@ufpr.br; guevarac@oregonstate.edu; eslopes@unicentro.br; gmiranda@unicentro.br; koehler@ufpr.br)

Most Brazilian forestry companies are using modern and high technology machines in performing wood harvesting operations. This situation requires constant precaution and new maintenance management models. The mechanical maintenance of wood harvesting machines is of great importance within the forest production process, as it is able to represent from 50 to 60% of the machine's total operational cost. Therefore, it is necessary to increase the mechanical availability of the machines and the reliability of the operations, since these factors are fundamental to increase the yield and to reduce costs in the production processes. Among the main maintenance programs, World Class Maintenance (WCM) stands out as a basis for preventive maintenance. In this sense, WCM promotes a culture change in respect to the reactive maintenance methods commonly employed by many industry segments. The objective of this research is to perform a comparative analysis between models of mechanical maintenance with a grapple skidder and to reduce operational costs. The comparative analysis included the Traditional Maintenance and the World Class Maintenance models, through determining mechanical availability, hydraulic oil consumption, and maintenance costs. The results showed an 8.2% increase in mechanical availability, a 1.1% decrease in maintenance costs, and a 77.8% reduction in hydraulic oil consumption using the WCM maintenance model. This would have a big impact preventing soil contamination by oil during harvesting operations, along with improving the efficiency and sustainability of forest operations. WCM models have the potential to enhance machine maintenance, operational safety, production capacity, and prolong machinery life.

Eucalyptus forest plantation management's effect on watershed's water quality in the atlantic rainforest: Sao Paulo, Brazil

Bianca Oliveira Fernandez¹, Yugo Matsuda², Isis Westphal de Oliveira³, Kelly Cristina Tonello¹

¹UFSCar, Sorocaba, Brazil; ²Suzano Papel e Celulose, Itapetinga, Brazil (bih.fernandez@hotmail.com; yugoma@gmail.com; isis.westphal@hotmail.com; kellytonello@yahoo.com)

A watershed soil management can alter water quality at its basin. Agricultural activities are one of the main sources of water pollution and quality change on rural areas. In this scenario, the management of Eucalyptus planted forests have the potential to influence watershed's water quality where its situated or at its downstream. The aim of this study was to verify the influence of Eucalyptus forest management for pulp production and the rainfall regime in watershed's water quality monitored in São Paulo state. The parameters evaluated were turbidity, pH, total nitrogen, phosphorous, potassium, dissolved oxygen (DO) and biochemical oxygen demand (BOD) at four watersheds in the Atlantic rainforest, being Eucalyptus forest plantations common to all of them. The data analysis, comprised up to 84 months, demonstrated that the Eucalyptus forest management did not modify the water quality parameters monitored. Phosphorus concentrations were above from the naturally found in Brazilian rivers references. However, it wasn't possible to correlate statistically phosphorous concentrations to the forest management. This conclusion motivates the necessity to study and understand specifically phosphorus behavior face to other influences (e.g.: soil characteristics and other natural resilient process). The rainfall regime influenced parameters such as turbidity, total nitrogen and potassium. The results indicate that basins containing forest areas may benefit from them to buffer effects of agricultural uses with intensive soil management.

E8s: NEXUS: FOREST, WATER AND CLIMATE

Tools for strategic decision making on water resources management under climate variability and drought conditions on the Caatinga's Biome of Northeast Brazil

Marcos Airton de Sousa Freitas¹

¹National Water Agency - Brazil, Brasilia, Brazil (masfreitas@ana.gov.br)

Drought impacts in Northeast Brazil, which tend to intensify due to climate change and overexploitation of the caatinga biome, have repeatedly brought famine, mass migration and social conflicts in this region. Drought prediction and monitoring, however, remain a central research theme. In water resources management in semiarid regions such as the Northeast of Brazil, it is fundamental to have tools to aid decision making. This work presents three components of the so-called SIGES (Drought Management System), the items related to drought prediction and monitoring, as well as many reservoir operation methodologies for water scarcity situations. Statistical models and artificial neural networks were used for drought prediction. In order to perform precipitation monitoring, several indexes were adapted and incorporated into a drought basic characteristic monitoring system (duration, severity and intensity), so that different mitigating

actions could be implemented in accordance with the values reached by these parameters. The following indexes have been used for this purpose: Rainfall Anomaly Index (RAI); Bhalme & Mooley Drought Index (BMDI); Lamb Rainfall Departure Index (LRDI). Finally, new adaptive reservoir operation strategies for water scarcity situations are presented and discussed. The described components were applied to all federal States of Northeast of Brazil.

A stand evapotranspiration model coupling the effects of environment and stand structure of larch plantation

Zebin Liu¹, Yanhui Wang¹, Ao Tian¹, Pengtao Yu¹, Yarui Wang¹, Lihong Xu¹

¹Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China (binarystar1989@163.com; wangyh@caf.ac.cn; tianao640249@126.com; yupt@caf.ac.cn; wangyaruio@163.com; xulh@caf.ac.cn)

Evapotranspiration (ET) is an essential component of the forest stand water budget. Both the quantitative expression and accurate prediction of ET require the models describing the ET response to changing environment and stand structure. For an easy application, a relatively simple but mechanism-based forest stand ET model coupling the effects of the potential ET (ET_{Tref}), relative extractable soil water (REW) of 0–60 cm, and forest canopy leaf area index (LAI) was developed, based on the field data of a larch (*Larix principis-rupprechtii*) plantation obtained in the non-rainfall days of the growing season (May. –Sep.) of 2015–2016 in northwest China. Results showed that: (1) with rising ET_{Tref}, the weather-dependent potential ET (ET_{max}) increases initially quickly and then slowly following a binomial equation; (2) Daily ET increases with rising REW firstly quickly, then gradually slowly till to a certain threshold, and thereafter tends to be stable. The ET response to LAI is similar to REW. The response can be described by a saturated exponential growth function; (3) The daily stand ET model coupling these response functions to individual factors was determined as: $ET = ET_{max}(ET_{Tref}) \cdot f(REW) \cdot f(LAI) = (-0.0992ET_{Tref}^2 + 1.3253ET_{Tref} - 0.1041) \times (1 - \exp(-15.729REW)) \times (0.900 - 0.262 / (1 + \exp((LAI - 1.381) / 3.294)))$, which showed a good performance in both calibration ($R^2 = 0.85$, Nash-Sutcliffe efficiency coefficient (NSE)=0.85) and validation ($R^2=0.73$, NSE=0.70). This indicated that the stand ET model coupling the effects of ET_{Tref}, REW, and LAI can provide a way to accurately predict the daily ET.

Evidence on the relationship between landscape pattern and water quality

Lígia M. B. Campanhão¹, Victor E. L. Ranieri¹

¹Universidade de São Paulo (USP), São Carlos, Brazil (ligiambc@hotmail.com; vranieri@sc.usp.br)

Strategies aiming at conserving and restoring natural forests can help mitigate the negative impacts of land use and land cover change on the provision of environmental services (ES). However, little is known about the relationship between landscape pattern and the provision of ES, particularly watershed services. We provide a review of the literature on the relationship between the pattern of natural forests in the landscape and water quality. The landscape pattern at multiple scales, i.e., watershed and riparian buffer, can influence water quality. There is strong evidence indicating that higher proportions of forest cover in both scales are related to better water quality. While landscape composition has a prominent effect on water quality, the importance of landscape configuration is less evident. A major role of landscape configuration has been observed in both landscapes with intermediary values of forest cover and landscapes with very low forest cover. There is evidence that habitat fragmentation affects water quality both positively and negatively. The positive effect would occur by the reduction of landscape homogeneity with forest patches that act as physical barriers to nutrient and sediment transport. Other factors; e.g., slope, soil erodibility, and nutrient input; can play a crucial role and override the effect of landscape pattern on water quality. These results indicate that the influence of landscape pattern on water quality, particularly landscape configuration, needs clarification. To further explain this issue, studies addressing different landscapes, scales, and covariates, are needed.

Sustainability and vulnerability of the Moju River Basin in eastern Amazonia in Pará, Brazil / Sustentabilidade e vulnerabilidade da bacia do Rio Moju, PA – Amazônia Oriental

Susane Ferreira¹, Aline Lima¹, José Augusto Corrêa¹

¹ Universidade Federal do Pará, Belém, Brasil (susane_cristini@hotmail.com; alinemeiguins@gmail.com; jamc@ufpa.br)

A água é um dos recursos naturais mais afetados pelo modelo de desenvolvimento adotado no Brasil. Fato relacionado ao sentimento generalizado de abundância de água no país que não ajuda a engajar plenamente todos os níveis de governo, como também obscurece os verdadeiros problemas de poluição, demanda, disponibilidade e conflitos da água. Este estudo visa fortalecer a gestão das águas e contribuir com a avaliação do processo de desenvolvimento da região nordeste do estado do Pará, utilizando Índices de Sustentabilidade de Bacias Hidrográficas, que considerem a situação hidrológica, a cobertura florestal, social e de gestão da bacia do rio Moju. Os resultados indicaram níveis moderados de sustentabilidade e governança. A Bacia possui 37,1% de seu território com cobertura florestal, correspondendo a uma área de 5803,7 km², entretanto sofre pressão devido ao seu potencial econômico, contemplando importantes atividades produtivas do Estado, que já ocupam 30% de sua área, dentre elas a dendeicultura. De forma geral, falta uma maior informação de demanda e disponibilidade hídrica, com a ampliação do número de empreendimentos regularizados quanto às vazões de captação e de diluição. O quadro de governança das águas é marcado por uma organização associada à gestão ambiental e hídrica pouco consolidada, comum da maioria dos municípios amazônicos. Desta forma, a bacia do rio Moju reproduz o perfil da gestão das águas na bacia Amazônica associada à necessidade de implementar as políticas de recursos hídricos e de meio ambiente existentes, para a redução dos conflitos que vinculam uso da terra e das águas.

The impact of leaf litter on runoff in a fragment of Atlantic Forest / Influência da serapilheira no escoamento superficial de um fragmento florestal na Mata Atlântica

Aline Gonçalves Spletzer¹, Sérgio Guedes Barbosa¹, Herly Carlos Teixeira Dias¹, Rodolfo Alves Barbosa¹

¹Universidade Federal de Viçosa, Viçosa, Brazil (alinespletzer_afmt@hotmail.com; sergioflora@hotmail.com; herly@ufv.br; rodolfo.ufv@gmail.com)

A função da serapilheira no escoamento superficial ainda não está esclarecida devido as características hidrofóbicas da matéria orgânica, portanto novos estudos principalmente de campo são necessários para esclarecer esse tema. O objetivo foi comparar o escoamento superficial em parcelas com e sem serapilheira em um fragmento florestal em estágio inicial de regeneração na Mata Atlântica. Seis parcelas foram construídas com bordas metálicas para a coleta do escoamento superficial, sendo três com serapilheira e três sem serapilheira. O escoamento superficial e a precipitação em aberto foram medidos após 28 eventos de chuva. A precipitação total foi de 1013,47 mm e os valores de escoamento corresponderam a 1,79% e 2,54% da precipitação para as parcelas com e sem serapilheira, respectivamente. O escoamento superficial das parcelas com serapilheira foi menor que as parcelas sem serapilheira, inferindo a isso a função dos resíduos vegetais na redução da velocidade do escoamento. A presença de serapilheira reduziu o escoamento superficial no fragmento florestal em estágio inicial de regeneração na Mata Atlântica.

Effects of composition and seasonality on transpiration of forest species in riparian zoneBruna Santos Lopes¹, Pietro Fernandes¹, Marina Otto¹, Silvio Ferraz¹, Robert Hubbard²¹Universidade de São Paulo, Piracicaba, Brazil; ²USDA Forest Service, Fort Collins, USA (bruna.santos.lopes@usp.br; pietro.fernandes@usp.br; groesalq@yahoo.com.br; silvio.ferraz@usp.br; r.m.hubbard@comcast.net)

Inadequate land use causes damage to the ecosystem, degrades the soil and waterways. Interventions for forest restoration seek the conservation of soils, as well as the recovery of ecosystem services. Although the beneficial effect of the tree vegetation around streams is known, little is known about the effect of forest restoration on the water regime of streams and the consumption of trees of different species and sizes. The aim of this study is to analyze how access to water by different native species influences their behavior in relation to water use. Sap flow measurements are being collected in three repetitions of four species of different successional stages. The variation in sap flow is measured by the Garnier method (1985), using heat dissipation probes. Preliminary results have shown differences in sap flow density and transpiration among different species. Faster growing tree species have consumed more water compared to slower growth species. It was observed that the trees present small differences in the transpiration rates between the rainy and dry periods, indicating that this may be due to the easier access to water in the riparian zone. From the results, it is hoped that this study can support the planning of the restoration areas aiming at maintaining the water available for consumption.

E8t: PLANT: SOIL INTERACTIONS IN FORESTS**Soil surveys in the Cascavel Sub-Plain area: PronaSolos, PR / Levantamento de solos no Subplanalto de Cascavel - PronaSolos, PR**Gustavo Ribas Curcio¹, Annete Bonnet¹, João Henrique Caviglione²¹Embrapa Florestas, Colombo, Brasil; ²Instituto Agronômico do Paraná, Londrina, Brasil (gustavo.curcio@embrapa.br; annete.bonnet@embrapa.br; jhcaviglione@gmail.com)

O PronaSolos Paraná tem como objetivo executar, concomitantemente, levantamento de solos e vegetação protetiva de rios e nascentes, respectivamente, nas escalas 1:50.000 e 1:10.000 na Bacia Hidrográfica Paraná III, a qual possui extensão territorial de 11.450 km². A metodologia de amostragem de solos é pedossequencial, partindo dos topos das paisagens, sendo concluída nas margens de rios e nascentes. O subplanalto de Cascavel se caracteriza por paisagens pouco declivosas (menores que 20%), com predomínio de paisagens constituídas por rampas de conformação convexa-divergente e côncavo-convergente. As rampas convexas-divergentes possuem os maiores comprimentos, frequentemente acima de 1,5 a 2 km ou mais de extensão, constituídas predominantemente por solos de alto potencial de uso - Latossolos Vermelhos Distroférricos típicos de textura muito argilosa, chegando praticamente até a beirada dos rios. As rampas côncavo-convergentes, em geral de menores dimensões, onde maciçamente se encontram nascentes, também são constituídas por Latossolos, tendo-se em alguns casos a presença dos Nitossolos Vermelhos mais próximos das nascentes. Chama a atenção a dicotomia ambiental no que se refere a estabilidade destas duas formas de rampa, pois nas rampas côncavo-convergentes há grande tendência de fortes concentrações de enxurradas. Este fato é preocupante devido as ocupações e manejos instituídos em passado recente, pois ao final destas rampas se identifica, com muita frequência, os Organossolos Háplicos Têrricos sápricos, solos com importantes funções ecológicas. Grande parte destes encontram-se degradados ou em fase de degradação, incorrendo em perdas funcionais, tanto no que se refere a sua flora específica como nas funções relacionadas às questões hidrológicas.

Quantifying above-ground biomass and nutrients in monoculture plantations of *Parapiptadenia rigida* in the Pampa biome / Quantificação da biomassa e nutrientes acima do solo de *Parapiptadenia rigida* em plantio mono específico no Bioma PampaHamilton Luiz Munari Vogel¹, Monique Pimentel Lagemann², Frederico Costa Beber Vieira¹, Mirla Andrade Weber¹, Mauro Valdir Schumacher²¹UNIPAMPA, São Gabriel, Brazil; ²UFMS, Santa Maria, Brazil (hamiltonvogel@yahoo.com.br; moniquelagemann@gmail.com; fredericobv@gmail.com; webermirla@gmail.com; mvschumacher@gmail.com)

O objetivo principal do estudo foi quantificar a biomassa, teores e estoques de nutrientes (N, P e K), de plantios de *Parapiptadenia rigida* (Benth.) Brenan, com presença e ausência de adubação NPK. O estudo foi realizado na área experimental da FEPAGRO Forrageiras, São Gabriel, RS. O solo da área é classificado como Argissolo Vermelho distrófico latossólico, com clima predominante Cfa (Köppen). O plantio do Angico-vermelho foi realizado com diferentes espaçamento (4x2, 6x2 e 10x2 m) em pastagem nativa nas entrelinhas, em três blocos com parcelas subdivididas com e sem adubação (15x36 m). Foram aplicados anualmente 50 kg ha⁻¹ de N, 40 kg ha⁻¹ de P₂O₅, e 70 kg ha⁻¹ de K₂O (recomendação para pastagens). A biomassa foi coletada em maio de 2017, quando as árvores tinham 4,5 anos. Foram cortadas três árvores médias por subparcela, e, fracionadas em madeira, casca, galhos e folhas, pesadas com balança de gancho no campo. Após procedeu-se com a metodologia de digestão sulfúrica, para determinação dos teores de N, P e K. Foi usado o *software* RStudio para análise estatística. Para todos os espaçamentos, o crescimento das árvores foi significativamente superior nas subparcelas adubadas; a produção de biomassa foi quatro vezes superior quando aplicou-se adubação, principalmente de galhos e madeira. Em todos os tratamentos, os maiores estoques de N, P e K estão nas folhas e galhos, com os maiores teores de N, P e K encontrados nas folhas, indicando a grande importância da deposição de matéria orgânica e nutrientes para o solo destes componentes.

Soil-plant interaction and its relationship to dominant height in stands of *Prosopis alba* / Interacción suelo-planta y su relación con la altura dominante en rodales de *Prosopis alba*Maria Gracia Senilliani¹ , Miguel Brassiolo¹¹Universidad Nacional de Santiago del Estero Facultad de Cs forestales - INSIMA, Santiago del Estero, Argentina (senilliani@yahoo.com.ar; mikyb@unse.edu.ar)

Prosopis alba es la especie nativa de mayor importancia en el Chaco semiárido para la forestación con múltiples objetivos. La actividad es incipiente en la región, gran parte de la superficie forestada se ha establecido en áreas muy diversas en función de la calidad del sitio, con comportamientos heterogéneos en el crecimiento de las plantaciones. Este estudio tiene como objetivo determinar factores edáficos que favorecen y limitan el desarrollo de la especie, información que será de utilidad para predecir la calidad de determinados sitios donde aún no hay plantaciones pero sí se conocen las condiciones edáficas. Los parámetros utilizados: Altura dominante (Hd), Edad (E) y área basal (AB), en relación a propiedades químicas como PH, Contenido de sales solubles (CE), Cationes solubles (Ca, Mg, Na), presencia de carbonatos, RAS y entre las propiedades físicas, humedad (hdad), Drenaje(D), Permeabilidad (P) y Textura (Text). Se realizó la primera evaluación de la correlación entre variables de crecimiento y variables edáficas mediante análisis de componentes principales en relación a 3 clases de calidad de sitio. Se determinó un modelo de proyección de HD en función de variables de mayor correlación, estimado a partir del análisis de

regresión lineal múltiple que explica más del 50% de la variación en Hd de los rodales implantados. Resultados preliminares reportan que el crecimiento está condicionado principalmente por propiedades químicas de los suelos, entre las cuales la presencia de sales (CE y cationes solubles) explicaría en mayor medida el impacto en el crecimiento.

Quantifying the leaf litter and nutrients in a native forest in the central region of Rio Grande do Sul, Brazil / *Quantificação da serapilheira e nutrientes em uma floresta nativa na Região Central do RS, Brasil*

Hamilton Luiz Munari Vogel¹, Monique Pimentel Lagemann², Mauro Valdir Schumacher²

¹UNIPAMPA, Santa Maria, Brazil; ²UFSM, Santa Maria, Brazil (hamiltonvogel@yahoo.com.br; moniquelagemann@gmail.com; mvschumacher@gmail.com)

Os estudos com deposição de serapilheira são considerados um importante indicador da qualidade ambiental dos ecossistemas florestais, constituindo a principal via de entradas de matéria orgânica e nutrientes para as florestas. O presente estudo teve como objetivo, quantificar a produção anual de serapilheira, sua sazonalidade, e a deposição de N, P e K pelas folhas, em um fragmento de floresta nativa do tipo Estacional Semidecidual, na região da Depressão Central, município de São Sepé, RS. No interior desta floresta, com condições homogêneas de sítio, foram alocadas sistematicamente cinco parcelas de 20 m x 15 m, onde foram distribuídos cinco coletores de serapilheira por parcela (0,1963 m² por coletor), envoltos por uma tela com 2 mm, a um metro a partir do solo. As coletas foram realizadas mensalmente por um período de dois anos (maio/2015 a abril/2017). No laboratório, as amostras foram separadas nas frações folhas, galhos finos (diâmetro < 0,5 cm) e miscelânea (cascas, sementes, flores e detritos não identificáveis). Após foi determinado os teores de N, P e K nas folhas. Verificou-se maior deposição de serapilheira na primavera, com os maiores picos de devolução principalmente no mês de outubro, indicando um comportamento sazonal de deposição. A deposição média de serapilheira foi de 6,87 Mg ha⁻¹ ano⁻¹; deste total as folhas foram responsáveis por 67,67%, seguido da miscelânea com 17,59% e dos galhos finos com 14,74%. As folhas foram responsáveis pela deposição média para o solo de 97,4; 4,2 e 25,5 kg ha⁻¹ ano⁻¹ de N, P e K respectivamente.

Assessing heavy metals using energy-dispersive X-ray spectroscopy in two conifers at the Chapingo Autonomous University / *Determinación de metales pesados mediante espectrometría de dispersión de energía por rayos x en dos coníferas de la Universidad Autónoma Chapingo*

Andrea Janet Granados Mendoza¹, Edgar Fernando Vázquez Soto²

¹Universidad Juárez del Estado de Durango, Durango, Mexico; ²Universidad Autónoma Chapingo, Texcoco, Mexico (andiimendoza@gmail.com; edgarvzz18@gmail.com)

Los metales pesados se encuentran en aire, agua y principalmente en el suelo, concentrándose esencialmente en raíces, mientras que, secundariamente estos elementos tóxicos se almacenan en tallos y hojas, causando graves problemas en estos, e inclusive ocasionando la muerte de la planta completa. Por lo tanto, los objetivos de este estudio son evaluar la presencia de metales pesados, así como la cuantificación de ellos en dos coníferas *Pinus pseudostrobus* Lind. y *Pinus maximartinezii* Rzed. de la Universidad Autónoma Chapingo. Para identificar y cuantificar los agentes nocivos acumulados en dichas especies, se tomaron muestras de estas, a una altura de 1.30 metros, con la ayuda de un taladro de Pressler, donde posteriormente las virutas fueron divididas en parte inicial, intermedia y final, para después ser sometidas a técnicas de Microscopía Electrónica de Barrido (MEB) y Espectrometría de Rayos X (EDX). Los datos obtenidos indicaron que el elemento con mayor acumulación en las muestras de *Pinus* fue el Arsénico (As) con un valor máximo de 75.10 % ubicado en la parte media y un valor mínimo de 31.19 %, mientras que el elemento con menor incidencia fue el Plomo (Pb) con un valor máximo de 5.94 % y con un valor mínimo de 1.02 % respecto de las muestras. Este estudio concluye que para asegurar que los pinos de la Universidad Autónoma Chapingo continúen proporcionando servicios ambientales claves, es necesario implementar programas enfocados en técnicas de biorremediación para la remoción de los metales pesados presentes en la zona de estudio.

Soil fertility and growth in a *Pinus taeda* plantation considering the residual effect of 30 years of accumulated detritus in Rio Negrinho, Santa Catarina, Brazil / *Fertilidade do solo e crescimento de um plantio de *Pinus taeda* dado o efeito residual de 30 anos do acúmulo de necromassa no município de Rio Negrinho - SC*

Ana Rosaria Scilfo Zucon¹, Antonio Carlos Vargas Motta¹, Shizuo Maeda², Cleiton Frigo¹, Edvaldo Renner da Costa Cardoso¹, Lenir Fátima Gotz¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil (zuconana@gmail.com; mottaacv@ufpr.br; shizuo.maeda@embrapa.br; cleiton.frigo@hotmail.com; edvaldorcardoso@hotmail.com; lenir_gotz@hotmail.com)

Durante a expansão da implantação de povoamentos florestais comerciais, áreas de vegetação primária foram convertidas, e os resíduos resultantes do desmate enleirados ou acúmulo de necromassa. Nesse contexto, inserem-se os plantios comerciais de *Pinus* da empresa Companhia Volta Grande, localizada no município de Rio Negrinho, SC, com talhões com leiras acumuladas há mais de 30 anos, atualmente ocupados por plantio de *Pinus taeda* com 12 meses de idade. Esse trabalho teve como objetivo a avaliação dos efeitos do acúmulo de material lenhoso (leiras) na fertilidade do solo e crescimento do povoamento de *Pinus*. O experimento foi instalado em um talhão da empresa, utilizando-se uma adaptação da metodologia de linha transectal, demarcando-se um transecto de 300 m de comprimento ao longo do talhão de forma transversal às leiras. Coletaram-se dados de altura das plantas e amostras de solo (0 a 20 e 20 a 40 cm de profundidade). Verificaram-se alturas médias dos indivíduos de 2,24 e 1,79 m para locais das leiras e sem acúmulo, respectivamente. Solo da leira comparativamente a fora da leira, apresentava menor pH para ambas profundidades avaliadas e maior valor para K, P, Mn, Fe e Zn disponível e menor valor de Cu disponível, na camada de 0-20 cm. Para a profundidade de 20-40 cm, verificaram-se maiores valores para K, P, Cu e Fe e diminuição de Mn para as áreas da leira. O acúmulo de resíduo afeta a fertilidade do solo e por consequência o crescimento da planta a longo prazo.

Fragility index of forest soils within the Chilean Forest Plantation Protocol / *Índice de fragilidad de suelos forestales en el marco del protocolo de plantaciones forestales Chile*

Samuel Francke¹, Celso Carnieletto¹

¹Corporacion Nacional Forestal, Santiago, Chile (samuel.francke@conaf.cl; celso.carnieletto@conaf.cl)

Los principales impactos ambientales a nivel nacional de operaciones forestales se expresan en la generación de procesos erosión, sedimentación y turbidez

de las aguas que contribuyen a disturbar el funcionamiento de las cuencas hidrográficas del país. En la actualidad, los sistemas de cosecha a tala rasa pueden extenderse hasta una superficie de 500 ha y se cosechan anualmente una superficie del orden 80.000 ha. Si bien la cosecha forestal debe estar acompañada de procesos de reforestación y mitigar los impactos en el suelo y aguas, provenientes de las operaciones forestales en el marco de los lineamientos FSC, resulta posible la adopción voluntaria del Protocolo de Plantaciones Forestales y la normativa vigente del plan de manejo “corta, explotación y reforestación”, que se presenta a Conaf. El presente trabajo, integrado a una guía respectiva para los actores del sector forestal, contempla lo siguiente: Los conceptos y definiciones técnico-legales, Los elementos metodológicos en la construcción de Índices de fragilidad de suelos forestales, Los factores a considerar edafo-climáticos, hidrológicos y topográficos, El Índice, clases de fragilidad y compendio de suelos forestales. a principal lección aprendida para el sector forestal se refiere a lograr armonizar una producción forestal sostenible con una conservación forestal sustentable a nivel de cuencas hidrográficas, de tal forma, que la fertilidad del suelo, la productividad sitio forestal y la conservación de los signos vitales de salud de la cuencas hidrográficas y recursos hídricos, resulten sostenible a través de sucesivas rotaciones forestales.

Soil attributes and yields from *Pinus taeda* in forests in southern Brazil / Atributos do solo e produtividade do *Pinus taeda* em florestas no sul do Brasil

Renato Marques¹, Carolina Benghi Pinto¹, Isabel Deliberali², Mauro Valdir Schumacher³

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ³Universidade Federal de Santa Maria, Santa Maria, Brasil (rmarques@ufpr.br; carolinabenghi@gmail.com; isabel@ipef.br; mauro.schumacher@ufsm.br)

O conhecimento das relações entre os atributos edáficos e a produtividade das árvores pode servir como base para a orientação das práticas de manejo em plantações florestais. Este trabalho de pesquisa é fruto do Programa Cooperativo sobre Produtividade Potencial do *Pinus* no Brasil (PPPPIB) desenvolvido pelo Instituto de Pesquisas e Estudos Florestais (IPEF) em plantações localizadas nos estados do Paraná e Santa Catarina. Teve por objetivo identificar os atributos edáficos relacionados com a produtividade do *Pinus taeda*. Dezesesseis perfis de solos sob reflorestamentos foram descritos e amostras de solos foram coletadas para a realização das análises físicas e químicas, sendo a classificação realizada até o quarto nível categórico conforme o Sistema Brasileiro de Classificação de Solos. Os dados de produtividade como índice de sítio (IS), volume (V) e incremento médio anual (IMA) foram obtidos dos inventários anuais realizados pelas empresas florestais. Foram identificados 2 grandes grupos de produtividade por meio de análise de agrupamento. Os atributos do solo que mais se relacionaram com a produtividade florestal, nestas plantações de *Pinus* no Sul do Brasil, foram o teor de argila no perfil do solo e a profundidade do horizonte A, associada ao carbono do solo.

E8u: PLANT: SOIL INTERACTIONS IN FORESTS

Soil fertility and earthworm activity are affected by dead trees in old-growth temperate forests of Northern Iran

Mehrasa Zare¹, Yahya Kooch¹

¹Tarbaat Modare University, Noor, Islamic Republic of Iran (mehrasazr@gmail.com; yahya.kooch@yahoo.com)

Dead tree is an important ecological factor for changing of soil features that attracts different livings. Due to investigation the decay degree effects of downed tree on soil properties and earthworms ecological groups, the Sardabrood forest (Mazandaran, Iran) was chosen. For this purpose, 306.2 ha areas considered at 700 - 1300 m altitude range and twenty seven downed trees of beech and hornbeam species were found. Decay degree of downed tree classified in four classes (DC1, DC2, DC3 and DC4). Whole of dead trees selected as the center of sample plots and mixed soil samples were taken from theirs besides and along at 0 - 10, 10 - 20 and 20 - 30 cm depth. Soil pH, water content, organic carbon (C), total nitrogen (N) and C/N ratio measured at the laboratory. The earthworms were collected simultaneously with the soil sampling by hand sorting. The maximum of soil pH and water content considered under DC4 of dead trees and significant differences were found. But, soil depth had no significant differences for these characters. Also, the most amounts of soil C and N found in DC4 of dead trees and upper layers of soil. DC1 of dead trees and soil lower depths devoted the maximum of C/N ratio. Principal component analysis (PCA) showed that the most assemblage of earthworms were around of dead trees with high decay degree (DC4). Density and biomass of earthworms group in dead trees positions indicating endogeics are due to creating significant statistical differences between beech and hornbeam downed trees.

Stomatal density of *Eucalyptus* and *Corymbia* species with different levels of drought tolerance

Patricia Andressa de Avila¹, Alexandre de Vicente Ferraz², Liamara Santos Masullo¹, José Renato Drago³, José Leonardo Moraes Gonçalves¹

¹ESALQ/USP, Piracicaba, Brazil; ²IPEF, Piracicaba, Brazil; ³Bahia Specialty Cellulose/Copener Florestal, Alagoinhas, Brazil (avilapa@usp.br; alexandre@ipef.br; liamaramasullo@usp.br; jose_drago@bahiaspeccell.com; jlmgonca@usp.br)

Many leaf morphological characteristics (e.g., stomatal density) are closely related to the level of drought tolerance (DT) in eucalyptus. Considering the expansion of *Eucalyptus* plantations in Brazil into areas with lower water availability (Northeast and West-central), it was studied stomatal density of *E. grandis* e *E. urophylla* (low DT), *E. cloeziana* e *C. citriodora* (intermediate DT), *E. camaldulensis* e *E. brassiana* (high DT). The study is located in the municipality of Itatinga-SP, Brazil, in a completely randomized design. At 11 months post-planting, 10 leaves of crown upper third of four tree were collected, totaling 40 healthy and totally expanded leaves of each specie. Epidermal impressions of middle abaxial portion of leaf surface were made using colorless adhesive. So, epidermal impressions were placed onto a microscope slide and photographed three times (20x objective). The stomatal number by mm² was evaluated by *ImageJ* software. The *E. cloeziana* had higher stomatal density (600 stomatos.mm-2), followed by *E. urophylla* and *E. grandis* (450 stomatos.mm-2). More tolerant species to drought (e.g., *C. citriodora*, *E. camaldulensis* and *E. brassiana*) showed lower stomatal density (300 stomatos.mm-2). Normally, plants with lower stomatal density values have lower leaf transpiration rate, resulting in a higher tolerance to water and thermal stress.

Woodland resilience to climate change: assessing tree-soil-water relations under elevated atmospheric CO₂

Susan Quick¹, Stefan Krause¹, Giulio Curioni¹, Neil Loader², Alan Jones³, Phillip Blaes^{1,4}, Carolina Mayoral¹, A.Rob MacKenzie¹

¹Birmingham Institute of Forest Research, University of Birmingham, Birmingham, United Kingdom; ²Geography Department, University of Swansea, Swansea, United Kingdom; ³Earthwatch Institute, Oxford, United Kingdom; ⁴Yorkshire Water (currently), Leeds, United Kingdom (seq616@student.bham.ac.uk; s.krause@bham.ac.uk; g.curioni@bham.ac.uk; n.j.loader@swansea.ac.uk; ajones@earthwatch.org.uk;

p.j.blaen@bham.ac.uk; c.mayoral@bham.ac.uk; a.r.mackenzie@bham.ac.uk)

Birmingham Institute of Forest Research (BIFoR) has a second generation Free Air CO₂ Enrichment FACE experiment set in mature UK broadleaf temperate forest dominated by 160-year-old and 25m tall oak (*Quercus robur*) trees interspersed with sycamore (*Acer pseudoplatanus*), hazel (*Corylus avellana*), hawthorn (*Crataegus monogyna*), and holly (*Ilex aquifolium*). The basic FACE treatment consists of +150 ppmv above ambient applied in daylight hours throughout the growing season (~April-November, depending on phenology). There are three eCO₂ treatment patches, three full-infrastructure control patches, three no-infrastructure control patches, and up to two years of pre-treatment baseline data. Elements of Tree-Soil-Water relations at BIFoR FACE, including total precipitation, throughfall, soil moisture, and xylem sapflow, were measured relating to the dominant species pedunculate oak (*Q. robur*). Preliminary baseline pre-treatment datasets (to April 2017) are compared, using seasonal and species specific approaches, with initial response datasets for enriched carbon dioxide (eCO₂) during the 2017-2019 seasons. Variability in response to eCO₂ is assessed and related to measurements of tree physiology, canopy structure, and meteorology (including incident radiation levels and air/soil temperature profiles).

Benchmarking edaphic properties of Arabuko Sokoke forest for long-term biodiversity monitoring

Mwadalu Riziki¹, Muturi Gabriel², Gathara Mary²

¹Kenya Forestry Research Institute, Malindi, Kenya; ²Kenya Forestry Research Institute, Nairobi, Kenya (zikimwa@gmail.com; gabrielmukuria2012@gmail.com; mwgathara@gmail.com)

Biodiversity monitoring is an essential aspect of effective forest resource conservation and sustainable management. Monitoring edaphic properties of a forest is a useful tool in forest biodiversity assessments due to the role played by different soil properties in forest regeneration. Spatial and temporal monitoring of soil functions and dynamics provides vital information on response of forest soil to changes in climate, pollution and forest management practices. In light of this, a study was initiated at Arabuko Sokoke forest to monitor changes in biodiversity indicators over a period of time. The experiment was set as a completely randomized design with three treatments (*Brachystegia spiciformis* zone, *Cynometra webberi* zone and mixed forest zone). A total of 27 permanent sample plots measuring 50 m x 30 m each were established. Baseline soil samples were collected for soil physical and chemical analysis using standard procedures. Baseline results indicate that Soil Organic Matter, Total Nitrogen and Carbon were significantly different across the different vegetation zones ($p < 0.05$). The *Brachystegia* and *Cynometra* zones recorded higher P concentration of 3.4 ppm and 3.35 ppm respectively, while the mixed forest zone which is dominated by white sand had a P concentration of 2.7 ppm. The pH was significantly different across the vegetation zones ($p < 0.001$). Bulk density of the forest soil was 1.34 g/cm³ dominated by sandy and sandy loam soils. The baseline soil data is crucial for providing information necessary for developing rehabilitation frameworks and supporting biodiversity related decision making in forest policy and management.

Soil diversity as influenced by different forest ecosystems in the Southern Western Ghats, India

Sujatha MP¹, Thomas TP¹, Kavitha C¹, Sandeep S¹

¹Kerala Forest Research Institute, Thrissur, India (sujatha@kfri.org; thomas@kfri.org; kavien2007@gmail.com; sandeep@kfri.res.in)

Soil, the key source of life in this planet is very dynamic and heterogeneous natural resource. The Southern Western Ghats of India, which occupy mostly in the State of Kerala is endowed with different types of natural vegetations and soils, owing to the wide variation in topography, litho sequence, rainfall and temperature. The major forest types of this region include wet ever green, semi evergreen, deciduous, shola grassland systems, natural bamboo etc. The diversity in soils with respect to morphological, physical and chemical properties as influenced by different forest covers is explored in this study. The study revealed that the occurrence of natural forest ecosystems in this region is mainly governed by the climatic and altitudinal variations, and each vegetation exerted significant influence on the soils supporting them. Among the ecosystems, shola forest was very unique in its soil characteristics with its higher stock of organic carbon (631.2 Mg C ha⁻¹) even up to 1.5 m along with higher content of exchangeable Al. But the same pattern with respect to carbon stock and Al was not seen in grasslands, which was adjacent to shola forest. The disturbance to natural forests showed a strong impact on weathering and laterisation processes while clay mineralogical make up was found associated with peculiar forest ecosystems.

