**Forest Research and Cooperation
for Sustainable Development**

XXV IUFRO World Congress, 29 sept - 5 October 2019,

Curitiba, PR, Brazil

Abstracts

It is with great satisfaction that Brazil is hosting the 25th edition of the IUFRO World Congress. This year's theme, "Forest Research and Cooperation for Sustainable Development," is very fitting now that the issues of production, preservation, environmental services, and their influences on a global scale have moved beyond purely technical debates in closed academic or business circles to become part of everyday life for urban as well as rural dwellers. In this sense, holding an event like the IUFRO World Congress in a country like Brazil, which has its forest DNA rooted in its large-scale diversity and the productive capacity of its planted forests, is very timely.

We are even prouder knowing that this is only the second time this event is taking place in the Southern Hemisphere, and the first time in Latin America. Participants will have an opportunity to exchange knowledge with researchers and professionals from over 120 countries on a wide range of forest-related topics. It will also be a chance for us to show off our Country, which so many people have heard about. However, only a few have had the chance to experience Brazil's unique characteristics and striking regional diversity.

This Special Edition of the Brazilian Journal of Forestry Research is a collection of approximately 2.700 abstracts. Each is one piece of a puzzle of questions and challenges faced by scientists in different social or regional conditions combined with a myriad of solutions. Coincident findings should support policy-making. Conflicting results or approaches should arise curiosity and trigger the search for consensus. We hope all together they pave the way to new products, new approaches, and new ways of looking at our future.

Colombo, August 2019

Sergio Gaiad
Deputy Head of Research and Development
Embrapa Florestas

Table of contents

Plenary	14
P2a: Biodiversity, ecosystem services and biological invasions	14
P4a: Forests and forest products for a greener future	14
Subplenary.....	15
A6a: Women and forests: promoting gender equality connecting research, public policies and forest management in the tropics.....	15
A9a: Political ecology and integrated landscape approaches: complementarity or unhappy marriage?.....	15
A9b: Solving wicked forest policy problems: lessons from practice	16
A9c: Sustainable development goals: their impacts on forests and people	17
B2a: Trees on the move: range shifts, potential for genetic adaptation and assisted migration	18
B4a: Climate smart forestry or how to integrate adaptation, mitigation and sustainable forest management	19
B8a: Forest adaptation and restoration under global change	20
C1a: Managing forest ecosystem resilience and biological and social diversity for future forest products.....	21
C3a: Moving towards sustainable forest operation for a greener future.....	22
D1a: Agroforestry for ecosystem services.....	23
D1b: Close-to-nature silviculture: for people, products and natural processes	24
D7a: Forest health challenges from globalisation and climate change.....	25
D8a: Forest biodiversity in the framework of global change and the role of landscape	26
E4a: Tropical wetlands, climate, and land-use change: challenges and opportunities	27
F8a: Wood and forest culture: addressing a sustainable future.....	28
Theme A: Forests for people.....	29
A1a: Agroforestry and production of nonwood forest products	29
A1b: Agroforestry in forest landscape restoration: towards a comprehensive approach	30
A1c: Assessing the cultural ecosystem services from forests: current challenges and future scopes	32
A1d: Fostering effective agroecological and agroforestry practices for sustainable transformation and food resilience.....	34
A1e: Rising issues in mountain forests and mountain forest management	36
A1f: Assessing the cultural ecosystem services from forests: current challenges and future scopes.....	38
A1g: Agroforestry and production of nonwood forest products.....	39
A1p: Ecosystem services and agroforestry systems in South America	40
A1q: Community involvement in agroforestry systems and ecosystem services.....	42
A1r: Agroforestry for environmental restoration and climate mitigation.....	44
A2a: Sustaining iconic and high-value species in natural forests and plantations	46
A2p: Sustaining iconic and high-value species in natural forests and plantations	49
A3a: Forest operations: a tool for forest management.....	52
A3b: The implementation of economics, forest policy, forest law and governance in Latin America forestry	54
A3p: The implementation of economics, forest policy, forest law and governance in Latin America forestry	56
A3q: The implementation of economics, forest policy, forest law and governance in Latin America forestry	58
A4a: Artificial Intelligence, machine learning and knowledge sharing: combining old and new skills to improve decision-making in forestry.....	60
A4b: Forests without borders: multi-national forest inventory cooperation and harmonisation to enhance sustainable development	61
A4c: Monitoring and Assessing Urban Forest Services and Values at the National to Local Scale.....	64
A4p: Monitoring and Assessing Urban Forest Services and Values at the National to Local Scale	66
A4q: Monitoring and Assessing Urban Forest Services and Values at the National to Local Scale	68
A4r: Monitoring and Assessing Urban Forest Services and Values at the National to Local Scale	69
A5a: Governing innovation for sustainability in the forest sector - I.....	71
A5b: Governing innovation for sustainability in the forest sector - II.....	74
A5p: Governing innovation for sustainability in the forest sector - I.....	76
A6b: Balancing environmental, productive and social needs to meet sustainable goals in the forest industry: experiences of cross-sectorial cooperation in South America	78
A6c: Challenges to sustainable forest management to enhance traditional communities and smallholders' livelihoods in the Amazon basin	79
A6d: Community and family forest management in Latin America: guaranteeing rights and citizenship with sustainability	82
A6e: Forests and Human Wellbeing: life satisfaction and behavioral approaches.....	83
A6f: Gender, forestry and rural communities: shaping power and agencies in an era of globalisation	85
A6g: Indigenous and traditional peoples and their forests: knowledge, management and governance towards sustainable development goals	87
A6h: Pathways towards sustainable resource use from African Sudanian and Zambebian woodlands: resolving conflicting points of view	90
A6i: Social and economic benefits in protected areas: partnerships and concessions for local development.....	92

A6j: Strengthening community and smallholder forestry for SDGs and other Forest-Related Goals	94
A6k: The bioeconomy: a sustainable way forward?.....	95
A6l: Indigenous and traditional peoples and their forests: knowledge, management and governance towards sustainable development goals - 2	98
A6m: Women and Forests: promoting gender equality connecting research, public policies and forest management in the tropics.....	100
A6p: Women and Forests: promoting gender equality connecting research, public policies and forest management in the tropics.....	102
A6q: Social aspects of forestry	103
A6r: Social aspects of forestry.....	105
A6s: Social aspects of forests and forestry	107
A8a: Ecology, silviculture and management of tropical dry forests.....	109
A8b: Forecasting the effects of land-use on wildlife communities and conflict at human-wildlife interface	112
A9d: Committed and held accountable? Exploring accountability relations of state, business and civil society organisations in multi-level forest governance	114
A9e: Forestry in transition? Forest policies in changing societies. Part 1: Europe	116
A9f: Governing farm-forest interfaces: lessons from practice and methodological advances to improve policy.....	118
A9g: Innovative forest laws and environmental legislation for enhanced forest ecosystem services in local communities	120
A9h: Nature's contribution to people in transitioning forest landscapes.....	122
A9i: Policy and practice for sustainable forest-based tourism and recreation.....	123
A9j: Politics of international forest regimes	126
A9k: Status and current developments in South-South cooperation in forestry.....	128
A9l: Sustainable development goals: their impacts on Forests and People.....	129
A9m: Political ecology and integrated landscape approaches: complementarity or unhappy marriage?	132
A9o: Forestry in transition? Forest policies in changing societies. Part 2: global examples	134

PLENARY

P2a: BIODIVERSITY, ECOSYSTEM SERVICES AND BIOLOGICAL INVASIONS

Voice of the mother treesSuzanne Simard¹¹University of British Columbia (suzanne.simard@ubc.ca)

In three decades of studying interspecific relationships in the forests of Canada, we have discovered that trees not only compete with each other, but also connect, communicate and cooperate through belowground mycorrhizal fungal networks. The largest trees are hubs of the networks, where they link with other trees and plants. The big trees convey resources such as carbon, nitrogen and water, and these are transmitted down source-sink gradients to smaller trees, resulting in a redistribution of matter and information throughout the forest. The big hub trees also facilitate the regeneration of new seedlings, particularly their own offspring, enhancing their survival and growth, and we have therefore taken to calling the hubs, “mother trees”. When the mother trees become sick or damaged, they transmit even more resources to the surrounding individuals, as well as defense information that enhances the recipient’s resistance to the disturbance. Deciphering such communications will take considerable more research, but it is clear that mother trees have a voice and what they have to say is crucial to forest resilience. In working with the Aboriginal people of British Columbia, we have learned that these discoveries resonate with traditional ecological knowledge. Based on this knowledge, and in collaboration with indigenous people, academics, government and the forest industry, we launched “The Mother Tree Project” in the Douglas-fir forests of British Columbia in 2015. This rigorous experiment, where we are testing how best to retain mother trees during harvesting so the forest remains resilient as climate changes, is designed as a hub for a century of collaborative research. It includes nine replicated forests that cover the climatic envelope of interior Douglas-fir, across which we are comparing five patterns of mother tree retention, from clearcutting to partial retention to no-harvest controls. The mother tree retention treatments have been planted with a wide range of species as well as local and migrated genotypes of Douglas fir, creating diverse mixes of regenerating trees that should enhance resource uptake and decrease risk of catastrophic mortality. We are measuring how these practices are affecting key ecological structures and functions, including species diversity, carbon storage, and forest regeneration. This presentation tells the story of the origins of The Mother Tree Project, provides early results, lays out a vision for globalization of the project, and gives information on how to get involved.

P4a: FORESTS AND FOREST PRODUCTS FOR A GREENER FUTURE

Forests and forest products for a greener futureVincent Gitz¹¹GCIAR Research Program on Forests, Trees and Agroforestry, Bogor, Indonesia (v.gitz@cgiar.org)

The strong scientific consensus on the need for more forests and trees, mainly for environmental reasons, especially to mitigate climate change, is broadly recognized by policy makers. It has led to numerous political commitments. As part of the Green Economy discourse there is also a growing political support for bio-energy and for substituting non-renewable, energy intensive, materials by wood products (and other comparable products like bamboo and rattan) that are both renewable and stock carbon. However, results on the ground are more mixed. One of the reasons being that economic development is a main driver of deforestation, and that the amounts of public money to be committed for forest conservation and forest restoration do not compare to short time economic benefits of alternative activities. One illustration of this is the recent debate on the potential for tree planting (Lewis et al. and rebuttals) between a biophysical approach and those recalling economic realities. This leads to the following questions, that the presentation will aim to articulate and address: How can more wood products be the way to more -rather than less- trees and forests? And which wood products and from which forests, given the social, environmental and economic performance of the associated production and transformation systems? Which “wood value webs” to prioritize and to optimize, given multiple objectives, differing characteristics of diverse silviculture/ plantation/ forest management types and their related objectives, as well as other development constraints, such as land-use, the time to grow wood and to develop the industrial infrastructure? And how will it work, especially considering that forest economies are very different in developed and developing countries? What would be the economic, trade and markets, financial, institutional, regulatory and legal conditions for it to happen?

Forests and forest products for a greener futureFrancisco Razzolini¹¹Klabin SA, São Paulo, Brazil (frazzolini@klabin.com.br)

There is a rising concern and global awareness related to climate changes, global warming, water and food scarcity, excess emissions and pollution all over – air, land and water. There is increasing scientific evidence that a significant proportion of the fossil resources need to stay underground if the world has to reach its climate goals. Bio-based products are of a huge importance for climate change mitigation, GHG emissions and sequestration. While the energy sector can be extensively decarbonized, the chemical sector and plastic industry depend heavily on carbon, and with this, there’s a great opportunity for renewable carbon to reduce the GHG impact. Currently, the only important source for renewable carbon is biomass. Klabin, Brazil’s largest packaging paper and paper packaging producer, has been focusing the development challenges for new bio-based, renewable, circular and compostable products. A corporate research, development and innovation (R&D+I) structure, including a brand new Technology Center, was established. Five technology routs being explored – forest, pulp, paper, environmental and new technologies based on planted forests. New applications and products from forest based materials, through technology, will enable Klabin enhance its products as well as explore new business opportunities. This is one of the most important steps in the company’s history aiming to improve sustainability. There is still a lot to do to scale up the basic research into industrial scale and many questions to answer. The presentation will address some opportunities and developments for multiple uses of the forest and trees into sustainable products.

SUBPLENARY

A6a: WOMEN AND FORESTS: PROMOTING GENDER EQUALITY CONNECTING RESEARCH, PUBLIC POLICIES AND FOREST MANAGEMENT IN THE TROPICS

The feminine space in forest management in the Amazon, Amapá case studyAna Margarida Castro Euler¹¹Embrapa Amapá, Macapá, Brasil (ana.euler@embrapa.br)

Amapá is a sui generis state located in Eastern Brazilian Amazon, with low historical deforestation rate and where 73% of its territory is under protected areas. It is the only one women wages are, on average, higher than men in the public sector. Also it is the only Brazilian Amazon state that has an Institute of Forests (IEF) with a function of forestry extension, protected areas management, forest concessions and environmental services. From 2011 to 2014, for the first time a female forest engineer headed the IEF. During this period, the state government had less than 20% of executive positions held by women. Challenges at the IEF ranged from the scarcity of budget resources to high demand in a region where forests occupy 80% of the territory. Remarkable outcomes were achieved such as the State Register of Public Forests, the 1st State Forest Program, and the 1st Forest Concession bidding notice. The launch of the Pro-extrativism programme, which assisted more than 1,500 families of agroextractivists, quilombolas, indigenous and riverine communities; and the weekly radio program “Vozes da Floresta”, a forum for the dissemination of information on market, forestry policies and projects. A major difficulty came up in the relationship with timber companies, run by men with patriarchal culture and retrograde practices. Confronting conflicts related to corruption associated with the public land tenure, and a tense relationship with the Legislative Assembly, whose the majority of representatives, advocate interests unrelated to the traditional communities and the protection of the environment.

Gender equality in forestry education in a Kenyan UniversityJane Kiragu¹¹University of Eldoret, Eldoret, Kenya (wambuikirash@gmail.com)

Women play a major role in the establishment and management of forests in the world and especially in the developing world, and Kenya in particular. Women are found in large numbers working in the tree nurseries and during tree planting in the field, but their numbers reduce drastically in the management positions. About 90% of the rural households use fuelwood for their cooking, heating and lighting. Fuelwood collection is done mainly by women and girls in the forest at a fee, while boys are left to play or look after cattle in the field. A lot of time is spent which can be reduced if both men and women can be encouraged to plant trees in their farms. In Kenya, this has not been easy due to land tenure, tree tenure, government policies, land sizes, the long term state of the crop and culture problems. To promote forests, more women should be in policy making positions both in the forestry sector and in politics where most decisions are made. Women should be encouraged to vie for those positions whenever advertised and given a level ground with their male counterparts. The government has put the 2/3 gender rule in the constitution, but its implementation is yet to be realized. More research should be done on why fewer women are found in forest related sectors and how this can be changed.

Women in forest governance policy: analysis and empirical studies from Latin America and AsiaPurabi Bose¹¹Landing Together, Mumbai, India (purabibose@gmail.com)

A search for the words women and gender in the Draft National Forest Policy, 2018 – which governs the formulation of all laws and schemes related to forestry – returns zero results. While terms like wood, economic or timber appear all over the 10-page draft policy released by the Indian government in March. Likewise, the policies on forest in Latin America's Colombia shows the challenge of integrating women's active role in collective forest governance, particularly in agro-forestry. This paper makes a comparative analysis between Latin America and Asia in understanding the role of women in forest policy. The two countries Mexico and Colombia from Latin America while India and Indonesia from Asia will be used as empirical case study. The study uses primary and secondary data to show how recent forest policies impact women from rural and indigenous areas. The findings indicate that forest policy rarely uses the words ‘women’ or ‘gender’ to ensure women's active role in forest governance. The first challenge is to overcome the challenge is for the environment ministry to acknowledge that the draft policy fails to discuss gender integration and women's issues in the management of forests, trees, agroforestry and afforestation. The next step will have to be to open up the dialogue for social and gender inclusion, and to ensure that environmental defenders, including women, are protected through India's forest policy. With these measures in place, this paper indicates a chance of saving India's forests and the communities who depend on them.

A9a: POLITICAL ECOLOGY AND INTEGRATED LANDSCAPE APPROACHES: COMPLEMENTARITY OR UNHAPPY MARRIAGE?

Context, power and equity in territorial planning multi-stakeholder commissions: a comparative analysis of two very different Brazilian StatesJazmin Gonzales Tovar^{1,2}, Grenville Barnes¹, Anne Larson²¹University of Florida, Gainesville, USA; ²Center for International Forestry Research, Bogor, Indonesia (jazmin.gonzalez@gmail.com; gbarnes@ufl.edu; a.larson@cgiar.org)

“Ecological-Economic Zoning” (ZEE) was regulated in Brazil as a territory planning tool aimed to organize the sustainable use of land and natural resources, through multi-stakeholder forums (MSFs) and other participation mechanisms. MSFs have gained global popularity as an innovative institutional reform in the governance of land use and forests. In territorial planning, the idea is to bring together diverse actors to advance “good governance” and “sustainable development” (e.g. Nolte et al. 2017). However, both territorial planning and MSFs constitute a double-edged sword: advancing certain goals, strengthening certain land use rights and benefiting certain actors can come at the expense of others. They can either challenge power asymmetries or merely reproduce them (e.g. Kohlepp 2002). Based on 10 months of research, we comparatively analyze the multi-stakeholder commissions created for the ZEE of Acre and Mato

Grosso, two Amazonian Brazilian States with very different characteristics and history. We delve into the influence of the national and regional context, and how power is exerted, distributed and shared between actors. We capture perceptions and collect empirical evidence from q-methodology and differentiated questionnaires. We reveal that land use planning MSFs have better chances to promote equitable power relations when they emerge from – and are nourished by – an historical context that embraces local movements, culture, identity and differences, rather than from technocratic top-down processes. Our ultimate goal is to offer a critical analysis and shed light on how to improve the equity of MSFs in decision-making around land use, forests and local people's wellbeing.

Linking landscape governance and system change in Global commodity markets

Pablo Pacheco¹

¹WWF, Washington, DC, USA (pablo.pacheco@wwf.org)

There is growing consensus on the potential of integrated landscape governance approaches to achieve landscape sustainability. These views emphasize socio-environmental dynamics, yet fail to acknowledge wider sustainability challenges in the global supply chains shaping landscapes' performance. Major sustainability challenges in landscapes in transition, are the pressures originated on Global sourcing of food, energy and materials, linked to disparate financial and corporate interests. Efforts to support sustainable landscapes through both corporate commitments to zero deforestation and governments' regulatory frameworks aimed at sustainable land use, face several barriers. Main are: 1) legacy issues associated with specific pathways of landscape development, where greater progress is likely to be achieved where stronger local economies have developed but there is likely little forest left; 2) leakage, since deforestation tends to move to poorly governed landscapes where greater short-term interests for capturing economic rents persist; and 3) legitimacy, since solutions often tend to reinforce asymmetric power relations in the landscapes, while excluding low performing farmers. More structural solutions to deforestation and forest degradation are needed by linking wider system change interventions of corporate actors in the supply chains, and state policies across landscapes undergoing different stages of social and economic development and resource use. This paper, by looking at the specific cases of Brazil and Indonesia, argues in favor of wider corporate engagement in 'nature-based solutions' across landscapes (moving beyond zero deforestation only) and 'hybrid governance mechanisms' for dealing with legacy and leakage across landscapes, and power disparities and competing values in each specific landscape.

A9b: SOLVING WICKED FOREST POLICY PROBLEMS: LESSONS FROM PRACTICE

Integrating diverse knowledge systems to address complex forest policy challenges: insights from large-scale genomics research

Shannon Hagerman¹, Robert Kozak¹, Guillaume Peterson², Richard Hamelin¹, Sally Aitken¹

¹University of British Columbia, Faculty of Forestry, Vancouver, Canada; ²University of British Columbia, Vancouver, Canada (shannon.hagerman@ubc.ca; rob.kozak@ubc.ca; guillaume.peterson@ubc.ca; richard.hamelin@ubc.ca; sally.aitken@ubc.ca)

The integration of diverse forms of knowledge is widely acknowledged as essential for addressing complex environmental forest policy challenges. While forest research spans multiple disciplines, the integration of knowledge in an interdisciplinary manner is often lacking. Recognizing that meaningful integration continues to be elusive, some funding agencies have tried to address this by explicitly incorporating a requirement for integrating natural and social science insights. One such program, the GE3LS program within Genome Canada, was developed to encourage integration across disciplines and, specifically, to consider the ethical, environmental, economic, legal and social issues involved in genomics research. Here, we draw from our collective experience across two large-scale interdisciplinary forest research projects (AdapTree and CoAdapTree) addressing genetic and reforestation choices for new climates, to evaluate opportunities and challenges of integration in applied research practice. We explore three examples of integration and ask: what is integrated, who integrates, at what stage of the research process, and what does/should integration achieve? Our inquiry is based on the premise that a common barrier to productive integration is an often-unquestioned assumption that the meaning and purpose of "integration" is known and shared across research teams and affected stakeholders. We identify success factors and persistent dilemmas by distinguishing between issues of "knowledge architecture" (e.g. relating to epistemological differences, including between western scientific and indigenous knowledge systems) on the one hand, and "project architecture" (e.g. relating to communication, trust, institutional incentives) on the other.

The Brazilian show-case for prevention and control of deforestation in the Amazon: PPCDAM's roots and results

Mayte Benicio Rizek¹, Anne Larson², Juan Pablo Sarmiento²

¹Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brasil; ²Center for International Forestry Research (CIFOR), Lima, Peru (mayte.cifor@gmail.com; a.larson@cgiar.org; j.sarmiento@cgiar.org)

During the first Worker's Party mandate (2003-2006), tackling deforestation took a central place in the presidential agenda and Brazil came up with the Action Plan for the Prevention and Control of Deforestation in the Legal Amazon (PPCDAM). Through an interministerial working group of 13 federal agencies led by the Chief of Staff Office, each institution proposed strategic actions leading to a more than 50% decrease in deforestation rates from 2004 to 2008. This research analyzes the PPCDAM political roots and approaches considering the perceptions across three conveners and eighteen mid-level bureaucrats who worked or still works on PPCDAM agenda representing environmental interests, such as protection-and-conservation goals, as well as the production interests, including traditional uses, mining and rural development interests. It all supplemented by seven non-participant relevant stakeholders interviews and research on official documents and third-party evaluations. Part of CIFOR's mixed-method global research into multi-stakeholder forums, the results show that when the federal government gave political weight and budget prioritization, PPCDAM changed Brazil's approach to deforestation. It happened by organizing multi-institutional command-and-control actions supported by remote sensing techniques, promoting access to public services as compensation for the economic impacts after command-and-control actions, and by raising awareness that land-use planning can optimize resources, including the creation of protected areas in deforestation hot-spots. However, local governments were not enough engaged, although many actions focused on their territorial performance. Thus, PPCDAM was unable to change the local economic matrix, and illegal deforesters shifted their patterns to subvert control by remote sensing.

Explaining variation in deforestation in Uganda: the role of forest sector decentralization, protected areas, and institutions

Michaela Foster¹

¹Yale University, New Haven, USA (michaela.foster@yale.edu)

Decentralization has been pushed as an effective strategy for forest governance. Policy makers across the globe have implemented decentralization reforms with the aims of improving environmental conditions and rural livelihoods. Many studies have assessed the impacts of decentralization across countries

and in case studies, presenting mixed evidence of the effectiveness of reforms. Fewer studies, however, have examined how decentralization influences the effectiveness of other existing conservation interventions, such as protected areas. In this study, I use a mixed methods approach to assess the impact of forest sector decentralization on forest cover change within protected areas in Uganda since 2000 and to investigate how forest management institutions emerging from the reform have operated to influence subnational forest outcomes. The decentralization process in Uganda devolved forest management under the jurisdiction of three managing authorities: Uganda Wildlife Authority, National Forest Authority, and District Forest Services, allowing for comparisons of deforestation outcomes on plots under the management of each authority over time. This study traces how the unique institutional arrangements of each managing authority, including agency mandates, capacities, and management rules, changed following the reform, and have, in turn, shaped forest management and led to heterogeneous effects across protected areas. Findings from this study point to the institutional conditions that appear to be conducive to effective governance and conservation and can be used to draw lessons about the opportunities and constraints emerging from decentralization in the governance of protected areas.

Governing wicked problems across boundaries: the case of wildfire governance in the Western US

Benjamin Gray¹, Daniel Williams^{2,3}, Carina Wyborn¹, Laurie Yung¹

¹University of Montana, Missoula, USA; ²USDA Forest Service Rocky Mountain Research Station, Fort Collins, USA; ³Luc Hoffmann Institute Gland Switzerland (*benjamin.gray@umontana.edu; drwilliams@fs.fed.us; cwyborn@wwfint.org; laurie.yung@umontana.edu*)

Mitigating wildfire risk is a particularly wicked socio-ecological problem. Climate change, on-going development in the wildland-urban interface, and other factors have made wildfires in the Western US increasingly problematic. Due to the patchwork of private land ownership and local, state, and federal government jurisdictions in the West, no single authority can direct or mandate wildfire risk mitigation efforts at the landscape scale. Effective mitigation of wildfire risk, therefore, requires cross-institution coordination and collective action in the form of wildfire governance. Governance refers to the ways that heterogeneous networks of individuals and institutions, both public and private, manage their shared interests through formal and informal norms and rules. This project uses interviews with fire and forest management professionals to examine the institutional tools, work arrangements, and cultures that enable or constrain the shared governance of fire risk across ownership and jurisdictional boundaries in two large landscapes in the western US. We find that, compared to the persistent cross-jurisdictional challenges of fire suppression among a small number of formal organizations, fire risk mitigation remains an especially wicked problem due to different concepts of forest health and management, the desires of private citizens, the cost of certain mitigation interventions, and the unique missions of the many government agencies involved in managing forests and wildfires. However, actors in each of the examined landscapes are building their capacity to mitigate wildfire risk through partnerships that span agencies and ownerships and that serve the needs of their unique stakeholders.