Influence of forest structure on soil respiration in different sites in Central Amazonia / Influência da estrutura da floresta na respiração do solo em diferentes sítios na Amazônia Central

Marcelo Teles¹, Roberval Lima², Celso Paulo de Azevedo², Jörg Matschullat³

¹Universidade Federal do Amazonas, Manaus, Brazil; ²Embrapa Amazônia Ocidental, Manaus, Brazil; ³Technische Universität Bergakademie Freiberg, Freiberg, Germany (renanteles@yahoo.com.br; roberval.lima@embrapa.br; celso.azevedo@embrapa.br; matschul@tu-freiberg.de)

O papel das florestas tropicais nas mudanças globais vem sendo estudado em função da sua dimensão e inter-relação com os gases de efeito estufa que influenciam no aquecimento global. O objetivo deste estudo é investigar a influência da estrutura da floresta na respiração do solo em diferentes sítios na Amazônia Central, abrangendo 5 municípios do estado do Amazonas. As variáveis dependentes selecionadas para as análises foram o efluxo de CO₂, CH₄ e N₂O, que apresentaram médias de 6,23 μmol CO₂ m⁻²s⁻¹; -4,86 μmol CH₄ m⁻²h⁻¹ e 1,33 μmol N₂O m⁻²h⁻¹, respectivamente. Foram realizadas análises de correlação para avaliar as relações entre as variáveis das florestas, onde área basal, DAP máximo e índice de Shannon apresentaram sinais de correlação com a respiração do solo; por sua vez as variáveis edafoclimáticas umidade do ar e do solo e temperatura do ar também apresentaram correlações com os fluxos de gases. Foram ajustados modelos de predição com as variáveis da estrutura da floresta e as edafoclimáticas. As médias dos parâmetros da estrutura floresta mostraram diferenças significativas entre os sítios estudados. O efluxo de gases a partir do solo, nos sítios sob cobertura de florestas não apresentaram diferenças relacionadas ao CO₂, entretanto apresentaram diferenças significativas entre alguns sítios para efluxos de CH₄ e N₂O. Detectou-se diferenças nos efluxos de gases entre os sítios sob florestas e aqueles em que ocorreram mudanças no uso da terra.

E8v: PLANT: SOIL INTERACTIONS IN FORESTS

Stands of norway spruce and scotch pine on postagrogenic soils of the Boreal Zone of the North-West of Europe

Dmitriy Danilov^{1,2}, Natalia Beliaeva²

¹Leningrad Research Institute For Applied Agricultural Science «Belogorka», Leningrad region, Gatchina District, Russian Federation; ²St. Petersburg State Forest Engineering University named after S. M. Kirov», St. Petersburg, Russian Federation (stovn200@mail.ru; galbel06@mail.ru)

To date, there is a significant amount of coniferous forests have arisen on lands previously used in agriculture. For the conditions of the boreal zone of Europe, the formation of stands of pine and spruce on post-agrogenic lands has its own characteristics different from similar stands growing on forest soils. In contrast to forest lands, the presence of a more powerful root profile on arable soils makes it possible to form more productive coniferous plantations. The structure of mixed stands of pine and spruce on the representation of trees of different classes of diameters differs from natural forest plantations. In mixed stands on post-agrogenic lands, the distribution rows of spruce pine trees have a greater number of classes of trunk diameter. Depending on the share of participation in the composition of pine and spruce plantations formed with different reserves to the age of mature stands. The stock of pine and spruce stands on former arable lands at the age of 80 years is equal to the stock of forest stands on forest soils at the age of 100-120 years. It is necessary to develop a regime of farming in coniferous stands on postagrogenic soils of the boreal zone.

Phytoremediation strategies using various cover plants for Mined-Out Areas in Bagacay Western Samar, Philippines

Angelito Exconde¹, Albert Piñon¹, Analyn Pasagdan¹, Allan Castillo¹, Maria Theresa De Alday¹

¹Ecosystems Research and Development Bureau, Department of Environment and Natural Resources, Los Baños, Laguna, Philippines (erdb.excondelito@gmail.com; alpinon@yahoo.com; arpasagdan@gmail.com; alan.castillo@usq.edu.au; mtvdealday@gmail.com)

Increasing mining activities brought by industrial progress causes heavy metal sedimentation that pollutes the surrounding landscapes. Since this condition is affecting the environment and the people living within the site adversely, it requires immediate rehabilitation. Fortunately, the trees' "phytoremediation" ability offers the best option as they are cheap and locally available. However, with the extreme micro-climate condition, looking for the best cover crop and soil amelioration to ensure the trees growth and survival is a challenge. Hence, this study sought to conduct soil amelioration, identify suitable cover plants, and ascertain the effect of mulching materials to plant's growth and survival in mined-out areas. Using nine soil amelioration treatments and various farm wastes as mulch, the experiment used a split-plot in Randomized Complete Block Design with three replicates and arranged in 5 x 10 meter individuals per plot to test the four species of cover plants such as *Saccharum spontaneum* L., *Wedellia trilobata* (L.) A.S. Hitchc., *Arachis pintoi* Krapov. & Greg., *Vetiveria zizanioides* (L.) Nash. After a year, all cover plants planted in soil media with a combination of forest soil + chicken manure + lime were found to have better growth and percent survival compared to control treatment (forest soil). *V. zizanioides* outperformed the other species in terms of growth and percent survival. Aside from protective cover, farm waste materials as mulch serves as nutrient-source of the cover crop's root systems.

Flora and vegetation characteristics of desertification restoration area for reduction of yellow sand

EungPill Lee¹, SeungHyuk Lee², SungBae Joo³, EunJoo Lee⁴, YongSik Hong¹, SeungYeon Lee¹, EuiJoo Kim¹, YoungHan You¹

¹Kongju National University/Life science, Gongjusi, Republic of Korea; ²Baekdudaegan national arboretum, Bonghwagun, Republic of Korea; ³National Institute of Ecology, Seochungun, Republic of Korea; ⁴Seoul National University, Seoul, Korea, Republic of (lyp2279@kongju.ac.kr; sensus@bdna.or.kr; doctorjoo@nie.re.kr; lyp2279@kongju.ac.kr; hongfin@smail.kongju.ac.kr; ecollee21@kongju.ac.kr; euijoo@kongju.ac.kr; youeco21@kongju.ac.kr)

Dust from dry and semi-arid areas is emerging as an environmental issue. In order to reduce the damage of desertification and dust caused by land degradation, restoration of vegetation was carried out in the Huronbeyar region of China. In order to understand the changes of plant diversity and the structure and characteristics of ecosystem, this study was conducted to investigate flora and vegetation, chlorophyll content, chlorophyll fluorescence and soil respiration in each year from 2014. As a result of the flora investigation of the Ganjiru restoration area, the main dominant species were the *Caragana koreana* and *Astragalus membranaceus* which appeared in all regions, and there was a difference in the plant classification which was found by restoration year. As a result of PCA and cluster analysis based on vegetation survey, it was found that plant communities were distinguished over time of restoration, and R-2008 and R-2011 were mixed a little so that plant composition had many common points. The chlorophyll content was much different from that of 2014, and the chlorophyll fluorescence was not significantly different but it seems to be under some stress. Soil respiration rate showed a tendency according to the restoration. This work was supported by the National Research Foundation of Korea(NRF) grant funded by the Korea government(MSIT) (No. NRF- 2018R1A2B5A01021358) and Joint Research on Dust and sandstorm among Korea, China, Japan in 2018.

Rhizosphere coenzymatic stoichiometry of over- and under-stories in subtropical plantation

Xiaoqin Dai¹, Yuqiu Gao¹, Huimin Wang¹

¹Qianyanzhou Ecological Research Station, Key Laboratory of Ecosystem Network Observation and Modeling, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, China (daixq@igsnr.ac.cn; gao_yuqiu@qq.com; wanghm@igsnr.ac.cn)

Identifying the nutrient status of root-soil interface of coexisting species is important for plantation ecosystem management. Soil extracellular enzyme activities and their stoichiometries, reflecting the relative microbial energy and nutrient limitations, are important indicators of soil nutrient status. Seven hydrolytic enzyme (C-, N- and P-acquiring enzyme) activities of rhizosphere soil of overstory trees, understory shrubs (*Loropetalum chinense*, *Adinandra millettii* and *Eurya muricata*) and herbs (*Woodwardia japonica*, *Dryopteris atrata* and *Dicranopteris dichotoma*) were measured in plant early growth stage (April) and plant vigorous growth stage (July) in *Cunninghamia lanceolata*, *Pinus massoniana* and *Pinus elliottii* pure plantations at Taihe, Jiangxi. C-acquiring enzyme was represented by β -1,4-glucosidase, α -1,4-glucosidase, β -xylosidase and β -d-cellobiosidase, N-acquiring enzyme was represented by β -1,4-N-acetylglucosaminidase and leucine aminopeptidase, and P-acquiring enzyme was represented by acid phosphatase. The C- and N-acquiring enzyme activities of rhizosphere soil of *L. chinense* in April were significantly higher than those of *P. massoniana* and *P. elliottii*. In July, three enzyme activities of rhizosphere soils of overstory trees and *L. chinense* were significantly higher than those of *E. muricata*, except for P-acquiring enzyme in *C. lanceolata* forest. The ratios of C-, N-, and P-acquiring enzymes averaged to 1:0.88:1.25 in April and 1:1:1.25 in July. More microbial investment in C-acquiring enzyme was found compared to N-acquiring enzyme in April. Higher P-acquiring enzyme was obtained compared to C- and N-acquiring enzymes whatever in April and in July. Considering forest stand types, understory species and sampling seasons is helpful for the understory vegetation management of subtropical plantation ecosystem.

Change in soil properties and plant growth at reclaimed land due to application of torrefied wood chip and vermicompost

Byung Bae Park^{1,2}, Aung Aung¹, Si Ho Han¹, Jeong Min Seo¹, Woo Bin Youn¹, Huong Thi Thuy Dao¹

¹Department of Environment and Forest Resources, Chungnam National University, Daejeon, Korea, Republic of; ²Korean Society of Forest Science, Seoul, Korea, Republic of (bbpark@cnu.ac.kr; baganaung777@gmail.com; bupleurumhan@gmail.com; jmseo3@naver.com; dbsdnqls95@naver.com;

thuyhuong.150495@gmail.com)

Soil salinity change in reclaimed land is one of major constraints for food production. However, soil properties in this land can vary by time as attempts for desalinization process accelerate. There are several soil-amendment methods to remediate reclaimed land. A field study was conducted for three years at Saemangeum reclaimed land to investigate effects of certain organic amendments to its soil. Three levels (0, 2.5 and 5.0 Mg ha⁻¹) of torrefied wood chip (TWC), and two levels (0 and 2.7 Mg ha⁻¹) of vermicompost (VC) were applied in split-plot design (n=3). *Populus euramericana* was used as crop tree. To observe soil properties, soil samples were collected twice at 2016 and 2017 in three depths (0~15, 15~30 and 30~45 cm), and analyzed its properties. We measured growth parameters of poplar, and biomass and nutrient analysis of weed to know the nutrient uptake across treatments. TWC, VC and soil depths did not show interaction for all soil elements. Similarly, TWC and VC did not have interaction on all soil properties, poplar growth, and weed nutrient uptake. However, higher TWC application showed removal of Na⁺, especially at 0~15 cm soil depth. For tree growth, VC showed significant positive response to height and diameter. VC application significantly affected on weed biomass and nutrient uptake of weeds too. These results suggested that TWC could be used in higher application rate to leach out Na⁺ concentration in salt-affected soil, whereas VC can be applied as an organic fertilizer to reclaimed soil.

Changes of physical properties of a soil reforested with *Tectona grandis* L. F. in the region of Urutaí, GO

Vitor Corrêa de Mattos Barretto¹, Matheus da Silva Araújo², José Eduardo Dias Calixto Junior³, Carlos Leonardo Pereira Bogas¹, Teresa Cristina Tarlé Pissarra⁴, Allan de Marcos Lapaz¹

¹São Paulo State University (UNESP/FCAT), Dracena, Brazil; ²University of São Paulo (USP), Piracicaba, Brazil; ³University of Brasília (UnB), Brasília, Brazil; ⁴São Paulo State University (UNESP/FCAV), Jaboticabal, Brazil (vitor.barretto@unesp.br; araujomatheus@usp.br; junplant@hotmail.com; carlospereirabogas@gmail.com; teresa.pissarra@unesp.br; allanlapaz60@gmail.com)

The changes of soil physical properties occur in several ways, influencing the development of plants. However, is not very well known the changes of soil physical properties in populations of teak (*Tectona grandis* L. F.). The teak is an arboreal specie that has been cultivated in Mato Grosso, and presents potential for planting in Goiás, Maranhão, Bahia and Minas Gerais, whose purpose is to obtain wood for the sawmill industry. To this end, the aim of this study was to evaluate changes of soil physical properties of Red-Yellow Latosol reforested with teak with 4 years of age. For that, chose a population of teak with 6 hectares, 3 x 2 meters spaced, PU farm in Urutaí-GO (220 km from Goiânia-Goiás). It was determined the particle size, the density of the soil, macroporosity, microporosity, total porosity, resistance to root penetration and gravimetric moisture. The soil sampling was carried out in 2 depths (0-0.20 and 0.20-0.40 m), 34 simple samples being collected for each depth. It was used a complete randomized design with 34 replications. The averages were compared by the Tukey test at 5% of significance, through the SISVAR program. There have been changes in porosity, soil density and resistance to penetration in depths. The highest values of total porosity was 0.56 m³ m⁻³, soil density was 1.48 g cm⁻³ and the resistance to penetration of 3.1 MPa in 0.20-0.40 m, due to the adoption of minimum tillage system in planting, no soil plowing and maintenance of litter on the surface.

Density of ammonifiers and nitrifiers bacteria in soils cultivated with pine and native forest in the South of Brazil

Kauanna Brok Ferreira Pepe¹, Rafael Hennel Tulio¹, Krisle Silva², Josiléia Acordi Zanatta², Marcos Fernando Gluck Rachwal²

¹Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; ²Embrapa Florestas, Colombo, Brazil (kauanna.pepe@hotmail.com; rafael.tulio@outlook.com; krisle.silva@embrapa.br; josileia.zanatta@embrapa.br; marcos.rachwal@embrapa.br)

This work aimed to evaluate the density of soil bacteria involved in the process of N mineralization and nitrification in soils cultivated with pine and native forest in the south of Brazil. Soils samples were collected at 0-10 cm depth in two areas: Rio Negrinho – Santa Catarina in a soil cultivated with pine (*Pinus taeda*) for 6 years and in a native *Mixed Ombrophilous Forest* and Telêmaco Borba – Paraná in an area cultivated with pine (*P. taeda*) for 4 years and a native seasonal Semideciduous Forest. Bacterial density was evaluated by the most probable number method utilizing media for ammonifiers (N mineralization) and nitrite oxidizers (nitrification). The soil pH was also evaluated. The mean values of ammonifiers ranged from 5.61 to 6.15 log cells g⁻¹ soil and there was no significant difference between pine and native forest in both areas. In the media for nitrite oxidizers significant differences were observed, with higher density values in soils with pine compared to native forest in the two areas. In Rio Negrinho/SC the mean values obtained were 7.29 (pine) and 6.24 (forest) log cells g⁻¹ soil and Telêmaco Borba/PR 7.65 (pine) and 6.85 (forest) log cells g⁻¹ soil. Also, a positive correlation between soil pH and density of nitrite oxidizers was observed. Thus, there were differences in the density of nitrite oxidizers in pine compared to native forest, which could be inferring in different rates of nitrification in these soils.

E8w: CURRENT UNDERSTANDING AND FUTURE CHALLENGES FOR FOREST RESEARCH AFTER THE TWO NUCLEAR ACCIDENTS OF CHERNOBYL AND FUKUSHIMA

Movement of radiocesium as litterfall in deciduous broad leaved forests with special reference to litter origin compost production

Tatsuhiko Ohkubo¹, Mineaki Aizawa¹, Kazuya Iizuka¹

¹Utsunomiya University, Utsunomiya, Japan (ohkubo@cc.utsunomiya-u.ac.jp; aizawam@cc.utsunomiya-u.ac.jp; kiizuka@cc.utsunomiya-u.ac.jp)

Litterfall is important agent in the process of radiocesium (RCs) movement from tree canopy to forest floor in forest ecosystems, and for litter origin compost production, however, the information on the relationships between them is limited. We clarified the process of radiocesium movement in Konara oak (*Quercus serrata*) coppice forest after the Fukushima Dai-ichi Nuclear Power Plant (FDNPP) accident for seven years in three studied sites with different RCs deposition level, and also predicted the time of resume of leaf litter collection for leaf litter origin compost production. RCs concentration of foliar litter is getting lower according to the level of RCs initial deposition, and also lower than that of A0 layer in three sites. The level of RCs deposition to the canopy depends on that of initial deposition, and also the initial deposition before flushing in March 2011 cause the difference of RCs concentration between foliar litter and A0 layer. Seasonal concentration of RCs in living leaf and branches in the canopy in 2015 showed the highest value in April and May, and the values are getting a decrease in living leaves and a increase in living branches in defoliation period. This suggested the transfer of RCs from flushing to defoliation is limited within the part of the branch. RCs concentration of A0 layer on the forest floor is fitted by negative exponential decay curve, and the availability of foliar litter for litter origin compost production after the FDNPP accident is predicted by the level of initial RCs deposition.

Effect of NH_4^+ and NO_3^- , i.e. nitrification, on uptake of radioactive Cs in Japanese cedar

Hitoshi Sekimoto¹, Keiko Sekiguchi¹, Yuri Shinohara¹, Kei Hirata¹, Kazuya Ilzuka¹

¹Utsunomiya Univ., Utsunomiya, Japan (hitoshis@cc.utsunomiya-u.ac.jp; sekiguchi.keiko.0511@gmail.com; friend-61m.beckoning-cat@yahoo.ne.jp; hiratak@cc.utsunomiya-u.ac.jp; kiizuka@cc.utsunomiya-u.ac.jp)

It is well known that the uptake of ^{137}Cs in plants is suppressed by K, the homologous element, which is the same monovalent cation as Cs. It is expected that NH_4^+ , the same monovalent cation, will also affect the uptake of ^{137}Cs in plants. Therefore, the influence of NH_4^+ and NO_3^- on ^{137}Cs uptake in Japanese cedar seedlings was compared. Humus containing ^{137}Cs was mixed with a granular volcanic ash soil, and Japanese cedar seedlings were planted and cultivated while giving 0.7 mmol / L of NH_4^+ and NO_3^- solution once a week for 20 weeks, and analyzed ^{137}Cs of Japanese cedar seedlings; ^{137}Cs of NH_4^+ seedlings was obviously lower than that of NO_3^- . Also, in the RI experiment of water culture, the uptake of ^{137}Cs was suppressed as the NH_4^+ ratio increased. It was found that NH_4^+ suppresses uptake of ^{137}Cs similarly to K, however the effect of NH_4^+ will decay with progress of nitrification from NH_4^+ to NO_3^- .

Role of arbuscular mycorrhiza in uptake of radiocesium by *Chengioplanax sciadophylloides*

Chisato Takenaka¹, Akihisa Fukushi¹, Yosuke Matsuda²

¹Nagoya University, Nagoya, Japan; ²Mie University, Tsu, Japan (chisato@agr.nagoya-u.ac.jp; pantera.meshuggah.terror2000@gmail.com; m-yosuke@bio.mie-u.ac.jp)

The accident of Fukushima Daiichi Nuclear Power Plant in 2011 caused a serious radionuclide contamination problem in Japan. Cesium-137 (radiocesium) has been the most concerned radionuclide due to its deposited amount and long half-life. Especially, the contamination in forest area has been an unsolved problem. Phytoremediation, through which radiocesium is accumulated in the specific plant and removed from the contaminated area, might be a useful decontamination method. *Chengioplanax sciadophylloides* is a hopeful candidate tree plant for phytoremediation of radiocesium. It has been known that this tree plant has arbuscular mycorrhiza (AM) in roots. Therefore, the purpose of this study is to clarify the role of AM fungi in uptake of radiocesium. Pot experiment was conducted using seedlings of *C. sciadophylloides* collected from the uncontaminated forest area in Aichi prefecture. Double structure pot, in which a small pot with nylon mesh (50 mm) in bottom filled with uncontaminated soil was put in a large pot filled with contaminated soil, was used. In order to understand the effect of K, three kinds of treatment with and without K application were performed. After 22 months growth in a greenhouse, radiocesium concentration in the seedlings and soils were analyzed. As a result, we confirmed that radiocesium concentrations in seedlings significantly increased, indicating that AM fungi contribute to the uptake of radiocesium by *C. sciadophylloides*. In addition, the application of K into the rhizosphere increased the uptake of radiocesium, as the contrary to the usual knowledge that K application depresses the radiocesium uptake by plants.

Suppression of cesium uptake in Konara oak using potassium: for a revival of mushroom production in Fukushima

Riona Kobayashi¹, Natsuko Kobayashi¹, Masaya Masumori¹, Keitaro Tanoi¹, Takeshi Tange¹, Kensuke Fukuda², Satoru Miura³

¹The University of Tokyo, Tokyo, Japan; ²Ibaraki Prefectural Forestry Research Institute, Ibaraki, Japan; ³Forestry and Forest Products Research Institute, Ibaraki, Japan (rkoba@fr.a.u-tokyo.ac.jp; anikoba@g.ecc.u-tokyo.ac.jp; masumori@fr.a.u-tokyo.ac.jp;uktanoi@g.ecc.u-tokyo.ac.jp; tange@fr.a.u-tokyo.ac.jp; ke.fukuda@pref.ibaraki.lg.jp; miura@ffpri.affrc.go.jp)

Radiocesium contamination of forests has been a severe problem after the Fukushima Daiichi Nuclear Power Plant accident in 2011. Bed logs of Konara oak (*Quercus serrata*), used for mushroom cultivation, were an economically important product from the forests prior to their contamination, and it is necessary to reduce radiocesium concentration in oak for a revival of the log production. We cultivated Konara oak seedlings through hydroponics with various rhizospheric potassium concentrations and investigated an effect of potassium to suppress cesium uptake in the seedlings. Cesium contents in seedlings under potassium-sufficient condition were $\frac{1}{2}$ to $\frac{1}{12}$ those in seedlings under potassium-deficient condition. This result suggests potassium suppressed cesium uptake in the seedlings, though an additional experiment focusing on potassium transporters implied differences of suppression mechanisms between Konara oak and other plants previously reported. We also investigated the effect of potassium through a pot experiment and an analysis of natural-growing seedlings. In the pot experiment, we cultivated seedlings in soils with different contents of exchangeable potassium by adding potassium fertilizer. Cesium contents in the seedlings were lower in fertilized soils than in non-fertilized soil, showing the suppression effect of exchangeable potassium on cesium uptake. On the other hand, results of the analysis of the natural-growing seedlings and soils collected at 106 sites showed no general relationship between exchangeable potassium contents in the soils and cesium contents in the seedlings. Mineral composition and organic matter of the soil may influence the effectiveness of potassium on cesium uptake suppression.

Differences in radiocesium concentrations among crown positions in several tree species in Fukushima, Japan

Tanaka Kenzo¹, Satoshi Saito², Takuya Kajimoto³

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Kansai Research Center, Forestry and Forest Products Research Institute, Kyoto, Japan; ³Tohoku Research Center, Forestry and Forest Products Research Institute, Morioka, Japan (mona@affrc.go.jp; stetsu@affrc.go.jp; tkaji@ffpri.affrc.go.jp)

To evaluate distribution in radiocesium among crown positions after accident of Fukushima Dai-ichi Nuclear Power Plant, we collected leaf and branch from upper to lower crown position in four tree species (*Chamaecyparis obtusa* (Co), *Cryptomeria japonica* (Cj), *Pinus densiflora* (Pd), *Quercus serrata* (Qs)) in 2014, 2015 and 2016 in Fukushima, Japan. We divided those samples into current-year and more than one-year-old (expressed as old leaf and old branch), which sometimes include direct contamination part. Radiocesium (^{137}Cs) concentration was measured for ground samples of leaf and branch by using a germanium semiconductor detector. There were complex differences in ^{137}Cs concentration among species and organ types such as current leaf and old branch between crown positions. In the case of 2016 samples, ^{137}Cs concentration in old branches in Pd and Qs tended to be higher in the lower crown position, but not significant difference was found in current branches and leaves among crown positions. The concentration in branches of Cj were higher in the lower and middle crown positions, but the differences in current leaf concentration were unclear; ^{137}Cs concentration in current leaves in Co were higher in upper crown position, while the concentration in branch and old leaves were lower in the position. Although factors on those differences on interspecific and crown position are unclear, there is a possibility that presence or absence on direct contamination by the accident, and interspecies traits in ^{137}Cs translocation and/or absorption from soil may cause the differences.

Seasonal changes in radiocesium and potassium concentrations in current year shoots in three tree saplings in Fukushima, Japan

Tanaka Kenzo¹, Satoshi Saito², Satoru Miura¹, Takuya Kajimoto³, Natsuko I. Kobayashi⁴, Keitaro Tanoi⁴

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Kansai Research Center, Forestry and Forest Products Research Institute, Kyoto, Japan;

³Tohoku Research Center, Forestry and Forest Products Research Institute, Morioka, Japan; ⁴The University of Tokyo, Tokyo, Japan (mona@affrc.go.jp; stetsu@affrc.go.jp; miura@ffpri.affrc.go.jp; tkaji@ffpri.affrc.go.jp; anikoba@g.ecc.u-tokyo.ac.jp; uktanoi@g.ecc.u-tokyo.ac.jp)

We studied the seasonal change in radiocesium (¹³⁷Cs) and potassium (K) concentrations in current leaves and branches in *Pinus densiflora* (naturally regenerated saplings), *Cryptomeria japonica* (planted saplings) and *Quercus serrata* (planted and sprouted saplings) in Tamura, Fukushima, Japan. Current year shoots were collected from June 2016 to December 2017 at intervals of one to four months. For deciduous species of *Q. serrata*, we also collected dead leaves that still attached on branches in December. All collected shoots were divided into leaves and branches and the samples were grounded. The concentration of ¹³⁷Cs was measured by a germanium semiconductor detector. K concentration was quantified by ICP-AES method. Regardless of tree species, there were seasonal changes in ¹³⁷Cs concentration, and those concentrations were higher in young leaves and branches at May or June, while the concentrations decreased thereafter and the change was relatively small from August to winter. Decreasing of ¹³⁷Cs concentration in dead leaves in *Q. serrata* also observed in several individuals in December. This reduction may indicate reabsorption of ¹³⁷Cs in leaves before shedding. K concentration was also higher in the younger leaves compared with the mature leaves. A positive relation between ¹³⁷Cs and K concentration in leaves was observed in *P. densiflora*, *C. japonica*, and sprouted *Q. serrata*. From these results, ¹³⁷Cs was thought to be high at relatively younger organs with higher K concentration in those three species.

Potassium content in the wood and bark of 38 tree species

Hisashi Abe¹, Yooko Tsuchiya², Akira Kagawa¹

¹FFPRI, Tsukuba, Japan; ²CRIEPI, Abiko, Japan (abeq@affrc.go.jp; yooko@criepi.denken.or.jp; akagawa@ffpri.affrc.go.jp)

After the Fukushima Daiichi Nuclear Power Plant accident, fallen radionuclides, especially radiocesium, have contaminated a vast area of Japanese forest. Potassium, which is an essential nutrient for plants, is believed to influence the behavior of radiocesium in the plant body. To understand the behavior of radiocesium in tree trunks, potassium contents in the wood and bark were measured for 27 native Japanese species (12 softwood and 17 hardwood), and 9 foreign species frequently used in Japan, by means of inductively coupled plasma emission mass spectrometry. The potassium content showed a wide range of values, from 70 to 20,000mg/kg, and very different values in each sample. For most of the species, the potassium content was higher in the bark than in the wood, except for the cases of *Chamaecyparis obtusa*, *Picea jezoensis*, and *P. jezoensis* var. *hondoensis*. In a *Ginkgo biloba* sample, the potassium content in the bark was 20,000 mg/kg, which was the highest value among all the samples. In the heartwood of the *Cinnamomum camphora* sample, the potassium content was 5,300 mg/kg, which was the highest value among all the wood samples. As for the wood, potassium contents were higher in the heartwood than in the sapwood, except for the cases of *Magnolia obovata*, *Pinus densiflora*, *Larix kaempferi*, *Cerasus sergentii*, and *Betula platyphylla* var. *japonica*. The potassium contents in the wood of tropical species belonging to the family Dipterocarpaceae (*Dipterocarpus*, *Dryobalanops*, and *Shorea*) were relatively lower than in other species.

Mobile radiocesium in felled logs of Sugi cedar

Masaya Masumori¹, Tetsuro Sakai¹, Takeshi Tange¹, Norio Nogawa¹

¹The University of Tokyo, Tokyo, Japan (masumori@fr.a.u-tokyo.ac.jp; t.sakai@fr.a.u-tokyo.ac.jp; tange@fr.a.u-tokyo.ac.jp; nogawa@ric.u-tokyo.ac.jp)

The accident of Fukushima Dai-ichi Nuclear Power Plant polluted vast areas of forest including plantations of Sugi cedar (*Cryptomeria japonica*), a major evergreen timber tree in Japan. The persistent radioactivity by radiocesium taken into the wood still impedes the resumption of timber production, local economy and consequently the restoration of local community of the affected area in wooded western Fukushima, Japan. Distributions of radiocesium within trunk of Sugi cedar were analyzed by radiographic imaging with storage phosphor screens. The most of radiocesium was found in the surface of bark even 6 years or more after the deposition, while some radiocesium was also detected in xylem, particularly in heartwood. When the cut log was dried by exposing to the air or experimentally using a drying oven, the radiocesium content in the cut end of log became much higher. If the cut end was sealed up with silicone caulk or plastic wrap, the radiocesium accumulated at another surface where was exposed to the air. These results mean that some portion of the radiocesium in xylem is soluble in water and can move along with apoplastic water movement during the wood drying after felling.

Aerologically reconstruction of spatial variation in global radiocesium fallout across Japan

Eriko Ito¹, Satoru Miura², Michio Aoyama³, Koji Shichi⁴

¹FFPRI, Sapporo, Japan; ²FFPRI, Tsukuba, Japan; ³University of Tsukuba, Tsukuba, Japan; ⁴FFPRI, Kochi, Japan (iter@affrc.go.jp; miura@ffpri.affrc.go.jp; michio.aoyama@ied.tsukuba.ac.jp; shichi@ffpri.affrc.go.jp)

Radioactive contaminations in forests were caused by ¹³⁷Cs discharged from the Fukushima Dai-ichi Nuclear Power Plant (FDNPP) accident. To provide scientific guidance on long-term forest management, insights on how ¹³⁷Cs will be redistributed across few decades are needed. Although it is often the case that ¹³⁷Cs would remain on forest surface soil for decades, it is unclear whether this holds true also in Japan, where topography is usually steep and precipitation is high. Nuclear weapon tests in the 1950s and 1960s have discharged global fallout ¹³⁷Cs (¹³⁷Cs-GFO). It has previously been reported that ¹³⁷Cs-GFO has remarkably high variation in spatial distribution across Japan, with high accumulation in the north-western area along the Sea of Japan. More recently, similar spatial patterns were found in ¹³⁷Cs-GFO inventories of forest soil (0-30 cm in depth), which were collected across Japan right before the FDNPP accident. One of the most clear differences between Japan and other countries is that this spatial variation in ¹³⁷Cs-GFO cannot be explained by spatial variation in the amount of precipitation. This inconsistency between ¹³⁷Cs-GFO and precipitation peculiar to Japan was likely related to the spatial and seasonal differences in ¹³⁷Cs-GFO concentration in the waterfall. To answer how much ¹³⁷Cs-GFO still remain in forest surface soil, this study aimed to re-construct the spatial distribution of initial ¹³⁷Cs-GFO based on polynomial calculation $p(x)$ of an element p as monthly precipitation using an argument x of atmospheric turbulence indexed by multiple tropopause structure.

Vertical distributions of ¹³⁷Cs in Japanese forest soils post Fukushima Dai-ichi Nuclear Power Plant accident: a meta-analysis

Naohiro Imamura¹, Masabumi Komatsu¹, Shoji Hashimoto^{1,2}, Hiroaki Kato³, Kazuya Nishina⁴, Kazumichi Fujii¹

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²The University of Tokyo, Bunkyo, Japan; ³University of Tsukuba, Tsukuba, Japan;

⁴National Institute for Environmental Studies, Tsukuba, Japan (nimamura@ffpri.affrc.go.jp; kopine@ffpri.affrc.go.jp; shojih@ffpri.affrc.go.jp; kato.hiroaki.ka@u.tsukuba.ac.jp; nishina.kazuya@nies.go.jp; fkazumichi@affrc.go.jp)

After the Fukushima Dai-ichi Nuclear Power Plant (FDNPP) accident, there has been a translocation of radiocesium at the litter and mineral soil layers over time. Parameterizing the vertical distribution of radiocesium within the soil compartment is useful for predicting its fate and estimating the ambient dose rate in the forests. We collected 99 radiocesium inventory data at the litter and mineral soil layers from six journal papers published after the FDNPP accident. The fraction related in the litter (F-lit: the ratio between litter and litter + mineral soil inventories), the half depth (X : the soil depth above which 50% of the total activity is present), and the relaxation depth (α : the necessary distance at which surface depth decreases to $1/e \approx 1/2.7$) were calculated using these data as the parameters of vertical distribution of radiocesium at the litter and mineral soil layers. A decrease in F-lit over time was observed, indicating that radiocesium moved from the litter layer to the mineral soil layer after the FDNPP accident. In contrast, the half depth and relaxation depth did not show changes. This finding supports the retention of radiocesium in the surface mineral soil layers.

Vertical radiocesium transfer process in soil via roots

Wataru Sakashita¹, Satoru Miura¹, Akio Akama¹, Shinta Ohashi¹, Shigeto Ikeda¹, Tomoyuki Saitoh², Masabumi Komatsu¹, Yoshiki Shinomiya¹, Shinji Kaneko³
¹Forestry and Forest Products Research Institute, Tsukuba, Ibaraki, Japan; ²Tohoku Research Center, Forestry and Forest Products Research Institute, Morioka, Iwate, Japan; ³Kansai Research Center, Forestry and Forest Products Research Institute, Fushimi, Kyoto, Japan (sakashita@affrc.go.jp; miura@ffpri.affrc.go.jp; akama@affrc.go.jp; shinta0084@ffpri.affrc.go.jp; ikedas@ffpri.affrc.go.jp; tsaitoh@ffpri.affrc.go.jp; kopine@ffpri.affrc.go.jp; shinomiya@affrc.go.jp; kanekos@ffpri.affrc.go.jp)

Radiocesium (¹³⁷Cs and ¹³⁴Cs) dynamics has been investigated in Japanese forests after the Fukushima Dai-ichi nuclear power plant (FDNPP) accident, but there are few reports about radiocesium transfer process in soil via roots. In this study, we report radiocesium concentrations of root and soil in Japanese cedar plantations, which obtained from four soil layers (0-5, 5-10, 10-15 and 15-20 cm) in two sites (Mitsuishi and Kanayama, Kawauchi Village, Fukushima Prefecture, Japan) in August, 2013. Comparisons between root and soil in Mitsuishi (26 km from FDNPP) showed that radiocesium concentrations of root at 15-20 cm layer were three times higher than those of soil, whereas root radiocesium concentrations at 0-5 cm layer were clearly lower than those of soil. Similar trends were also found in Kanayama site (28 km from FDNPP), and the difference between root and soil at 15-20 cm layer was larger than Mitsuishi site. Considering the turnover of roots in Japanese cedar forests, radiocesium transport following root dynamics (e.g., downward elongation and mortality) may play an important role in vertical migration of radiocesium in the soil.

Discharge of suspended sediments and radiocesium before and after thinning

Yoshiki Shinomiya¹, Masahiro Kobayashi¹, Tatsuya Tsurita¹, Yoshio Tsuboyama¹, Shinji Sawano¹, Yuko Itoh¹, Yasuhiro Ohnuki², Koji Shichi³
¹FFPRI, Tsukuba, Japan; ²FFPRI, Tohoku, Morioka, Japan; ³FFPRI, Shikoku, Kochi, Japan (shinomiya@affrc.go.jp; kmasa@affrc.go.jp; tatuya@affrc.go.jp; tsubo@affrc.go.jp; ssawano@affrc.go.jp; yuko106@affrc.go.jp; bhankan@affrc.go.jp; shichi@affrc.go.jp)

After the accident of the Fukushima Daiichi Nuclear Power Station (FDNPS) accident in March 2011, radiocesium was deposited in forests in East Japan. Understanding the relationship between forest operations and radiocesium dynamics is important to promote the resumption of forestry in Fukushima. In this work, the discharge of suspended sediments (SS) and radiocesium before and after line thinning in a forested watershed (located about 120 km southwest of the FDNPS) was investigated. Line thinning was conducted at a thinning rate of 35% across 17% of the watershed area in 2012 and at same rate for the rest of the watershed in 2013. Spur roads were constructed along all streams. The concentration of SS was decreasing with passing of time. High Cs-137 concentrations of SS were not observed during or after thinning. When the sampling period included heavy rainfall (>100 mm total rainfall), Cs-137 concentration of SS became low. SS concentration and SS load increased immediately after thinning. Although SS increased, it tended to decrease within a few years because bared areas were covered with litterfall and vegetation regrowth. From these results, SS load increased immediately after thinning but Cs-137 exports from the forested watershed did not increase sharply. This is caused by the suppressing of Cs-137 exports (e.g., declines in the Cs-137 concentration of SS in heavy rainfall, reductions in bared areas).