A9c: SUSTAINABLE DEVELOPMENT GOALS: THEIR IMPACTS ON FORESTS AND PEOPLE

Sustainable development goals: their impacts on forests and people

Pia Katila¹, Carol J. Pierce Colfer^{2,3}, Wil de Jong⁴, Glenn Galloway⁵, Pablo Pacheco^{2,6}, Georg Winkel⁷

¹Natural Resources Institute Finland, Helsinki, Finland; ²CIFOR, Bogor, Indonesia; ³Cornell University, Ithaca, USA; ⁴Kyoto University, Kyoto, Japan; ⁵University of Florida, Gainesville, USA; ⁶WWF, Washington, USA; ⁷European Forest Institute, Bonn, Germany (*pia.katila@luke.fi; c.colfer@cgiar.com; dejongwil@gmail.com; ggalloway@latam.ufl.edu; p.pacheco@cgiar.org; georg.winkel@efi.int*)

The presentation is an introduction to the session. It introduces the new IUFRO WFSE book Sustainable development goals: Their impacts on forests and people and the process for developing this book. The potential contributions of forests to achieving the SDGs were explored before the SDGs were formally adopted and have since been further discussed. Little attention, however, has been focused on possible and likely impacts that efforts undertaken to advance towards the 17 SDGs will have on forests and forest-related livelihoods/human wellbeing, and how these impacts, in turn, will contribute or undermine the contributions of forests to climate change (mitigation and adaptation) and development. The book provides a systematic, transdisciplinary, scientific assessment of potential and anticipated impacts of efforts to achieve the SDGs on forests and related socio-economic systems and forest-related development. It discusses the contextual conditions that influence how SDGs are implemented and prioritized, and how these conditions and the SDG implementation influence impacts on forests and related socio-economic systems. Furthermore it considers the important interconnections and interlinkages among the SDGs and potential or anticipated trade-offs and synergies among the SDGs from the perspective of forests and related socio-economic systems, and sheds light on how the implementation of the SDGs may transform existing forest-related development scenarios, and affect the roles of forests in sustainable development in the future.

Multi pathway impacts of the SDGs on forests and people

Wilhelmus de Jong¹, Pia Katila², Carol J. Pierce Colfer³, Glenn Galloway⁴, Georg Winkel⁵, Pablo Pacheco⁶

¹Kyoto University, Kyoto, Japan; ²Natural Resource Institute Finland, Helsinki, Finland; ³CIFOR, Ithaca, USA; ⁴University of Florida, Gainesville, USA; ⁵European Forestry Institute, Bonn, Germany; ⁶WWF, Washington, USA (*dejongwil@gmail.com; pia.katila@luke.fi; c.colfer@cgiar.org; ggalloway@latam.ufl.edu; georg.winkel@efi.int; pablo.pacheco@wwf.org*)

Forestry experts have pointed out the potential contribution of forests to achieving the SDGs. A fundamental question that needs addressing is how Agenda 2030 will likely affect forests and forests' capacities to contribute the multiple goods and services demanded by people whose livelihoods and well-being depend on forests and by society at large. We present the Synthesis and Findings chapter of the IUFRO-WFSE volume Sustainable development goals: Their impacts on forests and people. Many SDGs relate to their own policy domain and can be expected to have impacts on forests and people similar to the sectors that they relate to. The impacts of SDGs implementation are influenced at international, national, sub-national to a forest landscape scale, and multiple sets of factors influence SDG priority setting and implementation at every scale. The impact pathways of SDGs on forests and people are complex because of these factors shaping implementation, but also because of complex interactions when multiple SDGs are implemented simultaneously. It is possible to identify opportunities for synergies to achieve more desired outcomes, or to recognize and address unavoidable trade-offs. The recognition of positive and negative impacts of SDG implementation, but also of synergies and trade-offs allow for alternative implementation choices. The important contribution of the volume is to identify contextual factors and conditions that influence effective SDG implementation, recognize opportunities for synergies and trade-offs and identify alternative courses of action for enhanced SDG implementation outcomes and more positive impacts for forests and people.

The SDGs and their impacts on forest and people: conclusions from a collaborative global book project

Georg Winke¹

¹European Forest Institute, Bonn, Germany (georg.winkel@efi.int)

The SDGs describe a globally set agenda for sustainable development. They are, consequently, of critical importance for the world's forests and people that depend on them either directly or indirectly. This presentation summarizes the conclusions chapter of the IUFRO-WFSE volume Sustainable development goals: their impacts on forest and people, which has been written jointly by the editors and supported by the work of a huge set of authors of the entire volume. It, first, takes a step back and reflects in the very nature of the SDGs as being a conglomerate of objectives and approaches rooted in distinct sectoral policies, creating synergies and conflicts amongst them. Subsequently, the talk elaborates on the immense, but context-dependent distinct role that forest play for sustainable development, and vice versa the potentially very different effects the SDGs might have for forests and people. Issues such as critical context factors, distinct forest related development pathways, the necessity to accept related different trajectories for forest-related development, including the need to deal with trade-offs, and the possibility of universal principles for sustainable development are discussed. The talk concludes with assessing both possible "development potentials" of the SDG concept itself in view of forest related development, and perspectives for future research.

SDG's impacts on forests: discussion on perspectives to deepen our current understanding

Pablo Pacheco¹

¹WWF, Washington, DC, USA (pablo.pacheco@wwf.org)

This presentation offers critical reflections on the IUFRO WFSE book Sustainable development goals: their impacts on forests and people. This book argues that SDGs implementation will impact on forests and forest-related livelihoods, thus contributing to or undermining the role of forests in climate and development, depending on context-specific factors. This work provides important foundations to understand the role and impacts of the sustainable development agenda on forests with potential to catalyse future political and societal action. Nonetheless, to improve current understanding of the impacts of SDG implementation on forests, there is need to 1) advance our conceptualizations of place, as influenced by different pathways of societal development and natural resources use, to better foresee the likely impacts on forests associated with SDGs implementation under different types of local- or national-specific contexts; 2) embrace a system change perspective to understand the outcomes and trade-offs on forests and the forest-people nexus resulting from the simultaneous implementation of the SDGs, establishing synergistic and antagonistic interactions among them; and 3) conduct wider examinations on what would be the future threats on and opportunities for forests under wider agendas of food security, sustainable energy development, economic growth, and climate change mitigation, in a future in which it likely won't be possible to achieve all of them, and trade-offs are unavoidable. Adopting these lenses may contribute to visualizing the most effective pathways to SDG implementation that could preserve forest ecosystem services while contributing to enhancing people's livelihoods and low-carbon development options in different contexts.

B2a: TREES ON THE MOVE: RANGE SHIFTS, POTENTIAL FOR GENETIC ADAPTATION AND ASSISTED MIGRATION

Conifer ecotypic variation for traits related to light quality and photosynthesis

María Rosario García Gil¹ ; Sonali Ranade¹

¹SLU, Umea, Sweden (m.rosario.garcia@slu.se; sonali.ranade@slu.se)

It is a well-accepted fact that conifer breeding programs need to account for the climate change. An increase in temperature in the north of about three degrees in the next 100 years has been predicted in Scandinavia. Warmer temperatures in the north can be seen as an opportunity to assist migration (transfer) of southern genotypes to the north in order to gain on growth and biomass production; however, this interpretation only takes into account tree growth. Considering that response to the environment is governed at the canopy level where light sensing, and photosynthesis are regulated, understanding the genetic basis of adaptation to the local light conditions (i.e., light quality and intensity, and day length) is key in the design of assisted migration programs to ensure the expected gain. Our phenotypic and transcriptomic (RNAseq) results support ecotypic variation in conifer seedling growth in response to the light quality in conifers and in needle anatomy and chemical composition that can be related to the phenomena of local adaptation.

Negative selection and polygenic adaptation in maritime pine

Understanding the genetic basis of adaptive phenotypes is crucial to implement conservation and breeding programs in forest trees. Results from standard association and QTL mapping studies illustrate that many fitness-related traits are polygenic. Recent evolutionary frameworks, moreover, have identified soft sweeps involving a large number of loci as the dominant signature of natural selection. These soft sweeps are difficult to detect by traditional methods. Here, we investigate the underlying genetic architecture of fitness-related traits for maritime pine (*Pinus pinaster* Aiton) to assess importance of polygenic adaptation to shaping range-wide patterns of phenotypic and genetic variation for this iconic tree species. Using a multi-environment clonal common garden comprising rangewide populations, we assessed phenotypic variation for multiple fitness-related traits and genotyped 6,100 SNPs in all clones. Genetic control was moderate for height and phenology (mean $H^2 = 0.15$) and smaller (mean $H^2 = 0.05$), but still significant, for survival, needle morphology, and pathogen susceptibilities. Among-population genetic differentiation for adaptive traits (Q^{ST}) was about 2.5-fold that for molecular markers (F^{ST}), suggesting local adaptation. We performed genome-wide joint analysis of all SNPs in association with the evaluated phenotypes and calculated their level of polygenicity. Initial results highlight varying levels of polygenicity across phenotypic trait and growing environment (Mediterranean vs Atlantic). We also provide evidence of negative selection as a relevant factor explaining polygenicity. Polygenic approaches, such as those commonly used in human evolution studies, will thus significantly improve our understanding of the genetic basis of adaptation in forest trees and their expected genetic responses to environmental change.

Does local adaptation to drought need to be considered in assisted gene flow strategies for Douglas-fir reforestation?

Rafael Candido Ribeiro¹, Christine Chourmouzis¹, Pia Smets¹, Alex Girard¹, Dragana Vidakovic¹, Brandon Lind¹, Sam Yeaman², Sally Aitken¹
¹Department of Forest and Conservation Sciences, University of British Columbia, Vancouver, Canada; ²Department of Biological Sciences, University of Calgary, Calgary, Canada (rafael.ribeiro@ubc.ca; christine.chourmouzis@gmail.com; pia.smets@ubc.ca; algirard205@hotmail.com; dragana.vidakovic@ubc.ca; brandon.lind@ubc.ca; samuel.yeaman@ucalgary.ca; sally.aitken@ubc.ca)

Drought is a major concern in forest management and conservation around the world as it can directly or indirectly hinder tree growth and increase tree mortality, affecting ecological processes and ecosystem services. With climate change, droughts are expected to increase in frequency and intensity. Douglas-fir (*Pseudotsuga menziesii*) is an important species in North America, both ecologically and economically. In order to investigate how tolerance of summer drought varies among populations and varieties (coastal var. *menziesii* and interior var. *glauca*), we established a greenhouse common-garden experiment with seedlings from 87 different provenances spanning ~16° latitude, ~14° longitude, and ~1700 m elevation. The experiment had a split-plot design with a drought treatment gradually reducing soil water content, and a control treatment maintaining field capacity. Chlorophyll fluorescence (Fv/Fm), visual damage and height were assessed five times in 160 days. Drought reduced the photosynthetic performance of seedlings, which negatively affected growth in both varieties, but the rate of response differed among provenances. There were significant differences in drought hardness between varieties for all traits. However, within varieties, most of the variation observed was within provenances, suggesting local adaptation to drought is weak within var. *glauca* and even weaker for var. *menziesii*. Targeted exome capture and sequencing of DNA pools from each population are underway to detect candidate genes associated with the observed patterns in drought tolerance and other climate-related traits. Results from this study, which is part of the CoAdapTree Project, will be used to inform assisted gene flow strategies for reforestation.

Identifying adapted seed sources for major European tree species under climate change

Debojyoti Chakraborty¹, Jan-Peter George¹, Julian Gaviria², Jan Kowalczyk³, László Nagy⁴, Lea Henning⁵, Marcin Klisz³, Valerie Poupon⁶, Silvio Schueler¹
¹Austrian Research Centre for Forests, Vienna, Austria; ²The Bavarian Office for Forestry Seed and Plant Breeding, Teisendorf, Germany; ³Forest Research Institute, Warsaw, Poland; ⁴Forest Research Institute, Sopron, Hungary; ⁵Johann Heinrich von Thünen Institute Federal Research Institute for Rural Areas, Forestry and Fisheries, Eberswalde, Germany; ⁶Czech University of Life Sciences, Prague, Czech Republic (debojyoti.chakraborty@bfw.gv.at; jan-peter.george@bfw.gv.at; julian.gaviria@asp.bayern.de; j.kowalczyk@ibles.waw.pl; lnagy@erti.hu; lea.henning@thuenen.de; m.klisz@ibles.waw.pl; poupon@fd.czu.cz; silvio.schueler@bfw.gv.at)

Adaptive forest management aims at reducing vulnerability and enhancing the resilience of forest ecosystems in order to preserve the capacity of forests to provide multiple ecosystem services also under climate change. Adaptive management also includes a better utilization of the intrinsic genetic variation within tree species to identify adapted seed sources for planting under future conditions, following assisted migration and assisted gene flow approaches. Traditionally, seed material for plantations are identified based on the concept of “local is best” whereby local seed sources are considered to be optimally adapted to the regions where they grow. Here, we introduce a new harmonized dataset of in total 545 provenance trials of seven economically and ecologically important tree species of Europe. These data are the basis for Universal Response Functions (URFs) that combine both climate and genetic effects to model the phenotypic variation in functional traits. The URFs helped to identify the major drivers of phenotypic variation in functional traits and were used as a basis for reforestation tool guiding seed deployment and the identification of adapted planting materials for future climate conditions.