E8x: FOREST ENVIRONMENT

Effect of impounding of the Three Gorges Reservoir on seven kinds of soil metals contents in its abandoned farmland of hydro-fluctuation belt, China

Ruimei Cheng¹

¹Institute of Forest Ecology, Environment and Protection, Chieses Academy of Forestry, Beijing, China (chengrm9533@sina.com)

In order to provide a theoretical reference for soil ecological restoration in the Three Gorges Reservoir area, China, the impact of water level fluctuating on metals contents were explored, and typical abandoned farmland in hydro-fluctuation belt was selected in this study area. Then the contents distribution characteristics of heavy metals (Cu, Fe, Zn, Mn) and alkaline metal (Ca, Mg, Na) in different altitudes (145-155, 155-165, and 165-175 m) and soil layers (0-5, 5-10, and 10-20 cm) of the abandoned farmland were examined in 2009 and 2013. The results showed that the contents of 4 heavy metals were highest at 10-20 cm soil layer at 145-165 m in 2009, while those at 0-5 cm layer were highest in 2013, while contents of Ca were the highest at 10-20 cm soil layer both in 2009 and 2013. Compared with 2009, the contents of Cu, Fe, Zn and Mn (0.065, 59.37, 0.068 and 0.069 g·kg⁻¹) were increased by 50.75%, 18.84%, 27.46% and 27.44% respectively at 165-175 m in 2013. Meanwhile, water level fluctuating resulted in more Ca and Mn contents while less Na content. So, water level fluctuating can lead to distribution characteristics difference of soil metal contents in different year, but also result in accumulation of Cu, Fe, Zn, Mn, Ca and Mg contents and lost of Na content.

An experimental class on water-holding capacity in forestry using a handmade sprinkling instrument by vocational high school students

Takashi Higashihara¹, Koichiro Kuraji², Mariko Inoue³, Tadashi Ohtani⁴, Yuji Araki⁵, Yuji Ikami⁶, Eiji Watanabe⁷

¹Joetsu University of Education, Joetsu, Japan; ²The University of Tokyo, Tokyo, Japan; ³Forestry and Forest Products Research Institute, Hachioji, Japan; ⁴Tokyo Gakugei University, Koganei, Japan; ⁵Saitama University, Saitama, Japan; ⁶Forestry and Forest Products Research Institute, Tsukuba, Japan; ⁷Kimitsuaoba high school, Kimitsu, Japan (htakashi@juen.ac.jp; kuraji_koichiro@uf.a.u-tokyo.ac.jp; imariko@ffpri.affrc.go.jp; t-ohtani@u-gakugei.ac.jp; arakiy@mail.saitama-u.ac.jp; ikami@ffpri.affrc.go.jp; e.wtnb16@chiba-c.ed.jp)

This study reports on an experimental class on water holding capacity in forestry, involving the use of a handmade and low-cost sprinkling instrument by vocational high school students to detect Hortonian overland flow, as proposed by Tanaka and Kuraji (2016). The low-cost sprinkling instrument consists of three plastic garden stakes, an iron flower-pot holder, a two-liter plastic bottle with a hole in the bottom, and a shower nozzle attached to the plastic bottle-goods can be bought at “100-yen shops” (a dollar store). Using the proposed instrument, students examined thrice whether Hortonian overland flow occurred at the forest plantations at school. These experimental classes were conducted in 2017 and 2018 in Kimitsu City, Japan. No flow or a few flows were observed during the first experiment. A leaf lodged against the shower nozzle restricted the water flow at the time of the second experiment; as a result, the drop of water was big, and Hortonian flow was observed in the ground. No leaves affected the water flow from the shower nozzle in the third experiment; as a result, the drop of water was small, and the flow was low in the ground. Thus, the students could consider the relationship between water-holding capacity and rainfall in a forest plantation.

Conductividad hidráulica bajo bosques, una clave para el manejo hídrico de cuencas

Carlos Francisco García Olmos¹

¹Universidad Distrital Francisco José de Caldas, Bogotá D.C., Colombia (cfgarciao@gmail.com)

La conductividad hidráulica bajo el suelo de los bosques se relaciona con los flujos sub superficiales. Se buscó conocer estos comportamientos y sus diferencias, con enfoque al manejo hídrico de cuencas. Se caracterizaron áreas experimentales en bosques de *Cupressus lusitanica*, *Eucalyptus globulus* y bosque natural en la cuenca del río San Cristóbal, Bogotá, y se realizaron ensayos de pozo barrenado invertido. Se determinaron las curvas características de la velocidad de infiltración y según ellas se obtuvieron las curvas de conductividad hidráulica. Se verificó que no se presentaron diferencias significativas en la conductividad hidráulica saturada. Se desprende de esta investigación que los sistemas radiculares sub superficiales de las especies del sotobosque pueden llegar a disminuir la conductividad hidráulica en el sub suelo por el efecto del atrapamiento de aire que impide la saturación total de los poros del suelo, hecho que podría influir sobre el flujo de las aguas subterráneas y los procesos de erosión entre otros.

Linking deep soil water reliance to plant distribution and resource economy strategy among coexisting woody shrub species in a subtropical ecosystem

Peipei Jiang¹, Xiaoli Fu¹, Huimin Wang¹

¹Institute of Geographic Sciences and Natural Resources Research Chinese Academy of Sciences, Beijing, China (peipei769049728@126.com; fixl@igsnr.ac.cn; wanghm@igsnr.ac.cn)

Strategy of deep soil water acquisition is critical to plant's adaption to drought stress. However, it is unknown how the deep soil water acquisition determines species' distribution and resource economy strategy in an experimental context. With data from 13 woody shrub species of subtropical coniferous forests, we investigated the associations of deep water acquisition patterns (ability of deep water use and plasticity of deep water use between season), plant hydraulic traits (leaf water potential, water use efficiency), species distribution (relative occurrence frequency and importance), and economic traits across organs (first-order root diameter of shallow soil, wood density, specific leaf area, and leaf nitrogen concentration). Higher ability of deep resource utility acted synergistically with higher intrinsic water use efficiency to promote plants' adaption to seasonal drought, but was not a necessary trait possessed by the common species. Species with higher plasticity of deep water use (rather than higher ability of deep water use) had lower wood density, but not smaller first-order root diameter, indicating species being fast in deep soil resource acquisition not necessarily being fast in shallow fine root resource acquisition. Our result provide new insight in the mechanisms through which deep soil resource acquisition trait interacted with shallow soil and aboveground resource acquisition traits to integrate the whole-plant economic spectrum and thus community assembly process.

Contrasting root foraging strategies of native and exotic pine forests under an increased diversity of understory species

Han Yan¹, Liang Kou¹, Huimin Wang¹

¹Qianyanzhou Ecological Research Station, Key Laboratory of Ecosystem Network Observation and Modeling, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, China (419501806@qq.com; koul@igsnr.ac.cn; wanghm@igsnr.ac.cn)

Studies on the aboveground growth and traits of plants suggest that plants exhibit faster growth, with greater plasticity in leaf traits, to adapt to changing environments. However, our knowledge of belowground growth and trait responses, and associated root foraging strategies, under competition remains limited. Using an understory species-addition experiment, we investigated the responses of function-based root (absorptive fine roots [AFRs] vs. transport fine roots [TFRs]) growth, mycorrhizal association, and order-based root traits (morphological, architectural, and chemical traits) of *Pinus massoniana* (native species) and *Pinus elliottii* (exotic species), which are the dominant coniferous tree species in subtropical China. Higher understory-species diversity increased the biomass of AFRs, but not TFRs and total fine roots of both species. Higher diversity increased the biomass ratio of the AFRs and TFRs of *P. elliottii*, indicating a tradeoff in plant carbon investment between the two functional root modules for *P. elliottii*. Increased species diversity decreased the ectomycorrhizal colonization rate of *P. massoniana*, but increased that of *P. elliottii*. Increased species diversity altered the branching-related traits (increased branching ratio and intensity), but did not affect the morphological or chemical traits across the root orders of either species. Our findings indicate that *P. elliottii* employed dual root foraging strategies (growth and mycorrhizal strategies) and had a cost-benefit tradeoff between AFR and TFR construction. In comparison, *P. massoniana* only accelerated root growth under competition. These results facilitate a better understanding of the root foraging strategies of plants and the rapid adaptation of exotic species in novel environments.

Competition and coordination between understory vegetation and canopy trees in subtropical plantations

Huimin Wang¹, Xiaoli Fu¹, Xiaoqin Dai¹, Liang Kou¹

¹Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, China (wanghm@igsnr.ac.cn; fuxl@igsnr.ac.cn; daixq@igsnr.ac.cn; koul@igsnr.ac.cn)

Understory vegetation removal is an important management practice for plantations in China. However, the limitation of this management practice is still under debate. We conducted a series of field investigations and site experiments in subtropical plantations of China to study the interspecific interactions between understory and trees to explore suitable understory management practice. We found that understory plants exploited the advantage of occupying topsoil by filling the readily occupied soil macropores and being less affected by nearby stems. Understory plants may also increase their efficiency of topsoil-resource uptake by allocating a greater proportion of their absorptive roots to transport roots than trees in the topsoil. Because of the intensive competition for topsoil-resource between trees and understory plants, a substantial portion of the increase of the aboveground biomass of the understory was at the expense of the tree aboveground biomass. On the other hand, however, understory vegetation also had important ecological functions, e.g. increasing soil organic carbon content, alleviating soil acidification, and enhancing the functional traits of soil microbial communities. Therefore, a rational understory density around 113 g m⁻² for plantations in subtropical China was suggested based on our case study. Moreover, we found that the aboveground biomass of understory was more important than understory diversity in improving the ecological functions of plantations. Therefore, we advocated for optimizing the community structure of the understory vegetation based on the niche complementarity theory and controlling the understory density in subtropical plantations in China.

Changes in the floating meadows of Keibul Lamjao National Park, India and their implications for the conservation of globally threatened Eld's deer

Syed Ainul Hussain¹, Chongpi Tuboi¹, Ruchi Badola¹

¹Wildlife Institute of India, Dehradun, India (hussain@wii.gov.in; chongpituboi@gmail.com; ruchi@wii.gov.in)

Keibul Lamjao National Park, India is the last remaining home of the endangered Eld's deer or Sangai (*Rucervus eldii*). The characteristic feature of the park, the floating meadows locally known as *phumdis*, are important for the conservation of the Sangai. The thickness of the meadows is changing due to change in water regime and anthropogenic pressures. To understand these changes, the park was divided into northern and southern zones. Transects (N=138) of 500 m were laid and meadow thickness was measured at 50 m intervals at 1659 points during 2005–2010. The mean thickness in the northern and southern zone ranged between 91.75 ± 12.43 cm and 129.73 ± 17.2 cm, and between 87.58 ± 13.65 cm and 171.48 ± 26.55 cm, respectively. The overall thickness declined by factors of 0.01958 and 0.019/annum during 2005–2007 and 2008–2010 respectively. There was a decline by a factor of 0.1305/ annum during 2005–2007 in the north zone, but a slight increase by a factor of 0.0352/ annum during 2008–2010. The southern zone had declines by factors of 0.2516 and 0.0736/ annum during 2005–2007 and 2008–2010, respectively. Out of the total area of 22.3 km² where Sangai presence was observed, meadow thickness was >120 cm in 8.64 km², 60–120 cm in 7.32 km² and <60 cm in 6.33 km². Allowing a major portion of the floating meadows to settle during lean seasons by reducing the water level through a consultative process involving multiple stakeholders, could help reduce the rate of decline.

Effect of deforestation on stream water chemistry changes during rainfall events in small Carpathian catchments (Tatra Mts., Poland)

Joanna Siwek¹, Monika Sajdak¹, Mirosław Żelazny¹

¹Institute of Geography and Spatial Management, Jagiellonian University in Kraków, Kraków, Poland (joanna.siwek@uj.edu.pl; monika.sajdak@doctoral.uj.edu.pl; miroslaw.zelazny@uj.edu.pl)

The aim of the study was to recognize the role of deforestation on stream water chemistry changes during rainfall events in small catchments in the Tatra Mountains (Poland). Substantial damage in spruce and fir stands in the northern part of the Polish Tatra Mountains is result of hurricane-force winds that occurred on 25–26 December 2013. Since then, the decline of forests accelerated due to the bark beetles invasion and fungus expansion. Three small, adjacent catchments with a different degree of deforestation, 97.0, 66.1, and 19.9% were selected for the study. Fieldwork was conducted in 2017 and 2018. Stream water samples were collected during 24 rainfall events. Water level (discharge) and electrical conductivity (EC) of stream water were measured continuously in the field. Concentration of main ions and NO₃⁻ in stream water were analyzed in laboratory. In all streams, EC and the concentrations of Ca²⁺, Mg²⁺, Na⁺, HCO₃⁻, and SO₄²⁻ decreased with increasing discharge while the concentrations of K⁺ and NO₃⁻ increased with increasing discharge. In the forested catchment stream water Cl⁻ concentration decreased with increasing discharge while in the deforested catchments it increased with increasing discharge. Relationships between stream water chemistry and discharge took the form of a hysteresis. In the forested catchment, the concentration of Cl⁻, K⁺, and NO₃⁻ was higher during the falling limb than during the rising limb of hydrographs (counterclockwise hysteresis). In the deforested catchment higher concentrations of Cl⁻, K⁺, and NO₃⁻ were noted during the rising limb than during the falling limb (clockwise hysteresis).

E8y: FOREST POLICY AND ECONOMICS - IV

The effects of deforestation on the water balance of watershed using hydrological modeling (on the example of the Ukrainian and Slovak Carpathians)

Tomáš Hlásny¹, Martin Mareta¹, Zuzana Sitková¹, Taras Parpan², Dušan Kočický¹, Ivan Barka¹

¹Forest Research Institute, National Forest Centre, Zvolen, Slovakia; ²Ukrainian Research Institute for Mountain Forestry, Ivano-Frankivsk, Ukraine (hlasny@nlcsk.org; mareta@nlcsk.org; sitkova@nlcsk.org; tarasparpan@gmail.com; kocicky@nlcsk.org; barka@nlcsk.org)

The relationship between the forest cover and the degree of flood hazard in the Bodrog River basin on both sides of the Slovak-Ukrainian border was investigated. A hydrological modeling was carried out using the newly created hydrological model ISSOP using a theoretical example of large-scale deforestation. The results confirmed the importance of the forest cover influence on the hydrological regime in highly wooded watersheds of Eastern Slovakia and the Transcarpathian region of Ukraine. Continuous deforestation, that is, a theoretical replacement of forests occupying 4% of the basin with a grass cover can increase the total water flow by as much as 20.4%. This effect was particularly noticeable during the climax of water discharge, when the regulatory action of forests is particularly important. An assessment of the hydrological response of the catchment to simulated extreme precipitation showed that the forest significantly changes the parameters of the surface and flow path of the water and affects the time during which the simulated flood wave reached the final catchment. The research results are to some extent a response to the growing interest in multifunctional forest management due to their hydrological functions. They can be used for assessing flood potential, analyzing the causes of the current state and anti-flood measures, in integrated decision support systems, and can also contribute to conflicts of

interest in the provision of various ecosystem services by forest stands.

Multifunctional forests for revitalizing rural landscapes / Florestas multifuncionais para a revitalização da paisagem rural

Jozrael Henriques Rezende¹ , José Carlos Toledo Veniziani Junior¹, Brian Craig Campbell¹

¹Fatec Jahu, Jaú, Brazil (jozrael.rezende@fatec.sp.gov.br; jose.veniziani@fatec.sp.gov.br; briancampbell@outlook.com)

Este trabalho teve como objetivo identificar em Jaú/SP, cujo território é de 68.744,52 ha, áreas para a implementação de sistemas florestais multifuncionais. Por intermédio do QGIS e com as informações do Sistema de Cadastro Ambiental Rural do Estado de São Paulo, foram caracterizadas a declividade, a vegetação remanescente, as áreas de preservação permanente e a estrutura fundiária do município. O índice de vegetação remanescente encontrado foi de 4.354,26 ha (6,3%). A área potencial para florestas multifuncionais, sem considerar as áreas de preservação permanente, foi estimada em 4.823,24 ha, considerando o passivo de reserva legal e as áreas com declividades superiores a 12%, por serem inapropriadas a colheita mecanizada da cana-de-açúcar, matriz da paisagem na região permanente. O maior obstáculo para a recuperação da vegetação nesse contexto são os custos da restauração ecológica. É fundamental transformar estes custos em oportunidades, harmonizando conservação com produção. Nesse sentido, as florestas multifuncionais são uma alternativa promissora, pois elas permitem as atividades madeireira e não madeireira concomitantemente a prestação dos serviços ecossistêmicos. Estas florestas heterogêneas viabilizam a produção, conservam água e biodiversidade, possibilitam a regularização ambiental das propriedades e incrementam a geração de renda e a oferta de trabalho no âmbito regional por meio da diversificação das atividades rurais. O sucesso da implementação das florestas multifuncionais, entretanto, depende do planejamento sistêmico no âmbito da paisagem e da existência de conhecimento, modelos, métodos e assistência técnica que assegurem a viabilidade econômica e o uso sustentável dos recursos naturais, garantindo assim a reabilitação dos processos ecológicos.

Improving ecosystem services of fast-wood plantation landscapes in Brazil

Silvio Ferraz¹, Carolina Rodrigues², Carla Cassiano³, Lara Garcia⁴

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo Piracicaba, Brasil; ²Prática Sócioambiental, Piracicaba, Brasil;

³Universidade Federal do Mato Grosso, Cuiabá, Brasil; ⁴Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (silvio.ferraz@usp.br; cabreuva@gmail.com; carla_cassiano@hotmail.com; larajangada@gmail.com)

Fast-wood plantations in Brazil are increasing in last years reaching about 6 million of hectares in 2016, due to increasing demand for fiber and wood. Forest management plans are usually focused on keeping wood productivity, however, guided by crescent restrictions enforced by Brazilian government, environmental certification and society pressure, it seems to be necessary increasing their ecosystem services provision. Based on long-term stream monitoring data of several experimental catchments installed on forest plantation and native areas along Brazil and Uruguay, field data collection regarding biodiversity and pest damage, we tested effects of landscape composition and structure on ecosystem services related to provision (wood and water), support (terrestrial and aquatic biodiversity) and regulation (water, soils and pest control). Water use has been a major concern, and we propose a framework for water availability risk assessment based on aridity and seasonality indices. At local scale, it was considered the inherent risk offered by natural climatic constraints combined with local physical attributes, resulting into a natural resilience. Results show that natural condition could be enhanced by forest management in order to build resilience to forest plantation, increasing the provision of ecosystem services. Finally, we found evidences of forest management alternatives related to water provision and regulation, erosion control, insect damage control, and support avian biodiversity that could contribute to balance ecosystem services provision and productivity in forest plantation landscapes towards the Sustainable Development Goals.

Forestry and the carbon-water policy nexus

Gregory Valatin, Thomas Nisbet, James Morison

¹Forest Research, Farnham, United Kingdom (gregory.valatin@forestresearch.gov.uk; tom.nisbet@forestry.gov.uk; james.morison@forestry.gov.uk)

Forestry is widely recognised as having an important role to play in helping reach goals of both climate change mitigation and water protection, whether through carbon sequestration and storage, enhancing the hydrological cycle, water quality improvement, or reducing flood risk. The available evidence also points to forestry measures offering cost-effective options to help address associated policy goals. However, the multiple (e.g. carbon- and water-related) benefits that forests provide are often not accounted for in decision making, limiting forestry's role. Programmes at Forest Research cover a spectrum of research on carbon and water policy-relevant issues, including on the cost-effectiveness of UK woodland creation for climate change mitigation and water protection, carbon savings associated with harvested wood products and incorporating forest flood regulating services in natural capital accounts. Ongoing work within the PESFOR-W EU COST Action on developing a common approach to estimating the cost-effectiveness of woodland measures for reducing diffuse pollution is considering how to take wider benefits into account, and also potential for linking incentive (payment for ecosystem services) schemes for carbon- and water-related benefits more closely. An overview of work on these topics is provided, noting a number of existing evidence gaps and research opportunities, and highlighting ways to better capture forestry's potential in pursuing the goals of the carbon-water policy nexus.

The afforestation in Bulgaria: practice and research

Alexander Alexandrov¹, Ivan Iliev², Zdravko Bakalov¹

¹Forest Research Institute, Sofia, Bulgaria; ²University of Forestry, Sofia, Bulgaria (alexandrov_38@abv.bg; ivilievltu@yahoo.com; zdravko_bakalov@abv.bg)

The civilizations of Roman, Byzantine and Ottoman empires caused degradation and fragmentation of the Mediterranean and the Balkan forests. The forest territories of Bulgaria are 3,877,626 ha (woodiness - 34.4%), including primary forests - 15.9%, naturally regenerated forests - 62.2% and planted forests - 21.9%. The share of afforestation in Bulgaria is the highest compared with the other Southeast European countries (at average for the region 8.5%) while it is 9% for Europe. Three periods of afforestation activities are distinguished in this country: First - from 1878 (the Liberation) to 1944, second - from 1945 to 1989, third - since 1990. The afforestation types applied in Bulgaria are as follows: on torrential lands and dam basins, on forests destroyed by fires, on lands degraded by industry, on unregenerate forests after felling, for field-protecting shelter belts, with exotic and forest-fruit tree species. Due to afforestation programs to a great extent the growing stock has increased from 220 million m³ (1944) to 400 million m³ (1989), to 680 million m³ (2017). The triple enlargement of wood biomass and corresponding sequestration of CO₂ are some other results of afforestation apart from environmental benefits. The afforestation methods used in Bulgaria are applicable in other countries at appropriate latitude and altitude.

Origins Brasil®: operation and environmental impacts of added value and transparency in producing and marketing socio-biodiversity

products from the Brazilian Amazon / Origens Brasil®: funcionamento e impactos socioambientais da agregação de valor e transparência na produção e comercialização de produtos da sociobiodiversidade da Amazônia brasileira

Por meio da identificação da origem, rastreabilidade e de relações comerciais éticas de produtos da sociobiodiversidade originários de áreas protegidas da Amazônia brasileira, o Origens Brasil® contribui para manter e valorizar o patrimônio e a diversidade socioambiental de territórios. Para avaliar os impactos do Origens Brasil® foi desenvolvido um sistema de monitoramento baseado em um conjunto de indicadores socioambientais. O objetivo deste trabalho é apresentar como funciona o Origens Brasil® e os principais resultados dos dois primeiros anos do seu sistema de monitoramento de impactos. Alguns indicadores são monitorados anual e outros bienalmente junto à três públicos diferentes: consumidores e interessados nos produtos; organizações não-governamentais envolvidas no Origens Brasil®; e produtores, jovens e lideranças das comunidades atendidas. Os dados produzidos são enviados automaticamente para a Plataforma do Origens Brasil® para análise e geração de saídas gráficas. No início de 2019, o Origens Brasil® envolve 33 produtos, 1279 produtores, 14 empresas e 39 organizações não-governamentais, cobrindo 36 áreas protegidas que totalizam 28 milhões de hectares e uma movimentação financeira de cerca de R\$1,5milhão. Foram avaliados 22 indicadores sobre 10 temas diferentes e que representam 8 impactos (diretos e indiretos) sobre as dimensões econômica, socioambiental e de governança. Os resultados são observados em um painel de indicadores e subsidiam debates e decisões sobre o funcionamento do Origens Brasil®, permitem identificar alertas de resultados indesejados e propor aprimoramentos, além de possibilitar às empresas, produtores, organizações envolvidas, consumidores e demais interessados conhecerem e comunicarem os impactos alcançados.

Sustainable development of South Korea from an environmental perspective

Sea Jin Kim, Mina Hong, Cholho Song, Woo-Kyun Lee

¹Korea University, Seoul, Republic of Korea (bluegulcy@gmail.com; alsdk920902@naver.com; cholhosong@gmail.com; leewk@korea.ac.kr)

We all aim that our countries develop sustainably and the Sustainable Development Goals (SDGs) set by the United Nations cover social, economic and environmental development issues, which is virtually every aspect of our lives. Environmental development is both affected by and affects social and economic developments and is critical to achieving sustainable development. South Korea is often cited as one of the best practice cases of environmental development, especially on forest restoration and rehabilitation, having gone through a quantum shift over the last half century. After the Korean War, the land has been devastated and the people had to start from scratch to rebuild the shattered post-war environment. This study introduces the environmental development of South Korea in which the development paradigm can be identified within 50 years after the Korea War despite some limitations. This study aims to analyse the Korean development with relevant indicators in a narrative structure. As a result, the environmental development of South Korea can be considered as a model. To translate the theory into practice, some of the Mid-Latitude countries are sorted out to estimate the phase of environmental development in the perspective of Korean case. The results show the comparison among the countries based on the model and indicate Mid-Latitude countries has room for sustainable development for a better future. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (No; 2018R1A2B6005682).

Considerations in constructing a national policy on ecosystem services / Considerações na construção de uma política nacional sobre serviços ecossistêmicos

Michele Benetti Leite¹, Pablo Martínez de Anguita^{2,3}

¹LandsCare, Santa Maria, Brasil; ²Universidad Rey Juan Carlos, Madrid, Spain; ³LandsCare, Madrid, Spain (micheleleite@gmail.com; pablo.martinezdeanguita@gmail.com)

Apesar do enorme potencial do Brasil em ofertar os serviços ecossistêmicos, ainda não possuímos uma política específica sobre a gestão destes na esfera nacional, mesmo com um número considerável de projetos em funcionamento no país e com alguns estados e municípios já possuindo legislação específica. Dado que o Estado é o responsável da tutela dos recursos, o estabelecimento desta, regulamentada por lei, parece auxiliar para que as promessas sejam cumpridas, independente da administração. Após analisar as principais leis, decretos e projetos de leis relacionados aos serviços ecossistêmicos, mudanças climáticas e REDD+ existentes no Brasil, e algumas leis de outros países, nossa pesquisa recopilou diversos aspectos, que, em nossa opinião, devem ser trabalhados para a construção de uma política nacional e dividimos em temas: Econômicos, Legais, Financeiros, Ecológicos e Sociais. O planejamento de tal futura política afronta grandes desafios como o de ser um mecanismo flexível, eficiente e não vulnerável à corrupção, alinhando diversos setores do governo. Para que sua construção seja bem representativa é fundamental o envolvimento dos diversos setores da sociedade organizada, como as empresas, os governos e organizações não governamentais. Em geral falta boa vontade dos entes públicos para concretizar esquemas de compensação para a preservação no Brasil. É imprescindível mais integração das iniciativas federais, estaduais e locais, públicas e privadas, pois numerosos programas, projetos e atividades são realizados em diferentes etapas e escalas, de maneira desconectada. A falta de regulação favorece aos contratos especulativos, que podem ser prejudiciais para o nosso patrimônio natural, especialmente das comunidades tradicionais.

E9a: FORESTS FOR WATER PAYMENTS FOR ECOSYSTEM SERVICES: EVIDENCE &

Assessing the environmental effectiveness, design and governance, and cost-effectiveness of Woodlands for Water Payments for Ecosystem Services schemes: activities, findings and ambitions of the PESFOR-W COST Action

Gregory Valatin¹, Thomas Nisbet¹, Zuzana Sarvasova², Lars Högbon³, Rik De Vreese⁴, Paula Gatto⁵, Yiyang Cao⁶

¹Forest Research, Farnham, United Kingdom; ²Department of Forest Policy, Economics and Forest Management, National Forest Centre - Forest Research Institute Zvolen, Zvolen, Slovakia; ³Forestry Research Institute of Sweden – Skogforsk, Uppsala, Sweden; ⁴independent researcher, Ghent, Belgium;

⁵Department TESAF – Land, Environment, Agriculture and Forestry, University of Padova, Padova, Italy; ⁶RSK ADAS, Herts, United Kingdom (gregory.valatin@forestresearch.gov.uk; tom.nisbet@forestry.gov.uk; sarvasova@nlcsk.org; lars.hogbon@skogforsk.se; rik.devreese+pesfor@gmail.com; paola.gatto@unipd.it; yiyang.cao@adas.co.uk)

The PESFOR-W EU COST Action (15206) is a network of researchers and practitioners from 40 countries interested in the effectiveness of woodland measures in reducing agricultural diffuse pollution to watercourses, and the design and governance and cost-effectiveness of woodlands for water payments for ecosystem services (PES) schemes. Diffuse pollution from agriculture is a significant pressure affecting over 40% of Europe's river and coastal water bodies. Accumulating evidence indicates that the EU Water Framework Directive's objective that each water body reaches "Good Ecological Status" by 2027 in many cases will only be achieved by targeted land use change. Small-scale forest planting ("Woodlands-for-water") is a potential solution to this problem. To help underpin future development of woodlands for water projects, PESFOR-W is creating 'look-up' tables on the effectiveness of woodland creation for reducing a number of key diffuse pollutants. An initial evidence review found that woodlands buffers reduce nitrate concentrations by over 70% on average in both oceanic and Continental climates, with the strength of effect strongly related to buffer width. PESFOR-W is developing a common protocol for assessing the cost-effectiveness of woodlands for water PES, creating a spatial repository of case studies, and will develop guidance on development of new schemes. It is exploring the potential for creating a Woodland Water Code along similar lines to the Woodland Carbon Code developed for the carbon benefits of woodland creation projects in the UK, and for linking with existing schemes covering other woodland benefits to help achieve wider goals of the carbon-water policy nexus.

Assessing of payments for forest ecosystem services: Slovak examples related to water

Martina Sterbova^{1,2}, Zuzana Sarvasova¹, Zuzana Dobsinska², Klara Balikova², Jaroslav Salka²

¹National Forest Centre Zvolen, 96092, Slovakia; ²Technical University in Zvolen, 96053, Slovakia (sterbova@nlcsk.org; sarvasova@nlcsk.org; dobsinska@tuzvo.sk; xbalikova@gmail.com; salka@tuzvo.sk)

The aim of the paper is to analyse main approaches and types of payments for forest ecosystem services (PFES) mechanisms or financial arrangements related to water with the emphasis on three basic schemes: (i) public or government-financed PFES, (ii) private or user-financed PFES, and (iii) public-private schemes. The main classification of PFES schemes was based on Wunder's (2005) 5 criteria. The empirical part was based on the review of PFES schemes implemented in different Forest Europe signatory countries. The personal interviews with actors presented as ES providers were used to describe the main features of PFES schemes on chosen examples from Slovakia. The results pointed out, that only a few "core" PES schemes are applied in Europe that usually have a mixed public-private character. In Slovakia three types of public PFES schemes were identified: 1) forest land tax relief for protective and special purposes forests, 2) refunds for the restriction of ownership rights and 3) Forestry Support for non-productive forest functions, which are public schemes. Private PFES scheme related to the provision of drinking water for local use has been identified so far. In this case the "Piggy-backing" principle is applied where a single service generated from the water managing authority (Military Forests and Estates of the Slovak Republic, that provides water management in accordance with area needs and environmental regulations) is sold to one specific buyer (local water management and supply company, that manages and maintains forest land and is responsible for land improvements and stream dikes).

Incorporating agroforestry into water quality trading: evaluating economic-environmental tradeoffs

Samuel Scott¹, Kelly Cobourn¹, John Munsell¹, Kurt Stephenson¹, Brian Strahm¹

¹Virginia Tech, Blacksburg, USA (samuels6@vt.edu; kellyc13@vt.edu; jfmunsell@vt.edu; kurts@vt.edu; bstrahm@vt.edu)

Water quality trading (WQT) holds promise as a flexible policy approach to reduce agricultural nutrient pollution by encouraging the adoption of best management practices (BMPs). WQT can theoretically achieve water quality improvements at least cost, but its ability to do so in practice depends on how tradable credits are awarded. Ideally, crediting should reflect heterogeneity in water quality improvements under alternative management practices. However, because it is challenging to quantify the environmental outcomes associated with different BMPs, WQT programs often award uniform credit allocations to practices that deliver different water quality improvements. In the Chesapeake Bay Watershed of Virginia, USA, we estimate the water quality benefits and economic costs of a suite of alternative BMPs, including land retirement, forestry, and agroforestry practices (e.g., multi-zone riparian buffers and alley cropping). We implement a biophysical mass-balance model to quantify the marginal environmental benefits of each BMP in terms of reduced nutrient runoff. We couple this biophysical model with an economic model of the marginal costs associated with each practice to examine the tradeoffs between economic and environmental outcomes. We present evidence of significant heterogeneity in water quality benefits across BMPs and demonstrate that efficiency gains are possible with differentiated water quality crediting. Moreover, we find that the status quo uniform approach to crediting undervalues the water quality benefits of agroforestry practices, dampening farmers' incentives to adopt these systems. The economic-environmental approach presented here offers a practical approach to designing WQT policies that are both economically sound and biophysically grounded.

Evaluating willingness to pay for watershed protection in thika dam, murang'a county: case of nature based solution to water challenges in Kenya

Joram Kagombe¹, James Kungu², Daniel Mugendi³

¹Kenya Forestry Research Institute, Nairobi, Kenya; ²Kenyatta University, Nairobi, Kenya; ³Embu University, Nairobi, Kenya (jokagombe@gmail.com; kungu.james@ku.ac.ke; dmugendi@yahoo.com)

Payment for Environmental Services is an incentive based approach in natural resource management aimed at linking the suppliers and consumers of goods and services from a natural resource in a way that both parties contribute to improved delivery. Nairobi City has experienced serious water shortages in the past due to water levels in Thika dam subsiding to low levels and resulting in water rationing. The dam supplies 80% of water to Nairobi city but few of the residents are able to link availability of clean water in their pipes to conservation of water catchments areas. The objective of the study was to find out whether users of

water from Thika dam could participate in watershed protection scheme through Payment for Water Services. The study identified factors that could influence willingness of water users to pay for the environment services. Primary and secondary data were collected based on baseline survey and qualitative research approaches, interview schedules, questionnaires and, focus group discussions. Results showed that 83% of farmers are willing to participate in scheme aimed at improving conservation. There was significant relationship between farmer's source of water and amount of money they could give but attached condition of clean and regular water. Rewards in kind were more preferred. There was no framework in which consumers willing to pay could use to provide incentives to the providers of environment services. The government could make use of the findings of the study to develop a nature-based payment model for Nairobi residents.

Consequences of Mexico's Payment for Hydrological Services program for ecosystem service and economic trade-offs: an integrated field and modeling approach

Heidi Asbjornsen¹, Carter Berry², Kelly Jones³, Randall Kolka⁴, Nate Looker⁵, Sergio Lopez-Ramirez⁶, Robert Manson⁷, Alex Mayer⁶, Mariana Quetzalli⁷, Jacob Salcone⁸, Guadalupe Williams-Linera⁷
¹University of New Hampshire, Durham, USA; ²Chapman University, Orange, USA; ³Colorado State University, Fort Collins, USA; ⁴US Forest Service, Grand Rapids, USA; ⁵University of Minnesota, Minneapolis, USA; ⁶Michigan Technological University, Houghton, USA; ⁷Instituto de Ecología, Xalapa, Mexico; ⁸Colorado State University, Fort Collins, USA (heidi.asbjornsen@unh.edu; zcberry@gmail.com; jones.kelly.west@gmail.com; rkolka@fs.fed.us; nlooker@gmail.com; sergiomiguel009@gmail.com; robert.manson@inecol.mx; asmayer@mtu.edu; marianaquetzalli@gmail.com; jsalcone@gmail.com; guadalupe.williams@gmail.com)

Payment for Watershed Hydrological programs (PHS) are increasingly used worldwide as a policy tool to provide incentives for upstream landowners to adopt land use activities favoring sustainable provision of high quality water to downstream areas. Because PHS operate at the interface between human and biophysical systems, complex and often unexpected interactions often occur, yet knowledge about how these interactions affect ecosystem services and economic outcomes is currently lacking. We assessed the ecosystem service and economic tradeoffs of Mexico's PHS program in two watersheds in Veracruz, Mexico. We found strong consistencies between provisioning of different ecosystem services (i.e., water quality and quantity, carbon storage, and biodiversity) across land uses, such that provisioning for one service allowed for greater provisioning of another. Further, we found that conversion of primary forests to other land uses (i.e., coffee, sugarcane, pasture) would result in net decreases in ecosystem service provisioning, with the exception of young forests. All forest land uses had much greater ecosystem service benefits than other land uses but the specific provisioning of each land use to ecosystem services varied in unexpected ways. Additionally, many PHS participants (30%) indicated that PHS did not provide significant income benefits, and a majority highlighted that their motivations for participation included not only financial benefits, but also other factors such as environmental stewardship and community benefits. Current efforts focus on integrating these data into a modeling framework to assess the consequences of different PHS policy and land use change scenarios for watershed sustainability.

Transaction and implementation costs and the environmental effectiveness of the Water Producer Programme (Brazil)

Leidimari Neves do Prado¹, David Shanafelt²
¹INRA, Nancy, France; ²BETA, Nancy, France (leidimari.neves-do-prado@inra.fr; david.shanafelt@inra.fr)

This paper studies the economic impacts and the environmental effectiveness of a large-scale public investment in the Water Producer Program (WPP) in the Pipiripau River Basin in Brasília, Brazil. The WPP is a voluntary payment for ecosystem services (PES) program aimed to improve the quality and quantity of water via three types of actions: (i) soil conservation, (ii) restoration or conservation of areas under permanent protection and/or legal reserves, and (iii) conservation of native vegetation remnants. All three actions are required for landowners to be eligible for payment. However, contract signatories bear no costs of implementation - all works and services are offered free of charge to landowners. This incentive scheme deviates largely from the willingness-to-pay approaches predominant in the literature. Created in January 2012, the WPP is still in its implementation phase and there are questions as to its attractiveness and effectiveness. In this paper we develop a model of a PES program in which landowners are given traditional incentive schemes to enroll in the program, as well as subsidized implementation costs. We evaluate the effectiveness of the incentive scheme for enrollment and expected returns from ecosystem services. We complement the model with an empirical analysis of the WPP. We find that since the implementation of the WPP in 2012, over 350,000 seedlings of native trees were replanted in participating properties and over 200 ha of additional land are undergoing restoration. We find evidence of reductions in the cost of water treatment over the course of the study.

The Stick and the Carrot: explaining the decision to participate in the Water Producer Programme (Brazil)

Leidimari Neves do Prado¹, Serge Garcia², Pablo Andrés-Domenech³
¹INRA, Nancy, France; ²BETA, Nancy, France; ³AgroParisTech, Nancy, France (leidimari.neves-do-prado@inra.fr; serge.garcia@inra.fr; pablo.andres-domenech@agroparistech.fr)

In 2012 the Brazilian Government set up the Water Producer Programme (WPP) in the Pipiripau River Basin (Federal District). WPP is a voluntary membership programme focused in stimulating the protection of water resources and reducing damages from soil erosion through a policy of Payment for Environmental Services (PES). Since the creation of WPP roughly half of the landowners in the basin have joined the Programme. A non-negligible number of owners, however, have decided not to join. We interviewed landowners in the area covered by WPP to find out more about their motivation to join the programme. We conducted econometric analyses based on (i) observed participation to WPP and (ii) their compliance with the Brazilian Forest Code (BFC). A non-spatial probit model and both spatial binary probit models spatial auto-regressive (SAR) and spatial error (SEM) were used to explain the decision of landowners to participate. We found that programme's benefits (carrot-like incentives) alone were not strong enough to attract owners to join WPP as owners already complying with BFC have a much low participation rate. On the contrary, carrot-like incentives together with stick-like incentives greatly improved participation. This last result shows how important it is for landowners to sign the contract for fear to be punished by the BFC and in order to avoid regularisation costs, rather than for the programme's objectives and their own pro-environment values

“Water-solidarity” in management of planted forests / Manejo hidrossolidário de florestas plantadas

Yasmin Rocini¹, Felipe Faria¹, Marciano Silva¹, Arnaldo Gunzi², Maria José Zakia², Andreia Pimentel¹, Mariane Bueno de Camargo¹
¹Klabin S/A, Telêmaco Borba, Brazil; ²Klabin S/A, São Paulo, Brazil (yasminrocini@gmail.com; ffaria@klabin.com.br; marciano.silva@klabin.com.br; asgunzi@klabin.com.br; zeze.zakia@gmail.com; apimentel@klabin.com.br; maricamargo@klabin.com.br)

Todas as organizações têm procedimentos e rotinas que são necessárias para que os objetivos estabelecidos sejam alcançados, no entanto, esses padrões podem se tornar obstáculos para chegada de novas ideias. Estas devem ser embasadas em parâmetros técnicos e critérios relevantes para incorporação no manejo florestal, aperfeiçoando aspectos no âmbito econômico, ambiental e social. A operação de colheita é tida como item de destaque no processo produtivo, sendo determinada pela sequência de corte de talhões com bom rendimento operacional, que está diretamente ligado ao tamanho dos blocos e dispersão dos talhões, contribuindo para redução dos custos operacionais e deslocamento das frentes de trabalho. Para isso, diversos fatores devem ser considerados no momento do sequenciamento de corte, como produtividade das florestas, gênero plantado e distribuição espacial dos talhões. A mudança conceitual realizada foi a inserção do conceito de hidrossolidariedade no planejamento florestal, guiando a tomada de decisão das operações. Entende-se que o tamanho dos blocos de colheita pode acarretar prejuízos aos processos hidrológicos e à conservação da biodiversidade. Para compatibilizar os interesses foram avaliadas todas as microbacias de terceira ordem sob a influência das áreas plantadas e estabeleceu-se uma regra que propõem que pelo menos 40% da cobertura vegetal da microbacia seja mantida enquanto os outros 60% sejam manejados.

The forest based industry and SDGs most linked to water resources

Nathalia Granato Loures¹
¹Ibá, São Paulo, Brazil (n.granato@iba.org)

Water is an essential resource for any productive chain and its availability in terms of quality and volume has been significantly affected by a set of issues including climate change, increasing population and demand of resources and products, besides land use management amounts others. This session aims to show the ecosystem services related to water resources, including services on regulation, provision, support and culture. Additionally, the session aims to show the contribution of forest based industry in Agenda 2030 (Sustainable Development Goals) considering primarily the role of forestry and the forest-based industry on water resources. It seeks to present challenges that should be better addressed by private sector, academy, policy makers and civil society towards a better water resource management; and to propose solutions to promote and scale up good water management as an environmental service adding value to large scale producers, but particularly smallholders.

THEME F: COMMUNICATING, EDUCATING, NETWORKING & PUBLISHING

F1a: TEACHING AND TRAINING IN SILVICULTURE, SILVICS AND SILVOLOGY

Teaching and training in silviculture: contemporary challenges and future prospects

Jens Peter Skovsgaard¹
¹Swedish University of Agricultural Sciences, Alnarp, Sweden (jps@slu.se)

There are three main challenges for the classical approach to teaching in silviculture: (a) the economic basis for running a course, (b) the increasing diversity of students, and (c) the staff reductions in operational forestry. The economic basis is a major problem because silviculture courses generally are allocated similar budgets as other, purely classroom-based courses. For silviculture courses this is due mainly to transportation costs and severely challenges field tours as an integral part of the teaching. The increasing diversity of students is a pedagogic challenge. Many forestry curricula are based on optional subjects rather than following an essentially fixed progression of courses with a gradually increasing complexity. Moreover, students from other professions may wish to attend silviculture courses. Consequently, due to the lack of basic skills among some students, this generally lowers the entry-level requirements, demands more basic knowledge to be included in the course and prevents the course from reaching into advanced level silviculture. The staff reductions in operational forestry has a major impact on teaching options simply because the remaining potential hosts for field tours have less time available for apprentice training, supervision and teaching. This makes it increasingly difficult for forestry staff to plan and conduct field tours and to host students, and many decline to do so due to other competing and sometimes urgent work. Remote-distance teaching, virtual reality facilities and electronic media may help alleviate some of these problems in the future, but also pose challenges for the indispensable hands-on training in silviculture courses.

The cross-border further training for close to nature silviculture (CTN): best practice

Milan Sarvaš¹, Peter Balogh¹
¹National Forest Centre – Institute for Forestry Consultancy and Education, Zvolen, Slovakia (sarvas@nlcsk.org; balogh@nlcsk.org)

Logging and wood-processing industry is the main source of income in many areas of the Carpathians, especially in Slovakia-Ukrainian border region. The forest exploitation was very intense in the 19th and early 20th century, when many native forest stands were clear-cut. To improve sustainable forest management in border region the education project focused on close to nature silviculture (CTN) was implemented. The overall objective of the project was to develop conditions for further learning of forestry practitioners of the border regions of Ukraine and Slovakia. In addition the next objective was to change the paradigm of forest management among forestry practitioners thus changing the system of forest management towards multifunctional and sustainable close to nature management. The project was divided into four phases. During first phase analysis and concept development the assessment of the current situation was done. In the second phase—capacity building the training program and the practical manual was developed. During the third phase training activities the training of trainers was done. The fourth phase was focused on consolidation and dissemination. The projects outcomes: 4 sample plot areas were established and serve regularly as demonstration and training sites; 14 trainers, 160 forest practitioners, 20 engineer specialists and managers of forest administrations and 10 members of forest owner associations were trained; the new training manual was published and disseminated; four joint practical training events organized with participation of 80 forestry practitioners were carried out; cross-border web-platform (www.foresterslearning.eu) for further training and knowledge exchange was developed.

Bsc Forestry curriculum in University of Eldoret: teaching silviculture and its challenges

Jane Kiragu¹

¹University of Eldoret, Eldoret, Kenya (wambuikirash@gmail.com)

Silviculture is and will remain a core subject in forestry training. It deals with all aspects of forestry and its sustainability. Traditional forestry is changing due to changes in forest land size, climate change, population size and status, forest type i.e. changing from Natural forestry to plantation forestry, rain forest to dryland forest, gazetted forest to farm forestry etc, which leads to changes in species type, uses and management methods. This calls for the change in the teaching of Silviculture. For the Foresters to be able to cope with these changes, the curriculum needs revision, which is also a challenge due to the cost involved. Challenges encountered in teaching Silviculture in the University is mainly lack of recent book publications leading to relying on very old text books, research in forestry aspects especially, Silviculture, takes too long to get results, making the research expensive, lack of information on the proper propagation methods, tending and management of most indigenous and exotic species for the tropics, lack of enough land where these research can be undertaken and insufficient funds. The teaching is mainly theory which makes it even more challenging. There is therefore need for government intervention so as to allocate more funds for research and training in order to improve the teaching of the subject.

A network of university forests in Asia for long-term monitoring of forest ecosystems

Naoto Kamata¹, Toshiaki Owari², Koichiro Kuraji³

¹The University of Tokyo, Furano, Japan; ²The University of Tokyo, Kamogawa, Japan; ³The University of Tokyo, Tokyo, Japan (kamatan@uf.a.u-tokyo.ac.jp; owari@uf.a.u-tokyo.ac.jp; kuraji_koichiro@uf.a.u-tokyo.ac.jp)

Under changing environments, long-term monitoring and inventory data are important to detect temporal changes in environments and ecosystems. There have been so many attempts that aimed long-term research or monitoring. However, many of them have stopped due to the retirement of responsible researchers. On the other hand, university forests own various kinds of long-term data because they can obtain data as organizations, which is useful for forest research and education. The most typical one is meteorological data. Meteorological Agency in each country has been accumulated meteorological data for long. However, their observatory stations are normally located in urban areas so that data obtained by them need to be corrections before applying to forest research. On the other hand, university forests are normally located in remote areas so that climate data that have been obtained by university forests can be used for forest researches. The University of Tokyo Forests (UTF) consists of seven regional forests. The seven forests have accumulated basic long-term data that are available for researches and education: LTER plots, other stand plots, meteorological and hydrological data, bird community, plant and vertebrate inventory, and others. Since 2016, we teamed up with other university forests in Asian countries and started to share data and knowledge that have been accumulated in each university. We would also introduce activities of the network.

Forest science field education at the university of helsinki: a case study analysing learning diaries

Mika Rekola¹

¹University of Helsinki, Helsinki, Finland (mika.rekola@helsinki.fi)

A Helsinki University field course “Forest and peatland ecology”, organised in June 2017, was studied using qualitative text analysis of students’ learning diaries as a main source of data. Students’ self-regulative knowledge was explored and found rather limited which is in line with some earlier literature. Teaching methods during the course were evaluated very positively by students. One of the main results was that the more activating teaching methods were perceived more positively. Learning diaries included a few negative evaluations and these can be seen as a valuable source of feedback. It is concluded that the field course is an extremely relevant method in order to achieve professional knowledge in forest sciences. The recommendations for future teaching planning are that more emphasis should be put on communicating learning aims, modern learning technology, and finally, critical self-regulation knowledge.

Silviculture: Our way of beating the odds

Biing Guan¹

¹National Taiwan University, Taipei, Taiwan (btguan@ntu.edu.tw)

Silviculture is considered to be a core course in classical forestry education program. However, many undergraduate students in Taiwan, perhaps around many parts of the world as well, nowadays challenge the idea with the question and argument: “Why we need to learn silviculture? It is a waste of time because nature will regenerate trees for us.” From a probabilistic perspective, the likelihood of any single seed can survive and become a regenerating adult is next to zero. Nature uses hundreds of years, by continuously outputting seeds, to even the odds, but the outcomes are unpredictable. In this presentation, I will argue that silviculture is our way of beating the odds and obtaining more predictable outcomes. An example based on a restoration project in Taiwan will be offered to strengthen the arguments.

“Field cycle I:” a strategic educational model in professional education based on competencies among forest engineering students at FCF-UNALM in Lima, Peru / “Ciclo de campo I”: Modelo educativo estratégico en la formación profesional basada en competencias de los estudiantes de Ingeniería Forestal de la FCF-UNALM Lima- Perú

Ethel Rubin de Celis Llanos, Carlos Fernando Bulnes Soriano, Wilfredo Ojeda Ojeda

¹Universidad Nacional Agraria La Molina, Lima, Peru (erubin@lamolina.edu.pe; cfbulnes@lamolina.edu.pe; wojeda@lamolina.edu.pe)

La realización el Ciclo de Campo I mediante un análisis descriptivo, el objetivo es evaluar el papel que tiene el Ciclo de Campo I en la formación de los egresados forestales mediante su malla curricular. Este Ciclo de Campo I se inició en el 1995 a la fecha en la Facultad de Ciencias Forestales de la Universidad Nacional Agraria La Molina, se inició con un plan curricular compuesto por conocimientos teóricos y prácticos que son articulados directamente en el campo forestal y en la actualidad se encuentra migrando al currículo basado en competencias. En este ciclo se logra que estudiantes sean protagonistas de su aprendizaje, produce mejoras significativas como la motivación, integración de saberes mediante el conocimiento directo del recurso forestal, aumento en la colaboración entre estudiantes, mejor desempeño académico, conocimiento de la realidad peruana, expectativa de aplicar sus conocimientos en el quehacer forestal, así como en la formación integral y humanista del egresado. Los resultados obtenidos muestran que el Ciclo de Campo I es un momento adecuado para la evaluación de competencias del perfil del egresado forestal buscando satisfacer al mercado laboral y el manejo sostenible del recurso.

Intersection of arts and science: a conceptualization of motives, approaches and practices

Teppo Hujala¹

¹University of Eastern Finland, Joensuu, Finland (teppo.hujala@uef.fi)

Combining arts with science is not a new idea, but it seems to attract growing attention in different arenas, including bioeconomy and forest conservation. Reasons behind that trend may be several, but it is likely that the complex nature of today's scientific and societal problems calls for using diverse knowledge and communication domains. However, science may be linked with arts in various ways and for different purposes. This contribution proposes a conceptual framework for understanding, evaluating, and designing arts and science mixes. The framework is multidisciplinary, because it contains concepts adopted from philosophy, cognitive and social psychology, communication sciences, futures studies, and behavioral economics. The suggested dimensions of the framework are: ethical commitments; contributor balance; expected impact logic; performative nature; collaboration; and mode of creativity. As an illustrative example, a recent arts and science blending process from Finland is described and decomposed according to the framework's dimensions. The example, "Encounter on the Top" was an innovation workshop organized in collaboration between Human Security Finland, Greenpeace, and Eastern Finnish culture festivals in June 2017 at Koli Hill, Finland's national scenery. The event incorporated tens of artists as well as environmental and forest scientists, to collaboratively design a performance, an event, or a piece of art that communicates recent scientific research on climate change to relevant audiences in a fresh and impactful way. After analyzing the example, the potential value of the proposed conceptual framework will be summarized, and amendments and refinements will be queried from the audience.

The confluence of art, music and science fosters scientific discovery and conservation at long-term ecological research stations in the United States

Lindsey Rustad¹, Mary Martin², Xavier Cortada³, Marty Quinn⁴, Sarah Garlick⁵, Sarah Thorne⁵, Michael Casey⁶

¹USDA Forest Service, Durham, NH, USA; ²University of New Hampshire, Durham, NH, USA; ³University of Miami, Miami, FL, USA; ⁴Design Rhythms, Lee, NH, USA; ⁵Hubbard Brook Research Foundation, Woodstock, VT, USA; ⁶Dartmouth College, Hanover, NH, USA (lindsey.rustad@usda.gov; mary.martin@unh.edu; xcortada@gmail.com; martyq92@gmail.com; sarahgarlick@hubbardbrookfoundation.org; sarahthorne@hubbardbrookfoundation.org; michael.a.casey@dartmouth.edu)

Human societies in the 21st century are faced with increasingly broad, complex and connected social and environmental conservation challenges. An example is the competing need to provide a growing world population with food, water, and fiber, while at the same time maintaining the health, vitality and cultural values of the natural ecosystems that provide these very services. The integration of science, which provides knowledge on how humans impact the natural world, with the arts (writ large), which imbue scientific knowledge with empathy, provides a powerful unified approach to solving the inter-related ecological and social issues of the 21st century. Here we describe a program of research which integrates art, music and science to foster new scientific discoveries while simultaneously promoting education, conservation and shared stewardship of natural resources at long term ecological research stations in the United States. Focused on "Water in a Changing World," this program: (1) uses real-time environmental sensor data to create artistically-inspired data visualizations and musical sonifications of the water cycle (available online at <https://waterviz.org>), (2) employs neurobiological tools and theory to provide a mechanistic understanding for why the integration of arts and science can increase understanding of pattern and process in ecological data; and (3) uses the data visualizations and sonifications as an innovative and inviting approach to educating and connecting the public with water science and environmental literacy. Taken together, the program offers a model for the integration of art, science and education to address pressing contemporary socio-ecological and conservation issues.

Potential contribution of socio-environmental educational and communicative activities to Sustainable Development Goal 15, Life on Earth / Perspectivas de contribuição das práticas educomunicativas socioambientais para o objetivo do desenvolvimento sustentável, ODS-15 Vida na terra

Vania Beatriz Oliveira¹, Michelliny Bentes², Carla Fernandes³

¹Embrapa Rondônia, Porto Velho, Brazil; ²Embrapa Amazonia Oriental, Belém, Brazil; ³UFBA, Salvador, Brazil (vania.beatriz@embrapa.br; michelliny.bentes@embrapa.br; carla.visi@uol.com.br)

Integrar ciências, artes e culturas não é iniciativa recente. Cientistas renomados estabeleceram conexão entre a ciência e a arte, ao desenvolver suas pesquisas e comunicar os resultados, seja para a disseminação científica ou a popularização da ciência. Em âmbito mundial, a Agenda 2030, em seu ODS 15-Vida Terrestre, objetiva "Proteger, recuperar e promover o uso sustentável dos ecossistemas terrestres, gerir de forma sustentável as florestas [...] e deter a perda de biodiversidade". Uma mobilização planetária que requer a participação social. Originalmente, a produção coletiva de narrativas audiovisuais e vídeos ambientais em oficinas é uma prática educomunicativa socioambiental, desenvolvida e aplicada a partir de 2007, em projetos do Núcleo de Pesquisa Florestal da Embrapa Rondônia, como estratégia para produção coletiva de informação a partir da interação entre diversos atores sociais. Consiste no uso do discurso de músicas de artistas da Amazônia para a sensibilização ambiental, sendo a oficina o espaço de interação e de diálogo entre comunicadores, pesquisadores, artistas autores da música e a sociedade representada pelos participantes das Oficinas. A metodologia baseia-se na concepção de linguagem (Bakhtin) na qual a interação caracteriza-se pelo diálogo, entre a arte (discurso literário da música) e o cotidiano dos cidadãos. Foram realizadas oficinas com diversas temáticas e contextos, cujo resultado é a elaboração coletiva de um novo discurso. Atualmente a prática faz parte da proposta de capacitação de técnicos da extensão, professores e alunos de escolas rurais, no Projeto Manejo Florestal e Extrativismo (Fundo Amazônia), com enfoque na valorização de produtos da biodiversidade amazônica.

Scouting in Bolivia through forest planning, the scouting method of learning by doing: consolidating the restoration and recovery of

soils and the landscape in the field school at Arani, Cochabamba, Bolivia / El escultismo en Bolivia a través de la planificación forestal, el método scout aprender haciendo; consolida la restauración, recuperación de suelos y paisaje del campo escuela, en Arani, Cochabamba Bolivia

Huascar Camacho¹

¹Asociación de Scouts de Bolivia, Cochabamba, Plurinational State of Bolivia (huascachoo@hotmail.com)

La asociación de scout de Bolivia (ASB) a través del método scout, desarrolló en coordinación, con profesionales forestales, biólogos, agrónomos, voluntarios scouts, un programa de restauración, recuperación de suelos y paisaje, en un espacio físico de 12 has. de tierras desertificadas por la erosión eólica, en el municipio de Arani, departamento de Cochabamba Bolivia. Se estableció un plan de acción en el que participaron scouts de la ASB y de varios países miembros de La Organización Mundial del Movimiento Scout (OMMS) con los objetivos de: *recuperación de áreas degradadas y la creación de un bosque de biodiversidad para convertirse en un centro de educación ambiental y para la vida*, que permita reconectar a los scouts en sus diferentes ramas, con el cuidado, la conservación y el manejo de la biodiversidad; en un espacio propio que facilita *desarrollar sus métodos educativos y actividades en contacto directo con la naturaleza y la biodiversidad.*; a través del programa scout mundial de medio ambiente y aplicar los objetivos de desarrollo sostenible. Transcurridos más de 10 años de constante trabajo de voluntariado, la aplicación de técnicas forestales y el trabajo en equipo del método scout, aprender haciendo, hicieron posible consolidar el campo escuela en el que se desarrollan actividades permanentes de educación ambiental y para la vida, con la participación de grupos conformados desde 30 personas hasta 2000 en eventos departamentales, nacionales e internacionales.

Education regarding culture-forming value of the forest implemented in a Polish State Forests Holding: the forest culture centre in Goluchów: case study

Alicja Antonowicz, Benedykt Roźmiarek

¹The Forest Culture Centre in Goluchów, Goluchów, Poland (alicja.antonowicz@okl.lasy.gov.pl; benedykt.rozmiarek@okl.lasy.gov.pl)

Non-productive functions of the forest have been gaining on significance and appreciation in a sustainable social and economic development of the society. Throughout stimulating the sense of wonder about the forest ecosystems, emphasizing the beauty of wooden artifacts, environmental inspirations in painting, literature or sculpture, one may directly develop the better understanding of the forest potential. The effectiveness of environmental protection depends on the level of the society's awareness, which can be increased by taking particular actions. The Forest Culture Centre in Goluchów holds special place in the forest culture in Poland, as well as fulfills educational functions of the Polish State Forests. It enables participation of the wide public in active and passive educational forms. Since 1986 the FCC has been making available six permanent exhibitions, an extensive exhibition on culture-forming function of the forest among them. Since 1988, the Center organizes *National Exhibition of the Art Achievements of Foresters*. Other periodic didactic events organized by the Centre include: *International Open-air Painting Event Forest Inspirations* and *National Competition Storytellers from the Forest Glade*. The Centre also serves as a place, where projects propagating artistic creation of children and youth are held. It cooperates on a permanent basis with institutions and associations propagating culture and publishes books, albums and catalogues that popularize forest in human creativity. The work of the FCC has a profound impact on the public throughout promoting the interest in the forest and encouraging reflection on the individual's attitude towards the natural environment.

Illustrated videos: bringing art to science communication

Jennifer Hayes, Nehalem Clark

¹USDA Forest Service - Rocky Mountain Research Station, Fort Collins, USA (jennifer.hayes@usda.gov; ncclark@fs.fed.us)

Art is a powerful tool for communicating complex science. Visual images paired with narration improve information uptake as different parts of the brain are engaged as opposed to written or oral information alone. Further, artistic videos (animated videos in our case) excite viewers because of the motion related to drawing. At the USDA Forest Service Rocky Mountain Research Station, we worked with an artist to create illustrated videos to help communicate complex social science concepts related to wildland fire. For example: How can communities use risk management principals to guide pre-season suppression readiness? Our creative team included scientists, skilled communicators and an artist. Together we identified the science concepts we wanted to convey and then created a story around those concepts. The artist took that story and illustrated the concepts using hand-drawn and painted images. The artist video'd her illustration process and we paired this with our scientists narrating the story - creating a set of visually appealing illustrated videos for various audiences. We use these videos to communicate with the general public, managers and decision makers. The final illustrations were framed and will be part of a new art exhibit at our Station headquarters that also features a loop of these videos and photography submitted by our researchers. During this presentation we will showcase several of our short videos (~2 minutes). We will share how we balanced needing to convey challenging ideas with simple messages and how for each video we worked with the artist to bring these to life.

Poetic Science: artistic-scientific approximations of El Yunque (an arts and science collaboration in Puerto Rico)

Grizelle González¹

¹USDA FS - IITF, San Juan, Puerto Rico (ggonzalez@fs.fed.us)

POETIC SCIENCE: Artistic-Scientific Approximations about El Yunque is an interdisciplinary project created by the Museo de Arte Contemporáneo de Puerto Rico (MACPR) in alliance with the USDA Forest Service—International Institute of Tropical Forestry (IITF). The project unites art and science for the purpose of celebrating Earth and its resources, and the resources protected under the Wilderness Act enacted in 1964 in order to establish the National Wilderness Preservation System. The project commenced in March 2013, with an artistic residence in El Yunque National Forest (EYNF), organized by IITF together with the Aldo Leopold Wilderness Research Institute and the Colorado Art Ranch. Said residence was the first of a series of collaborations that took place in six different ecosystems in the United States throughout 2013. This presentation will focus on the benefits of the residence that took place in Puerto Rico which resulted in an innovative project that creatively depicts the value and ecosystem of EYNF and the collaboration that took place between the invited artists and scientists from IITF. Poetic Science presents the artistic and scientific projects born from that collaboration. The projects were exhibited at the MACPR in 2014 with great success, making the institution a recipient of the 2014 Best Collective Art Exhibit Award granted by the Puerto Rico Chapter of the International Association of Art Critics (AICA).

F6b: EFFECTIVE EDUCATIONAL STRATEGIES FOR THE NEXT GENERATION OF FOREST

Green jobs in the forest sector

Alicja Kacprzak¹

¹UNECE/FAO Forestry and Timber Section, Genève, Switzerland (*alicja.kacprzak@un.org*)

Until recently, forest jobs were associated with traditional activities related to silviculture and timber harvesting. Today, the potential for the creation of new job opportunities is enhancing all forest ecosystem functions. The green economy is creating job opportunities in the forest sector in a variety of areas, such as recreation, leisure and sports, ecotherapy, urban forestry, and the control of pests, fire and disease. The further development of green jobs in the forest sector will strongly depend on the revision of existing curricula aimed at addressing existing skill gaps and adapting to new career paths. This can improve the public perception of the forest sector as an innovative sector that attracts qualified workers and offers modern careers in a green economy. This paper focuses on understanding the potential of green jobs in the forest sector and provides guidance on how to carry out the identification of current and anticipated skill needs for green jobs. Examples of green jobs presented in the study, along with emerging tasks, depict new employment opportunities in the forest sector, which can facilitate the integration into the labor market of vulnerable groups, such as young people, women or rural populations. The publication identifies “green” skills needed for the careers of the future. New, environmentally-driven competencies will feature the application of new technologies and business management models. New careers will stem from enhanced awareness of environmental and social consequences of economic activities in the forests and from the willingness to apply sustainable development values at the workplace.

Contents of specialized education on forest and forestry in high schools and universities in Japan

Mariko Inoue¹, Yasuhiko Oishi¹, Natsuko Joko², Katsuaki Sugiura²

¹Forest and Forest Products Research Institute, Hachioji, Japan; ²Nihon University, Fujisawa, Japan (*imariko@ffpri.affrc.go.jp; oishi@ffpri.affrc.go.jp; brn15081@g.nihon-u.ac.jp; sugiura.katsuaki@nihon-u.ac.jp*)

Specialized education on forest and forestry is provided at 28 universities and colleges and 72 vocational high schools that have forest related courses in Japan. Education on forest and forestry has changed as a result of educational reforms, and so there are various curriculum which differ at each school. In this study, we tried to grasp an overview of the contents of education on forest and forestry in high schools and universities. The high schools were following the Ministry’s official guidelines for school teaching, which have been published nine times since 1947, so we analyzed the contents based on them. In the universities, we analyzed based on school subjects include in the curriculum in two universities that have forestry departments. As the result, 15 items of education in high school were extracted and 9 items in universities. Six items were included in both: forest policy with timber processing, forest management with forest mensuration, forest engineering and forest utilization, silviculture with ecology, forest disaster prevention and hydrology, and forest products and wood research. Forest animals and insects were taught only at university, whereas the relationship with society and forest functions was emphasized in high school. We grasped an overview of the contents of education on forests and forestry, including both compulsory and optional subjects. In addition, forest education should be updated to include essential contents in line with social demands.

Educating without colonizing?: graduate education in forestry for international students at Northern Arizona University

Yeon-Su Kim, Peter Fule, Kristen Waring

¹Northern Arizona University, Flagstaff, USA (*ysk@nau.edu; pete.fule@nau.edu; kristen.waring@nau.edu*)

Educating for global engagement is becoming more urgent for training all future forest professionals in the face of worsening global challenges, such as climate change and loss of biodiversity. The National Science Foundation estimates that more than a quarter of graduate students in agricultural and biological science in the US are international students. Providing effective education to those students is not only important to the future of the countries of their origin, but also vital to global engagement of the US students and faculty who benefit from the presence of international students on campus. The School of Forestry at Northern Arizona University has experience in educating ethnic minority students, especially Native Americans, though personal attention, small class size, and a structured curriculum on research methods, philosophy of science, statistics, and effective science communication. The recent influx of international graduate students, especially from Indonesia through the USAID/CIFOR fellowship program, provided an opportunity for us to re-evaluate our program and the factors promoting student success in graduate education. We will present our ongoing efforts to improve the existing program through development of innovative curriculum and strategies for personal mentoring. We will also encourage participants to share their own experiences and facilitate a discussion on global forestry education.

Generational differences in the wood products industry

Michelle Maller¹, Ashley Plagmann¹, Eric Hansen¹

¹Oregon State University, Corvallis, USA (*michelle.maller@oregonstate.edu; plagmana@oregonstate.edu; eric.hansen@oregonstate.edu*)

In the next 10 years, we will see an incredible turnover of the leadership in the North American wood products industry. To maintain the successes industry is accustomed to, we must address the transition and inform the current leadership in the best ways to relate to, train, and support the younger generations. Focusing more on the backgrounds, values, and workplace motivators of each generation will help to create an understanding that will affect both generations. In short, the end goal is to ensure that the leadership change is smooth and does not disrupt the current status of economic and financial success the industry is currently experiencing. Based on information gleaned from a national survey, this presentation will highlight the differences and similarities between each generation and how the workplace culture can change to ensure the successful transition of generational leadership.

TRANSatlantic FORestry Master (TRANSFOR-M) An award-winning program for developing the next generation of globally-

minded forest and environmental managers and scientists

Heinrich Spiecker¹, Jorma Neuvonen², Brigitte Leblon³, Marjoriitta Möttönen⁴, Sopan Patil⁵, Raffaele Cavalli⁶, Andreas Hamann⁷, Georg Gratzler⁸
¹Institute for Forest Sciences/Chair of Forest Growth Albert-Ludwigs-Universität Freiburg, Freiburg, Germany; ²Faculty of Forestry, University of British Columbia, Vancouver, Canada; ³University of New Brunswick Faculty of Forestry and Environmental Management, Fredericton, Canada; ⁴University of Eastern Finland, Faculty of Science and Forestry School of Forest Sciences, Joensuu, Finland; ⁵Bangor University School of Natural Sciences, Bangor, United Kingdom; ⁶Università degli Studi di Padova, Padova, Italy; ⁷University of Alberta Department of Renewable Resources, Alberta, Canada; ⁸BOKU Vienna Department of Forest- and Soil Sciences, Institute of Forest Ecology, Vienna, Austria (instww@uni-freiburg.de; jorma.neuvonen@ubc.ca; bleblon@umb.ca; marjoriitta.mottonen@uef.fi; s.d.patil@bangor.ac.uk; raffaele.cavalli@unipd.it; andreas.hamann@ualberta.ca; georg.gratzler@boku.ac.at)

The sustainable management of forests is crucial in addressing the growing global challenges of this century. Forest ecosystems need to be stable yet adaptive to changes, and multifunctional providing protection, recreation, sustainable production, and use of valuable goods. Management must be responsive to not only the changing site and forest conditions but especially the increasing complexities of evolving economic and social circumstances. Tackling these complex challenges requires talented people who are educated in a combination of disciplines including the natural, technical, and social sciences. They need to have social skills, the ability to identify and solve problems, to work in teams, and to understand different point of views. They have to learn from global experience and adapt the knowledge to meet local needs of both today and the future while meeting environmental and social standards. They have to manage complex projects involving various disciplines in a multicultural environment. *TRANSatlantic FOREstry Master (TRANSFOR-M)* is a dual-degree Master's program in forest and environmental management, which is aiming to educate the next generation of globally minded forest and environmental managers and scientists on the cultural differences, diverse historical contexts, and differing economic drivers that exist in Canadian and European natural resource management approaches. As detailed in Leblon et al. (2013), *TRANSFOR-M* draws from the expertise and opportunities of graduate programs across eight institutions through a blended practical and theoretical approach. *TRANSFOR-M* won an international award in 2014 for the most innovative graduate program across Northeastern US, Ontario, Québec, and Atlantic Canada.

Quality assurance of MSc in European forestry

Marjoriitta Möttönen¹, Harald Vacik², Heinrich Spiecker³, Mériem Fourier⁴, Cristina Vega Garcia⁵, Lucian Curtu⁶, Timo Tokola¹
¹University of Eastern Finland, Joensuu, Finland; ²BOKU, Vienna, Austria; ³University of Freiburg, Freiburg, Germany; ⁴AgroParisTech, Nancy, France; ⁵University of Lleida, Lleida, Spain; ⁶Transilvanian University of Brasov, Brasov, Romania (marjoriitta.mottonen@uef.fi; harald.vacik@boku.ac.at; instww@uni-freiburg.de; meriem.fourier@agroparistech.fr; cvega@eagrof.udl.cat; lucian.curtu@unitbv.ro; timo.tokola@uef.fi)

Forest based bio-economy is a global business and requires wide competences and the use of different methods for different temporal and spatial scales ranging from regional differences in practices and cultures. The Master of Science in European Forestry (MSc EF) is a two-year programme that provides academic education in the field of sustainable resource management with special emphasis of bio-economy. Six European top-class forestry universities collaborate intensively to offer interdisciplinary courses of global relevance in a multicultural environment. Based on the specific competences of the partners thematic profiles have been developed. In addition, Associate Partner Universities in Brazil, Canada and China and Associate Industrial and Scientific Partners contribute to the programme delivery by providing challenging internships. The programme has been financed by the European Commission (2004–2014, 2016–2019). Since 2004 over 186 students, representing 72 countries, have graduated under the programme. The process of quality assurance is very important for the Consortium and detailed feedback is evaluated annually. Questionnaires are also sent to graduated students to get suggestions on how to make the study programme better fitted to the professional requirements. An external Quality Review Board is the authority responsible of external quality assurance. Currently, consortium is carrying out an accreditation process of “European Approach for Quality Assurance of Joint Programmes” based on Standards in the European Higher Education Area (ESG). This contribution will demonstrate the key findings of the feedback analysis and how they have contributed to the overall improvement of the course program through the years.

From the university into the field: connecting the next generation of forest professionals through the international society of tropical foresters

Ruth Metzler¹
¹International Society of Tropical Foresters/Fundación Pro Eco Azuero, Los Santos, Panama (ruth@proecoazuero.org)

Multidisciplinary programs in academic institutions related to forest fields are incredibly important, but what happens when these budding foresters go out into the world, often with little support network and in disparate rural locations, to work within the landscape? The International Society of Tropical Foresters (ISTF) is an institution that over the decades has worked to connect and support forest-related professionals as they navigate this transition and the challenges and opportunities that come with working in tropical forests worldwide. The movement to strengthen the Global International Society of Tropical Foresters has grown rapidly since the 2018 Yale ISTF conference, with the passage of global bylaws and chapter establishment guidelines, over 1000 members, 50+ chapter formation requests, and the nomination of a new Board of Directors. Come to this session to discover and discuss ISTF's approach to connecting forest practitioners navigating real life resource management problems and help shape the way forward for this rapidly growing global movement.

Global Outlook on Forest Education: university curricula meet competence needs in current working life, results from Behavioral Event Interviews (BEI) and gap analysis

Mika Rekola¹, Terry Sharik², Tara Bař, Dalia Abbas³, Sandra Rodríguez⁴
¹University of Helsinki, Helsinki, Finland; ²Michigan Technological University, Houghton, USA; ³American University, Washington, USA; ⁴Universidad Autónoma de Chihuahua, Chihuahua, Mexico (mika.rekola@helsinki.fi; tsharik@mtu.edu; tlbal@mtu.edu; daliaabbas@yahoo.com; sandra_osu@yahoo.com)

The Global Outlook on Forest Education (GOFE) study focuses on the working-life competence needs and forestry education on the university level. These working-life competence needs were analyzed using Behavioral Event Interviews (BEI) of recent forestry and natural resources graduates in more than 10 countries in 5 continents. After conducting the work-competence needs of forestry graduate students in the work place, a gap analyses compared these needs based on BEIs and the content of forestry education university curricula. The BEI method is based on McClelland's proposal to use deep interviews about success and failure stories of working life for revealing the most evident lacking competencies (*threshold*) and highly beneficial ones (*differentiating*) that make an employee superior among peers. Results have shown that the most frequently observed *threshold* and also *differentiating* competencies were related to generic skills such as leadership and management, human interactions, and communication. The subject-specific competencies were not so frequently observed

in BEIs indicating that graduates have presumably been satisfactorily prepared in these skills for success in their working life. Gap analysis results are reflecting threshold competences. Finally, based on the results of this study, there are recommendations made to review existing university curricula.