B4a: CLIMATE SMART FORESTRY OR HOW TO INTEGRATE ADAPTATION, MITIGATION AND SUSTAINABLE FOREST MANAGEMENT

Uncertainty of carbon economy in forestry

Rasoul Yousefpour¹, Andrey Augustynczyk¹
¹Albert-Ludwigs-University of Freiburg, Freiburg, Germany (rasoul.yousefpour@ife.uni-freiburg.de; andrey.lessa@ife.uni-freiburg.de)

Forest growth predictions are used to build expectations about future economic performance of management decisions. Most of the predictions and consequently expectations are based on empirical knowledge, assuming a steady state in climate and a deterministic forest growth approach. However, climate may change to a different degree in the coming decades causing a dynamic and uncertain forest growth and carbon budget. The uncertainty of modeling systems' parameters and climate state propagates over time to the final decision about carbon economy and optimal management solutions. Here we quantify this uncertainty using Bayesian inference to predict the growth of European beech (*Fagus sylvatica*) in central European conditions as an example. The results show a strong influence of model parameters uncertainty on the final decisions about timber based and carbon economy. To deal with deep uncertainty, a robust decision-making approach has been applied to find solutions with minimum regret or maximum value at risk regarding all scenarios. Moreover, we applied the concept for realizing European Climate Smart Forestry. We conclude that communicating uncertainty is a fundamental issue for forestry economics under changing climate conditions. The key message for designing global forest governance policy in the uncertain times of climate change will be the necessity to take into account both the uncertainty of demand side, i.e. socio-economic developments and regional population needs for forest ecosystem services such as wood, but also the uncertainty of supply side and the inherent ecological uncertainties in predicting the forests growth, responses, and climatic conditions.

Climate-effective reduced-impact logging (RIL-C) can nearly halve emissions from selective logging and meet one tenth of nationally determined contributions from tropical countries

Rosa Goodman¹, Peter Ellis², Trisha Gopalakrishna², Matias Harman³, Anand Roopsind⁴, Bronson Griscom², Peter Umunay⁵, Joey Zalman⁶, Eddie Ellis⁷, Karen Mo⁸, Francis Putz⁹
¹Swedish University of Agricultural Sciences, Umea, Sweden; ²The Nature Conservancy, Arlington, USA; ³World Wildlife Fund, Lima, Peru; ⁴Boise State University, Boise, USA; ⁵Yale School of Forestry and Environmental Studies, New Haven, USA; ⁶Foundation for Forest Management and Production Control, Paramaribo, Suriname; ⁷Centro de Investigaciones Tropicales Universidad Veracruzana, Morelos, Mexico; ⁸World Wildlife Fund, Washington, USA; ⁹University of Florida, Gainesville, USA (rosa.goodman@slu.se; pellis@tnc.org; trisha.gopalakrishna@tnc.org; matiasharman@gmail.com; aroopsind@gmail.com; bgriscom@tnc.org; peter.umunay@yale.edu; joeyzalman92@gmail.com; ellis_eddie@yahoo.com; karen.mo@wwfus.org; fep@ufl.edu)

Selective logging is responsible for over half the emissions from forest degradation in the tropics. We assessed carbon emissions from felling, skidding, and hauling in 61 forest management units across seven tropical countries to establish baseline emissions from selective logging and estimate potential emissions

reductions through ‘climate-effective reduced-impact logging’ (RIL-C). Emissions per Mg carbon in extracted timber (termed ‘carbon impact factor’; CIF) varied greatly both within and between countries—from 2.3 to 20.0. Within the studied geographies, CIF typically decreased with increasing logging intensity, but we found the opposite trend between countries. In general, Latin American countries had the lowest harvest intensities and lowest CIFs, and African countries had intermediate harvest intensities and the highest CIFs. The majority of logging emissions (59%) came from felling (felled tree residuals and collateral damage), but emissions from the countries with the highest CIFs were dominated by roads. Scaling-up, we estimated that tropical selective logging emitted 831 Tg CO₂ in 2015—6% of all greenhouse gas emissions from tropical countries. We propose a target CIF of 2.3 through RIL-C implementation. Such changes include improved bucking to increase timber recovery and reduce wood waste, building narrower haul roads, and using lower impact skidding equipment, as well as improving employee retention. If our target were achieved, timber supplies could be maintained while emissions from logging operations are reduced by 44% (365 Tg CO₂ year⁻¹). On average, 11% of nationally determined contributions by tropical countries to the Paris Climate Agreement could be met through RIL-C implementation.

Integrating climate change adaptation and mitigation objectives in British Columbia’s forests

Guillaume Peterson St-Laurent^{1,2}, George Hoberg³, Bruno Locatelli⁴, Shannon Hagerman¹

¹Faculty of Forestry, University of British Columbia, Vancouver, Canada; ²Pacific Institute for Climate Solutions, Victoria, Canada; ³School of Public Policy and Global Affairs, University of British Columbia, Vancouver, Canada; ⁴Centre de Coopération In (peterson.guil@gmail.com; george.hoberg@ubc.ca; bruno.locatelli@cirad.fr; shannon.hagerman@ubc.ca)

Climate change mitigation and adaptation objectives have usually been treated separately in policies and interventions addressing climate change in the forests. However, increasing efforts have been directed towards the joint consideration of adaptation and mitigation objectives during the design of forest management interventions and policy. Not only are both climate objectives often compatible, but they also sometimes display synergies so that their combined effect is greater than the sum of their effects if implemented separately. Despite this potential, very few integrative initiatives have been attempted in practice. We use the case of the Canadian province of British Columbia (BC) to better understand the relationship between climate change adaptation and mitigation policy in the forests. Drawing on the review of existing forest management policy and a survey and semi-structured interviews with BC government officials, we address two major research objectives: (1) To what extent do current climate and non-climate BC forest management policies effectively integrate adaptation and mitigation objectives? (2) What challenges and opportunities are associated with the joint consideration of both objectives when developing forest management interventions and policy? Our results highlight the potential positive and/or negative ecological (e.g., ecosystem resilience, biodiversity), economic (e.g., cost or profitability) and social (e.g., effect on livelihood) outcomes of considering both adaptation and mitigation objectives together during the design of forest management interventions. We also provide policy insights into when and how to consider mitigation and adaptation together and to successfully mainstream both objectives into climate and non-climate forest management policies.

Mitigating climate change through Climate-Smart Forestry

Hans Verkerk¹, Pekka Leskinen¹, Marc Palahi¹, Mariana Hassegawa¹

¹European Forest Institute, Joensuu, Finland (hans.verkerk@efi.int; pekka.leskinen@efi.int; marc.palahi@efi.int; mariana.hassegawa@efi.int)

To achieve the objective of the Paris Climate Agreement, a significant reduction in CO₂ emissions is needed, as well as increased removals by carbon sinks. Forests play an important role in the discussion how to meet this objective. Storing carbon in forest ecosystems provides mainly benefits during the next few decades, but such a strategy is not free of risks. Many existing climate impact studies suggest an increasing risk from natural disturbances and accumulating more biomass in forests in high risk conditions may exacerbate the impact of future natural disturbances. A long-term, successful mitigation strategy must therefore consider adequate adaptation measures to ensure the resilience of forest resources in the future. A mitigation strategy that only emphasizes storing carbon in forest ecosystems also disregards the urgent need to decarbonize the global economy. In this presentation, we argue that a regionally-tailored Climate-Smart Forestry approach is needed to (a) increase the total forest area and avoid deforestation, (b) connect mitigation with adaption measures to enhance the resilience of global forest resources, and (c) produce wood-based products that store carbon and substitute emission-intensive fossil and non-renewable products and materials. We provide examples of measures related to each of the three issues. The challenge for forest management will be to find the right balance between short and long-term goals as well as between the need for wood production and other important ecosystem services. Such optimal balance may vary from country to country and region to region.

B8a: FOREST ADAPTATION AND RESTORATION UNDER GLOBAL CHANGE

Implementing forest landscape restoration under the Bonn Challenge

John Stanturf¹ ; Michael Kleine², Stephanie Mansourian³, Palle Madsen⁴, Promode Kant⁵, Janice Burns²

¹Estonian University of Life Sciences, Tartu, Estonia; ²IUFRO, Vienna, Austria; ³University of Geneva, Geneva, Switzerland; ⁴InNovaSilva, Vejle, Denmark;

⁵Institute of Green Economy, Delhi, India (drdirt48@gmail.com; kleine@iufro.org; smansourian@infomaniak.ch; pallemdsen47@gmail.com; promode.kant@gmail.com; burns@iufro.org)

The Bonn Challenge sets a goal for societies globally to restore 350 million hectares of forested landscapes by 2030. The Bonn Challenge is not a new commitment but rather a practical means of realizing many existing international commitments. Underlying the Bonn Challenge is forest landscape restoration (FLR), which aims to restore ecological integrity at the same time as improving human well-being through multi-functional landscapes. Translating the high level of political enthusiasm into real accomplishments requires a long-term commitment. Successful FLR is based on the premise that healthy landscapes provide a diversity of long-term benefits that can only be sustainably managed by and for local populations. Past experience with broad-scale restoration has shown the importance of defining and reconciling multiple objectives, a process that begins with well-defined goals and proceeds through implementation, monitoring, and adaptive management. FLR recognizes the need for local and adaptive options and avoids the “one size fits all” model. The emphasis on restoring mosaic landscapes requires integration of various land uses such as forestry (including timber plantations), agroforestry, agriculture, wildlife, biodiversity conservation, and infrastructure (roads and settlements). Although FLR favors historic fidelity, native species, and strongly advises against converting even degraded native forests to exotic plantations, the challenges imposed by climate change may in some circumstances also require adaptation to novel conditions. Implementing FLR requires detailed planning for what will be done, where, when, by whom, and at what cost. Included in the planning should be long-term monitoring and data archiving as well as on-going sustainable management.

Policies to engage the private sector in forest restoration in South East Asia

Rodney Keenan¹

¹University of Melbourne, Melbourne, Australia (rkeenan@unimelb.edu.au)

Forest landscape restoration aims to restore landscape function through a mix of forest conservation, reforestation and productive uses of trees in conjunction with other land uses. There is an estimated 110 million hectares of degraded forest lands in South East Asia, 60 percent of the total forest area, and widespread recognition of the need to restore ecological function to these forest landscapes. This could sequester carbon, conserve biodiversity, improve water quality and provide spiritual and cultural benefits. However, there are differing views on the processes, actors and desirable end points for restoration goals. While many of the technical aspects of forest restoration are well understood, institutional, regulatory and policy issues are key challenges for implementing restoration. Constraints include lack of devolution, lack of clarity on tenure and lack of participation by communities and the private sector. Using forest transition theory as a basis for analysis, this paper describes new approaches to overcoming the policy and financial challenges of forest restoration in this region. Analysis included governance issues, property, tenure and access rights, and strengthening capacity of public organisations. A key focus was policies for integrated investment models that engage the private sector and markets and that empower rural people and small landholders to become more engaged in sustainable forest management and restoration.

Adaptive Forest Management (AFM) and its role for adapting forests to climate change

Andreas Bolte¹ , Peter Spathelf, Magnus Löf, Palle Madsen⁴, Klaus Puettmann⁵

¹Thünen Institute of Forest Ecosystems, Eberswalde, Germany; ²University of Sustainable Development, Eberswalde, Germany; ³Swedish University of Agricultural Sciences, Alnarp, Sweden; ⁴InNovaSilva, Vejle, Denmark; ⁵Oregon State University, Corvallis, Uni (andreas.bolte@thuenen.de; peter.spathelf@hnee.de; magnus.lof@slu.se; pallemadsen47@gmail.com; klaus.puettmann@oregonstate.edu)

Adaptive forest management (AFM) is a dynamic and future-oriented concept to maintain and further develop forest functions and the associated variety of ecosystem services consistent with respective management goals. To accomplish these goals, AFM needs a frequent or even continuous effect monitoring of both growing conditions and management practices in order to modify or adjust management to changing environmental and societal conditions. Since climate change has been considered as the major driver of the variation of growth, in particular of survival conditions, the dynamic and flexible concept of AFM also has come into the focus for adapting forests to changing climatic conditions. The core principle of AFM is improving management by learning of its outcomes. A core element is a frequent feedback loop that adjusts management to changing forest ecosystem status or structure and varying goals. This loop is meant to be flexible in time, but typical loop frequency may vary between five and 20 years. Based on this, we suggest to define AFM as a process of frequently monitoring and adjusting three components: (1) biophysical conditions (“what?”), (2) management goals (“what for/why?”), and (3) management techniques (“how?”). Based on this approach, we evaluate examples of AFM application in boreal and temperate zones with regard to their effectiveness for increasing forest resistance and resilience to more extreme weather events driven by climate change. Finally, we discuss best practice strategies for different regions and draw conclusions for a future optimized AFM.