F6c: HOW TO TEACH FOREST SCIENCES IN THE FUTURE - CHALLENGES AND OPPORTUNITIES OF CHANGING ECOLOGICAL, SOCIO-ECONOMIC, AND TECHNOLOGICAL CIRCUMSTANCES.

Challenges and solutions to the development of MOOC for forestry higher education

Youqing Luo¹, Yu Lin¹, Yong Liu¹

¹Beijing Forestry University, Beijing, China (youqingluo@126.com; duke_lin@163.com; lyong@bjfu.edu.cn)

It is a consensus for Chinese educational authorities that information technology will bring revolutionary influences to modern education, and the deep integration with information technology will overwhelmingly increase the quality of education and teaching. Having held 5 international conferences on MOOC in the past 5 years, China has become a big country of MOOC, with over 5000 online courses and more than 70 million users. Non-governmental capital has also attached great significance to the development of MOOC. *Yidan Prize*, for example, was launched in 2016 with a donation of \$ 320 million by Hong Kong high-tech entrepreneur, Mr. Chen Yidan. As one of the most influential educational prizes in the world, *Yidan Prize* is awarded to 2 winners every year (\$ 3.8 million to each winner), and one of the 2018 winners was exactly the CEO of edX, Anant Agarwal. This presentation analyzes the logics and hierarchical relations of key elements in modern educational information technologies, investigates the advantages and limits of MOOC which is not almighty in all circumstances, and illustrates the adaptation of MOOC in different course types. Meanwhile, the development and application of MOOC have been going through four phases, namely general consensus, joint development, wide sharing and extensive recognition. Based on the status quo of China's education, this presentation hence elaborates on the key elements in each phases and particularly focuses on the challenges and solutions to wide sharing and extensive recognition, especially for forestry higher education.

Innovative education in sustainable forest management

Guangyu Wang^{1,2}, Min Qian (Michelle) Zeng^{1,2}

¹The University of British Columbia, Vancouver, Canada; ²Asia Pacific Forestry Education Coordination Mechanism, Vancouver, Canada (guangyu.wang@ubc.ca; michelle.zeng@ubc.ca)

Challenges such as climate change and deforestation have created a high demand for sustainable forest management (SFM), and access to relevant education is important for improving forest management and helping to create a balance between environmental, economic, and social values in the Asia-Pacific Region. To improve capacity building, a joint educational program entitled Innovative Sustainable Forest Management Education in the AP region has been established by a group of international renowned forestry universities including UBC, Beijing Forestry University, University of Melbourne, University Putra Malaysia, and University of the Philippines Los Baños. This program has developed a series of online courses by using an innovative pedagogical method to convey SFM knowledge. As the open educational resources (OER), this program has attracted over 9000 global learners. The program won the CNIE-RCIE Award and the IUFRO Best Practices in Forest Education. This study will present technology, curriculum, pedagogy used in the course development, discuss strategies and methodology in creating courses, share lessons learned from the program development and introduce new initiatives of new courses in tropical forest and potential SFM online program. In addition, we will demonstrate our current practices. It will display good examples in delivering SFM knowledge using available quality OER to global audiences from various cultural backgrounds, meanwhile creating an effective learning community to promote learning and experience sharing in forestry practices in the Asia Pacific region. We believe this study will provide useful experience and information to benefit online education in the field of natural resources worldwide.

The future of employment in the global forest sector: reviewing trends with a focus on “green jobs”

Juliet Owuor¹, Lisa Prior¹, Georg Winkel^{1,2}

¹European Forest Institute, Bonn, Germany; ²University of Freiburg, Freiburg, Germany (juliet.acheng@efi.int; lisa.prior@efi.int; georg.winkel@efi.int)

The overall goal of this study is to evaluate global employment trends and competence needs in the forest sector with a special focus on the recently much debated field of “green jobs”. The forest sector is currently facing significant changes, including globalization, digitalization, changing societal demands, and climate change. These developments have caused the nature of employment in the sector to shift, partly, away from traditional occupations in forest services or companies. More emphasis is being placed on jobs that promote the general well-being of people while at the same time promoting sustainable development. Yet, at the same time, significant regional differences prevail. This study based on literature review and expert interviews, will give an overview on the available knowledge in scholarly and grey literature relating to the topic. In this way the paper analyses how employment in the forest sector is changing globally, and the dynamics that drive such changes in different regions. Skills and competencies needed for future employment will also be explored. The paper will conclude with elaborating knowledge gaps and possible points of departure for further research.

The health of tomorrow's forests depend on the actions of young forest scientists today

Darryl Herron¹

¹FABI, Pretoria, South Africa. University of Pretoria, Pretoria, South Africa (darryl.herron@fabi.up.ac.za)

The human race depends deeply on forests; natural forests as well planted forests. Yet these vital resources are deeply threatened by invasive insect pests and pathogens. Global organizations, such as IUFRO, have made considerable contributions to bring forest scientists together to protect forests and provide communities and governments with evidence-based knowledge to inform policies aimed at protecting the world's forests. But much remains to be done. The fight against pests and diseases rests strongly on the shoulders of young professionals who must commit to this cause. Pests and diseases know no borders and do not discriminate between countries. Young forest professionals should break down the barriers – in what ever form — that divide us and seize the opportunities offered by digital connectivity, i.e. digital conferences, skype meetings, social media, etc., to more effectively tackle the scourge of pests that threaten our forests. My call is for young forest professionals to become ambassadors for their countries, institutions, companies, etc. and to use these opportunities to engage broadly and regularly, outside of IUFRO meetings and conferences. As ambassadors of our forests and for their protection, we not only have

opportunities to communicate with each other but we can also provide lines of contact between IUFRO and the institutions where we reside and where we have influence. In this way, we will establish meaningful networks that are built on a foundation of understanding to drive real change across the different divisions of IUFRO and to ensure sustainable forest protection.

Fostering the transformative potential of roleplays in forestry education: learning for an uncertain future

Ida Wallin¹, Vilis Brukas²

¹University of Freiburg, Freiburg, Germany; ²Swedish University of Agricultural Sciences, Alnarp, Sweden (ida.wallin@ifp.uni-freiburg.de; vilis.brukas@slu.se)

Higher-education study programs mainly equip forestry students with subject-specific knowledge such as biology, ecology, wood technology and forest economics. Typically lacking in the study programs are skills related to social relationships and communication. This is problematic since dialogue and collaboration with the public and stakeholders in various participatory processes is an increasingly important feature in everyday forestry practices. Forestry professionals often have to handle complex decision-making situations including conflicting interests and high levels of uncertainty regarding future states of forests, climate and market conditions. Coupled with an increased uncertainty in general society, this means that we can no longer rely on specific or generic skills alone to give us adequate tools to understand and deal with reality in all its forms. We describe how forestry education can adapt to this changing reality through engaging students on a deeper level and facilitate their personal development. Transformative learning aims to raise students' self-awareness and self-reflection, and help the individual to better understand his/her own and others perceptions and norms. These are necessary skills for effective collaborative problem-posing and -solving in any modern democracy. Such learning conditions are accomplished by introducing unpredictable elements in the teaching and encouraging the students to take own standpoints. Roleplaying plausible real-life forest management situations in the classroom allow for experimentation under safe conditions and can foster transformative learning. The presentation will critically examine practical findings from a roleplay and transformative learning intervention, and convey challenges and opportunities to integrating such elements in regular curricula.

Cross-hemispheric international academic exchange: lessons from more than 50 years of cooperation between the forest faculties at University of Paraná, Curitiba, Brazil, and University of Freiburg, Germany

Hans-Peter Kahle¹, Christel Lingnau²

¹Chair of Forest Growth, Institute of Forest Sciences, Albert-Ludwigs-University Freiburg, Freiburg, Germany; ²Departamento de Ciências Florestais, Universidade Federal do Paraná, Curitiba, Brazil (hans-peter.kahle@iww.uni-freiburg.de; lingnau@ufpr.br)

Although it possesses one of the world's greatest forest resources, Brazil had no academic forestry school until 1960. On May 30, 1960 the first university-based course in forestry engineering was created under the name 'National School of Forestry' and started to function at the then Federal University of Minas Gerais, now Federal University of Viçosa; 3 ½ years later, on November 14, 1963 the school was transferred to Curitiba and incorporated to the Federal University of Paraná (UFPR). From 1961 to 1969 the academic development was promoted through an agreement with the Food and Agriculture Organization of the United Nations (FAO). The cooperation program between the forest faculties at UFPR and at Albert-Ludwigs-University Freiburg, Germany, which existed in two phases from 1972 to 1991 paved the way for the development of postgraduate curricula in forest sciences and forestry at UFPR, which was later complemented by a doctoral program. In the following years until today, the cooperation continued with several joint research and student exchange programs between the two faculties. In this presentation, we analyse the challenges that evolved during this more than 50 years lasting cross-hemispheric international academic exchange and conclude with lessons learnt for the development of effective multicultural and multidisciplinary educational strategies for the new generations of forest professionals to come.

Assessing graduates of a forest engineering course over the past decade: the case of two traditional teaching institutions / Diagnóstico dos egressos do curso de engenharia florestal na última década: estudo de caso em duas instituições tradicionais de ensino

Rodrigo Hakamada¹, Silvio Ferraz², Italo Cegatta³, Rafael Braz¹

¹Federal Rural University of Pernambuco, Recife, Brazil; ²University of Sao Paulo, Piracicaba, Brazil; ³Forestry Science and Research Institute, Piracicaba, Brazil (rodrigo.hakamada@ufrpe.br; silvio.ferraz@usp.br; italo.cegatta@usp.br; rafael.braz@ufrpe.br)

Apesar da larga abrangência de atuação e da sua importância socioambiental e econômica para o país, não é do nosso conhecimento um estudo que identifique as áreas de atuação dos engenheiros florestais no Brasil. Visando cobrir parte dessa lacuna, o objetivo deste trabalho foi identificar, através de questionário e contato direto, quais as áreas de atuação dos profissionais graduados entre 2008 e 2017 da Escola Superior de Agricultura "Luiz de Queiroz" (ESALQ) e da Universidade Federal Rural de Pernambuco (UFRPE). De 40 e 68 ingressantes por ano, respectivamente, 20 e 66% desistiram do curso ao longo da graduação e 15 e 22% se formaram e atuam fora da área, em áreas correlatas ou estão em busca de oportunidades. Assim, 65 e 12% dos ingressantes da ESALQ e UFRPE (80 e 35% dos egressos) atuam em atividades diretamente ligadas às ciências florestais. Dentre aqueles formados pelas duas instituições e que trabalham na área, 47 e 21% desenvolvem atividades ligadas à silvicultura e manejo florestal e 41 e 62% à conservação de recursos naturais e ecologia, evidenciando diferentes perfis de atuação. Detectou-se ainda que 40% daqueles que atuam na área desenvolvem atividades de administração e gestão. Outra característica distinta entre as instituições é a permanência na região em que estão inseridas: 67 e 84%. Esse diagnóstico não procura esgotar o tema, mas fornecer subsídios para o aprimoramento dos cursos de engenharia florestal em escalas regional e nacional.

The need to teach digital technologies in forestry education: new perspectives in forest inventories / A necessidade do ensino de tecnologias digitais na educação florestal: novas perspectivas em inventários florestais

Esthevan Augusto Goes Gasparoto¹, Mateus Yamamoto¹, Marcos Isaac Junior¹, Maycow Berbert¹, Emily Shinzato¹, Marcel Mello¹

¹Treovia Forest Technologies, São José dos Campos, Brazil (esthevan@treovia.com.br; mateus.yamamoto@treovia.com.br; isaac.junior@treovia.com.br; maycow.berbert@treovia.com.br; emily@treovia.com.br; marcel.mello@treovia.com.br)

A quarta revolução industrial já é realidade em diversos setores da economia. Essa revolução está associada principalmente à utilização de tecnologias viabilizadoras, também conhecidas como tecnologias exponenciais como a Internet das Coisas, a Computação em Nuvem e a Inteligência Artificial. Tais tecnologias, há menos de uma década atrás, apresentavam restrições técnicas que inviabilizavam o uso operacional em grande parte das aplicações. Entretanto, devido ao seu caráter exponencial, atualmente é possível fazer uso do benefício de tais tecnologias diariamente em smartphones, por exemplo. No setor florestal, o uso de sensores IoT, para o monitoramento do crescimento florestal já é aplicado operacionalmente. Sensores sem-fio podem ser instalados nas árvores permitindo o acompanhamento remoto do crescimento da floresta e as suas interações com as variáveis climáticas, em tempo real e com

precisão submilimétrica. A alta resolução temporal na coleta de dados associada a grande variedade de parâmetros coletados automaticamente, permite a aplicação de abordagens matemáticas inéditas no setor. O ensino florestal nas universidades deve acompanhar também a velocidade das mudanças tecnológicas vivenciadas no setor, cenário necessário para a formação do profissional florestal já imerso no meio das tecnologias digitais na sua ementa curricular. O mercado florestal demandará dos novos profissionais, além do conhecimento florestal, conhecimentos típicos da ciência da computação e estatística, bem como a proficiência em linguagens de programação e algoritmos. Sendo assim, uma instrução com mais pluralidade de um acadêmico na área florestal, isto é, combinando sua formação com tecnologias modernas, traz poderosas ferramentas para toda a ciência florestal.

F6p: COMMUNICATING, EDUCATING, NETWORKING & PUBLISHING

Digital onboarding for natural resource extension professionals- pilot “Seeds Success” for next generation professionals

Mark Megalos¹, Leslie Boby^{2,3}, William Hubbard⁴, Janean Creighton⁵, James Johnson⁵, Karen Bennett⁶, Jeff Stringer⁷

¹NC STATE University, Raleigh, NC, USA; ²University of Georgia, Athens, USA; ³Sou. Regional Forestry Extension, Athens, USA; ⁴University of Maryland, College Park, USA; ⁵Oregon State University, Corvallis, USA; ⁶University of New Hampshire, Durham, USA; ⁷University of Kentucky, Lexington, USA (mamegalo@ncsu.edu; lboby@uga.edu; whubbard@uga.edu; janean.creighton@oregonstate.edu; jim.johnson@oregonstate.edu; karen.bennett@unh.edu; stringer@kyu.edu)

A USDA grant offered an opportunity to stand up a synchronous webinar series to onboard next generation extension professionals via a national platform. After 9 months of planning, a comprehensive needs assessment, 33 expert videos and a pre-course survey, the principals refined and delivered 8 module synchronous webinar course during the autumn of 2018. Pre-course survey of 88 likely participants showed a moderate level of understanding of extension philosophy, networking, mentoring, needs assessments, program delivery, and evaluation. Those same respondents expressed below average level grasp of scholarship, financing program enhancement and negotiating external partnerships. The typical student (mode) was female, forestry or natural resource agent with state-wide responsibility, less than 5 years on the job, with a completed master’s degree and located in an off-campus location. A social media page allowed for interactive questions, additional reading or video clips and tips for newly-hired professionals. A course website complete with readings, video and recorded lectures was built during the course and allowed current and future participants to conduct self-paced work by topic or the entire course as desired by the professional. A post-course survey is under way and results will be shared during the presentation at the XXV World Congress.

Discourse analysis on sustainability in forest-based engineering / Análise do discurso em sustentabilidade nas Engenharias de Base Florestal

Marcelo Langer¹, Dimas Agostinho da Silva¹, Alexandre Behling¹, Julio Eduardo Arce¹, Silvana Heidemann Rocha²

¹Universidade Federal do Paraná, Curitiba, Brazil; ²Universidade Tecnológica Federal do Paraná, Curitiba, Brazil (marcelolanger@ufpr.br; dimas.agostinho.silva@gmail.com; alexandre.behling@yahoo.com.br; jarce@ufpr.br; silvanaheidemann.ufpr@gmail.com)

O termo “sustentabilidade” é livre e amplamente empregado em todas as áreas de conhecimento; nos diferentes setores econômicos; e, nas amplas esferas governamentais. Desde o final dos anos 70 vem se tornando componente de análise e orientação para as ações e decisões públicas e privadas, entretanto, as divergências sobre seu conceito, definição e aplicação ainda estão longe de uma unanimidade. O conceito de sustentabilidade nas engenharias de base florestal apresenta diferentes compreensões, sua aplicação surgiu nos modelos matemáticos para produção e gestão dos recursos florestais e atualmente busca integrar os aspectos sociais, ambientais e econômico em toda a cadeia de valor dos produtos florestais madeireiros e não-madeireiros. Programas mundiais promovem a sustentabilidade e o desenvolvimento sustentável das atividades antrópicas, como: normas de padronização, mudanças climáticas e os objetivos de desenvolvimento sustentável. Estes programas buscam orientar as decisões de empresas, governo e academia no desenvolvimento dos princípios da sustentabilidade. Outros programas como certificações voluntárias, índices de sustentabilidade ou desenvolvimento sustentável, avaliação do ciclo de vida de produtos servem para a avaliar os desempenhos das atividades econômicas e governamentais. Esta pesquisa teve como objetivo analisar como os aspectos de sustentabilidade são empregados nos discursos dos atores das engenharias de base florestal, quais são suas percepções intermultidisciplinares e como definem suas ações pessoais e profissionais. Foi aplicada a técnica de “análise de discurso” por meio da pesquisa Survey a profissionais e representantes das instituições de ensino e pesquisa brasileira. Foram obtidas 517 respostas e tratadas por meio de análise fatorial de correlação.

The perceptions of young people on urban trees: construction of a questionnaire

Liz Farleidy Villarraga Flórez¹, Diana Patricia Morales Espinosa¹, Sandra Rodriguez-Pineros²

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia; ²Universidad Autónoma de Chihuahua, Chihuahua, Mexico (lizv@udistrital.edu.co; dianamoralesespinosa@hotmail.com; sandra_osu@yahoo.com)

Forest education in Colombia has always been addressed at the University level, leaving a gap in the basic educational level where most of the attitudes and values of the citizens are developed. This study aimed to build a questionnaire that helps to inquiry about perceptions of the secondary students towards urban forests. Using the photovoice technique students were asked to build the ideal city. Two hundred and thirty-four students were divided in 36 groups to build their ideal city based on pictures of their favorite places in the city of Bogota, Colombia. Students were asked to explain the importance of each place; 97% of the students included green areas in their ideal cities stating that trees are important to produce oxygen, reduce the pollution, preserve species of fauna and flora, regulate the temperature of the city, and provide places for recreation. The results of this academic project served as the basis to design a questionnaire to assess perceptions of urban forests. The resulting questionnaire is composed of 38 statements that contained the three categories of the ecosystems services, regulation, provision, and cultural. The questionnaire was applied to 64 students for validation. Results showed a Cronbach’s alpha of 0.852 and non-negative correlations indicating that questionnaire is unidimensional and it can be applied in further studies.

The Forestry Practices Group at the Federal Rural University of Pernambuco: a case study in applying problem-based learning

methodology in forest engineering / Grupo de Práticas Florestais da Universidade Federal Rural de Pernambuco: um estudo de caso de aplicação do método de aprendizagem baseada em problemas na engenharia florestal

Rodrigo Hakamada¹, Luiza Lucena¹, Sandra Porfirio¹, Tainá Sabino¹, Elyenay Bandeira¹, Renata Nascimento¹, Lorena Paulina¹, Jonatas Carlos¹, Ana Santana¹

¹Federal Rural University of Pernambuco, Recife, Brazil (rodrigo.hakamada@ufrpe.br; luizaalmeidaluca@hotmail.com; sandraborbap@gmail.com; coelhos.taina@outlook.com; naaybandeira@gmail.com; renata_nascimento02@outlook.com; lorena_ah2011@hotmail.com; jonatascarlos00@gmail.com; anaclarasantana_12@outlook.com)

A vivência prática associada à multidisciplinaridade resulta na consolidação do conhecimento teórico adquirido em sala de aula. Uma das maneiras de explorar estes conceitos ocorre pelo método de Aprendizagem Baseada em Problemas, que consiste em atribuir aos estudantes a busca pela resolução de problemas atuais relacionados à área e estimula os alunos no desenvolvimento da criatividade e do empreendedorismo, habilidades indispensáveis para atuação no mercado de trabalho. Como forma de unir estas temáticas dentro de um curso tradicional de engenharia florestal no Brasil, relataremos a formação e funcionamento do Grupo de Práticas Florestais (GPFlor) da Universidade Federal Rural de Pernambuco. O grupo é formado por alunos de todos os anos do curso, que trabalham de maneira voluntária em atividades divididas na forma de projetos. Os principais projetos são: “Mudas Florestais” que visa produzir mudas para plantios de florestas de uso múltiplo e restauração de áreas degradadas; “Reflorestar Rural”, que objetiva restaurar áreas degradadas no entorno da universidade; “Vem da Floresta”, com o objetivo de transformar árvores em produtos madeireiros e não-madeireiros e o projeto “Agroflorestar” que maneja dentro da universidade uma área de integração agrossilvicultural. Com cerca de um ano de existência, o grupo já proporcionou a vivência prática e a busca por resolução de problemas florestais a cerca de 40 estudantes (25% do total de estudantes matriculados). No total, cerca de 10.000 horas de atividades práticas já foram realizadas. Espera-se que ações como esta possam no longo prazo serem convertidas em benefícios à sociedade através de engenheiros melhores capacitados.

Role of nature education camps in creating nature awareness among school children in Haryana State of India

Subhash Chander¹, Vivek Saxena¹, Dasharathi Hembram²

¹Haryana Forest Development Corporation, Gurugram, India; ²Haryana Forest Development Corporation, Panchkula, India (syadavhfs02@gmail.com; viveksax1@gmail.com; dhembram@gmail.com)

Haryana Forest Department has developed some of nature camps at different sites of the state during recent past. The main objective of establishing these nature camps is to provide nature education and creating awareness among school children by involving them in various on site learning by doing activities like plantation, nursery raising, forest trailing, film shows, camping at site etc. The initiative keeps the children from routine classroom and will help in inculcating and sensitisation them towards nature. This initiative will future generations in conservation of forests and other natural resources. The initiatives taken by State Forest Department will be presented in the Congress.

Introduction of the Japan committee of the International Union of Forestry Research Organization (IUFRO)

Sumire Kawamoto¹, Alexander Buck²

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²IUFRO, Vienna, Austria (sumirekw@gmail.com; buck@iufro.org)

The IUFRO-Japan (IUFRO-J) Committee is an organization launched by the Forestry and Forest Products Research Institute (FFPRI) to promote global and domestic partnerships in forest-related research in cooperation with IUFRO. FFPRI originally established in 1905 as a forest experiment center of the Forestry Service, Ministry of Agriculture and Commerce, Government of Japan, has contributed to science, technology, policies, and promoting international partnerships through research that uses the rich and diverse forests in an environmentally sound way. FFPRI has been cooperating with IUFRO since its establishment. The activity with IUFRO Headquarters led to the formal establishment of the IUFRO-J Committee in 1976 and since then FFPRI has maintained the secretariat of IUFRO-J. The 600 IUFRO-J members represent 35 Japanese organizations and individuals who wish to further global contributions to the role of research in sustaining forests and people. In order to give IUFRO-J members up-to-date information regarding international forest issues, the IUFRO-J secretariat has published IUFRO-J NEWS three times a year since 1977. IUFRO-J Committee and IUFRO-J News can serve as an effective model also for other countries and institutions for promoting research collaboration and partnership with IUFRO.

Raising voices together to communicate about the forests of Latin America and the Caribbean / Levantando la voz juntos para comunicar sobre los bosques en América Latina y el Caribe

Marianella Argüello L¹, Cristina Miranda Beas², Raúl Pérez Albrecht³

¹CATIE, Turrialba, Costa Rica; ²PUCP, Lima, Peru; ³(cristinamirandabeas@gmail.com; marguello@catie.ac.cr)

Comunicar es más que la simple transferencia de información. Comunicar sobre ciencia forestal y ambiental representa la construcción y sostenibilidad de espacios de diálogo e interacción, capaces de influir y orientar percepciones acerca de los bosques de América Latina y el Caribe, su manejo sostenible y el papel que juegan las plantaciones forestales en el desarrollo de los países, entre otros. En ese sentido, es indiscutible la relevancia y la imperativa necesidad de articular esfuerzos entre tomadores de decisión, técnicos, investigadores y usuarios, para fortalecer la comunicación de ciencia forestal, generando nuevos sentidos en los imaginarios de ciudadanos de los países de la región acerca de temas clave relacionados con bosques, sus usos y servicios ambientales. Por ello, comunicadores de Latinoamérica y el Caribe trabajan juntos para levantar la voz, impulsar y visibilizar el tema forestal y ambiental que caracteriza a la región, por medio de la Red de Comunicadores Forestales y Ambientales de América Latina y el Caribe (Recofalc). Por lo tanto, con el objetivo de crear espacios de información y reflexión dentro del contexto social y cultural latinoamericano, la Recofalc realiza campañas y utiliza sus diferentes canales para contribuir positiva y estratégicamente a través de la comunicación.

F6q: FORESTRY EDUCATION

Education of forestry professionals in Slovakia

Peter Balogh¹, Milan Sarvaš¹

¹National Forest Centre, Zvolen, Slovakia (balogh@nlcsk.org; sarvas@nlcsk.org)

Further forestry education in Slovakia is offered by the National Forest Centre – Institute for Forest Consulting and Education Zvolen (NFC – IFCE Zvolen) and by the Further Education Centre of the Technical University in Zvolen. NFC – IFCE Zvolen is one of four institutes forming National Forest Centre (NFC), state contributory directly managed organization with countrywide occupation. The NFC was founded to provide a modern national platform for the integration of forest research, planning, consulting and further education into one coherent unit able to better respond to challenges facing forestry in the 21st century. Consultancy, further education, and public relation activities in the NFC are being ensured by NFC – IFCE Zvolen. Composition of its educational activities reflects the needs of forestry practice with emphasis on sustainable forest management. It includes mainly short term courses, workshops, fieldtrips, etc. The institute carries out activities assigned by Ministry of Agriculture and Rural Development of the Slovak Republic, especially examinations and life-long learning of certified forest managers, forest management planners and experts for work with forest reproduction material. To increase quality of these education activities, new didactical approaches have been implemented. It means mainly blended learning approach, combining distance and presence learning. Mentioned life-long learning of certified forest managers and further development of consulting services are vital for sustainable development of small-scale forest properties as well as whole forestry sector. It is important to ensure continual support of the Government and effective use of available financial instruments of the EU.

The Forest of Experiments – promoting forestry science in Slovenia

Urša Vilhar¹, Boris Rantaša², Špela Planinšek¹, Marjana Westergren¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Slovenian Forestry Service, Ljubljana, Slovenia (ursa.vilhar@gozdis.si; boris.rantasa@zgs.si; spela.planinsek@gozdis.si; marjana.westergren@gozdis.si)

Slovenian Forestry Institute prepared a “Handbook for learning and play in the forest” for everyone who wants inspiration or starting point for creating new, interesting activities that will bring people in nature to gain knowledge and experience. With interesting and fun content Slovenian forest researchers, joined under brand Forest of Experiments, wants to bring an incomprehensible scientist into the world of popular science, where both children and adults will listen and learn with curiosity. The Handbook contains innovative activities for learning through play that will bring people of different ages (children and teachers) closer to the forest science. Activities are divided into four chapters: Trees, Forest animals, Water and Genetic diversity. Slovenian researchers have designed the activities according to the principle of “flow learning”, with a certain sequence of steps: the excitement of enthusiasm, the focus of attention, the direct experience and the sharing of inspiration. Content is adjusted to follow the learning program of kindergartens and schools. The Forest of Experiments is designed with the help of passionate young researchers, working on different research, demonstration or applied projects in Forestry institute. Our opinion is that it is the utmost duty of any scientist, expert or person with knowledge to spread this knowledge in an ethical way and for the betterment of human society. As people gather new experience, they connect, upgrade and expand their interests while developing a positive attitude towards nature in future – just try it!

Goods and services from the forest: environmental education in the Cazumbá-Iracema extractivist reserve directed at high school students in Rio Branco / Bens e serviços da floresta: prática de educação ambiental na Resex Cazumbá-Iracema aos alunos de Ensino médio de Rio Branco

Berenice Silva¹ , Neila Fernandes¹, Keiti Pereira¹, Patricia Amorim¹, Leila Peters¹, Maria da Costa¹, Paloma Izaldino¹, Marco Amaro¹ , Moisés Lobão¹

¹Universidade Federal do Acre, Rio Branco, Brazil (bereniccka@gmail.com; neila.fernandes@hotmail.com; keiti.roseane@hotmail.com; patriciagomesribeiro@gmail.com; leilappeters@gmail.com; natureza.2@hotmail.com; hizaldinopaloma@hotmail.com; marcoantonioamaro@hotmail.com; moiseslobao.6@gmail.com)

Apesar da educação ambiental fazer parte das propostas curriculares de ensino, a mesma esbarra na dificuldade dos professores em implantar projetos desta natureza em suas programações letivas. Portanto, o principal objetivo desse projeto foi auxiliar os professores das escolas de ensino médio, a trabalhar valores e atitudes ecológicas valorizando os múltiplos produtos e serviços ambientais oferecidos por nossa floresta amazônica, seguindo-se a concepção do manejo sustentável defendido pela comunidade tradicional ali existente. Para tal, alunos de graduação da Universidade Federal do Acre (UFAC) após realizarem um estágio de vivência na Reserva Extrativista Cazumbá-Iracema montaram conjuntamente com os professores, estratégias de ensino sobre a preservação ambiental e o uso sustentável das florestas. Foram realizadas palestras em três escolas de Ensino Médio de Rio Branco, logo após houve visita às trilhas do Parque Zoobotânico da Ufac para visualização das espécies que fornecem produtos madeireiros e não madeireiros, além dos serviços ambientais proporcionados pela floresta. Após as visitas foram realizadas oficinas: de confecção de quadros artísticos utilizando-se produtos coletados na floresta, de pequenos objetos de madeira e bambu e de papel reciclável. Ao final do projeto, as atividades foram avaliadas pelos alunos das escolas participantes para mencionar os pontos que necessitam ser melhorados para continuidade das atividades. Como produto final foi confeccionado um e-book a partir das entrevistas sobre a vida e experiências dos extrativistas da Reserva Cazumbá-Iracema que servirá de apoio aos professores para a continuidade do ensino de Educação Ambiental nas Escolas participantes.

Professional forest science education and employers preference between the University of Yaounde I and University of Dschang Cameroon

Atebeh Lekah¹ , William Mala¹

¹University of Yaounde I, Yaounde, Cameroon (rein.bcyui@gmail.com; williammala@yahoo.fr)

Marketplace demand for professional skills and competencies of forest science graduates is evolving very quickly and forestry schools need to continuously track these changes and adapt their institutions to respond appropriately. Professional master’s degree in Forest science was created by the Minister of higher education in the University of Yaounde I and University of Dschang to meet up with this growing trend. This study seeks to highlight employers’ and graduates perception of the strength and weakness of the two institutions providing professional forestry training. Questionnaires captured information on the forest science specialties highly demanded in the job market, which university is believed to be stronger in terms of content delivery, field trip and enrollment; ⁶⁰ graduates making sure that ⁵⁰% of this number came from each university and ²⁵ employers were interviewed; ⁷⁰ percent of graduates from the University of Dschang were recruited by government organizations as opposed to ²⁵% graduates from the University of Yaounde I. Employers prefer graduates from the University of Dschang. Most of the students that easily found employment were those specialized in Forest certification, biodiversity and protected

area management. Graduate were satisfied with their training but University of Yaounde I graduates were not comfortable with the administrative disorder surrounding the program which may be the reason of the dwindling enrollment number. Harmonization of forest science curriculum should be considered when designing policies to improve forest education to provide graduate with equal opportunities in the job market.

Necessary competencies in forest soils for superior education in forestry: a new perspective for future generations / Competencias requeridas en suelos forestales para la educación forestal superior desde una nueva perspectiva para futuras generaciones

Samuel Francke¹

¹Conaf, Saantiago, Chile (samuel.francke@conaf.cl)

En el marco de los objetivos de desarrollo sostenible, los objetivos de la convención de lucha contra la desertificación, sequía y de cambio climático la educación forestal superior debiera incorporar las siguientes funciones asociadas a suelos de acuerdo a paradigmas: i) funciones de protección, preservación y conservación de suelos y aguas en áreas protegidas y bosque naturales ii) las funciones de recuperación y recuperación de suelos devastados por el flagelo de la erosión y la desertificación iii) las funciones de fomento a la forestación y recuperación de suelos degradados, procesos de con técnicas de conservación de suelos y aguas, iv) Las funciones de ordenamiento territorial de cuencas hidrográficas, de sitios y suelos forestales. Se recomienda incluir en curriculum academico la formación de las competencias que se indican: a) cartografía, inventarios, catastros, clasificación y pedo- genética de suelos, sistemas de información de suelos b) nutrición, fertilidad, manejo de nutrientes, permacultura, agricultura biodinámica y orgánica, biofiltros, zonas buffer, eutroficación c) conservación de suelos y aguas, control de erosión, recuperación, rehabilitación y restauración, manejo integral de suelos y cuencas hidrográficas d) descontaminación de suelos, bioremediación, desalinización, manejo de relaves, pasivos ambientales, oasificación, enmiendas, estándares de eco-calidad de suelos y certificación ambiental e) suelos y ecosistemas naturales, ciclos y balances, asociaciones e interrelaciones suelo-sitio-agua- bosque-vegetación - biodiversidad /cuencas hidrográficas en áreas silvestres f) legislación y ordenamiento territorial en suelos urbanos, rurales, cuencas hidrográficas pre- cordilleras y cordilleranas, borde costero g) suelos y cambio climático, captura de carbono, servicios ambientales, manejo adaptativo y mitigación.

Modernization of the study at the Czech University of Life Sciences Prague with an emphasis on forestry and environmental fields of study

Jiří Remeš¹

¹Czech University of Life Sciences Prague, Czech Republic Prague (remes@fld.czu.cz)

The aim of the contribution is to inform about the project, which is focused on the modernization of study and increasing the quality of study programmes on the Czech University of Life Sciences Prague (CULS). Currently the university has more than 19 000 students (15% are international students), 6 Faculties (including Faculty of Forestry and Wood Sciences and Faculty of Environmental Sciences) and 1 Institute. CULS offers over 170 accredited study programmes at BSc, MSc and PhD levels. The modernization of studies and study programs is a response to the developments and changes such as globalization of the economy, climate change and new technologies. Significant socio-economic changes that have taken place during the past years in the Czech Republic also have a major impact on the demands that society places on education. The new education strategy is based on the development of teaching facilities (teaching laboratories equipped with the most modern technology) together with new educational methods (requiring an increase in the competencies of academic staff) and study programme innovation (including preparation of new study programs). A key role is played by a new way of university accreditation which was adopted in the Czech Republic in 2016. With the acquisition of institutional accreditation, the possibility of creating multidisciplinary and international study programs was opened for the CULS.

Recognizing traditional knowledge and forest practices in the Cochabamba Valley, Bolivia / Reconocimiento de saberes y practicas forestales tradicionales en el Valle de Cochabamba, Bolivia

Juan Carlos Medrano Vargas¹

¹Colegio de Profesionales Forestales de Cochabamba, Cochabamba, Plurinational State of Bolivia (jcarlosmedrano@hotmail.com)

La Constitución Política del Estado Plurinacional de Bolivia, declara que los bosques naturales y los suelos forestales son de carácter estratégico para el desarrollo del estado, y se plantea como política la promoción del manejo sustentable e integral de los bosques con participación de las comunidades, que acepte la complejidad y diversidad de los sistemas boscosos y el reconocimiento de los saberes y prácticas tradicionales. La Universidad Mayor de San Simón, han implementado programas académicos desconcentrados, que responden a las demandas de formación, las necesidades y potencialidades locales, siendo una de ellas el Programa de Técnicos Básicos Forestales. Se ha desarrollado el programa, dirigido a personas de instituciones públicas (Gobernación y Municipios de Cochabamba, Bolivia); que se dedican al sector forestal, a la producción de plántulas y al manejo de plantaciones forestales; la mayoría eran personas que no han tenido formación formal pero si han desarrollado capacidades de forma empírica, sus edades oscilan los 20 a 60 años. Producto de cada curso, se observaba el intercambio de información y conocimiento que se daba entre los docentes y los alumnos; reconociendo los saberes y prácticas que tradicionalmente habían aprendido y por otro lado adquirir conocimientos científicos de los docentes. Cada estudiante realizo una investigación, sobre acciones que realizan cotidianamente pero ajustadas al método científico, siendo sorprendente los resultados obtenidos y que fueron plasmados en documentos técnicos, se otorgó un título de Técnico Básico Forestal como reconocimiento a los saberes y prácticas forestales tradicionales de personas que promueven el sector forestal.

A tunnel to virtual reality: an immersive experience with knowledge on integrated crop-livestock-forest systems / Túnel de realidade virtual : uma experiência de imersão e conhecimento sobre a ILPF

José Heitor Vasconcellos¹, Gabriel Faria²

¹Embrapa Milho e Sorgo, Sete Lagoas, Brasil; ²Embrapa Agrossilvipastoril, Sinop, Brasil (jose.heitor@embrapa.br; gabriel.faria@embrapa.br)

Como forma de atrair a atenção do público e de proporcionar uma experiência imersiva e de conhecimento, em 2018 trabalhou-se na adaptação do conteúdo do aplicativo “Maquete Virtual de ILPF em Realidade Aumentada” para um formato de realidade virtual (RV). Pensando-se na participação da Associação Rede ILPF no Congresso Mundial de Ciência do Solo, realizado no Rio de Janeiro, criou-se um túnel por onde os visitantes passavam por dezesseis painéis utilizando óculos de RV. Em cada painel uma cena mostrava uma etapa de um sistema ILPF ou abordava algum aspecto do sistema, como comportamento de raízes, infiltração de água, ciclagem de nutrientes, ciclo de gases de efeito estufa, etc. Um áudio, em português ou inglês, explica cada imagem. Além da experiência imersiva da RV, foram utilizadas também experiências sensoriais, como iluminação diferenciada, vento simulando o conforto térmico da sombra e uso de essência de eucalipto e folhas espalhadas pelo chão nas cenas com o componente arbóreo. No Congresso de Solos, 370 pessoas, de 30 países passaram

pelo túnel. A experiência levou a várias aquisições para sua instalação em eventos do setor agropecuário e em exposições voltadas para público urbano. Uma grande vantagem dessa ferramenta é a facilidade de ser replicada. Basta imprimir os 16 targets e montá-los num caminho sequencial. Também é necessário ter um smartphone com o aplicativo baixado, fone de ouvido e óculos de RV. Modelos simples, vendidos por R\$ 25 na internet, são suficientes. Tanto o aplicativo quanto os targets estão disponíveis para download gratuito em www.ilpf.com.br.

F8b: WOOD AND FOREST CULTURE: ADDRESSING A SUSTAINABLE FUTURE

Immortal Wood Traditions in India and their contemporary relevance

Sangeeta Gupta¹

¹Forest Research Institute, Dehradun, India (sangeeta.fri@gmail.com)

Wood has been part of Indian culture since time immemorial. Most religious and domestic architecture in India, from its very inception, was wood-based. In the year 1918 a detail account was published on Indian timbers mentioning the usage of over 1400 tree species. This knowledge became the basis for furthering scientific studies on wood identification, their properties and efficient utilization. Indian Standards were formulated to list wood species recommended for various purposes like Railway sleepers, Defense tools, construction, cooling towers, sports goods etc. The presentation shall draw a chronology of wood traditions in India through pre-historic period and would throw light on how this knowledge has been utilized in recent time. An account shall be given on woods used traditionally for construction, dockyard, mortars, coffins, charcoal, sculptures, wicker work, toys, musical instruments, agriculture implements, incense etc. utilizing various properties of wood like strength, durability, shock absorbance, self lubricating, weight, calorific value etc. It shall also throw light on how this already prevailing age old knowledge has been presently useful in efficient utilization of the wood. Wood species used in temples, shipbuilding, furniture, musical instruments, toys etc. suggest well-developed and immortal wood traditions in India that still holds relevance today. The tradition of usage of various medicinal woods is still in practice today, the account of which dates back to several centuries. The wood explorations have also led in throwing light on broad distribution of trees and thus provide useful information for their rehabilitation. ■

Schwarzenberg Floating Canal: An unwanted forest cultural heritage?

Jiří Woitsch¹

¹Czech Academy of Sciences, Institute of Ethnology, Praha, Czech Republic (jiri.woitsch@post.cz)

The aim of presentation is to describe and analyse history and current status, including ongoing conflicts and future prospects, of perception and protection of Schwarzenberg Floating Canal as an important cultural monument and heritage object of forestry, timber and wood utilisation in the Central Europe. The paper is based on study of historical sources, analysis of current conservation and heritage policies in the Czech Republic, public and media coverage of the topic and field anthropological research. The Canal - one of the most remarkable water structures of its times - was built in two phases from 1789 to 1822 to transport firewood and timber from the Šumava (Böhmerwald) mountains to Vienna, thus enabling utilization of formerly inaccessible parts of the Šumava forests. Total length of the waterway was 89,7 km and was complemented with hundreds of bridges, sluices, water moats and gates. Construction of the Canal intensified logging in the South-Western Šumava, provoked the colonisation of area and led to gradual transformation of the Šumava forests in the course of 19th Century. However only a shorter part of the Canal was used in the 20th Century and after the 2nd WW the waterway was abandoned and heavily damaged. On the other hand it has been listed as a cultural monument since 1963 and partly renovated from 1980s to 2001. After the establishment of Šumava national park in 1991, however, the Canal became an unwanted heritage: it clearly shows that forests in Šumava are much more of a biocultural heritage than untouched nature.

Wood culture programs: paving the way for responsible wood usage and a sustainable future

Charlotte Chia Hua Lee¹, Howard Rosen^{2,1}

¹IWCS, Newport Beach, USA; ²US Forest Service, Silver Spring, USA (chiahua.lee@iwcs.com; howard.rosen@verizon.net)

Wood culture can be defined as “The value and the way we use wood in our society.” The International Wood Culture Society (IWCS) was established over a decade ago to raise public awareness of wood as an eco-friendly biomaterial and encourage academic research and responsible wood usage for a sustainable wood future. The Society established World Wood Day (WWD) on March 21st each year to celebrate the human use of and activities with wood, as well as attitudes toward wood, wood products and wood-related environments. To manage these celebrations, the World Wood Day Foundation (WWDF) was established in 2013. The Foundation also manages funds and grants for World Wood Day and the global research, education and promotion of wood culture. The first World Wood Day (WWD) celebration was held in Dar Es Salam, Tanzania in 2013; followed by a new country each year. Activities at each celebration include wood carving, wood turning, a technical symposium, tree planting, a wooden instrument musical festival, furniture making, wooden folk art, a children’s program, wood design, and a collaborative project. These programs continue our wood heritage and traditions with creative new ideas for our daily development and provide a greater appreciation for the interplay between wood, nature, and the people who work with and use wood. This talk will give examples of how these goals are accomplished.

Characterization of municipalities in the timber production chain in the north of Mato Grosso, Brazil

Vinicius do Prado Capanema¹, Maria Isabel Escada¹

¹Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil (livia_cipriano@hotmail.com; edulongui@gmail.com; lech.muszynski@oregonstate.edu; awballarin@fca.unesp.br)

Selective logging have been occurred for more than three centuries in the Amazon and, in the past, it was made for subsistence in lowland forests and, therefore, it was very low impact. The intensification of logging occurred in the 1970s, mainly due to the construction of roads, depletion of southern and southeastern stocks, and uncontrolled exploitation. These factors led the Amazon to the position of the world’s second largest producer of tropical timber, in which Pará and Mato Grosso the main producing states. At Mato Grosso state, timber sector plays an important economic role, contributing strongly to the state’s revenues and generating jobs. In this context, the present study aimed to characterize the municipalities in the north of the state of Mato Grosso considering their participation in the wood production chain, according to a typology of municipalities’ influence patterns in the state’s timber sector, and the profile socioeconomic context in which they are inserted. The results showed that there are five different patterns: 1) municipalities with highly developed industry, 2) municipalities with primary industries with high wood processing capacity, 3) municipalities with industries with low processing capacity and high lumber stock, 4) few lumber and small

timber industries, and 5) municipalities with virtually no logging and poor-quality stock. Regarding the socioeconomic characterization, the results showed that the municipalities with high industrialization have the highest indicators analyzed.

Comparative environmental impact assessment between natural and plastic Christmas tree: a case study

Andrea Laschi¹, Azzini Lapo¹, Francesco Nicese¹, Francesco Del Pero², Enrico Marchi¹, Massimo Delogu², Giacomo Goli¹

¹DAGRI – Dipartimento Scienze e Tecnologie Agrarie, Alimentari, Ambientali e Forestali - Università di Firenze, Firenze, Italy; ²DIEF – Dipartimento di Ingegneria Industriale - Università di Firenze, Firenze, Italy (andrea.laschi@unifi.it; lapo.azzini@stud.unifi.it; francesco.nicese@unifi.it; francesco.delpero@unifi.it; enrico.marchi@unifi.it; massimo.delogu@unifi.it; giacomo.goli@unifi.it)

The production of natural Christmas trees is a niche between forest and agriculture sectors. In Italy, Christmas tree cultivation is a traditional activity, typical in upper hills and mountains, which was very common and remunerative in some areas. Since a long time, the market of natural tree underwent the competition of the plastic one, which is often considered by customers as more practical, durable and efficient in terms of environmental sustainability. The aim of this study was to answer to the question: “*is it better the natural or the plastic Christmas tree?*”. To answer, under an environmental point of view, a Life Cycle Assessment (LCA) was applied to compare the two different kinds of product. The study has been divided in four phases: - Analysis of customer preferences about Christmas tree; - Data collection on the production of both natural and artificial trees, considering the most common products available on the market in central Italy (local production chain for natural trees and industrial production in China for plastic ones). - Identification of system boundaries; the analysis is a cradle to grave LCA, being all the phases of life cycle included in the analysis, from raw material production to disposal of the product at the end of its life. - Life cycle impact assessment (LCIA) and comparison of results with Gabi software. In this contribution, the best environmental profile and the hotspot in CO₂e emission, which is a parameter used as indicator for Greenhouse Gas (GhG) impact category, will be presented.

Linking the tradition and modern technology: how the Japanese traditional tea culture using bamboo and solid wood being adopted into the modern society?

Sumire Kawamoto¹, Takako Nikaidou², Mariko Inoue¹

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Food and Agricultural Materials Inspection Center, Saitama, Japan (sumirekw@gmail.com; takako_nikaidou@nm.famic.go.jp; imariko@ffpri.affrc.go.jp)

The art of Tea as it exists in Japan today is the legacy of Sen Rikyu, a 16th century Tea Master who lived when war prevailed among the provinces in Japan. After his death, his philosophy that focused on simplicity has lived in the art of Tea. Various kinds of utensils made from bamboo and solid wood that can be returned to the soil have been representing an important philosophy in old Japanese culture. It comes from a background that Japanese people tend to consider that beauty exists in humble simplicity, a gradual deterioration caused by the service life, and some fragility of biological materials. This paper includes introduction of traditional tea culture and craft items, which has survived for long years in Japan. It might give us some insight on how we can keep linkage between the tradition and the modern society.

F9b: DELIVERING AND COMMUNICATING FOREST SCIENCE FOR PEOPLE AND A GREENER FUTURE

A link between Foresters and the general public: forest and wood in 100 questions

Jean-Luc Peyron^{1,2}, Yves Birot², Bernard Roman-Amat²

¹GIP Ecofor, Paris, France; ²Académie D'agriculture de France, Paris, France (jean-luc.peyron@gip-ecofor.org; yves.birot@numericable.fr; bernard.roman-amat@wanadoo.fr)

Communication on forest issues with the general public is more often the work of environmental non-governmental organisations than forest professionals and scientists. Naturalistic films and best-selling books on man-to-nature relations have a large audience. They usually focus on ecological or sociocultural aspects, using frequently over-simplistic arguments. They rarely, if ever, deal with sustainable forest management. Foresters are ill-equipped to meet the challenge of communication: they often have little affinity and time for communication activities and their task is difficult: how to communicate on how to seek the right compromise, for each place considered both now and for the future, between ecological, economic and socio-cultural aspects? One of the ten sections of the French Academy of Agriculture deals with the forest-based sector. Under the coordination of Yves Birot, this section took the initiative of developing a digital book: “Forest and wood in 100 questions”. Based on up-to-date scientific and technical knowledge, it is intended to support the dialogue between science and society. Answers to a hundred questions, organized in ten chapters, are given in the form of articles of four pages each. The set is available free of charge on the website of the “Académie d'agriculture de France”. The majority of these forest and wood-related questions are general in scope. The answers are aimed preferentially at the French public but most of the articles could easily be adapted to other contexts. This contribution aims to present this initiative, the main lines of its realization and some comments on its interest.

Communicating about forest issues with schoolchildren

Débora Lingner¹, Alexander Christian Vibrans¹, André de Gasper¹, Laio Oliveira¹, Manoela de Aguiar¹

¹Fundação Universidade Regional de Blumenau (FURB), Blumenau, Brasil (deboravanessa.ef@gmail.com; acv@furb.br; algasper@furb.br; laiooliveira@gmail.com; manoaguiar@gmail.com)

Involving young people is a well known strategy to provoke awareness of environmental issues and changes in behaviour of the present and future generations. We created a virtual forester named “Pedro Carvalho” who guides kids through the universe of Santa Catarina State Forests (Southern Brazil), object of a long-term systematic inventory and studies on species composition, structure, ecology and dynamics. The inventory team members desired to improve the communication with rural populations through schoolchildren and decided to engage efforts on this goal. Our approach is simple and threefold: we published a booklet with specially designed illustrations, for free distribution at primary schools. Additionally, we created an itinerant exhibition with banners, panels and showcases, which was also made virtually available on the project's homepage (www.iff.sc.gov.br). We visited more than a hundred of primary schools in rural regions of Santa Catarina State. An adequate language, focusing on local known practices, on multiple uses of a large range of forest species, on environmental problems like floods and droughts, and cartoon like illustrations facilitated the interaction with young audiences, catching their attention and raising their

curiosity. The joint effort together with the local teachers, using booklets, exhibition and class-room activities stimulated vivid discussions on ecosystem services, sustainable uses of forests, the importance of forests for survival as for local populations as at global scale, and their role in the context of climate change. We hope to achieve long-term gains in consciousness and responsible acting into a greener future of our target group.

Rethinking forest landowner outreach: applying targeted marketing principles to promote prescribed burning on private lands

Jennifer Fawcett¹, Laurel Kays¹

¹North Carolina State University, Raleigh, USA (jlevans3@ncsu.edu; lekays@ncsu.edu)

Forest research is most meaningful when it gets into the hands of those who can apply it to the land, including private landowners. In the Southern United States, private landowners hold 86 percent of the forest area. These landowners are a diverse mix of people, from farmers to environmentalists and a host of other groups, who have many and varied reasons for owning land. It is important to be able to translate and disseminate research findings to these various types of landowners through outreach programs. However, unsurprisingly, each of these groups are motivated by different messages and emotions, often making outreach efforts difficult. The Tools for Engaging Landowners Effectively (TELE) program assists practitioners in designing outreach programs to bring about a specific behavior change in a selected group of people, rather than using a broad-brush approach that tries to appeal to everyone. This approach has been shown to be an effective and efficient way to change behaviors and norms in a variety of fields. We used the TELE methodology to promote the use of prescribed fire by applying targeted marketing principles to reach specific landowner audiences. Using this method allowed us to design fliers and other outreach materials using effective messaging that aligned with their needs and values, thus ultimately allowing us to better deliver and communicate fire science. Lessons learned from the approach of using targeted marketing to promote increased prescribed fire use on private lands will be shared as a case study during this presentation.

Voice lessons for scientists: what to say and how to say it

Nehalem Clark¹, Jessie Golding²

¹USDA Forest Service, Fort Collins, USA; ²USDA Forest Service, Missoula, USA (ncclark@fs.fed.us; jessie.golding@usda.gov)

Communicating just the right information in the right tone often does not come naturally. Just ask parents of young children. Like parents, scientists are unlikely to have received training in effective communication for diverse audiences. Different approaches are required for scientists sharing information outside of their network of science colleagues. For science to be integrated into realms such as decision-making and land management applications, understanding the needs of users and packaging the information in accessible and appealing formats is paramount. The U.S. Forest Service is a large agency where effective science communication is essential at every level. From the technician setting up the remote camera in the field, to the leadership teams creating national strategies, science needs reach every part of the organization. Science communication training today has illuminated the need for better storytelling. Further, we suggest that science communication and the teaching of it needs a different message. To set the tone for successful communication, be flexible and responsive to user needs. We share a variety of case studies from our experiences at multiple levels of science communication within the U.S. Forest Service to illustrate our main lessons learned: start with the end in mind, tell a story that resonates with your audience, keep your equations to yourself, leave them wanting to know more, brief is better, and do not be afraid of novelty. As in parenting, these approaches take practice and continual adaptation.

Inspiring climate action through role play and interactive computer simulation: world climate simulation experiences in Kenya

Sheila Shefo Mbiru¹

¹The Low Emission and Climate Resilient Development (LECRD) Project, Nairobi, Kenya. World Climate Ambassador, Nairobi, Kenya (sheilambiru@gmail.com)

Climate change is difficult to communicate by its very nature and should be communicated in such a way that it is easily understood and relevant to the audience. There are various climate change communication tools that bring complex climate change issues to public attention, understanding and action. One such tool is *World Climate*. *World Climate*, an interactive climate negotiation role playing simulation enables learning through scientifically grounded and socially engaging experiences. Participants play the role of negotiators for different nations and blocs of nations and work together to limit global warming to well below 2°Celsius in line with the Paris Agreement. Using C-ROADS simulation software, participants find out, in real-time how their proposed policies impact the global climate system. In Kenya, *World Climate* has been used in various settings including with policy makers, media practitioners and youth in high school and church. Results were extremely positive with most participants indicating they now have a deeper understanding of climate change, its impacts and the need for urgent action at all levels; global, national, sub national, community and most importantly individual level.

Rooting forest science through knowledge co-creation and the arts and the transition to a biosociety

Nina Tokola, Irmeli Mustalahti

¹University of Eastern Finland, Joensuu, Finland (nina.tokola@uef.fi; irmeli.mustalahti@uef.fi)

We argue that acceptability is a key issue in the transition towards forest bioeconomy. Young citizens are the decision-makers of the future decades and thus a focal audience for forest science communication. We study the visions of Finnish youth regarding a green transition and sustainable well-being in the multidisciplinary research project *All youth want to rule their world*. We explore the capabilities of youth (aged 16-30) and the obstacles that hinder their engagement with society and environment. Our key ideas for sustainable well-being are responsive governance and transition towards a biosociety, based on a circular- and bioeconomy. We see communication and delivering as two-way processes and as genuine interaction between scientists, youth, project partners, decision-makers, and the public. Thus, we chose action research as research strategy, allowing us to study the activities of various forest bioeconomy and youth sector actors. Our goal is to root “living knowledge” through knowledge co-creation and to develop trajectories that our partners consider relevant. We further aim to translate the co-created results into a language of the arts. The following methods of communication are applied: i) citizen science: young people as co-researchers of sustainable well-being, ii) co-development of a mentoring model for boosting youth employment in the bioeconomy sector, iii) art meets science in an art-inspired dialog series, iv) co-production of policy recommendations: youth voices included in the National Forest Strategy 2025. We propose participatory and deliberative ways of knowledge creation that enable the communicating forest science more effectively to target audiences.

Using RIU-Model to assess impact of big research projects in the practice: example of ALTERFOR

Mirjana Stevanov^{1,2}, Max Krott¹, Nataly Juerges¹

¹University of Goettingen, Faculty of forest sciences and forest ecology, Chair of forest and nature conservation policy, Goettingen, Germany; ²University of Novi Sad, Institute of lowland forestry and environment, Novi Sad, Serbia (mzavodj@gwdg.de; mkrott@gwdg.de; nataly.juerges@uni-goettingen.de)

ALTERFOR (Alternative models and robust decision-making for future forest management) is a joint European Horizon 2020 project examining existing forest management models (FMMs) in the light of different alternative scenarios over 100-years period in ten case studies: Germany, Italy, Ireland, Lithuania, the Netherlands, Portugal, Slovakia, Sweden, and Turkey. The project develops robust FMM alternatives for delivering ecosystem services and reducing vulnerabilities at stand to landscape level and aims to provide based on the innovative results policy support in practice. The knowledge transfer activities are oriented toward the RIU-model which claims to bridge science and practice. The RIU-model assumes Research and Utilization of scientific results (which comprises politics) as independent phases which follow their own rational: science is looking for new theoretical and empirical based knowledge whereas utilization by practice and politics is an interest and power driven process. Nevertheless, the both different areas can be bridged by "Integration". Integration builds a link by fully respecting the autonomy of science but selecting specific results and research questions which fits into the interests of actors. These actors will become allies for scientific knowledge transfer who put their power behind specific science-based solutions forcing other actors to follow them. In all cases ALTERFOR analyzed existing networks of forest-related actors, organized workshops with targeted actors and critically analyzed experiences with such Integration activities. They show that a big project like ALTEROF creates promising linkages into practice but lacks resources to implement the RIU-model on a high level and trigger major impact that way.

Storytelling for science communication and media engagement

Ewa Hermanowicz¹, Michele Bozzano¹

¹European Forest Institute, Bonn, Germany (ewa.hermanowicz@efi.int; michele.bozzano@efi.int)

Storytelling is one of the most effective and natural mechanisms to supply new knowledge to the human brain. Using a storytelling approach in communications enables audiences of different professional and social backgrounds to learn about forest research projects. It also increases the likelihood of engaging media, thus increasing the visibility of the work. The session will focus on digital storytelling and filmmaking, which can be used effectively in a broad range of projects to drive change. I will outline the building blocks of an effective story and explain how these translate into film production. An essential building block is a character to whom viewers can relate, who conveys the key messages through un-scripted interview as an authentic voice. The session will include a screening of a successful film to illustrate the proposed ideas and will analyze the steps necessary for pre-production, production and promotion.

Explaining my PhD through cartoons

Alex Giurca¹

¹University of Freiburg, Freiburg, Germany (alex.giurca@jfp.uni-freiburg.de)

During my PhD studies, I rediscovered my love for art, and learned that science and arts are not necessarily mutually exclusive. My thesis dealt with the emerging bioeconomy paradigm, the actors and political coalitions that shape the bioeconomy discourse in Europe. Political science is complex, the general stereotype being that it heavily relies on large amounts of dense, ambiguous text and scientific jargon. This preconception is not necessarily wrong. Indeed, communicating and simplifying the main points of ones research into small digestible bits of "take-home" or "key messages" is not always easy. Dealing with the bioeconomy issue from a political science perspective, made the task of communicating my research results even more daunting. An old saying goes, a picture can tell a thousand words. So I started experimenting with illustrations/cartoons that would explain my main findings in a fun and engaging way. I started creating digital art for my scientific papers and posting them on my personal blog. Later I experimented with explainer-animated videos in PowerPoint. So far the response has been nothing but positive. In this presentation, I aim to share my approach and the lessons I've learned from my attempts to communicate science with the help of cartoons.

Forestry and natural resources webinars: success, challenges, and implications based on 10 years of experience

Robert Bardon¹, William Hubbard²

¹North Carolina State University, Raleigh, USA; ²University of Maryland, College Park, USA (rbardon@ncsu.edu; whubbard@umd.edu)

To help forestry professionals, landowners, and others increase their forestry and natural resource management knowledge, Universities have turned to using learning management systems for online education. The *Webinar Portal for Forestry and Natural Resources* is a learning management system designed to transfer research-based information from scientists and educators to practitioners, landowners and others, through live and on-demand webinars. The portal was developed through a partnership of university extension programs, government agencies and others to provide an effective platform for delivering webinars. Post webinar evaluations of approximately 3,700 participants utilizing the portal in 2018 indicate webinars are an effective tool for increasing participant knowledge and aspiration; two factors known to lead to adoption and implementation. Based on post evaluations 34% of the participants indicated an increase in knowledge and 65% aspire to further investigate the topic. These changes in knowledge and aspiration have resulted in 55%, 24% and 54% of the participants indicating they will improve their land management skills, business practices, and ability to respond to client questions respectively. By training online in 2018, verses on site, participants achieved over \$11 million dollars in costs savings due to elimination of travel expenses. The portal is an effective tool for scientists and educators to disseminate knowledge to forestry professionals, landowners and others. Within the scope of this presentation, the authors will discuss lessons learned from delivering approximately 200 webinars, focusing on challenges faced in developing and delivering the webinars, and how webinars may increase the effectiveness and efficiency of technology transfer.

Use of an augmented reality app to disseminate integrated crop-livestock-forest systems / Uso de aplicativo de realidade aumentada para a divulgação dos sistemas de integração lavoura-pecuária-floresta (ILPF)

Gabriel Faria¹, Jose Heitor Vasconcellos²

¹Embrapa Agressilvipastoril, Sinop, Brasil; ²Embrapa Milho e Sorgo, Sete Lagoas, Brasil (gabriel.faria@embrapa.br; jose.heit@embrapa.br)

A necessidade de expandir o entendimento de diferentes públicos sobre a complexidade dos sistemas de integração lavoura-pecuária-floresta (ILPF) levou à busca por novas ferramentas de comunicação que pudessem ser facilmente utilizadas por qualquer pessoa, em qualquer local, a qualquer momento. A tecnologia da realidade aumentada (RA) mostrou-se com grande potencial, tanto pela expansão do número de smartphones no país como pela sua praticidade

e interatividade. Desenvolveu-se, então, o aplicativo Maquete Virtual de ILPF em RA, que mostra a evolução de um sistema ILPF desde sua implantação, passando por todas as combinações possíveis entre lavoura, pecuária e floresta. O usuário pode acompanhar as diferentes etapas não só no que ocorre sobre a terra, mas também abaixo dela, como a mudança no perfil do solo, o ciclo de nutrientes e de carbono, a infiltração de água e o comportamento de raízes. O aplicativo foi disponibilizado nas versões Android e IOS, em português e inglês, e pode ser baixado gratuitamente nas lojas online. Para usá-lo é preciso imprimir uma imagem (target), para onde se aponta a câmera do celular ou tablet. Este aplicativo pode ser usado em palestras por pesquisadores, extensionistas e professores, sendo didaticamente adaptável aos seus diversos públicos. Além disso, esse app pode ser usado para divulgar a ILPF em feiras, exposições, congressos, entre outros eventos.

F9c: FOREST SCIENCE EDITING IN THE CONTEXT OF OPEN SCIENCE: WHAT CHANGES ARE AHEAD FOR US?

Global, regional, local: What kind of peer-reviewed forestry journals are being published?

Maja Peteh^{1,2}, Alan Pottinger³

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia; ³International Forestry Review, Shropshire, United Kingdom (maja.peteh@gozdis.si <https://orcid.org/0000-0002-9636-1155>; alan.pottinger@cfa-international.org)

Bibliometric analysis of scholarly journals in forestry shows us high publishing in journals primary covering other disciplines (eg. Chirici, 2012), mostly due to low impact (eg. Bojovic et al., 2014). A key objective of IUFRO WP 9.01.06 (Forest Science Publishing) is to clarify the range of forestry journals within an overall goal of assisting both authors and readers to further our knowledge of forestry. In this study we expanded this list of forestry journals prepared by Vanclay (2008) using the ISSN database, journals indexed and cited in Web of Science and listed in Scopus, journal indexed in the Forest Science Database (or CAB s), and other sources. Each title was recorded with the ISSN, publisher, language of publication, web page, and geographical coverage (i.e. local, regional, national or international). It is hoped that the list will be published and regularly updated on the IUFRO website and therefor thereby available to forestry students, researchers, and practitioners.

What level of publication transparency should we request in forest sciences?

Pekka Nygren¹

¹Finnish Society of Forest Science, Helsinki, Finland (pekka.nygren@metsatiede.org)

Publication transparency is an important dimension of open science. Naturally, transparent publication with adequate opening of data, methods, and code is needed for fully understanding how a research was done and avoiding serious misunderstanding. Second, transparency is needed for evaluating the quality of the research even when good scientific practice is followed. Third, transparency is needed for reproducing new research findings or verifying results of inherently non-reproducible work, e.g. long-term ecological research. Fourth, reuse of research data in new studies or meta analyses requires full understanding on the study environment and methods. Fifth, transparency is needed for detecting questionable research practices. While serious scientific misconduct is quite rare, lighter deviations from good research practice, or sloppy science, are quite common: A recent survey indicated that up to 60% of ecology researchers have sometimes used questionable research methods. A peer-reviewer or an editor can detect them only if publication transparency is required. Both general and discipline-specific transparency guidelines have been published and major publishers have created their own versions of them yet the policies require stronger enforcement. Journals are in the frontline for bringing transparent practices to the main steam of research. Without a signal from journals, scientists' expectations for publication transparency are not likely to shift en masse towards open data, methods, and codes. Forest science journals should develop common guidelines on publication transparency because the typical characteristics of forest research, especially the large spatial and temporal scales, call for specific applications of common or publishers' standards.

The opportunities offered by open science to forest and wood science journal editors

Erwin Dreyer¹, Aurore Coince¹, Odile Hologne²

¹Inra, Champenoux, France; ²Inra, Versailles, France (erwin.dreyer@inra.fr; annforsci@inra.fr; odile.hologne@inra.fr)

The movement towards open science has gained strong momentum across the world, which is good news for the editors of forest and wood science journals who favour the broadest possible dissemination of research results. The current trend is towards open data, open access to published papers, open review of submitted manuscripts, posting of pre-print manuscripts in open repositories. The number of submitted manuscripts increases readily and peer review is made difficult given the overload of work it induces. In parallel, the number of journals and outlets increases continuously. There is a strong competition between publishers and between journals, all aiming to attract the best and potentially most cited paper. This context, opposing the ideal of open science and the reality of competing interests of publishers may lead to the end of the traditional model of science editing/publishing and our good old journals. In the contrary, we believe that our journals still have a bright future ahead if they adapt to this new context and serve forest and wood sciences requiring long lasting time series, large data bases and tight cooperation across disciplines and countries. In this presentation, we will address following questions: (i) how can our journals adapt to this context and develop innovative and open editorial processes; (ii) how can they enhance their cooperation to develop the innovative editorial processes required by open science. Our final aim is in all cases to support the development of forest and wood sciences while their contribution is absolutely required.

Developing a sustainable solution to funding open access publishing

Michael Donaldson¹, Philip Burton^{2,3}, Suzanne Kettley¹

¹Canadian Science Publishing, Ottawa, Canada; ²University of Northern British Columbia, Terrace, Canada; ³Co-Editor in Chief, Canadian Journal of Forest Research, Canada (michael.donaldson@cdnsiencepub.com; phil.burton@unbc.ca; suzanne.kettley@cdnsiencepub.com)

Despite a widespread desire for Open Access (OA) publications from the research community and its stakeholders, one of the major stumbling blocks to OA remains the cost of publishing research. Publication costs are often covered by authors themselves, through an Article Processing Charge (APC), despite limited research budgets to do so. With funding agencies and institutions more commonly requiring published research to be made OA, there is a pressing need to identify alternative models for funding OA publishing. To tackle this issue, Canadian Science Publishing, a not-for-profit scholarly publisher, hosted a national summit with various Canadian stakeholders, including researchers, research administrators, librarians, publishers, and research funders. The purpose of the

summit was to propose and refine various funding models with the goal of moving away from the author-paid APC. Following the summit, we are convening a working group to take a solutions-based approach to alternative funding models. The purpose of the working group is to further develop the models and take an experimental approach to test and refine them by applying them in practice to one or more existing journal(s). This presentation will discuss our progress to date including a critical analysis of the strengths and limitations of our new models and ideas for improving them. The ultimate goal of this work is to develop a model that could be applied broadly to other journals in order to move to a sustainable model for OA publishing.

Results vs. discussions in journal articles: lessons for authors

Warren Moser¹

¹USDA Forest Service, Flagstaff, AZ, USA (warren.k.moser@usda.gov)

The function of a scientific journal article is to present a hypothesis, evaluation of data and the results of a study or analysis. Readers can better evaluate the results and implications of a study if they understand the place that the article occupies in the overall constellation of work in a particular discipline. Authors all too often enter into a study inspired by an idea but do not place the study and its results in the context of other work or important issues. This failure to provide context most frequently occurs in two places in a manuscript: the objectives of the study and the relevant literature review, and the discussion of the results and the implications thereof. Authors often present the results as if the implications are self-evident and pay limited attention to the “so what?” of their results. This paper will present the authors’ view of what constitutes a discussion of study results and how it differs from the results section. Examples of successful and less successful result-discussion combinations will illustrate this distinction. This paper is intended both for both more experienced authors and for newer authors. The suggestions can help authors with a longer publication record to sharpen their skills at sharing their findings with land managers and other practitioners in a way that is practical and applicable to users of this research. New authors will find clear guidance as they publish their own work.

The influence of European Framework Programmes on researcher’s publishing activity: bibliometric case study of Slovenian research groups in the filed of forestry

Maja Peteh^{1,2} , Primož Južnič³ 

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia; ³Faculty of Arts, Department of library and information science and book studies, Ljubljana, Slovenia (maja.peteh@gozdis.si; primoz.juznic@ff.uni-lj.si)

To develop a researcher’s career, it is important to participate in international and domestic research projects. With bibliometric approach we investigated the influence of selected EU Framework Programmes on researcher’s publishing activity of Slovenian research groups in the filed of forestry. Additionally, we tested fulfillment of double requirements: the requirement on open access mandate for publications (via OpenAIRE) and acknowledgment of co-financing (via Web of Science). The presentation contributes to the aims and means of the project LIFEGENMON (LIFE13 ENV/SI/000148) LIFE For European Forest Genetic Monitoring System which is in line with goals of EUFORGEN (European Programme for Forest Genetic Resources).

In-Sylva-France a new research infrastructure for forest adaptation and silvicultural innovations

Christian Pichot¹, Laurent Saint-André², Alain Bouvet³, Christine Deleuze⁴, François Ehrenmann⁵, Christian Ginisty⁶, Céline Meredieu⁵, Eric Paillassa⁷, Christophe Plomion⁸, Sonia Said⁸, Lucile Savagner³, Plinio Sist⁹

¹Institut National de la Recherche Agronomique, Avignon, France; ²Institut National de la Recherche Agronomique, Nancy, France; ³Institut Technologique Forêt Cellulose Bois-construction Ameublement (FCBA), Champs-sur-Marne, France; ⁴Office National des Forêts (ONF), Paris, France; ⁵Institut National de la Recherche Agronomique, Bordeaux, France; ⁶Institut national de recherche en sciences et technologies pour l’environnement et l’agriculture (IRSTEA), Nogent-sur-Vernisson, France; ⁷Centre National de la Propriété Forestière (CNPFF), Bordeaux, France; ⁸Office National de la Chasse et de la Faune Sauvage (ONCFS), Birieux, France; ⁹Centre de coopération internationale en recherche agronomique pour le développement (CIRAD), Montpellier, France (christian.pichot@inra.fr; laurent.saint-andre@inra.fr; alain.bouvet@fcba.fr; christine.deleuze@onf.fr; francois.ehrenmann@inra.fr; christian.ginisty@irstea.fr; celine.meredieu@inra.fr; erich.paillassa@cnppf.fr; christophe.plomion@inra.fr; sonia.said@oncfs.gouv.fr; lucile.savagner@inra.fr; sist@cirad.fr)

Forests have to cope with three interlinked transitions: climatic transition, energetic transition and economic transition with an up-rising demand on wood such as new needs to feed up the emerging bioeconomy. Meanwhile, forests are part of a world-wide, nature-based solution for climate warming mitigation, although forests are at the center of territorial conflicts. Thus, it is urgent to foster the development of innovative forest management practices taking into account the quadruple interaction ‘which forest resources x in which biogeoclimatic zones x with which forest managements x for which purposes’. By doing so we expect to provide decision tools for forest managers and policy makers. The French national infrastructure IN-SYLVA federates in a common organization tropical and tempered in situ experimentation networks managed by the public and private sectors (5,000 experimental trials covering 4,000ha) as well as in lab facilities (functional ecology, wood properties and genomics) and in silico resources (data bases and models). In such a way IN-SYLVA deals jointly with forest management, biogeochemical features, genetics and economy. IN-SYLVA will guide public policies by scientific or technical enlightening and will be the link to the academic and professional sphere. Within the Open Science framework IN-SYLVA data policy and practices will contribute to the sharing of data and knowledge. Our first practical goal is to set up an information system federating the distributed resources and providing through the IN-SYLVA data portal the necessary metadata for discovery and access to the data collected by the experimental networks.

F9p: DELIVERING AND COMMUNICATING FOREST SCIENCE FOR PEOPLE AND A GREENER FUTURE

Social perception of forestry in the Northern region of Uruguay: beyond the economic impact

Virginia Morales Olmos¹, Isabel Bortagaray¹, Diego Passarella¹, Cecilia Marrero¹, Aylene Paiz¹

¹Universidad de la República, Tacuarembó, Uruguay (vmolmos@gmail.com; isabelbortagaray@gmail.com; diego.passarella@cut.edu.uy; ceciliamarrero3@gmail.com; aylenepaiz@gmail.com)

The measurement of the impact of a new economic activity on a territory beyond the economic impact is a topic of special interest for different sectors of a society, especially for activities involving the use of natural resources. In Uruguay, forestry has been increasing its relevance on the national economy over the last decades. As a consequence, the adoption of a comprehensive assessment of its impact is of common interest for the population. The changes in forest sector the Northern region lead to raising questioning of the sustainability of the forest-related investments and their long-term impact on the territory. A multidisciplinary approach was used to elucidate the perception of the forestry sector and to learn on the society's perceptions. The project consisted on: a review of different approaches of sustainability assessment; a collaborative construction of the sustainability assessment of the forestry sector on the northern region of Uruguay; and a collaborative definition of the communication strategy of the assessment parameters previously obtained. The local peculiarities of the forestry sector were investigated through interviews to a set of experts and workshops with targeted audiences. A web-based consulting platform have been launched in order to elucidate and construct the society perception to assess the forestry sector and its sustainability. Preliminary results indicate that the perception of the population on the sector and its impact varies by sub-regions. It confirms the existence of some "myths" about the sector, as well as the demand for available and reliable information for the population.