Exploring adaptive capacity in forest ecosystems

Klaus Puettmann¹

¹Oregon State University, Corvallis, USA (klaus.puettmann@oregonstate.edu)

In the last years, themes around adaptability have emerged as a major research agenda related to global change. Adaptive capacity has been proposed as the component of the IPCC’s vulnerability framework that is “most amendable to influence”. As such, adaptive capacity is of great interest to forest managers. The presentation provides conceptual insights into adaptive capacity of forest ecosystems to make the concept more “operational” to researchers and managers. First, adaptive capacity of ecosystems is placed within the larger context of the socio-ecological system. Next, I discuss how ecological adaptation strategies can vary as a function of uncertainty, by ecosystem characteristics, and by organizational levels. Finally, I provide examples, how information obtained in studies of ecosystem stability can be used to develop management strategies that increase adaptive capacity of forest ecosystems.

C1a: MANAGING FOREST ECOSYSTEM RESILIENCE AND BIOLOGICAL AND SOCIAL DIVERSITY FOR FUTURE FOREST PRODUCTS

Computer vision technology for improving forest operations sustainability

Woodam Chung¹, Lucas Wells¹

¹Oregon State University, Corvallis, USA (woodam.chung@oregonstate.edu; lucas.wells@oregonstate.edu)

Forest harvesting is an essential part of sustainable forest management that deals with the provision of forest goods and services. A recently developed concept of sustainable forest operations by Marchi et al. (2018) calls for a paradigm shift from conventional productivity and cost-driven forest operations toward a balance of operational performance across economic, environmental and social sustainability. In this presentation, we introduce computer vision technology as a new tool that supports sustainable forest operations. It has potential to facilitate implementation of complex, ecology-based silvicultural prescriptions, improve both the working environment of humans and efficiency of forest operations, and maximize utilization, quality and value of wood products. Specifically, we introduce a purpose-built camera system for forest harvesting machines for detecting and measuring individual trees in real-time. The computer vision algorithms developed for this system can estimate angle, distance, diameter at breast height and stem taper for trees while producing an accurate stem map of the stand. This individual stem information can be coupled with a silvicultural prescription to provide equipment operators with cut/leave decision aids enabling the implementation of individual tree-level treatments. The stem taper information coupled with optimal bucking can maximize value of wood products and minimize waste. Real-time stem mapping of residual trees can ensure treatment compliance for quality control of forest operations. The paradigm shift from conventional forest operations toward sustainability requires extensive modifications to current practices in all stages of forestry. Computer vision is one of the promising technologies that can help realize such a transition.

Future forest products and sustainability

Pekka Saranpää¹

¹Natural Resources Institute Finland (Luke), Helsinki, Finland (pekka.saranpaa@luke.fi)

The challenge of research related to forest resources and forest products is related to rapid increase of human population and growing demand of materials and products. The potential for irreversible changes in our environment and far reaching consequences increases. Indicators of environmental stress include the loss of biodiversity, increasing greenhouse gas emissions, increasing deforestation and shortages of fuel-wood in many parts of the world. Norway spruce and Silver birch are important tree species in Nordic forestry and their bark contains valuable compounds. However, the bark is mainly used for energy production. Part of this important side product is possible to use to improve properties of wood and fibre based products and thus, promote the cascading use of them. For example, birch bark contains suberin which could be used to create hydrophobic and antimicrobial surfaces. These are a few examples of the diversity of the future products based on forest biomass. Cellulose based textile fibres are under development and lignin is intensively studied to replace fossil raw materials in various products. The diversity of future forest products and the impact of both environmental, economic, cultural and social sustainability on utilisation of forest biomass will be discussed.

Dipterocarps protected by Jering local wisdom in Jering Menduyung Nature Recreational Park, Bangka Island, Indonesia

Eddy Nurtjahya¹ ; Akrima Risyda¹, Cindy Ika Putri¹, Lastri Dwi Saputri¹, Lanita Sakila¹, Tiwi Mandasari¹, Tuning Wiji Jepari¹

¹Universitas Bangka Belitung, Sungailiat, Indonesia (eddy_nurtjahya@yahoo.com; akrima.risyda@gmail.com; cindyikaputri03@gmail.com; lastridwi78@gmail.com; lanitasakila01@gmail.com; tiwi.mandasari97@gmail.com; tuningwjr97@gmail.com)

Apart of the oil palm plantation expansion, the Jering Menduyung Nature Recreational Park has relatively diverse plants. The 3,538 ha park is located at the north west of Bangka Island, Indonesia. The minimum species-area curve was 0.82 ha which is just below Dalil conservation forest that is 1.2 ha, but it is much higher than measurements of several secondary forests in the Island that are 0.2 ha. The plot is inhabited by more than 50 plant species. Of 22 tree species, there are 40 individual poles with the average diameter of 15.3 cm, and 64 individual trees with the average diameter of 48.9 cm. The density of *Dipterocarpus grandiflorus* (Blanco) Blanco or kruing, is 20.7 individual/ha with the diameter ranges of 12.1 – 212.7 cm or with the average diameter of 69.0 cm. The relatively intact park is supported by the local wisdom of Jering tribe, one of indigenous tribes in the island. People has regulated in cutting trees especially in the cape. The conservation agency designates the park as one of the kruing propagules sources in the province. The growing oil palm plantation and the less adoption of local wisdom among the youth is a challenge to forest conservation in the province where tin mining activities have been the economic driver for decades. More socialization from the conservation agency and the involvement of university students in raising environmental awareness is important to be done.

C3a: MOVING TOWARDS SUSTAINABLE FOREST OPERATION FOR A GREENER FUTURE

An overview of forest operations in Europe within the concept of Sustainable Forest Operations (SFO)

Andrea Laschi¹, Tomas Nordfjell², Piotr Mederski³, Enrico Marchi¹

¹Università di Firenze, Firenze, Italy; ²Sveriges lantbruksuniversitet, Umeå, Sweden; ³Uniwersytet Przyrodniczy w Poznaniu, Poznan, Poland (andrea.laschi@unifi.it; tomas.nordfjell@slu.se; piotr.mederski@up.poznan.pl; enrico.marchi@unifi.it)

The importance of the concepts ‘Sustainability’ and ‘Sustainable Development’ has increased in recent years in order to meet the changing needs of society. The forest sector and research activities should support sustainability to enhance all the benefits from the various functions of forests and the ecosystem. Forest operations play a key role in forest management and wood production, thus leading to an important role in the sustainability of the forest sector. In recent years, within the IUFRO Task Force on Climate Change and Forest Health, the new paradigm of ‘Sustainable Forest Operations – SFO’ has been developed in order to change the approach to wood harvesting. The aim of this contribution is to give an overview of forest operation issues in Europe, considering the main relations between forest management, wood production, environment and society in the light of the SFO paradigm. Wood production is strategic worldwide, but it cannot compromise the efficiency of forests, increase environmental impact or affect social and economic issues. In this context, Europe with its 1015 million hectares of forest is an important geographic area. However, many different social, economic and environmental conditions exist on this continent, from north to south and east to west. Moreover, in most European countries, forests play important roles beyond wood production, for example, hydro-geological protection, recreation, pollutant protection, as well as social and cultural services. For these reasons, forest operations have to guarantee environmental protection and enhance the ecosystem functions related to forests while at the same time respecting social needs.

The “Sustainable Forest Operations” concept: an overview of forest operations in Africa

Andrew McEwan¹, Michal Brink², Elisha Ngulube³

¹Nelson Mandela University, George, South Africa; ²University of Pretoria, Pretoria, South Africa; ³Mzuzu University, Mzuzu, Malawi (andrew@loggingon.net; michal@cmogroup.net; esn12003@yahoo.co.uk)

Forest operations in Africa have been associated with unsustainable harvest levels and operations. The deforestation of Africa’s tropical forests has been well documented. Simultaneously, the operations used to log the forests have focussed on the minimisation of costs with little regard to other societal values such as safety and environmental concerns. The exceptions to this include some of the well managed plantations that occur in South Africa and on a smaller scale in certain other African countries. Globally, the concepts of “Sustainability” and “Sustainable Development” have recently received increasing attention to ensure that forest management is practised in a way that meets societal values. Even considering the geographic variability of forests and their uses, African countries have begun to realise the importance of managing their forests according to more modern sustainability principles. This is primarily driven by the need to preserve the few remaining tropical forests, the need to ensure that current operations do not jeopardise future growth potential, the need to carry out operations in a way that reflect the more modern principle of “Sustainable Forest Operations – SFO”, the requirements of investors of new plantations or forest operations, and the requirements of markets, often outside the boundaries of the African continent. The aim of this contribution is to give an overview about forest operation issues in Africa, considering the main relations between forest management, wood production, environment and society in the light of the SFO paradigm.

Environmental impact of forest operations - silviculture and harvesting - in Uruguay: an evaluation program

Alejandro Olivera Farias¹, Carlos Perdomo¹

¹Centro Universitario de Tacuarembó, Universidad de la República, Tacuarembó, Uruguay (alejandro.olivera@cut.edu.uy; cperdomo@fagro.edu.uy)

Fast growing *Eucalyptus* and *Pinus* plantations in Uruguay have increased in the last decades, rising from less than 100,000 hectares in 1990 to 1,100,000 in 2015. A process of mechanization of forest operations have accompanied this growth in both, area and wood availability. Forest mechanization brings advantages for large-scale operations, such as, increase productivity, reduce costs, and improve health and safety conditions. However, it also increases the environmental impact. The use of heavy machinery, affects the soil causing compaction (direct impact), and erosion (indirect impact); while, the consumption of fossil fuels by machines contributes to the green house effect. The mechanization of forest operations in Uruguay has some decades, however, there is no scientific studies quantifying its environmental impact. We propose a research program aiming to quantify the impact of forest operations in Uruguay in the sequence Harvesting – Plantation; comparing two harvesting systems and two technologies for planting. These impacts are, soil compaction and erosion, energy balance, and carbon balance. Moreover, we plan to evaluate the costs of the treatments, to obtain an integral evaluation of the alternatives; i.e. environmental and financial indicators. The program would quantify the changes in the first four years; however, we plan to maintain plots during a rotation. The knowledge generated from this program, could be used for companies and police makers in a series of manners: to weight the evaluation of technologies for harvesting and Silviculture according their environmental impact; to establish benefits or taxes to promote the adoption of different technologies.

An overview of forest operations in the United States within the concept of Sustainable Forest Operations (SFO)

Dalia Abbas¹, Enrico Marchi²

¹American University, Washington, USA; ²Università degli Studi Di Firenze, Florence, Italy (daliaabbas@yahoo.com; enrico.marchi@unifi.it)

In 2018, March et al. 2018 developed a study that outlines the modern interpretation of sustainable forest operations (SFO) and their practices. The study was highlighted in the July 2018 IUFRO Spotlight #60 - Creating a virtuous circle in forest operations. The study intended to complement existing studies by integrating environmental, economic, ergonomics, quality and people and society aspects. These aspects are concerned with the forests operations supply chain. The purpose of this study is to test the relevance of the SFO study in the United States and identify issues related to its applicability. It develops an understanding of the potential for, or lack thereof, of applying the SFO framework.