Creative and didactic communication through infographics / Comunicação criativa e didática por meio de infográficos

Cindy Correa, Milena Serro

¹Ibá, São Paulo, Brazil (cindy.correa@iba.org; milena.serro@iba.org)

A Indústria Brasileira de Árvores (Ibá) é a entidade responsável pela representação institucional da cadeia produtiva de árvores plantadas em nível nacional, do campo à indústria, com ênfase em celulose, papel, painéis de madeira e pisos laminados. Nosso principal desafio de comunicação é apresentar aos stakeholders a importância da agroindústria para o meio ambiente, a economia e as pessoas. Além de fornecer produtos essenciais para o uso diário da população, as plantações de árvores também desempenham papel fundamental na prestação de serviços ambientais, como a conservação de florestas naturais e da biodiversidade, a regulação do clima e da água, entre outros. Apesar do compromisso desta indústria com esses serviços ecossistêmicos, ainda há pouco conhecimento por parte do público em geral sobre os benefícios gerados por uma plantação florestal e o manejo das paisagens pelas quais estas indústrias são responsáveis. Muitas vezes, a indústria de árvores plantadas ainda é alvo de críticas e de antigos mitos sobre sua atuação. Para combater esses mitos, a Ibá adotou como estratégia de comunicação a construção de uma nova narrativa sobre a atuação sustentável deste setor, por meio da criação de infográficos que demonstram, de forma ilustrativa e didática, como se faz gestão da paisagem, a gestão de recursos hídricos e a conservação da biodiversidade, entre outros. Os infográficos também são compostos de textos que contextualizam tudo o que é representado graficamente por meio das ilustrações. Os textos trazem, em linguagem amigável, informações técnicas baseadas em estudos e pesquisas de fontes renomadas - nacionais e internacionais.

"Science and the media:" the importance of forestry research for communicators / "Ciência e mídia": a importância da pesquisa florestal para comunicadores

Ana Laura Lima¹, Priscila Viúdes², Adriano Venturieri¹, Sabrina Gaspar¹, Dulcivânia Freitas³

¹Embrapa Amazônia Oriental, Belém, Brazil; ²Embrapa Acre, Rio Branco, Brazil; ³Embrapa Amapá, Amapá, Brazil (analaura.lima@embrapa.br; priscila.viudes@embrapa.br; adriano.venturieri@embrapa.br; sabrina.gaspar@embrapa.br; dulcivania.freitas@embrapa.br)

Os comunicadores são importantes influenciadores e formadores da opinião pública. Além disso são mediadores do debate entre a sociedade e instituições. Para aproximar desse público o debate sobre as questões ambientais na Amazônia, a Embrapa – Empresa Brasileira de Pesquisa Agropecuária - realizou ao longo de dois anos encontros denominados "Ciência e Mídia", em nove cidades dos sete estados da Região Norte e no Maranhão. Este pôster apresenta a experiência de realização dos cursos e o impacto no público-alvo. O público participante totalizou 250 pessoas, entre profissionais da imprensa, lideranças comunitárias e estudantes de Comunicação. As temáticas abordadas foram: "Clima, mudança no uso da terra e o papel da floresta", "Sistemas sustentáveis de produção na Amazônia", "Jornalismo de Dados: um novo olhar sobre a Amazônia – acesso e uso do Prodes" e "Uso e cobertura da terra na Amazônia". Com base nas avaliações dos cursos, 66% do público considerou o evento ótimo e 33% excelente. Ficou evidente que eventos dessa natureza são importantes para ampliar o debate sobre o papel da floresta e as questões ambientais globais, e qualificar a cobertura jornalística sobre esses temas. Além disso é uma boa oportunidade para aproximar as instituições de pesquisa dos formadores de opinião. Os especialistas nas temáticas ambientais ainda apresentam dificuldade em se comunicar com o público por diversos motivos, em especial a linguagem. A análise apontou também que é necessário buscar outros formatos de apresentação, utilizar exemplos da pesquisa com a realidade, inferir sobre o impacto dos resultados no cotidiano, direta ou indiretamente.

Communication as a strategy for awareness among the urban public on forestry issues / Comunicação como estratégia para sensibilização do público urbano para as questões florestais

Katia Regina Pichelli¹, Luciane Cristine Jaques¹, Paula Geron Saiz¹

¹Embrapa Florestas, Curitiba, Brazil (katia.pichelli@embrapa.br; luciane.jaques@embrapa.br; paula.saiz@embrapa.br)

A presença das florestas no dia a dia das pessoas ainda é desconhecida pela maioria dos brasileiros. Percebe-se isso quando a frase "não imprima, assim você evita o corte de árvores" ainda é vista em diversas assinaturas de e-mail, ou quando o conceito "não use as florestas" permeia fortemente discussões equivocadas em mídias sociais. Diante disso, a Embrapa Florestas tem procurado trabalhar com o público urbano para desmistificar estes conceitos. Para isso, tem produzido materiais voltados a este público, em especial vídeos, animações, página web, mídias sociais e materiais impressos. São estratégias usuais de comunicação, mas que pretendem atingir um público diferenciado, que não está habituado à ciência e à temática florestal, levando a informação científica de forma acessível, criando sentido e despertando interesse. A mensagem principal destes materiais é "a floresta está presente em seu dia a dia". Alguns materiais: 1) animações: "Florestas no dia a dia", "Florestas nas propriedades rurais", "Plantios florestais para geração de energia"; 2) vídeos: "Pesquisas com araucárias", "Estradas com Araucárias", "Sistema silvipastoril"; 3) Páginas web: "Araucária", com infográficos; 4) Cartões postais (belas imagens com impressão diferenciada,

estimulando que as pessoas guardem como decoração/recordação - no verso, QR Codes levam ao portal da Embrapa com links sobre o tema): pesquisa florestal, Integração Lavoura-Pecuária-Floresta, Araucária, erva-mate, pragas florestais, pupunha; 5) impressos: quebra-cabeça e desenho de propriedade rural com florestas para crianças colorirem; folders diversos com linguagem acessível ao público leigo. Estes materiais são utilizados em palestras, feiras/exposições e, em paralelo, divulgações em mídias sociais.

Narrowing the distance between public research and the Brazilian population: the climate change impacts in the Atlantic Forest study

Jennifer Viezzer^{1,2}, Mariana Egler¹, Marco Follador³, Martin Becher⁴, Armin Deitenbach⁵, Melina Amoni Silveira Alves⁶, Virgílio de Almeida Pereira⁶, Felipe Bittencourt⁶, Henrique de Almeida Pereira⁶, Priscila Lopes Soares da Costa¹

¹Ministério do Meio Ambiente (MMA), Brasília, Brazil; ²Universidade Federal do Paraná (UFPR), Curitiba, Brazil; ³European Commission - Joint Research Centre (JRC), Ispra, Italy; ⁴NIRAS - IP Consult GmbH, Berlin, Germany; ⁵Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ), Brasília, Brazil; ⁶Waycarbon, Belo Horizonte, Brazil (jen.viezzer@gmail.com; mariana.egler@mma.gov.br; marco.follador@ec.europa.eu; martin.beche@niras-ip.de; armin.deitenbach@giz.de; melina.amoni@waycarbon.com; virgiliobio@gmail.com; felipe.bittencourt@waycarbon.com; hpereira@waycarbon.com; priscila.costa@mma.gov.br)

The Brazilian Ministry of Environment (MMA) developed an integrated modeling tool to assess the potential climate change impacts in the Atlantic Forest, aiming at supporting the definition of local adaptation measures in instruments such as protected areas' management plans, and municipal land use plans. This study resulted in hundreds of georeferenced maps and a technical report, available on the MMA's website, even though an effective subnational communication strategy did not take place. Consequently, the research outcomes were hardly accessible and usable by non-experts, such as local decision-makers and practitioners, which are supposed to be the end users of this study. Identifying, filtering and sharing available scientific evidence about climate change impacts to support territorial planning at the local level are necessary activities to guarantee the best selection of adaptation measures and allocation of available resources for each context. To address this issue and improve the dissemination of the study outcomes the MMA decided to: i) elaborate a summary for decision-makers, highlighting the most significant and impending results; ii) make a substantial effort to format, organize and visualize the 812 georeferenced maps, through the MMA's geoprocessing platform; and iii) organize and participate in webinars, workshops, and courses with different stakeholders from both the public and private sectors, civil society and academy. However, further communication efforts - through different formats and platforms - must be implemented by MMA. Making sense of scientific data, information and knowledge is an imperative goal of every project and must be correctly planned from its very beginning.

Embrapa Mais Amazônia: a communication network for agricultural and forest research in the Brazilian Amazon / Embrapa Mais Amazônia: comunicação em rede para a pesquisa agropecuária e florestal no Brasil amazônico

Ana Laura Lima¹, Priscila Viúdes², Vinicius Kuromoto³, Dulcivânia Freitas⁴

¹Embrapa Amazônia Oriental, Belém, Brazil; ²Embrapa Acre, Rio Branco, Brazil; ³Embrapa Informática Agropecuária, Campinas, Brazil; ⁴Embrapa Amapá, Macapá, Brazil (analaura.lima@embrapa.br; priscila.viudes@embrapa.br; vinicius.kuromoto@embrapa.br; dulcivania.freitas@embrapa.br)

“Embrapa Mais Amazônia” é um projeto de comunicação executado em rede pelos profissionais das nove Unidades da Empresa Brasileira de Pesquisa Agropecuária (Embrapa) na Amazônia Legal. O objetivo é divulgar resultados da pesquisa e estimular junto à sociedade o debate em torno da floresta, uso sustentável dos recursos naturais e questões ambientais na região. O projeto atua em três vertentes: desenvolvimento de produtos de comunicação; ampliação dos fluxos de informação e canais de diálogo; e capacitação de cientistas das áreas florestal e agropecuária e de profissionais de comunicação. Entre os principais resultados estão: cursos para comunicadores sobre temáticas florestais; cursos de fotografia para pesquisadores; media trainings para pesquisadores; e desenvolvimento de folders e aplicativo sobre as principais fontes de informação técnico-científicas sobre as temáticas florestais e agropecuárias trabalhadas pela Embrapa na região. Ao final do projeto foi realizada pesquisa de imagem para aferir o impacto das ações a respeito da ampliação do debate sobre as questões ambientais na região, bem como as referências (instituições) dos jornalistas quando o assunto é pesquisa florestal e agropecuária na Amazônia. Verificou-se que as temáticas ambientais na Amazônia ganham amplitude junto à imprensa quando são realizadas as conferências internacionais sobre clima e mudanças climáticas e/ou grandes eventos no tema. Entre as instituições citadas como referência na temática “mudanças climáticas”, ONGs aparecem em primeiro lugar, seguidas de perto pelas universidades; na temática “pesquisa florestal” e “pesquisa agropecuária”, Embrapa ocupa a primeira posição; e na temática “uso sustentável dos recursos naturais”, instituições de ensino aparecem primeiro.■

Illustrations and infographics in scientific journalism: the experience of Embrapa Eastern Amazonia / Ilustração e infografia no jornalismo científico: a experiência da Embrapa Amazônia Oriental

Sabrina Maria Morais Gaspar¹, Ana Laura Silva de Lima Costa¹, Vinicius Milleo Kuromoto², Joice Nunes Ferreira¹

¹Embrapa Amazônia Oriental, Belém, Brazil; ²Embrapa Informática Agropecuária, Campinas, Brazil (sabrina.gaspar@embrapa.br; analaura.lima@embrapa.br; vinicius.kuromoto@embrapa.br; joice.ferreira@embrapa.br)

A infografia traduz temas complexos em linguagem de fácil entendimento. No Jornalismo esse recurso contribui na construção de narrativas. Em materiais produzidos pela Embrapa – Empresa Brasileira de Pesquisa Agropecuária - o seu uso é comum em cartilhas e manuais que apresentam práticas agropecuárias, mas na comunicação institucional ainda é pequeno. Apresentamos a experiência de construção e uso de ilustrações e infografia em uma série de quatro reportagens sobre a relação da floresta e o uso da terra, resultantes de artigos científicos elaborados no âmbito da Rede Amazônia Sustentável e publicados em revistas internacionais. As reportagens foram publicadas na Agência Embrapa de Notícias, focando no conteúdo científico sobre o impacto do uso da terra nos estoques de carbono e biodiversidade em florestas primárias, secundárias e com exploração madeireira e queima. Com dados complexos gerados pela pesquisa foi necessário o tratamento para publicação em formato visual e jornalístico, onde o conteúdo pudesse ser compreendido pelo público. O analytics do portal Embrapa indicou que as quatro reportagens tiveram 2.712 acessos únicos com tempo médio de quatro minutos de leitura cada. Na rede social Facebook a reportagem com infográfico na chamada obteve 192 compartilhamentos, 80% a mais que aquela sem o recurso na chamada. As duas postagens alcançaram 29.458 pessoas. Os dados são relevantes também quando analisamos a replicação das reportagens em outros portais sobre temáticas florestais. Isso mostra a importância do uso de recursos visuais e gráficos para comunicar informações complexas, contribuindo para o debate sobre conservação e uso sustentável das florestas.

Aspects of communication in rural communities / Aspectos comunicacionais em comunidades rurais

Mauricilia Pereira da Silva¹, Priscila Viudes¹, Marcio Muniz Albano Bayma¹, Selma Lucia Lira Beltrão², Antônio Luiz Oliveira Herbelê³
¹Embrapa Acre, Rio Branco, Brazil; ²Embrapa Sede, Brasília, Brazil; ³Embrapa Café, Brasília, Brazil (mauricilia.silva@embrapa.br; priscila.viudes@embrapa.br; marcio.bayma@embrapa.br; selma.beltrao@embrapa.br; antonio.herbele@embrapa.br)

Conhecer os principais fluxos de comunicação existentes nos territórios da cidadania do Vale do Juruá, de Capixaba e do Alto Acre, no estado do Acre, Brasil, foi o objetivo da pesquisa realizada em dezembro de 2018, no âmbito do projeto “Interação, intercâmbio e construção do conhecimento e comunicação nos projetos do Fundo Amazônia – Amazocom”, que busca articular ações com foco nas estratégicas de comunicação, transferência de tecnologia, intercâmbio e construção de conhecimentos para atendimento de ações de outros projetos Integrados da Amazônia. Mesmo com as facilidades de comunicação oferecidas pelas tecnologias digitais que proporcionam amplo acesso à informação, é fundamental investigar como ocorre a troca de informações, conhecimentos e tecnologias na interação entre agricultores e extrativistas da região Amazônica e profissionais de diversas instituições que atuam no universo da extensão rural, ensino e pesquisa. O resultado das 39 entrevistas com informantes de sete municípios do Acre revelou uma diversidade de aspectos comunicacionais nesses territórios amazônicos. Há quem viva em total isolamento, distante dos centros urbanos, e o rádio ainda é o protagonista. Em outras localidades, há moradores que possuem televisão e utilizam dispositivos móveis com frequência para estabelecer a comunicação. A pesquisa também revelou grande potencial de jovens agricultores e extrativistas no processo de comunicação. Eles dominam a tecnologia móvel no espaço da família, mesmo em localidades onde o uso do equipamento é restrito devido à falta de acesso à internet, como, por exemplo, em boa parte das comunidades que vivem na floresta amazônica.

INNOVATION AND EXCELLENCE IN EMERGING RESEARCH: IUFRO STUDENT AWARDS

Recovery of a tropical rain forest over 30 years following silvicultural interventions

Angela Luciana de Avila¹, Ademir Roberto Ruschel¹, José Natalino Macedo Silva¹, Lucas Mazzei¹, João Olegário Pereira de Carvalho¹, Jürgen Bauhus¹
 (angela.avila@forst.bwl.de)

Tropical rain forests are highly biodiverse and provide globally important ecosystem services. In the face of increasing dominance of human-modified landscapes in tropical regions, managing these forests sustainably may contribute to maintain ecosystem integrity while fulfilling society’s demand for forest goods. Nonetheless, little knowledge is available regarding tropical forest responses to silvicultural interventions, especially in the medium to long-term. Here, we investigated how silvicultural intervention intensity and type (harvesting and thinning) influenced the recovery of important forest attributes and functions related to biodiversity conservation, carbon sequestration and timber provision. Furthermore, the effect of post-logging (remaining) biological legacies (basal area and species diversity) on above ground biomass recovery was also investigated. We analysed data from a unique long-term experiment located in the Tapajós National Forest, Pará, Brazil, where trees ≥ 5 cm DBH were measured on 8 occasions in 41 permanent sample plots including unlogged forest. Management intensities comprised logging (1982) with associated damage and follow-up thinning (1993-1994). Tree species diversity was not impaired by silvicultural interventions, but basal area reduction above 20% impaired recovery of composition, biomass and timber stocks over 30 years after initial logging. Additionally, stand-level aboveground biomass recovery rates were largely determined by basal area remaining and less by post-disturbance composition. These results indicate that the resilience of these forests of the Eastern Amazon depends primarily on harvesting and thinning intensity and, therefore, silvicultural interventions must be carefully controlled for the ecosystem to be able to recover rapidly.

International forest policy by International and Transnational Organizations: case studies of the World Bank and forest certification organizations in Argentina and Armenia

Sarah Lilian Burns¹

¹Facultad de Ciencias Agrarias y Forestales, Universidad Nacional de la Plata, Buenos Aires, Argentina (angela.avila@forst.bwl.de)

In recent decades, globalization and internationalization led to an increase in the number of international regimes attempting to influence national behaviour over many different issues. By using the case of the international forest regime the thesis sought to answer how do international and transnational organizations influence domestic forest policies? The cases of Argentina and Armenia were selected as examples of developing countries open to international influences with weak forest sectors that went through an administrative restructuring. The results show that: First, which issues from the International Forest Regime become relevant in different countries depends on the domestic actors and their interests. Second, by means of funding and capacity building, the World Bank, as an international organization, assisted the coalition of agricultural bureaucracies and landowner associations that emerged after the economic crisis in Argentina at the beginning of the 1990s. Third, the influence of the World Bank in Argentina and Armenia through direct access pushed the forest sector towards deregulation. Fourth, state bureaucracies play an important role in the implementation of transnational regimes at the national level. In forest certification processes international actors seek coalitions with different state bureaucracies. However, in situations where new promising venues for political influence open, private actors prefer ad hoc coalitions with weaker bureaucracies with less technical knowledge. Fifth, the political system of federal countries provides multiple institutional access points for policy change that international and transnational regimes try to use in order to influence the domestic level, consequently changing the power balance of domestic networks.

Influence of pruning on development of even-aged *Pinus radiata* D. Don and *Pinus pinaster* Aiton stands in SW Europe

Andrea Hevia Cabal^{1,2}, Juan Gabriel Álvarez González³, Juan Majada Guijo²

¹Dept. de Ciencias Agroforestales, Escuela Técnica Superior de Ingeniería, Universidad de Huelva, Huelva, Spain; ²Forest and Wood Technology Research Centre (CETEMAS), Siero, Spain; ³Department of Agroforestry Engineering, Unit of Sustainable Forest Management (UXFS), School of Engineering, University of Santiago de Compostela, Lugo, Spain (aheviacabal@gmail.com; juangabriel.alvarez@usc.es; jmajada@cetemas.es)

Demand for wood products is one of the main drivers of investment in forest management. Additionally, a major challenge being faced by forest managers is related to wood quality, particularly on timber species where forests productivity is higher. Silvicultural treatments allow to obtain higher quality of wood and increase the value of forests. However, optimal interventions and better understanding of the variation of wood quality in response to silviculture is still unclear in the main timber species. The influence of silviculture on fuel management and wildfire mitigation is also a key research question. The objective of this study is

to evaluate the effect of silviculture on wood quality and to ensure a sustainable forest management under forecasting forest risks. A network of permanent plots was established in two of the most important timber species, *Pinus radiata* D. Don and *Pinus pinaster* Ait., in SW European Atlantic forests. Forest inventory (before and after silvicultural treatments) together with modelling approaches of forest growth, wood quality and fire risk have proved of importance for guiding forest policy in the Atlantic region. Models were based on tree-growth, productivity, dominance, pruning variables -central knotty-core, diameter over stubs, epicormic sprouting, pruning wounds occlusion-, stem taper and form, above-ground biomass -total and by-heights, nutrients and carbon, and also vertical profile of canopy fuel. Moreover, the established network of silvicultural experiments is, nowadays, the study site in several national and European projects, and provide unique long-term datasets in forest research.

Characterization of variability, growth and production of Stone pine (*Pinus pinea* L.) in Chile according to climate and some silvicultural practices

Verónica Loewe-Muñoz¹

¹Instituto Forestal, Santiago, Chile (vloewe@infor.cl)

Stone pine (*Pinus pinea* L.) is one of the most economically important species in the world due to its pine nuts, the most expensive nuts. Advances in semi-intensive and intensive management for its cultivation as a fruit tree have been limited, with cones being harvested mostly from natural forests. In this PhD thesis, a comprehensive study was conducted including: 1) assessment of growth and cone production along a climatic gradient; 2) description of the species variability through morphometric and chemical variables comparing pine nuts harvested in Chile, Argentina, Italy, Spain, Turkey, and Israel; 3) the use of Near Infrared Spectroscopy (NIRS) for identifying pine nut geographical origin; 4) molecular analyses –proteomic–, to differentiate populations growing in Chile; 5) evaluation of adaptation of European provenances to Chile by assessing growth and cone production; 6) effects of two intensive silvicultural practices, fertilization and irrigation, on cone production and growth. Three macrozones showing marked growth differences were defined. Climatic and biometeorological variables, defined based on 11 physio-phenological reproductive phases, were related to cone production traits. Stone pine was found to be well adapted to soil and climate of Chile within a wide range of conditions, and to have a production capacity that allows predicting productive levels similar to or even higher than those in its native distribution. These results show that the species cultivation is a productive alternative for Chile and for other countries with similar environmental conditions. This thesis makes a valuable scientific contribution to the advance of stone pine domestication.

Entropy or inequality?: indicators of tree size heterogeneity and other adaptations of Lorenz curves to forest science.

Ruben Valbuena¹

¹School of Natural Sciences, Bangor University, Bangor, LL57 2UW, United Kingdom (r.valbuena@bangor.ac.uk)

On the outset of national programmes covering entire countries with lidar surveys, I envisaged that these datasets could be employed to derive trans-national indicators and classifications of habitat structure, and secured a scholarship for “Obtaining Pan-European Indicators of Forest Structural Diversity by means of Airborne Laser Scanning” at the European Forest Institute. The starting point was a range of indicators available in the literature for describing the structural complexity of forests, most typically the Shannon index of tree size classes or foliage height diversity. However, taking a deeper insight in the mathematical foundations of diversity and equitability ordering and elaborating diversity profiles instead of observing single indices, I concluded that indices based on theory of information were unsuited for such purposes. This made it clear that Lorenz curves were the fundamental basis for describing heterogeneity in tree sizes, and thus I further focused in adaptations of Lorenz ordering to forest science. These included proving that Gini Coefficient = 0.5 is a beacon for maximum entropy which serves as a boundary between even-sized and uneven-sized forests. Also, the inflexion point of the Lorenz curve signals the quadratic mean diameter, and it is key in describing asymmetry and competitive conditions in forest assemblages, because it yields the proportion of basal area larger than mean (BALM), a population-level indicator similar to those commonly used at tree level in growth models involving competition (BAL). After learning how to read them, Lorenz plots become a powerful tool to diagnose forest structure and competition conditions promptly.

Forest management and governance in Sweden: a phronetic analysis of social practices

Ida Wallin¹

¹Chair of Forest and Environmental Policy, University of Freiburg, Freiburg, Germany (ida.wallin@ifp.uni-freiburg.de)

The transition to a sustainable society requires improved knowledge about what determines forest management and the relationship to governance and policies. My doctoral thesis constitutes a phronetic analysis of social practices in forest management in Sweden and of how social practices materialize and influence forest governance and ultimately, forest management more broadly. The research applied a case study approach where interviews and foresight workshops were carried out together with forest owners and other stakeholders on local and national level. Social practices found relevant for forest management were related to local social context, family circumstances, conflicting logics of practice, social values and personal, trusting relations to different actors. Especially, trusted advisors were a major factor determining forest management and policy outcomes. A tendency of social practices to streamline rather than to diversify forest management actions was observed. From a policy-making perspective, trying to balance the different services from the forest requires diversification of outreach strategies and fostering of trustful relationships between responsible authorities and stakeholders. Digitalization of communication provides both opportunities and challenges in this regard. I conclude that participatory and collaborative forest governance efforts could build on and strengthen the strong social capital and willingness to cooperate found at the local level. Power structures embedded between governance levels and among local stakeholders should not be underestimated and more research into the pre-conditions for collaboration is needed. Social practices as the object of study provides a promising path for future studies in order to find effective policy solutions.

Forest ecosystem services assessments via evaluation of biophysical responses

Zhen Yu¹

¹School of Applied Meteorology, Nanjing University of Information Science and Technology, Nanjing Jiangsu, China (zyu@mix.wvu.edu)

Terrestrial ecosystems are likely to be affected by climate change, as climate change-induced shift of water and heat stresses patterns will have significant impacts on species composition, habitat distribution, and ecosystem functions, and thereby weaken the terrestrial carbon (C) sink and threaten global food security and biofuel production. This dissertation focuses on forest ecosystem services assessments via evaluation of biophysical responses (NDVI, LAI, and phenology) and biochemical responses (e.g. water flux, carbon dioxide exchange such as NPP, GPP, NEE) to climate change and human management. Specifically, using field measurements, spatial modeling, and remote sensing technique, the doctoral research revealed that 1) temperate vegetation phenology (green-up) is dependent

on both seasonal air temperature and soil thermal conditions regulated by snowfall and snow depth; 2) winter ecosystem respiration in the Northern forested area significantly decreased in responses to decreasing snow cover depth, which accounts for approximately 25% of the simulated annual carbon sink trend in non-permafrost region of Northern forest area from 1982 to 2009; 3) the impacts of drought extremes on ecosystem GPP, evapotranspiration ET, and water use efficiency varies between biomes; and 4) planted forest has been more sensitive and consumed more water than natural forest in dry regions of China.

Economic optimization of forest biomass collection, processing and transportation for aviation fuel production

Rene Zamora Cristales

Food, Forest and Water / World Resources Institute, USA (rzamora@wri.org)

In 2018 more than 355 billion liters of aviation fuel were consumed by commercial airlines. There is substantial interest by the aviation industry in reducing the dependence on fossil fuels and promote the use of alternative renewable energy sources. The production of liquid fuels from forest residues are particularly relevant for the industry given the characteristics of the commercial aircraft technology that cannot use at scale other renewable sources such as electricity, nuclear power or wind turbines. However, Aviation fuels derived from forest biomass must compete with traditional fossil fuel supply chains to become a successful alternative. My doctoral research focuses on the Economic optimization of forest biomass processing and transport for aviation biofuel. The production of energy from forest harvest residues constitute an opportunity to develop a supply chain for producing heat, electricity and liquid fuels from renewable materials. This research is path-breaking in that it combines operational and tactical planning methods, as well as simulation, in a decision support system. A mixed integer programming/simulation solution procedure was developed to provide support to biomass processing and transportation decisions at the operational level, taking into account operational factors not considered in previous models; such as residue pile location, road characteristics, turnaround and turn-out location, processing, and transportation equipment available, and truck-machine interactions. I also developed an innovative costing model for the standing cost of equipment. All the methodologies proposed have been validated with real-world operations which confirmed the accuracy of his simulation and optimization models.

Connecting nature to people: ecosystem services in adaptation to a changing climatean insight from the Panchase Mountain Ecological Region of Western Nepal

Shankar Adhikari¹

Ministry of Forests and Environment, Kathmandu, Nepal (adhikarishankar@gmail.com)

Ecosystem services (ES) are considered critical for facilitating adaptation to climate change and improving human well-being, particularly in developing countries. Various anthropogenic and natural drivers however pose a myriad of environmental challenges to the sustainable supply of ES. Improved understanding of the interactions between ES and drivers of change is required to help people adapt; however, many relationships between drivers of change and ES are largely unknown and are likely to be context specific. To determine the role of ES in adaptation to a changing climate and how they can enhance human well-being, this study applies the Intergovernmental platform for biodiversity and ecosystem services (IPBES) conceptual framework. The study uses a catchment of the Panchase Mountain Ecological Region (PMER) in Western Nepal as a case study. Major natural drivers of change were identified as climate change, drought, and invasive species, whereas anthropogenic drivers included agriculture land abandonment, planting of new species, and change in population demography. All drivers were found to have an impact on the availability of ES and the livelihoods of the people reliant on them. Current anthropogenic assets and institutional mechanisms were found to be effective in managing some of the challenges. Proper governance and adequate financial and technical support are likely to be essential for addressing environmental challenges that influence the sustained flow of ES and help people adapt to a changing climate in the region.

Impacts of environmental change and forest management on mountain forest ecosystem services

Katharina Albrich¹, Werner Rammer¹, Dominik Thom^{1,2}, Rupert Seidl¹

¹Institute of Silviculture, University of Natural Resources and Life Sciences (BOKU), Vienna, Austria; ²Rubenstein School of Environment and Natural Resources, University of Vermont, Burlington, USA (katharina.albrich@boku.ac.at)

Mountain forest ecosystems provide important ecosystem services (ES) such as timber production, protection from natural hazards and carbon storage. Climate change and accompanying changes in disturbance regimes are putting increasing stress on forests and on their ability to provide ES. Forest managers therefore may need to find approaches which ensure stable ecosystem services provisioning in a highly uncertain future. In this study, we used the simulation model iLand to investigate the ecosystem services supply on an 8100 ha landscape in the Northern Front Range of the Alps. We imposed four different forest management strategies on the landscape, ranging from a management approach which tries to maximize timber harvest to a strategy trying to adapt the forest to future climate conditions. In addition to differences between the management strategies, the analysis focused on ES provisioning both under past and future climate and disturbance regimes. We also paid special attention to the trade-off between level and temporal stability of ES provisioning under future climate. While traditional, conifer-focused strategies performed well under past climate and disturbance regimes for several ES, they showed clearly reduced provisioning under future climate. The two future-adapted strategies faced a smaller reduction in performance under climate change and were less susceptible to disturbance impacts. They also had a smaller trade-off between level and stability of ES provisioning. This emphasizes that forest managers will have to adapt their silvicultural approaches in order to ensure ecosystem services provisioning even under future climate and disturbance regimes.

Effects of mixed plantations of *Acacia auriculiformis* with *Swietenia macrophylla* and *Gmelina arborea* on growth, biomass and soil Fertility

Shourav Dutta^{1,2,3}, Mohammed Kamal Hossain³

¹Faculty of Environment and Natural Resources, Albert-Ludwigs-Universität, Freiburg, Germany; ²Faculty of Science and Forestry, University of Eastern Finland, Joensuu, Finland; ³Institute of Forestry and Environmental Sciences, University of Chittagong, Chittagong, Bangladesh (shourav.forestry@gmail.com; mkhossain2009@gmail.com)

The replacement of pure plantations by mixed stands with suitable nitrogen-fixing species is a possible way to maintain soil fertility together with highest growth and biomass. The study was conducted to assess the effect of mixed plantings of *Acacia auriculiformis* (A) with *Swietenia macrophylla* (S) and *Gmelina arborea* (G) on growth, biomass and soil fertility in 16 month old tropical plantations of Bangladesh. The plantations consist of three pure planting plots (100%A, 100%G, 100%S) and eleven mixed planting plots (1A:1S, 1A:1G, 1A: 1G: 1S, 1A:2S, 1A:2G, 1A:3S, 1A:3G, 2A:1S, 2A:1G, 3A:1S and 3A:1G)

of three common plantation trees of Bangladesh. The methods consist of measurement of growth performance of plants, soil pH, soil organic carbon, nutrient contents and finally statistical analysis. It was found that *Swietenia* was significantly tallest when planted with nitrogen-fixing *Acacia* in a proportion of 1A:3S. *Gmelina* attained maximum height and diameter in a mixture of 1A:1S:1G, whereas *Acacia* was tallest in the pure 100%A plantation. The study showed that in comparison with the pure plots of *Swietenia* and *Gmelina*, mixed plantings have positive relationships with increasing soil pH, organic carbon, N, P, and available K. Results from the periodic measurement of growth parameters of plants revealed that there was a significant difference in height and diameter increment due to the variation of nutrient uptake by the individuals. The research findings suggested that in comparison to mono-plantation plots, species mixture has significantly ($p < 0.05$) better growth and biomass in addition to increasing positive effects on soil fertility.

Climate change threat to protected areas in Madagascar

Ange Raharivololainaina¹

¹Biogeography Department, Bayreuth Center of Ecology and Environmental Research, University of Bayreuth, Germany (ainaange@gmail.com)

Madagascar figures among the most extraordinary biodiversity hotspots and is identified in the same time as an important conservation priority in terms of vulnerability and irreplaceability. Protected areas is one of the most efficient way to conserve biodiversity and to halt deforestation but anthropogenic climate change is now a growing threat to protected areas. In the present study, I quantify the exposure of climate change effect on protected areas network in Madagascar. Using climate similarity classification rules, I computed and mapped novel climates within protected areas in Madagascar under two future time periods (2050 and 2070), two climate scenarios (RCP 4.5 and RCP 8.5), four different global circulation models and compared two different conceptual approaches. The overall result of my research showed that at least eight percent of the entire protected areas network in Madagascar is under threat of novel climates in the future. To my knowledge, this is the first quantitative analysis of the potential impact of climate change on protected areas in Madagascar. Results of this study can help guide conservationist with management planning in the era of anthropogenic climate change.

Indigenous federations in the Peruvian Amazon: perspectives from the Ashéninka and Yine-Yami peoples

Andrea M Vásquez Fernández¹

¹Faculty of Forestry, University of British Columbia, Vancouver, Canada (andrea.vasquezfernandez@alumni.ubc.ca)

The emergence of a globalized model of development in Peru, based on extraction of natural resources, has led to the rise of Indigenous movements. One of the strategies to address the negative impacts of public policies generated to support this model is through the creation of Indigenous federations. Indigenous federations have emerged as a strategy of Indigenous Peoples to make their voices heard and to determine their own futures. Scholars, Indigenous community members, and federation representatives themselves have identified the strengthened relationships between representatives and community members as a major challenge for Indigenous movements. In alliance with six Ashéninka and Yine-Yami communities and their local Indigenous federations, we conducted a collaborative research. The question that frames this research is: How could Ashéninka and Yine-Yami Peoples improve Indigenous federations' representational work from their own ontologies (ways of being), epistemologies (ways of knowing), axiologies (values), and methodologies (ways of doing)? Through culturally sensitive methods of co-creating knowledge using Indigenous theories and decolonizing methodologies, this study addresses two objectives: (1) to identify factors that contribute to Indigenous federations' representatives ability to effectively achieve communities' objectives; and (2) to articulate recommendations to improve Indigenous federations. Results show that the principal factors that explain representatives' sources of capacity to address member communities' objectives are primarily to establish close interpersonal relationships and to cultivate spiritual, ethical, and moral behaviours between representatives and community members. Five recommendations are identified by Ashéninka and Yine-Yami Peoples to enhance their institutions: (1) to define the jurisdiction of the federations; (2) to formalize the federations; (3) to improve the processes of interaction; (4) to strengthen their self-determined Indigenous economies; and (5) to increase political participation. The results inform current Indigenous politics that aim to have a larger influence on the regional and even national formulation of public policies that impact the Peruvian Amazon. The recognition and practice of a pluri-national state and the need to establish more meaningful indicators of endo-development are important in the formulation of the factors influencing a positive change and a way to address current and future conflicts around use of natural resources.

Sustainable forest management and soil quality: an enhanced virtual educational experience

Khalil Walji¹, Maja Krzic¹, Ben du Toit¹, Saeed Dyanatkar¹, Chris Crowley¹, Michael Sider¹

¹International Forestry Students Association, IFSA, Freiburg im Breisgau, Germany (khalilwalji@gmail.com)

Soils play a crucial role in food and fiber production, carbon and nutrient cycling and many other environmental processes. Effective responses to these issues require not just scientists but also citizens with a sound understanding of sustainable soil management. Hence, post secondary institutions need to provide students with a strong foundation and core knowledge applicable to the context of current global issues and should focus on creating more innovative curricula in the process. This project aimed to develop an open access web based learning resource, combining problem based learning (PBL) with virtual tours and other multimedia to illustrate soil quality changes brought by various forestry practices used in the Western Cape of South Africa. Two PBL study cases were developed, highlighting the importance of sustainable forestry and impacts to the surrounding ecosystem, focusing on soil preparation treatments and their impacts on soil water dynamics, nutrient supply and their influence on tree growth and health. The incorporation of media with PBL cases enriched student learning, allowing them to gain international perspectives by transcending boundaries and experiencing forests across the globe. The project also facilitated better understanding of dynamic and varied ecosystem functions in new and novel environments as well as the opportunity for students to reflect on how these specific contexts equate or differ from forest ecosystems in their own geographical region. Overall, the project aimed to enhance student engagement with course material and comprehension of a complex material.

Forensic timber identification: the authenticity diagnostics of species using DNA barcode

Lichao Jiao¹

¹Wood Anatomy and Utilization Department, Research Institute of Wood Industry, Chinese Academy of Forestry, Beijing, China. Wood Collections (WOODPEDIA), Chinese Academy of Forestry, Beijing, China (jiaolc@caf.ac.cn)

Deforestation represents a massive threat to global biodiversity with illegal logging and the associated trade in illegally sourced wood products. Timber identification of tree species is crucial and essential for monitoring and control of illegal activities in timber production and thus enforcement of species trade regulations around the world. Currently, timber identification based on the anatomical features of wood is a well-established science in botany. To improve the

resolution of wood recognition, we have developed the technical system combined traditional wood anatomy technology with DNA barcode methods together; that is, the identification of wood on the genus level (or to a specific classification under genus) is the first step according to wood anatomical structure; when species identification could not be achieved successfully using wood anatomy method, DNA barcoding will be carried out to make it. In recent less than 10 years, we have demonstrated the application of DNA barcoding method for species discrimination of endangered and precious commercial timber, such as *Aquilaria*, *Dalbergia*, *Pterocarpus* and *Santalum*. The work is now ready for monitoring of the trade of these valuable resources, and provides an effective approach for wood species identification and product authentication.