D1a: AGROFORESTRY FOR ECOSYSTEM SERVICES

Agroforestry for ecosystem service enhancements across U.S. landscapes: science status and a path forward

Susan Stein¹, Gary Bentrup²

¹USDA National Agroforestry Center, Washington, D.C., USA; ²USDA National Agroforestry Center, Lincoln, NE, USA (susan.stein@usda.gov; gary.bentrup@usda.gov)

There is rising interest among U.S. farmers, ranchers and forest owners, as well as public and private entities, in the use of agroforestry to enhance ecosystem service values of working lands in the United States. Science-based data and information is critical to informing policies and programs that support agroforestry, in addition to decisions by landowners regarding agroforestry adoption. What information do we have and what more is needed? This presentation will review the state of science on agroforestry ecosystem service benefits in the United States, based on a recent assessment by the United States Department of Agriculture Forest Service, National Agroforestry Center [1] [file:///C:/3A/Users/ssstein/Documents/My%20Documents/Presentations/IUFRO/IUFRO%20D1A%20session%20description.docx#_ftn1]. It will also highlight additional research needed to better-inform landowner decisions on agroforestry adoption, as well as decisions by national and regional entities on the integration of agroforestry into sustainable land management programs. The presentation will highlight the role of agroforestry in carbon sequestration, air and water quality, soil enrichment, and biodiversity conservation, with a special focus on the delivery of these services under a changing climate. [1] [file:///C:/3A/Users/ssstein/Documents/My%20Documents/Presentations/IUFRO/IUFRO%20D1A%20session%20description.docx#_ftnref1] Schoeneberger, Michele M.; Bentrup, Gary; Patel-Weynand, Toral, eds. 2017. Biodiversity conservation in silvopastoral systems in Colombia

Julian Chara¹, Enrique Murgueitio¹, Carolina Giraldo¹

¹CIPAV, Cali, Colombia (julian@fun.cipav.org.co; enrique@fun.cipav.org.co; carolina@fun.cipav.org.co)

Among agroforestry systems, those that purposely combine fodder plants, such as grasses and leguminous herbs, with shrubs and trees for animal nutrition, timber production and other uses are known as silvopastoral systems (SPS). In addition to the improved animal production, the presence of shrubs and trees in these arrangements have demonstrated effects on biodiversity by creating more complex habitats for wild animals and plants, harboring a richer soil biota and increasing connectivity between forest fragments. In farmed landscapes, SPS provide food and cover for birds and other organisms, serving as wildlife corridors where unique species assemblages can be found. The introduction of the tree component has also demonstrated effects on the physical, chemical and microbiological properties of the soil since they provide more layers of vegetation capable of transforming solar energy into biomass that is, in part, deposited on the soil in the form of leaves, branches, fruits, legumes and exudates that have positive effects on soil properties and carbon sequestration. In a study in Colombia, the areas with SPS were found to have three times as many bird species as pasture areas without trees and complemented forest fragments in the conservation of birds by providing temporary habitats for forest-dependent species. Population and richness of dung beetles and ants was also increased when compared to tree-less pastures. Due to these characteristics, SPS are an important alternative for the development of sustainable livestock production systems with generation of timber and fruits and the provision of important environmental services for the society.

Natural capital accounting: a useful framework for valuing agroforestry plantings?

Zara Marais^{1,2}, Mark Hunt^{1,2}, Thomas Baker^{1,2}, Anthony O'Grady³

¹University of Tasmania, Hobart, Australia; ²ARC Training Centre for Forest Value Hobart Australia; ³National Research Collections Australia Land and Water, Hobart, Australia (zara.marais@utas.edu.au; m.hunt@utas.edu.au; thomas.baker@utas.edu.au; anthony.o'grady@csiro.au)

One way of approaching the challenge of sustainable production in agriculture is to expand the use of ecosystem services to increase productivity and in doing so reduce or replace external inputs. Agroforestry systems have received some recognition, notably from FAO, for their capacity to enhance the provision of a range of beneficial ecosystem services. However, few studies have attempted to quantify these services or to account for trade-offs and additive interactions between them. Natural capital accounting (NCA) provides information on stocks and flows of natural resources and services in physical or monetary terms. This may provide a useful mechanism for assessing the economic value of the trees and shrubs that comprise agroforestry plantings, based on the ecosystem service inflows that they provide to agriculture. NCA has been widely applied at national and regional scales. However, this project explores the challenges, limitations, and potential opportunities associated with applying NCA to agroforestry at the farm scale. Our findings suggest that NCA may indeed be a useful framework for quantifying and comparing the value of various types of agroforestry plantings, based on the ecosystem services that they provide at the farm scale. Use of NCA as a tool in this context presents opportunities to better understand.

D1b: CLOSE-TO-NATURE SILVICULTURE: FOR PEOPLE, PRODUCTS AND NATURAL PROCESSES

Close-to-nature silviculture: an introduction

Jens Peter Skovsgaard¹ ; Khosro Sagheb-Talebi²

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²Ministry of Jihad-e Szandegi, Agricultural Research and Education Organization, Research Institute of Forests and Rangelands, Tehran, Islamic Republic of Iran (jps@slu.se; saghebtalebi@rifra.ac.ir)

Most forestry objectives claim to maintain the forest to benefit people, to produce various goods and products (again, to benefit people) and to rely on, conserve or even improve natural forest processes. Moreover, essentially all of these subscribe to the paradigm of sustainability. One such approach is called close-to-nature silviculture. Occurring in various disguises, close-to-nature silviculture dates back to the introduction of planned forestry and was developed based on more-or-less scientific arguments originating mainly in Central Europe. For example, even-aged clearcutting was, and is still, viewed as an opposite to close-to-nature silviculture which, in turn, relies mainly on continuous cover forestry principles, often accompanied by large variation in species and age class composition. Following two centuries of alternating fashion waves in silviculture, the concept of close-to-nature silviculture has become established and is now being applied, often in locally adapted variations, in many forest types across the world. Although close-to-nature silviculture is well-established and is generally accepted as a management paradigm in most of Europe, we believe that scientifically-based modifications are needed to successfully implement this concept in other regions and for other forest types. Moreover, there is a need to clarify and further develop a consistent and logical terminology. What do we talk about when we refer to close-to-nature silviculture? Do we speak a common language in silviculture or do we need an interpreter?

Silviculture and management in uneven-aged temperate forests

Hubert Hasenauer¹

¹University of Natural Resources and Life Sciences, Vienna, Austria (hubert.hasenauer@boku.ac.at)

Uneven-aged or selection systems are implemented for a variety of reasons, one of which is their apparent sustainability. This sustainability is assumed to be achieved through a relative steady state of structure and function over time as compared with even-aged systems. As a result, uneven-aged systems are often considered as 'close-to-nature', 'diversity-oriented' etc. The sustainability of stand management regimes is important as stands are the land unit for implementation in forestry. Even-aged stands differ in stand characteristics over a rotation, while uneven-aged or multi-aged stands seem to be relatively consistent in their stand variation and without a beginning or end point in the cutting cycle. In this presentation we give an historical overview from a central European perspective, assess the term "close to nature" in the context of uneven-aged forestry, and provide three examples (i) for the soil dynamics of uneven-aged versus even aged forests, (ii) harvesting models within uneven aged forests, and (iii) the forest management implications if uneven-aged silvicultural management systems are applied at an enterprise level.

Close-to-nature silviculture in Asia: geospatial technology facilitates its practical application

Toshiaki Owari¹ ; Pil Sun Park²

¹The University of Tokyo, Tokyo, Japan; ²Seoul National University, Seoul, Republic of Korea (owari@uf.a.u-tokyo.ac.jp; pspark@snu.ac.kr)

Close-to-nature silviculture is a type of silvicultural approach, in which the intrinsic processes of forest ecosystems are regarded as highly important. Partial cutting with natural regeneration is typically used, so that the stability and diversity of stand structure can be maintained. It is increasingly gaining attention worldwide as an effective method for sustainable forest management and enables to harmonize the use of renewable natural resources with the conservation of multiple ecological functions. Close-to-nature silviculture has been applied uniquely in each country and region, because forest ecosystems are locally inherent in nature. Following a brief historical overview, we present the current trends and major developments of close to-nature silviculture in Asia. Our presentation mainly focuses on the potential of geospatial technology for facilitating close-to-nature forest management practices. Emerging technologies such as light detection and ranging (LiDAR) and unmanned aerial vehicle (UAV) photogrammetry can be utilized to characterize forest canopy structure and vegetation type and to estimate stand volume and carbon stock over uneven-aged mixed forests managed under close-to-nature principles. It is possible to pinpoint the location of tree individuals and canopy gaps using such technologies, and the information can be used to develop spatially explicit, individual-based models for predicting long-term stand dynamics, to identify the sites with poor natural regeneration for restoration planning, and to manage high-value tree species on a single-tree basis. As a unique application of geospatial technology in Asia, we present close-to-nature silviculture practices at the University of Tokyo Hokkaido Forest, Northern Japan.

Close-to-nature silviculture from a tropical viewpoint

Sven Günter¹

¹Thünen Institute of International Forestry and Forest Economics, Hamburg, Germany (sven.guenter@thuenen.de)

Historically, silviculture in the tropics was mainly targeting the production of high-value timber in natural forests for centuries. Degradation and deforestation are still ongoing in the tropics endangering hotspots of biodiversity and livelihoods of poor people. Additional pressure is attributed to climate change. Today, tropical forests have to fulfill increasing demands for various ecosystem services from different stakeholders ranging from provisioning services and fuel wood for poverty alleviation, conservation of biodiversity, control of water fluxes and soil fertility to climate change mitigation. Consequently, this implies the development of multipurpose forestry strategies in addition to sustainable timber production. How can close-to nature silviculture in natural forests deal with invasive species, changing disturbances regimes, e.g. hurricanes or fires which finally could lead to novel forest ecosystems with unknown consequences for resilience? Species-specific and site-specific management plans are not yet business as usual in tropical forests. While remaining old-growth forests are increasingly facing a balancing act between sustainable use and conservation strategies, the focus is shifting to reforestation and landscape restoration. Bonn Challenge, and AFR-100 are prominent examples for this trend setting new priorities on the silvicultural agenda: from management of seed sources over provision of suitable planting material to the identification of optimum species-mixtures for plantations. Although the trend towards reforestation and restoration might be too slow to reduce pressure from remaining natural forests, it might be ambitious to develop the necessary silvicultural tools in a short time at a large scale, and thus enabling multifunctional close-to nature-forests for the future.

D7a: FOREST HEALTH CHALLENGES FROM GLOBALISATION AND CLIMATE CHANGE

Invasive insects in plantation forests in South America: ecological patterns and management challenges

Juan Corley^{1,2}, Maria Victoria Lantschner¹, Jose Maria Villacide¹

¹IFAB (INTA Bariloche/CONICET), Bariloche, Argentina; ²Departamento de Ecología, Universidad Nacional del Comahue, Bariloche, Argentina (elmallin@gmail.com; vlantschner@gmail.com; josevillacide@gmail.com)

In the last decades, growing international trade and tourism have significantly increased the rate at which non-native species reach new ecosystems. Plantation forests systems in South America are especially exposed to alien insects, partly because forestry is dominated by pines and eucalypts which have been introduced to produce timber and pulp, based, among other things, on the benefits related to the lack of native herbivores (i.e., the “natural enemy release hypothesis”). As noted worldwide, where the invasion by non-indigenous forest insects is also rising, often strong negative economic and ecologic impacts on the invaded ecosystems are reported. Remarkably, the most damaging non-native forest insects found in plantation forestry are common to large parts of South America and also to other regions of the Southern Hemisphere. This could suggest common traits among invasive species and between the invaded systems that may allow us to identify broad ecological patterns behind invasion success. By focusing on several case studies of established alien insects feeding on pines and eucalypts in South America, I look into likely ecological patterns and explore how these affect the main strategies for the management of both, the species already present and, to prevent the establishment of new forest pests.

Oxidative stress effects on the Brazilian Atlantic Forest

Marisa Domingos¹, Marisia P. Esposito¹, Solange E. Brandão¹, Francine F. Fernandes¹, Marcela R.G. S. Engels¹, Ricardo K. Nakazato¹, Giovanna Boccuzzi¹, Douglas D. Santos¹, Milton A. G. Pereira¹, Mirian C. S. Rinaldi¹, Marcia I. M. S. Lopes¹, Patricia Bulbovas², Claudia M. Furlan³, Poliana Cardoso-Gustavson⁴

¹Instituto de Botânica, São Paulo, Brasil; ²Universidade de Guarulhos, Guarulhos, Brasil; ³Universidade de São Paulo, São Paulo, Brazil; ⁴Oxiteno S/A, Mauá, Brasil (mmingos@superig.com.br; biompe@gmail.com; solangeeu35@gmail.com; fran_fernandess@hotmail.com; marcelaengela@gmail.com; ricardo.nakazato@outlook.com; giovanna.boccuzzi@gmail.com; dougdourados@gmail.com; milton.augustogp@gmail.com; mrinaldi@ibot.sp.gov.br; mimlopes2001@yahoo.com.br; pbulbovas@hotmail.com; furlanmc@ib.usp.br; cardoso.poliana@gmail.com)

The tolerance potential against the oxidative injury in forest species affected by environmental stressors depends on how efficiently they keep their pro-oxidant/antioxidant balance. Great variations in plant tolerance are expected, highlighting the high relevance of measuring chemical, anatomical, physiological and biochemical leaf trait indicators of oxidative effects in species with similar functions in the forest. The use of the functional approach has been very useful in the Brazilian Atlantic Forest because its high plant diversity. We have been focused our studies on forest remnants in SE Brazil, the most developed region in the country, aiming at determining the tolerance potential of pioneer and non-pioneer tree species against multiple oxidative environmental stressors. The studies were carried out in Atlantic Forest remnants, which differ in physiognomy, species composition, climatic characteristics and air pollution exposure (e.g. NO₂, O₃ and particulate material). Leaves of the most abundant tree species in each forest were collected during wet and dry periods, for analyses of concentrations of soluble nitrogen, trace elements and polycyclic aromatic hydrocarbons, anatomical traits and levels of non-enzymatic and enzymatic antioxidants and oxidative injury indicators. Pioneer species accumulated proportionally more N-NH₄ than N-NO₃ compared to non-pioneer trees, and higher contents of trace elements were observed in non-pioneer trees. The pioneer tree species generally displayed anatomical and biochemical leaf traits that indicate their higher potential tolerance against oxidative environmental stressors than non-pioneer species. In conclusion, the pioneer species have better conditions to acclimate to the oxidative stress imposed by environmental conditions.

Converging threats to ash (*Fraxinus*): is an invasion meltdown imminent?

Michelle Cleary¹, Pierluigi Bonello², Patrick Sherwood¹, David Showalter³, Yuri Baranchikov⁴

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²The Ohio State University, Columbus, USA; ³University of Minnesota, Greater Minneapolis-St. Paul Area, USA; ⁴Sukachev Institute of Forest FRC KSC, Siberian Branch Russian Academy of Sciences, Krasnoyarsk, Russian Federation (michelle.cleary@slu.se; bonello.2@osu.edu; patrick.sherwood@slu.se; showa028@umn.edu; baranchikov_yuri@yahoo.com)

The global decline of ash (*Fraxinus*) can be linked to two invasive alien species: the ascomycete fungus *Hymenoscyphus fraxineus* and the emerald ash borer (EAB; *Agrilus planipennis*, Coleoptera: Buprestidae), both of which are native to Asia. In Europe, the spread and intensification of *H. fraxineus* has caused large-scale decline in European ash (*Fraxinus excelsior*) which is now Red-listed. In North America, devastation to ash populations by EAB has caused nine North American *Fraxinus* species to become Red-listed; six of those are considered ‘on the brink of (functional) extinction’. In European temperate broadleaved forests where *F. excelsior* is a keystone species, the loss of ash is likely to cause wider community impacts to many other obligate or highly-associated

organisms, and cause cascading effects in these ecosystems. Luckily, ash shows high genetic variation in resistance. Efforts at breeding for resistance against *H. fraxineus* are currently underway, however, such efforts are variable in scale among countries, and with their level of committed resources. Recent research shows huge promise in rapid resistance breeding coupled with advanced phenotyping methods, and gives hope that European ash will rise from the ashes of devastation. More pressing though is the imminent invasion of EAB, now occupying the European part of Russia and Lugansk District of Ukraine, and on the fringe of invading the rest of Europe – invoking the fear of a **pseudo-invasional meltdown** which may prove to be highly devastating. The European preparedness for these converging threats and futuristic outlook for ash must rely on regional/global cooperation, science-based knowledge and intervention, and coordinated investments in solutions.

D8a: FOREST BIODIVERSITY IN THE FRAMEWORK OF GLOBAL CHANGE AND THE ROLE OF LANDSCAPE

Forest conservation, building local capacity and enhancing livelihoods: the potential for synergies through agroforestry

Maria J. Santos¹, Rosalien Jezeer^{2,3}, Sergio Galaz-Segura², Pita Verweij²

¹University Research Priority Program in Global Change and Biodiversity and Department of Geography, University of Zurich, Zurich, Switzerland;

²University of Utrecht, Copernicus Institute for Sustainable Development, Utrecht, Netherlands; ³Tropenbos, Wageningen, Netherlands

(maria.j.santos@geo.uzh.ch; rosalien.jezeer@tropenbos.org; sgalaz@protonmail.com; p.a.verweij@uu.nl)

Agroforestry has been widely proposed as a solution for small holders and communities to overcome common pool management dilemmas to maintain and prevent the decline of their common resources. However, such management actions might conflict with required outcomes for forest conservation. Here we question the extent to which can forest conservation, building local capacity and enhancing livelihoods can be synergistic through agroforestry practices. We propose that achieving such goals requires a scaling process similar to that through which innovations are accepted to scale. When properly using livelihood capitals will be enhanced and allow for reaching the desired scaling and synergies between forest conservation and livelihoods achieved. We test this hypothesis in two contrasting agroforestry cases, in avocado farms in Mexico and coffee plantations in Peru, to assess the extent to which livelihood capitals change with a given intervention (interventions aimed at forest conservation or enhancing biodiversity and other ecological processes). We find that (i) in the case of Mexico, the intervention only increased natural capital, and (ii) in the case of Peru, the intervention increased both natural and social capital. These cases illustrate how interventions to build local capacity to implement agroforestry systems may produce counter-intuitive outcomes, and that we need to better understand how and whether the livelihood capitals can indeed be useful to provide the necessary scaling effects and prevent trade-offs between conservation and livelihoods.

Do ecoparks support multifunctional forests and high biodiversity?

Anne-Maarit Hekkala¹ , Paulina Bergmark¹, Johan Svensson¹, Joakim Hjältén¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden (anne.maarit.hekkala@slu.se; paulina.bergmark@slu.se; johan.svensson@slu.se;

joakim.hjalten@slu.se)

The Fennoscandian forests are extremely efficiently managed, and since the industrialized forest management begun in 1950's, the forested land cover and forest productivity has significantly increased. This economically positive development has however led to simplified forest structure and loss of biodiversity within the boreal forests of Fennoscandia. Today the forest management aims to secure multifunctional forests that provide a wide variety of ecosystem services, high wood production, good possibilities for human recreation (hunting, camping, berry picking) and maintain high biodiversity. The largest forest owner in Sweden and Europe has established 37 so called ecoparks across Sweden to maintain all above functions of forests in the landscape scale. These landscapes of 860 to 14 000 ha in size are managed by using a combination of restoration, conservation and silviculture. At the same time, most forested landscapes are managed by "business as usual" (BAU), including rotation times of ca. 80 years, and thinning operations 2-3 times within the rotation time, assuring good timber and biomass production but with negative effects on biodiversity. This study aims to assess the short-term efficiency of ecoparks to maintain higher biodiversity in comparison to landscapes that are managed by BAU. To start with, we investigate the biodiversity of deadwood-dependent beetles and hymenopterans in the ecoparks and in the nearby BAU-landscapes, and discuss the further plans of the project to quantify the effects of sustainable landscape management on biodiversity.

Biodiversity responses to local and landscape-level forest structures and dynamics in Northern European forests

Olav Skarpaas^{1,2}, Anne Sverdrup-Thygeson³, Siri Lie Olsen²

¹University of Oslo, Oslo, Norway; ²NINA, Oslo, Norway; ³NMBU, Ås, Norway (olav.skarpaas@nhm.uio.no; anne.sverdrup-thygeson@nmbu.no;

siri.lie.olsen@nina.no)

Balancing forest management across multiple objectives including biodiversity and conservation requires frameworks for tradeoff assessments. While simple metrics for tradeoff analyses exist for e.g. forest products and climate regulation, biodiversity metrics need further development, especially with respect to spatial scales and dynamics. I present and integrate results from a selection of studies in northern forest landscapes considering various metrics of biodiversity and ecosystem service tradeoffs. The studies are based partly on systematic monitoring (e.g. forest inventories and biodiversity monitoring), and partly on remote sensing and publicly available citizen science data (e.g. GBIF). Results from these studies suggest that both the spatial context, at local and landscape scales, and the temporal dynamics matter. For instance, the occurrence and distribution of veteran oaks, local biodiversity hotspots for insects, fungi and epiphytes, is shaped both by the fundamental climatic and edaphic oak niche as well as logging patterns and other anthropogenic factors affecting the long-term persistence and quality of oak trees and their surroundings. Similarly, the occurrence and abundance of fungi, lichens and plants in forests are partly related to landscape structure and partly forest age, at local and landscape scales. While individual species show different responses to the various ecological and anthropogenic drivers, common responses can be seen within taxonomic/functional groups. In sum, this suggests that biodiversity metrics may be developed on the basis of appropriate species assemblages and that local and landscape-level spatial patterns, as well as temporal dynamics should be taken into consideration in ecosystem service tradeoff assessments.

Managing biodiversity across the landscape: an approach developed for the Tasmanian forest practices system

Anne Chuter¹, Amy Koch¹, Sarah Munks¹

¹Forest Practices Authority, Hobart, Australia (anne.chuter@fpa.tas.gov.au; amy.koch@fpa.tas.gov.au; sarah.munks@fpa.tas.gov.au)

In Tasmania, forest biodiversity conservation is achieved through maintenance of a permanent native forest estate, the reserve system, and through applying management prescriptions in wood production forests, conducted in accordance with the forest practices system. Management prescription in wood production areas have traditionally been planned and applied at the local scale on a case-by-case basis. However, this approach is not always an effective or efficient way to manage the biodiversity values, or to take account of social and economic considerations. For example, wide-ranging species may benefit from a landscape-scale approach to habitat management, and this approach may also be more cost effective for the land manager.

E4a: TROPICAL WETLANDS, CLIMATE, AND LAND-USE CHANGE: CHALLENGES AND OPPORTUNITIES

New research results on the extent and the nature of degradation of peatlands in Northwestern South America

Louis Verchot¹, Kristell Hergoualc'h², Mayesse da Silva¹, Rosa Maria Roman-Cuesta³

¹CIAT, Cali, Colombia; ²CIFOR, Lima, Peru; ³CIFOR, Nairobi, Kenya (l.verchot@cgiar.org; k.hergoualch@cgiar.org; m.a.dasilva@cgiar.org; r.roman-cuesta@cgiar.org)

Tropical peatland maps have been developed using national data and from surveys undertaken by the International Peat Society. Much of the underlying primary data is untraceable and uncertainty information is often unavailable. Thus, a fresh approach was warranted. We used an expert system model to develop a new map of tropical and subtropical peatlands that shows that tropical and subtropical peatlands are more widespread in South America than on any other continent, with extensive areas in Brazil, Colombia, Peru and Venezuela. The massive scale, isolation and unavailability of most tropical South Latin American peatlands has protected them from large-scale human degradation, keeping them out of the interest of the international community, in contrast to the heavily disturbed Southeast Asian peatlands. New climatic stresses, such as increased droughts and fire frequencies could, undo their forgotten status. Our fieldwork looked at peatlands in 2 biomes: the Peruvian Amazon and the Colombian Savannas. In a 350,000 ha area in Ucayali and Marañon River basins we found that 73 percent were degraded. Much of the degradation was associated with unsustainable harvesting of the fruits of *Mauritia flexuosa*. This degradation is characterized by a loss of palm density and vegetation carbon stocks. In the Colombian Savannas, the existence of peat soils has not been reported previously. We report new estimates for the extent of peat soils in the “flooded” savannas and we extrapolate field measurements to estimate the carbon stock for the region. This exercise validates and refines the results of pan tropical peatland map.

The national wetland strategy in Peru / La estrategia nacional de humedales del Perú

José Álvarez¹, Walter Huamani¹

¹MINAM, Lima, Peru (jalvarez@minam.gob.pe; whuamani@minam.gob.pe)

Los humedales son ecosistemas vitales para la humanidad, dado que albergan una gran biodiversidad y proveen de importantes servicios ecosistémicos, que van desde el abastecimiento de agua dulce, alimentos y otros insumos para el desarrollo local hasta la regulación de crecidas y recarga de aguas subterráneas, así como la mitigación del cambio climático. En reconocimiento a ello, el Perú adhirió a la Convención de Ramsar en 1991 y actualizó su Estrategia Nacional de Humedales en el 2015. Esta estrategia busca promover la conservación y el uso sostenible de los humedales a través de la prevención, reducción y mitigación de la degradación de estos ecosistemas, garantizando la provisión de servicios ecosistémicos y medios de subsistencia vitales para muchos pueblos indígenas y poblaciones locales. El Perú está implementando su estrategia nacional, habiendo realizado acciones importantes, como la conformación de su Comité Nacional de Humedales y la gestión de sus sitios Ramsar, asimismo, está avanzando en los lineamientos generales para el inventario nacional de humedales; en este caso, realizó en el 2012 una estimación cartográfica de la extensión de humedales, obteniéndose como resultado un área de 7 953 191 ha. considerando lagos, lagunas y cochas, bofedales, aguajales y pantanos amazónicos. Esta presentación brindará a nivel general información acerca de los avances, logros y desafíos en la implementación de la estrategia nacional de humedales del país.

Tropical Andean mountain peatlands are more extensive, carbon dense, and vulnerable to global change than previously recognized

Erik Lilleskov¹, Rodney Chimner², John Hribljan^{2,3}, Esteban Suarez⁴, Laura Bourgeau-Chavez⁵, Sarah Grelik⁵

¹USDA Forest Service, Northern Research Station, Houghton, USA; ²Michigan Technological University, Houghton, USA; ³Colorado State University, Fort Collins, USA; ⁴Universidad San Francisco de Quito, Quito, Ecuador; ⁵Michigan Tech Research Institute, Ann Arbor, USA (elilleskov@fs.fed.us; rchimner@mtu.edu; jahriblj@rams.colostate.edu; esuarez@usfq.edu.ec; lchavez@mtu.edu; slendres@mtu.edu)

Until recently, tropical peatlands in general, and especially tropical mountain peatlands, were largely ignored by the international scientific community. Mapping in particular focused on lowland peat swamp forests, completely overlooking mountain peatlands. Our ongoing mapping efforts are revealing much more extensive areas of peatland in the tropical Andean páramo and jalca than previously recognized, representing over 20% of mapped páramo in Ecuador, and about 5% of mapped jalca in Peru. Despite their low-stature vegetation, these peatlands are some of the most carbon-dense ecosystems in the world, harboring on average >1800 Mg C ha⁻¹, several times higher than tropical rainforests. Formed since the end of the last glaciation, they also support high long-term carbon accumulation rates. These rates are especially high in the younger peatlands at higher elevations, declining in older peatlands near the lower elevation limits of the páramo, and are expected to decline further in response to global warming. Mountain peatlands are critical to the livelihoods of millions of people, providing pasture, farmland, and clean water for many Andean cities. They are often ditched for agriculture, and sometimes overgrazed or otherwise damaged by sheep or cattle. These activities can shift these peatlands from net sinks for atmospheric CO₂ to sources. Additionally, intensive cattle disturbance can drive high emissions of methane, a potent greenhouse gas. Currently efforts are underway to improve our understanding of the distribution, carbon storage, and vulnerabilities of mountain peatland ecosystems, and to integrate this understanding in efforts supporting local sustainable livelihoods.