S4a: STUDENT INCUBATOR - 1

Nature conservation challenges in peri-urban landscapes: the case of a protected area in Bengaluru Metropolitan Region, India

Harini K S^{1,2}, Dhanya B²

¹The University of Trans-Disciplinary Health Sciences and Technology, Bengaluru, India; ²Azim Premji University, Bengaluru, India (harini.pg2@tdu.edu.in; dhanya.b@apu.edu.in)

Conservation strategies in India often overlook the complex social- ecological interactions that have historically shaped ecosystems. This study highlights the livelihood and conservation impacts of a recently initiated conservation project in the periphery of India's fastest growing metropolis: Bengaluru. We focus on how the change in legal status of the protected area (PA) from a reserve forest to wildlife sanctuary for conserving endangered vultures, along with urbanization pressures have reconfigured nature- society interactions around the area. We use ecosystem services (ESS) framework to understand the transformations in societal preferences for the PA. Exploratory interactions, participatory mapping and ranking of ESS were conducted in six villages in ecosensitive zone (ESZ) of the PA. Land use changes in ESZ were temporally traced during 2004-2018 using open source data in QGIS platform. The study reveals a shift in use of ESS owing to change in governance status and urbanisation. Provisioning services including forest produce collection and grazing of livestock have declined, while cultural services such as tourism are actively promoted. Local livelihood dependency has shifted from forest based to urbanisation induced opportunities like construction work. Landuse change analysis shows significant changes in rainfed farming to horticulture plantations to cater to urban demand. Land acquisition by government for developmental projects and increasing land values triggered landuse changes. Such changes are impacting the PA in terms of decline of nesting trees and food (animal carcasses) for vultures. The study highlights the necessity of evolving participatory governance paradigms recognising social-ecological interactions and feedbacks.

Restoration and indigenous stewardship of (post)fire landscapes: towards co-management and (re)connection to place in Secwépemc'ecw, Canada

Sarah Dickson-Hoyle¹, Secwepemc'ecw Restoration and Stewardship Society²

¹University of British Columbia, Vancouver, Canada; ²Secwepemc'ecw Restoration and Stewardship Society, British Columbia, Canada (sarahedh@mail.ubc.ca; ceo@srssociety.com)

Worldwide, recent decades have seen increasing socio-economic and ecological impacts resulting from high severity wildfires. In British Columbia (BC), Canada, 20th century practices of fire suppression and exclusion, coupled with climate change, have resulted in longer and more severe fire seasons. The 2017 and 2018 wildfire seasons burned a record-breaking 2.5 million hectares across the province and disproportionately affected First Nations communities. These impacts catalyzed many communities into action, and the 2018 Provincial Flood and Fire Review recommended establishing equal partnerships with First Nations governments, and incorporating Indigenous knowledge, across all stages of fire management and planning. Along with Canada's current emphasis on advancing reconciliation with Indigenous peoples, this points to a clear need to advance Indigenous-led collaborative approaches to landscape-scale forest restoration and adaptation. Drawing on my developing research with the Secwépemc Nation, I will present the case study of the 2018 *Elephant Hill Initiative Agreement* as an example of successful government to government collaboration and Indigenous forest stewardship. I will highlight the processes of collaborative decision-making between the BC government and the eight Secwépemc communities directly impacted by the 2017 192,000 hectare 'Elephant Hill' wildfire, which have informed principles for post-fire salvage harvesting, reforestation and understory vegetation management. Finally, I will explore how proposed co-management initiatives that have emerged from this collaborative agreement seek to support Secwépemc people in implementing traditional stewardship systems, adaptive management, and forest restoration across Secwépemc'ecw (the Secwepemc traditional territory), while advancing reconciliation and wildfire resilience.

Management and conservation strategies for *Nothofagus* forests: landscape scales and factors that determine variations in the assemblage of vascular plants

Alejandro Huertas Herrera¹, Vanessa Lencinas¹, Guillermo Martínez Pastur¹, Juan Manuel Cellini²

¹CADIC-CONICET, Ushuaia, Argentina; ²UNLP, La Plata, Argentina (alejandrohuertasherrera@gmail.com; mvlencinas@gmail.com; cadicforestal@gmail.com; cellini@gmail.com)

This work analyses the factors related to environment and human that influence over the assemblage of vascular plant species in timber forests of *Nothofagus pumilio* and their associated environments of Tierra del Fuego. Analyses used a multi-scale approach that integrated regional, landscape and stand spatial levels. The main results indicated that: (i) At a regional level, although the distinct ecosystems share plant species, the assemblages were significantly different from each other in almost all studied areas, where the influence of climate explained these variations beyond human impacts (e.g. cattle grazing). (ii) At a landscape level, differences observed among environmental gradients (e.g. aspect) and human impacts (harvesting > cattle grazing) were found, and not only the geographical area determines the diversity and plant assemblages, but also the intrinsic properties of the forest environments and associated open environments (forest vs open-lands). (iii) At the stand level, different harvesting schemes (e.g. different levels and types of retention) influenced over the conservation of the understory plants, where vascular plant assemblages remained more similar to primary forests in aggregate retention than in dispersed ones. It was concluded that the exclusion of environments for forestry or cattle use does not guarantee the conservation of all species. The retention approach in each environment must be implemented at spatial scales, e.g. at the stand scale by private or public landowners, or at larger scales by the government through medium-scale reserves or the design of a new network of protected areas.

LULC dynamics in Mesopotamia: trends and driving factors to validate priority areas for socioecological restoration.Victoria E. Espinoza-Mendoza¹¹DECA - Universidad Maimonides, Buenos Aires, Argentina. CONICET, Buenos Aires, Argentina (espinoza.victoria@maimonides.edu)

Mesopotamia region covering around 20 Mha in Argentina and includes four provinces Buenos Aires, Entre Rios, Corrientes and Misiones. The landscape is dominated by a significant eco-regional gradient from temperate, subtropical forest to wetlands and is composed by seven ecoregions. The aim of the PhD thesis is analyzing and determine multitemporal dynamics related to land use and land change (LULC) for a period of 30 years: (1) deepening on identify proximate and underlying drivers of LULC, (2) establishing trends through the generation of projected regional scenarios by 2050 and (3) propose public – private policy focus on validate priority areas for socioecological restoration. The methodology contains: (1) exhaustive scientific and historic review with data around 500 years to understand the landscape and their historic process of change, (2) supervised classification and interpretation of LANDSAT images for period 1985 – 2015, (3) development and application of a cross-tabulation matrix to calculate transitions in terms of gains or losses and (4) participatory workshops and extensive interviews with stakeholders. Is considered highly relevant the use of spatial tools at all levels to develop the work.

Understanding beneficiaries' needs to improve ecosystem service deliveryVasja Leban¹, Lidija Zadnik Stirn¹, Špela Pezdevšek Malovrh¹¹University of Ljubljana, Biotechnical faculty, Department of forestry and renewable forest resources, Ljubljana, Slovenia (vasja.leban@bf.uni-lj.si; lidija.zadnik@bf.uni-lj.si; spela.pezdevsekmalovrh@bf.uni-lj.si)

Current misunderstanding regarding different land and ecosystem service (ES) uses originates also from inadequate consideration of people's actual needs, historical flows of ESs, ecosystem potential to provide relevant ESs and impacts of external drivers on ES allocation. As a consequence, beneficiaries do not experience all potential benefits, natural resources are being under- or over-used and the region's biodiversity is jeopardized. From a theoretical perspective, the solution lies in allocating ESs in an efficient way, where the ecosystems' condition and benefits provided to the ESs beneficiaries are balanced. In this study, we take the position that the current allocation of ESs on a landscape level is primarily subject to interactions between ESs beneficiaries and other land users, historical experiences and related traditional ecological knowledge. Direct users and ESs beneficiaries perceive the ESs and potential benefits differently than regional stakeholders (e.g. regional planners, public service employees), despite their minor role in regional planning. We argue that in a setting with small and heterogeneous land uses, ecosystems are more vital and ESs allocation is more efficient when policy regulations are less restrictive and obligatory. This insight is decisive to design better regional policies, secure sustainable management practices and enhance biodiversity.

Divergence of evapotranspiration after replacement of *Eucalyptus regnans* with *Acacia dealbata* in response to climate change and fireW.A. Shyanika Lakmali¹, Richard G. Benyon¹, Patrick N J Lane¹, Gary Sheridan¹¹The University of Melbourne, Melbourne, Australia (swasalamuni@student.unimelb.edu.au; rbenyon@unimelb.edu.au; patrickl@unimelb.edu.au; sheridan@unimelb.edu.au)

Climate, fire and vegetation have the potential to produce complex sets of feedbacks. Changes in climate may influence the structure and function of forest ecosystems. A significant intensive cumulative effect of climate change may result in species replacement and vegetation shift. Persistence of *Eucalyptus regnans* forest in South East Australia is highly vulnerable under increasing climate change. High intensity, multiple interactive fires cause regeneration failures in *E. regnans* forests, which then allows fast-growing common understorey species (e.g. *Acacia dealbata*) to dominate over *E. regnans*. This is a significant species replacement in natural forests in response to changes in climate-driven fire regimes. These forests are water supply catchments; any change in species mix may have significant implications for catchment water yield. However, it is largely unknown what eco-hydrological responses are associated with this climate-related vegetation shift. This study used field measurements of annual evapotranspiration (ET) in sample plots of *E. regnans* and *A. dealbata* aged 10, 20, 35 and 80 years to understand the ecohydrological implications of species replacement. Both species had similar ET during the first 10 years of their life but ET began to diverge by age 20 (lower in acacia), with maximum divergence by age 80. This difference between species is attributed to differences in sap velocity and sapwood area. Therefore, species replacement in these forests has significant implications for catchment water yield.

Spatio-temporal effects of climate change on southern pine beetleHolly L. Munro¹, Cristian R. Montes¹, Kamal J. K. Gandhi¹¹University of Georgia, Athens, USA (hmunro@uga.edu; crmontes@uga.edu; kgandhi@warnell.uga.edu)

Southern pine beetle (*Dendroctonus frontalis* Zimmerman) (SPB) is an economically and ecologically important bark beetle pest of forest ecosystems. Historically, the range of SPB has been confined to the southeastern United States (U.S.), likely due to temperature constraints. Researchers have expressed concern about future warmer temperatures facilitating the species niche expansion into the northeast U.S. and eastern Canadian Provinces, and this new distribution range may devastate naïve pines lacking defenses against SPB. The objective of this study was to evaluate the effect of temperature on the occurrence of SPB using dynamic models, to allow for further evaluation under future climatic scenarios. The model was built using SPB trap catch data for 2014-2017 and average monthly temperatures for each of the preceding 12 months. Temperature data used in the model were obtained from DAYMET (NASA Earth Data), and future data used for forecasting were obtained from WorldClim. Analyses were performed using a two-step regression approach relying on Akaike Information Criteria for model selection. Our study found 7°C as the February minimum critical temperature needed to support SPB. Thus, temperatures were unlikely to support SPB populations in the lower northeast U.S. until early-1900s. When combined with future temperature scenarios, we hypothesize that all the northeast U.S. and the lower eastern Canadian Provinces will have adequate temperatures to support SPB populations by 2050. Our information may allow forest managers to design management regimes tailored to reduce future outbreaks proactively and provide critical pest management technology for maintaining healthy pine forests.

Prediction of *Eucalyptus grandis* chemical compounds in a climate change context using hyperspectral imaging

Mariana Pires Franco^{1,2}, Gilles Chaix², Mario Tomazello-Filho¹, Cristiane Vidal³, Celio Pasquini³, Nathalie Gorretta⁴, Jean-Michel Roger⁴

¹USP/ESALQ, Piracicaba, Brazil; ²Cirad, Montpellier, France; ³Unicamp, Campinas, Brazil; ⁴Irstea, Montpellier, France (ma.pires@hotmail.com; gilles.chaix@cirad.fr; mtomazel@usp.br; cristiane.vidal@iqm.unicamp.br; pasquini@iqm.unicamp.br; nathalie.gorretta@irstea.fr; jean-michel.roger@irstea.fr)

The study of wood chemistry to explain the response of trees to climate variation is efficient for retrospective analysis of changes induced in wood during the process of adaptation to seasonal variations. Hyperspectral imaging (HSI) in near infrared could be useful for prediction of several wood chemical components. The objective is understand how water constraints influence wood formation. Wood disks of *E. grandis* clone from six treatments (100% and 65% of rainfall crossed with potassium and sodium fertilizations) were sampled. HSI were obtained on transversal section of the disks using a line scan hyperspectral camera from 1000-2500 nm with a pixel size of 625 x 625 μm . For calibration, were selected 60 wood solid samples from an Eucalyptus collection, which were measured the total extractive values. HSI of these samples were acquired from transversal section with the same camera. We regressed the mean spectra for each sample with extractives values by Partial Least Square Regression. Due to the model, the total extractives for each pixel to produce an image for the wooden disks were predicted. Based on them, the total extractive distribution according to growth conditions were compared, revealing that trees under stress conditions show a higher heterogeneous chemical profile from the pith to bark. Eucalyptus demonstrates sensitive precipitation variations, with rapid growth and considerable increase in DBH during rainy seasons and the reverse in drought. Consequently, is possible to discriminate different patterns of chemical compound distribution according to the growth conditions.

Alternatives for soil nitrous oxide emission reduction associated to nitrogen fertilization in eucalyptus

Mariana Ibarra¹ 

¹Universidade Federal do Paraná, Curitiba, Brazil (marianaibarr@gmail.com)

The aim was to select nitrogen sources with potential for reduce soil nitrous oxide (N_2O) emission under eucalyptus in controlled environment conditions, and from this selection, to evaluate its emission reduction potential under field conditions. Eight nitrogen sources were evaluated in greenhouse over six months. Urea and ammonium sulphate sources with nitrification inhibitor dicyandiamide (U-DCD and AS-DCD, respectively) significantly reduced N_2O emission in relation to conventional source most used in Brazilian forest sector (urea). The same pattern occurred when these sources were evaluated in the field, where U-DCD and AS-DCD had similar cumulative N_2O emission to soil without nitrogen fertilization (2.55 kg $\text{N}-\text{N}_2\text{O}$ ha^{-1} year⁻¹), although U-DCD had emitted 4.1 kg $\text{N}-\text{N}_2\text{O}$ ha^{-1} year⁻¹. Besides that, U-DCD and AS-DCD treatments presented emissions two and three times lower than those without inhibitor, urea and ammonium sulfate, respectively. In this sense, it is concluded that urea and ammonium sulfate sources associated with nitrification inhibitor dicyandiamide have potential for reduce soil N_2O emission from eucalyptus nitrogen fertilization.

Efficiency of biostimulants in promoting *Eucalyptus* sp. growth under water stress

Vitor Augusto Cordeiro Milagres¹, Bruna Sampaio Crivilin², Luiza Belfort³

¹Gerdau Aços Longos, Três Marias, Brazil; ²Universidade Federal de Lavras, Lavras, Brazil; ³Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brazil (vitor.milagres@gerdau.com.br; brunacrivilin@gmail.com; luiza.belfort@gerdau.com.br)

Despite the adaptability of *Eucalyptus* in the diverse Brazilian edaphoclimatic situations, water limitations can affect its development. In periods of drought, the irrigation in more than one application becomes essential in the implantation of a stand, providing the development of the seedlings. However, this operation considerably increases operating costs. Biostimulants have been an alternative in promoting rooting and improving productivity. In this sense, the objective of this work was to compare different biostimulants and irrigation management in the growth of a planting of *Eucalyptus* sp. The study located in Três Marias, Minas Gerais, under a dystrophic Red-Yellow Latosol, medium sandy texture, was installed in May, the beginning of the dry season. The treatments were two and three irrigations, two irrigations + Fertiactyl Sweet® (FW), two irrigations + KSC PHYT Actyl 1® (KP) and two irrigations + Fertiactyl Sweet® + KSC PHYT Actyl 1® (FWKP). Three parameters were evaluated: Height (m), uniformity index PV50 (%) and distribution of fine roots at 365 days. FWKP obtained the highest growth in height differing statistically from the others. This was the only one that presented a PV50 above the optimal index of uniformity. In all treatments, the highest root density was observed in the 36 cm layer of the soil, concentration region of at least 47% of the total roots. It was observed that the higher the tree height, the higher the number of roots in the profile. It is concluded that the use of biostimulants promotes the development of *Eucalyptus* seedlings on water stress.

Value of physiological assessments for monitoring initial development of *Pinus radiata* D. Don young plantations under water stress

Thiago Wendling Gonçalves de Oliveira¹, Rafael Rubilar², Alex Mauricio Medina³

¹Universidade Federal do Paraná, Curitiba, Brazil; ²Universidad de Concepción, Concepción, Chile; ³Florestal Mininco, Los Angeles, Chile (thiago.wgdeoliveira@gmail.com; rafaelrubilar@udec.cl; alex.medina@cmpc.org)

This study compares gas exchange response of six *Pinus radiata* genotypes during a progressive drought period. Experiment was planted in volcanic sands soils in central South Chile. Climate is Mediterranean (Csb) with a mean annual temperature of 14°C and 1300 mm of rainfall. One year old seedlings were submitted to drought by stopping irrigation during maximum atmospheric demand conditions. Weekly gas exchange assessments considering stomatal conductance (g_s), photosynthesis (A), predawn water potential (Ψ_{pd}) and leaf area index (LAI) were measured during a month after drought. Statistical analyses showed significant differences in g_s , A and LAI, and time was only significant for Ψ_{pd} , which was the best variable monitoring increasing water stress. Nonlinear modeling for g_s x Ψ_{pd} showed significant differences by genotype. Our results suggest that specific genotypes decrease g_s in order to avoid water losses. Modeling for A x Ψ_{pd} showed that genotypes maintain A rate even when g_s is decreasing. Nonlinear modeling between g_s and A with LAI showed that genotypes with largest LAI maintain higher values g_s and A. Physiological responses are an effective way to monitor genotypes stress. Use of this information may help on assessing strategies for early management of forest plantations on critical sites.

S4b: STUDENT INCUBATOR - 2**“Flopal” model plantation: creating sustainable values through qualification of the productive process**

Samara Lazarotto¹, Rafaelo Balbinot¹

¹Universidade Federal de Santa Maria Campus Frederico Westphalen, Frederico Westphalen, Brasil (samara.fk@hotmail.com; rafaelo.balbinot@gmail.com)

Forestry of the genus Pine is considered as a threat to the Pampa Biome, especially on the southern coast of Rio Grande do Sul. This concept disregards its productive potential, its social and economic importance, and its effective environmental services. The study area is located in the city of Santa Vitória do Palmar – RS and has a total area of 17.000 ha of which 6.727 ha is effective planting of *Pinus elliottii* Engelm. Thus, the objective of this work is to link production values with conservation values and to develop a qualified production model. The environment studies began in 2015 by means of initiatives like the invasion control of its natural regeneration; experiments with pine hybrids; analysis of soil physical and chemical attributes; forest inventories and analysis of the social impacts of the resin. There are three main phases. First, understanding and characterizing the process of resin production: how it began in Brazil and the state of the art today. Second, diagnosing and identifying the social and economic interactions seeking information directly with the workers. Finally integrate this historical and social information to develop a grid of values that assign production function to the areas of conservation and conservation function for the production areas, within the methodology of the triple bottom line. Achieving this goal, the previous conflict between tree monoculture and environmental conservation can be mitigated. Highlighting the role of good forestry practices to create positive impacts to forest products for a greener future.

Mill dynamics: exploring mill entry and exit patterns in the Southern U.S.

Nidia Panti¹, Donald Hodges¹, Consuelo Brandeis²

¹University of Tennessee, Knoxville, USA; ²U.S. Forest Service, Knoxville, USA (npanti@vols.utk.edu; dhodges2@utk.edu; consuelo.brandeis@usda.gov)

Timber is the most valuable commercial commodity taken from most forests. The US South produces approximately 60% of the Nation's timber products, where the majority is obtained from private forests. U.S. mills were studied using information from the US Forest Service, Forest Inventory and Analysis (FIA) Timber Products Output (TPO) program survey of primary wood-using mills. Surveys were conducted biennially from 2005 to 2017 in 12 southern states and participants included all primary mills varying from sawmills, veneer mills, poles and post production mills. This historical TPO mill information was analyzed using a time to event analysis (survival analysis), controlling for size and other internal and external factors likely affecting its survival. Variables included plant size, plant structure (single-firm or multi-firm), mill consumption capacity, county demographics, etc. In terms of size and structure, studies have shown that larger plants are less likely to close while multi-firm plants are more likely to close. Competition is also another factor which has shown a positive influence on plant closure. We also studied how the changes in mill numbers and distribution affect wood procurement patterns. Studies indicate that plants aim to minimize the transportation costs for inputs which in turn determines the optimal location of the mills. Other studies also suggest that there is an increasing trend of industrial concentration regardless of economic influences.

How policies and market incentives have affected the expansion of planted forests in Brazil?

Manuela Czinár¹

¹Imperial College London, London, United Kingdom (m.czinar@imperial.ac.uk)

The objective of this study was to identify the main policies and market incentives that have affected the expansion of planted forests in Brazil. The methods used included literature review and the interview of nineteen stakeholders during field work in 2017. It was possible to identify four distinctive phases in the evolution of planted forests in the country. The first phase of ‘policy-driven expansion’ occurred between the 1960s and 1980s, when the Brazilian government has imposed to the steel industry to move away from charcoal from natural forests and has given tax rebates for reforestation projects. The second phase was the ‘policy-driven collapse’ when tax rebates were abolished and planted area fell as a consequence. The market-driven phase started in the early 2000s when commodities prices faced a strong upside following the strong Chinese demand. On the other hand, similar reasons resulted in the ‘market-driven collapse’ of the late 2000s, when the planted forest area stagnated and even reduced in some regions because of the strong reduction in prices caused by the global economic crisis, the Brazilian political turmoil and the increase of the steel production capacity in China. Based on the historical experience, this study argues that the next expansion phase should be both market and policy driven, otherwise Brazil risks to repeat the same mistakes of the past.

Determining the potential contribution of utilising forest biomass resources for bioenergy production and climate change mitigation in Queensland, Australia

Sam Van Holsbeeck¹

¹University of the Sunshine Coast, Maroochydore, Australia (svanhols@usc.edu.au)

By 2020 the Australian government anticipates 23.5% of its total energy will be derived from renewable energy sources. Forest biomass has proven its potential as climate change mitigating renewable in other continents and are identified as a large potential contributor of biomass for renewable energy to replace fossil fuels in Australia. However, the share of forest biomass contributing to the total bioenergy production in Australia remains unknown. With the help of the Australian Renewable Energy Mapping Infrastructure (AREMI), this research will determine the potential contribution of utilising forest biomass for bioenergy production and climate change mitigation in Queensland, Australia. The study aims to (1) provide information on the available energy in forests in Queensland, (2) optimise the location of power plants, and (3) simulate the cost and emission balance of using forest biomass resources for bioenergy and impacts on climate. An exclusion and suitability analysis in GIS identified 13.5 million hectares of harvestable forest with a theoretical forest biomass potential over 1 million dry metric tonnes per year. A GIS decision support system was developed to define strategic and tactical locations for power plant and to evaluate existing plant-locations based on biomass availability, capacity, transport distance and plant quantity. A total of 138 tactical locations are then used to simulate supply chain costs and related emissions using mixed integer programming in Python. The developed GIS-Python decision support tool will help Australian industry, investors and governments in the design and implementation of forest biomass for bioenergy supply chains.

Wood use in traditional toy-making in Channapatna: resource conservation and livelihood implications

Samudyatha Ramananda^{1,2}, Dhanya Bhaskar²

¹The University of Trans-Disciplinary Health Sciences and Technology, Bengaluru, India; ²Azim Premji University, Bengaluru, India (samudyatha1096@gmail.com; dhanya.b@apu.edu.in)

The famous wooden toy crafts of Channapatna in Karnataka employing over 5000 artisans is heavily dependent on *Wrightia tinctoria* (ivory wood), a common native tree species in farmlands. Our study focuses on the sustainability of wood resource use in the handicrafts industry. The industry had faced stiff competition from cheaper imported toys, but was revived recently by a Geographical Indication tag. In the context of recent boom and bust phases of the industry, we investigated the trends in use and status of ivory wood. We used diverse methodological approaches including Focus Group Discussions and Semi-Structured interviews with artisans, tree-growing farmers and saw mill owners supported by ecological assessment of ivory wood populations in farmlands. Our analysis indicated more than 90% dependency of artisans on ivory wood followed by *Tectona grandis* (60%), *Ficus amplissima* (40%) and *Dalbergia latifolia* (35%) as alternative wood sources. Substitution though possible, comes at a huge social cost of depriving poor sections of the resource. Farm assessments shows few trees in mature size (above 20 cm) and age classes (above 10), and low tree to sapling ratio indicating intensive extraction and unsustainable harvesting. Higher tree density was found closer to protected forests, indicating the critical role of the Forest Department in maintaining healthy populations of *Wrightia* in forests to promote tree growth in farmlands. The study further provides recommendations to promote sustainable use of this lowcost resource to sustain artisanal livelihoods.

Physicochemical properties of bio-oil from the pyrolysis of *Pinus caribaea* (Morelet) Needles in Southwest, Nigeria

Popoola Ayodeleola¹

¹University of Ibadan, Oyo, Nigeria (ayodeleolapopoola@gmail.com)

The objective was to investigate the physical and chemical properties of Bio-oil from the pyrolysis of *Pinus caribaea* Needles obtained from an urban environment in Southwest, Nigeria. Pine Needles were collected from a felled tree and it was ground to 6mm particles. Approximately 4.92 kg of pine needles was oven dried at 103 °C until constant weight was obtained to determine the moisture content; 820 g of shredded pine needles was loaded into the vacuum pyrolysis chamber reactor at 600 °C and 700°C in triplicates. Physico-chemical analyses of the Bio-oil were achieved through carbon-hydrogen-nitrogen-sulfur (CHNS) studies, Calorific Values, Fourier transform-infrared (FT-IR) spectroscopy and Gas chromatography-mass spectrometry (GC-MS) through standard procedures such as American standard for Testing and Materials (ASTM). The physical properties such as density, pour point, fire point and flash point agreed with the typical values of conventional fuels and the result from the GC-MS spectrum indicates mostly aromatic hydrocarbons (phenolic in nature) and some aliphatic compounds also. From FT-IR analyses, it can be deduced that there is a larger amount of saturated compounds. The knowledge of chemical composition will aid its use as fuel and as raw material in chemical industries. The results also showed promising indication that Bio-oil from *Pinus caribaea* needles has high potentials for fossil fuel substitution.

Perspectives of productive conservation: situational status of agrobiodiversity in the Mariño Micro-Basin, Apurimac, Peru

Marianella Crispin Cunya¹

¹Universidad Nacional Agraria la Molina-Unalm, Lima, Peru (20161595@lamolina.edu.pe)

The conservation of local cultivated biodiversity is an issue that is becoming increasingly important among decision makers, academy, civil society and mainly those directly involved in conservation. The approach involves an adequate analysis of the image of the territory where a socio-agricultural profile is adequately developed, identifying characteristics of the study area, which allows the construction of an agricultural identity, identifying the variety of existing native species, analyzing the role of women and of family members in the conservation of cultivated biodiversity. It is worth noting, not to forget that climate change exists and therefore the impacts are escalating more and more, where the first affected are the main actors in productive conservation. It is important to mention that if you do not act on time, not only run the risk of losing native species but also their genetic content as national heritage and affecting food security mainly of directly related producers and Peruvian population. This research shows how an image of territory could be constructed from an adequate schematization of productive conservation and identifying the own variables of the study area, which can be considered as a model and starting point for the formulation of conservation policies in different territories where agrobiodiversity or cultivated biodiversity are developed.

Zoning of green infrastructures to reduce the runoff volume and mitigate the vulnerability to flood in Páez river basin, Cartago, Costa Rica

Kevin Alfaro-Jiménez¹

¹Instituto de Investigación y Servicios Forestales (INISEFOR), Heredia, Costa Rica (kevin15aj@gmail.com)

The change of more than a third of the terrestrial ecosystems has unbalanced the regulatory and stabilizing capacity of the environment, increasing the vulnerability to flooding in urban and peri-urban environments. Forest management has advanced in silvicultural practices that take advantage of the water regulation capacity of vegetative structures. The green infrastructure (GI) is an approach to restoring urban and peri-urban areas, which integrates the multifunctionality of the landscape and takes advantage of the properties of the vegetation, to improve the retention capacity of the river basin. The study was in the Páez River sub-basin and presents a new methodology for the determination of the development zones of GI, in order to reduce the volume of runoff and mitigate the floods. The effect of GI on the surface runoff of the landscape was verified through a hydrological modeling. The scene of GI proposed, reduced the runoff between 14% and 5% at the sub-basin scale, and up to 44% at the micro-basin scale, consequently, it generates less vulnerability to flooding.

The state of the art in research and development of agroforestry systems in Colombia / Evaluación del estado del arte de la investigación y desarrollo sobre sistemas agroforestales en Colombia

Maria Riaño, Paula Alejandra Alba Martínez

¹Universidad Distrital Francisco José de Caldas, Bogota D.C., Colombia (mfrianop@gmail.com; pau.alba.m@gmail.com)

El propósito de la investigación es identificar hasta donde se ha avanzado en las temáticas agroforestales del país por medio de la crítica y el uso de publicaciones de manera ordenada, precisa y analítica. El conocimiento del estado del arte, la seriedad en términos de publicación, justificación con datos de respaldo, aceptación, entre otros; y la rigurosidad de la investigación en los sistemas agroforestales no lo hacemos únicamente con la finalidad de hacer investigación.

La importancia de esta revisión resulta en brindar una herramienta básica para avanzar en la práctica; abre las puertas a la inspiración y difusión de nuevas ideas, poniendo sobre la mesa las contradicciones en los conocimientos actuales. Este proyecto posibilita la evaluación de las prácticas vigentes y formulación de recomendaciones. Por medio de una recolección de documentos se hará la organización inicial de los mismos de categorías conceptuales con el fin de determinar la saturación teórica en el tiempo, una codificación axial y selectiva de la información y finalmente, estará la generación de una matriz condicionada para delimitar la teoría que ponga en evidencia el vacío de información en el campo de investigación de los sistemas agroforestales con base en un grupo de conceptos de alta abstracción. ■

Volatile monoterpene ‘fingerprints’ of resinous *Protium* tree species in the Amazon Rainforest

Luaní Rosa de Oliveira Piva¹, Kolby Jardine^{2,3}, Bruno Oliva Gimenez², Ricardo de O. Perdiz², Leticia O. Cobello², Carlos Roberto Sanquetta¹, Niro Higuchi², Jeffrey Chambers^{2,3}
¹Federal University of Paraná, Curitiba, Brazil; ²National Institute for Amazon Research, Manaus, Brazil; ³Lawrence Berkeley National Laboratory, Berkeley, USA (luanipiva@yahoo.com.br; kjjardine@lbl.gov; bruno.oliva.gimenez@gmail.com; ricoperdiz@gmail.com; cobelloleticia@gmail.com; carlossanquetta@gmail.com; higuchi.niro@gmail.com; jchambers@lbl.gov)

Volatile terpenoid resins represent a diverse group of plant defense chemicals involved in defense against herbivory, abiotic stress, and communication. However, their composition in tropical forests remains poorly characterized. As a part of tree identification, the ‘smell’ of damaged trunks is widely used, but is highly subjective. Here, we analyzed trunk volatile monoterpene emissions from 15 species of the genus *Protium* in the central Amazon. By normalizing the abundances of 28 monoterpenes, 9 monoterpene ‘fingerprint’ patterns emerged, characterized by a distinct dominant monoterpene. While 4 of the ‘fingerprint’ patterns were composed of multiple species, 5 were composed of a single species. Moreover, among individuals of the same species, 6 species had a single ‘fingerprint’ pattern, while 9 species had two or more ‘fingerprint’ patterns among individuals. A comparison of ‘fingerprints’ between 2015 and 2017 from 15 individuals generally showed excellent agreement, demonstrating a strong dependence on species identity, but not time of collection. The results are consistent with a previous study that found multiple divergent copies of monoterpene synthase enzymes in *Protium*. We conclude that the monoterpene ‘fingerprint’ database has important implications for constraining *Protium* species identification, phylogenetic relationships and enhancing understanding of physiological and ecological functions of resins and their potential commercial applications.

Class Insecta as bioindicators of ecological restoration in the Brazilian Ombrophilous Dense Montana forest

Taise Cristina Plattau Arenhardt¹, Marcelo Diniz Vitorino², Sebastião Venâncio Martins¹
¹Universidade Federal de Viçosa, Viçosa, Brazil; ²Universidade Regional de Blumenau, Blumenau, Brazil (taise.arenhardt@hotmail.com; ditzvitorino@gmail.com; venanciofv@gmail.com)

Insects are not a common bioindicators to evaluate ecological restoration in Brazil. However, these organisms have many advantages as bioindicators, and can be used in the characterization of different successional stages during the ecological restoration process. In this study, we investigated leaf litter insect fauna in different degraded areas by pastures submitted to ecological restoration from different techniques. We compared the litter fauna from a preserved forest and a natural regeneration area with our restoration sites to identify insect diversity during this process. Fauna was sampled with pitfall traps in the period of April/2017 until December/2018. The study area is located in Serra do Itajaí National Park in the Santa Catarina state, southern Brazil. To compare the areas, parameters of richness, abundance, diversity, equability, similarity, univariate and multivariate analyzes, species indicators indices and correlations with microclimatic variables and plant community were used. Analysis of taxonomic sufficiency was also performed (Insecta families and Formicidae species). From the results, we conclude that less specific taxonomic levels (family) allow us to observe and interpret the differences resulting from changes in ecological succession during the restoration process. The structure of the insect community was influenced by vegetation structure and microclimate. We identified indicative families and species of the different restoration process stages (for example, Ptiliidae, Staphylinidae and Leiodidae for advanced stages and Cicadellidae and Delphacidae for initial stages). In this context, they are organisms that can be used in the monitoring of the ecological restoration stages and basis for decisions making regarding restoration strategies.

Mixed forests of *Nothofagus pumilio* and *N. betuloides*: are they stable? Approximation based on the study of the first stages of natural regeneration cycle

Mónica Toro Manríquez, Rosina Soler¹  María Vanessa Lencinas, Guillermo Martínez Pastur¹
¹Centro Austral de Investigaciones Científicas CADIC-CONICET, Ushuaia, Argentina (monicatm@cadic-conicet.gob.ar; rosisolera@yahoo.com.ar; mvlencinas@gmail.com; cadicforestal@gmail.com)

Flowering, seeding, seedling are a paramount process for tree regeneration, forest conservation and management. In mixed forests, the impact of limiting (biotic and abiotic) factors on tree reproductive success regulate the maintenance of species in balanced proportions or the conversion towards monospecific forests. Tree reproductive phenology were studied in three forest type (pure deciduous *Nothofagus pumilio*, pure evergreen *Nothofagus betuloides* and mixed forests) considering two location (coast and mountain), during three years in Tierra del Fuego, Argentina. The incidence of different loss factors (e.g., premature abortion, fruit, seed predation) was evaluated. Flowering and seeding varied interannually for both species for forest type. Both species showed advantages in pure forests than in mixed forests. A strong effect of location on seeding and in losses factors were detected. The main limiting factor in flowering results in empty seeds due to the pollen self-incompatibility. Premature abortion was associated with extreme climatic events (e.g., late frosts). *N. pumilio* presented in general higher losses associated with seed foraging and stratification losses in *N. betuloides*. Finish for each cycle, the seedling proportion was higher for *N. pumilio* in the mountains and coast than for *N. betuloides*. *N. pumilio* presents a better probability of transition than *N. betuloides* in the mixed forest. Therefore, in mixed forests the tendency would be to be non-stable forests. This study contributes to an understanding of the possible roles of reproductive phenology for detecting shifts in forest communities between pure and mixed forests under natural dynamics and the current climate change.

Leaf wax abundance and distribution in vegetation and soils from a South American Temperate Forest

Carol Cerda-Peña¹, Sergio Contreras^{1,2}, Eduardo Tejos¹
¹Universidad Católica de la Santísima Concepción, Concepción, Chile; ²University of Pittsburgh, Pittsburgh, USA (carolpecer@gmail.com; scontreras@ucsc.cl; edutejos@gmail.com)

Leaf wax compound classes (i.e long chain alkanolic acids and alkanes) from plants are naturally deposited in soils and sediments, where abundance and

distribution have been used as a vegetation and terrestrial biomarkers. This study compares the leaf wax from dominant plant temperate forest community (n=178 individuals) and soils collected in 9 sites at the Andean part of the South-Central American temperate forest. The leaf wax fingerprint of the plant community is heterogeneous, with significant differences in alkanes abundance and distribution and only in abundance for alkanolic acids between sites ($p < 0.05$). The plant community of the forest has a major abundance of alkanolic acids than alkanes with significant differences ($p < 0.001$) between the compound classes, with the same pattern observed in the soil. Considering the abundance and distribution of both leaf waxes and all sampled sites only alkanolic acid abundance is not significantly different between plant community and soil. The mean distribution of alkanolic acids from the plant community and soils in each site are similar, with higher values in plant than soils. However, alkane distribution showed different results, with higher values in soils than in the plant community, observing some sites with almost two units of difference. These results provide valuable information of leaf wax composition from temperate forest in South America. Moreover, the observed patterns suggest that alkanolic acid abundance and distribution in modern leaves from the temperate forest community are reflected in soils and therefore are useful as a vegetation biomarker in the area.