Ecological, social, economic and cultural aspects of the third largest tropical peatland region: the Peruvian Pastaza Marañon Basin

Jhon del Aguila Pasquel¹, Euridice Honorio Coronado¹, Ximena Tagle Casapia¹, Luis Freitas Alvarado¹, Gerardo Flores Llampazo¹, Manolo Martín Brañas¹, Dennis del Castillo Torres¹, Timothy Baker², Ian Lawson³, Katherine Roucoux³

¹Instituto de Investigaciones de la Amazonia Peruana (IIAP), Iquitos, Peru; ²University of Leeds, Leeds, United Kingdom; ³University of Saint Andrews, Saint Andrews, United Kingdom (jhonpasquel@gmail.com; euridice@yahoo.com; xtagle@iiap.org.pe; lfreitas@iiap.org.pe; gerardo.rfl@gmail.com; manolomartinb@gmail.com; ddelcastillo@iiap.org.pe; t.r.baker@leeds.ac.uk; itl2@st-andrews.ac.uk; khr@st-andrews.ac.uk)

The vastest peatland complex in South America, the Pastaza-Marañon Basin (PMB), is dominated by palm swamp forests characterized by native *Mauritia flexuosa* palm trees. Our research group in the Peruvian Amazon Research Institute (IIAP) has been studying the PMB ecosystems under an interdisciplinary approach and our aim is explain the relevance of these ecosystems for local people livelihood and for mitigation of climate change. Our up-to-date map of PMB (stock: ~3.14 Pg C) was used as a baseline for an on-going program of payments for ecosystem services. We manage a network of 17 permanent vegetation plots within PMB with the aim to understand the long-term dynamics of vegetation, structure, and carbon balance and hydrology of the PMB. We are studying the drivers of peat accumulation in a short term basis: organic matter inputs, organic matter decomposition, water table changes and weather conditions. We also quantified the methane emissions released from PMB peat surface and found the emissions are ~120 mg m⁻² day⁻¹ under natural conditions. We have promoted sustainable harvest techniques of *M. flexuosa* fruits (e.g. usage of climbing equipment) in PMB. Likewise, we are working with the Peruvian Service of Protected Areas to generate tools to estimate the production of *M. flexuosa* fruits (e.g. forest inventories and UAV analysis). We have re-validated the traditional knowledge about the relationship between an Urarina native community and the usage of peatland resources within PMB. Our interdisciplinary research is making the importance of peatlands gain more visibility for stakeholders and decision makers.

Managing and understanding wetlands in Colombia

Brigitte Baptiste¹

¹Instituto Alexander von Humboldt, Bogotá, Colombia (brigittebaptiste@humboldt.org.co)

For natural hydrological regimen and extreme events like El Niño and La Niña, wetlands play a role in water regulation among others services. Then is necessary has an integral understanding of this ecosystems, so that in Colombia, the Humboldt Institute in partnership with other institutions has been developing many research in wetlands, from a national scale to a local scale, support in three blocks: institutional information, the scientific community, and dialogue of knowledge. The results of these works included the first "Identification Wetlands Map of Colombia Inland Territory" using official information available at 1:100.000 of soils, geomorphology, and associated wetland vegetation coverage, as well as radar satellite images. The cartography processes identified 30.781.149 hectares of wetlands (26.99% of the national inland area). This characteristic implies that many organisms and the human must be adapted for the availability of water, for this reason, we can call our country like "Colombia an amphibian territory". In a regional scale in La Mojana, located in a lower land of Magdalena and Cauca Rivers, many works are framed in a restoration of wetlands behind 3 years of flooding after La Niña 2010-2011, where 700 ha of wetlands were restored into a participatory process, this work had an important collaboration of local communities of fishers and farmers, who through their relation whit a complex system of swamps give us the tools for understanding the functionality of wetlands and we returned nature based solutions for the improvement of their life quality and the health of the wetlands.

F8a: WOOD AND FOREST CULTURE: ADDRESSING A SUSTAINABLE FUTURE

The cultural importance of nontimber forest products in the United States

James Chamberlain¹, Michelle Baumflek², Frank Lake³

¹US Forest Service, Blacksburg, USA; ²US Forest Service, Asheville, USA; ³US Forest Service, Orleans, USA (jchamberlain@fs.fed.us; michelle.baumflek@usda.gov; franklake@usda.gov)

Many nontimber forest products (NTFPs) have deep and significant cultural meaning for people around the world. In the United States (US), NTFPs contribute notably to the traditions, livelihoods, food sovereignty and well-being of indigenous peoples and minority communities, as well as immigrant and settler social groups. Presenting findings from a recent national assessment of NTFPs in the US under changing climates, the authors discuss cultural importance of NTFPs for indigenous and nonindigenous peoples of the United States. They explore traditional and local ecological knowledge related to the harvest, preparation and distribution of plants and fungi, and report on the crucial need for access to NTFPs for sustaining cultural identity and practices. Drawing on regional case studies from the Pacific Northwest and Southeast US, this presentation also examines the potential impacts of climate variability on cultural uses of specific NTFPs. Key knowledge gaps where research can contribute to a sustainable future for cultural practices around NTFP harvest and utilization are identified.

Social and cultural dimensions of sustainable forest management

Elisabeth Johann¹

¹Austrian Forest Association, St. Margareten, Austria (elisabet.johann@aon.at)

Social and cultural dimensions of sustainable forest management are reflected in landscapes, historical sites and buildings, in artistic and linguistic knowledge, in traditional forest management practices, and in the use of wood and non-wood goods and forest services. The forest is the indispensable prerequisite for the cultural development of society. However, behaviour and attitude of humans in dealing with forests have been characterized both in the past as today by a contrast between exploiting destruction and careful use. Thus, the role of social and cultural aspects of sustainable forest management, including the role of traditional knowledge in the overall goal of sustainable development, is becoming increasingly important throughout the world. The paper deals with the interactions between forest and humans, especially in the context of diverse social and economic frame conditions. The aim of the study is to examine how in the past the society has reconciled its increasing demand for wood with the maintenance of the forest area. It examines the manifold ways in which the forest has been used, how these multiple uses related to the social and economic power structures, and how the population has dealt with the threat of natural hazards and climate change. The study looks at the early advanced knowledge and techniques that have been developed in order to ensure the preservation of the locally available forest resources.

Acoustics features of ten kinds of small ethnic wood musical instruments

Ping Yang¹

¹Kumamoto University, Kumamoto, Japan (yangping@educ.kumamoto-u.ac.jp)

Wood musical instruments are good educational components in elementary schools not only for kids to enjoy wood characteristics in auditory but also to understand easily the reason why there are so many wood musical instruments relating to their cultural and religious background. This study conducted the experiments for measuring the acoustic features from ten kinds of small ethnic wood musical instruments. They were divided in four groups of idiophones, membranophones, chordophones and aerophones, including Bolivian matraka, Brazilian caxixi, Tanzanian kalimba, West African talking drum, Egyptian barrel drum, Angolian cuica, Indian manduka and gopichand, Ethiopian lyre, as well as Nigerian shawm. Their acoustic data were collected within a recording studio fully surrounded by the walls in three-dimensional wedge structures to insure the sound energy traveling away from the source with almost none reflected back, which is called as anechoic chamber. An integral sound level meter (NL-05) made by Rion Ltd. was used. All musical signal was detected by an AUDIO Capture(UA-30) made by EDIROL Ltd. Their acoustic features such as sound pressure and frequency were analyzed respectively in real time by using DSSF (Ver.5.1.X.X) software installed in a computer. Such ethnic wood musical instruments made from different wood species, with various interesting shapes and diverse acoustics features played a great role in stimulating the strong curiosity of elementary school kids and opening their mind to the diversity of wood culture worldwide.

THEME A: FORESTS FOR PEOPLE

A1a: AGROFORESTRY AND PRODUCTION OF NONWOOD FOREST PRODUCTS

Systemic vision in planning and managing agroforestry systems / Visão sistêmica utilizada no planejamento e gestão dos sistemas agroflorestais

Martin Ewert¹, Marcelo Francia Arco-Verde², Viviane Helena Palma³, Daniele Cristine da Silva Kazama¹

¹Universidade Federal de Santa Catarina, Florianópolis, Brasil; ²Embrapa Florestas, Colombo, Brazil; ³Universidade Federal do Paraná, Curitiba, Brasil (nitram.ewert@gmail.com; marcelo.arco-verde@embrapa.br; viviane-palma@outlook.com; danielkazama@yahoo.com.br)

A fim de contribuir com o desenvolvimento dos Sistemas Agroflorestais (SAFs), a pesquisa tomou como base um estudo de caso realizado no Assentamento Contestado, localizado no município da Lapa, Paraná. O objetivo foi apontar fatores que podem melhorar o desempenho dos SAFs por meio de uma visão sistêmica de gestão das unidades produtivas. A matriz metodológica ocorreu em diversas reuniões e envolveu diferentes atores sociais na avaliação do processo de implantação e ajustes do sistema. Nesse período foi acompanhado o cotidiano de 5 famílias de agricultores agroecológicos associados a Cooperativa Terra Livre que desenvolvem SAFs desde 2011. Os resultados apontam que o enfoque sistêmico aliado a gestão e planejamento estratégico pode contribuir para criar projetos eficientes, produtivos e rentáveis. Para tanto, é preciso realizar análise financeira do projeto com visão de curto, médio e longo prazos; planejamento estratégico com objetivos e metas bem definidos; planejamento da demanda da mão de obra, insumos e possibilidade de mecanização; diversidade, interação, espaçamento e escolha das espécies de acordo com suas funções e conexões; logística, mercado e comercialização; meio físico e condições edafoclimáticas; experiência, habilidade e vocação do agricultor; fatores sociais e culturais; capacitação periódica e criar relação de confiança com o agricultor. Conclui-se que a visão sistêmica é fundamental pois considera múltiplas perspectivas, relações, variáveis sendo possível conhecer todo o sistema, cada parte ou interação. Além disso, integra de forma interdisciplinar os diferentes conhecimentos tradicionais, técnicos e científicos ao valorizar práticas e falas de cada indivíduo no processo da construção de soluções satisfatórias.

Assessing the economic feasibility of Noni (*Morinda citrifolia*) production model to increase income for Forest Villages in Laos

Bohwi Lee¹ , Se bin Kim¹ , Hakjun Rhee¹ , Joon-Woo Lee¹, Sangjin Lee¹

¹Department of Environment and Forest Resources, Chungnam National University, Daejeon, Republic of Korea (bohwi00@gmail.com; sbkim@cnu.ac.kr; hakjun.rhee@gmail.com; jwlee@cnu.ac.kr; sangjin78@cnu.ac.kr)

This study developed and applied an agroforestry product model to a local forest village, Nongboua in Laos, and analyzed its economic feasibility to increase income for villagers who earned most of income from rice production. Possible strategies were considered to increase the village revenue, and Noni was chosen as the short-term agroforestry product due to its high price and demands from tourists. A total of 1,100 Noni seedlings were planted in one hectare at 3m by 3m spacing. Noni fruits from the village can be sold to Noni product companies at a price of \$0.29/kg. For an economic feasibility analysis, a project period of 20 years was assumed and three scenarios were simulated by seedling survival rate and purchase price of Noni fruits. This study used conservative seedling survival rates to consider potential risks such as inexperienced management and, tree disease; Scenario 1 used survival rates of 50%, 60%, and 70% with the current purchase price for the first, second, and third year and after; scenario 2 used, 10% less, (40%, 50%, and 60%); and scenario 3 used, 10% less with purchase price of \$0.26/kg, 10% less than the current price. All three scenarios resulted in economically-feasible IRRs: 24.81%, 19.02%, and 16.30% with a discounting rate of 10%. The B/C ratios of three scenarios were 1.71, 1.47, and 1.31. The study found that the plantation and management of an alternative agroforestry product, such as Noni, could improve current low-income structures of local forest villages in Laos.

Underutilized species of the walnut-fruit forests of Southern Kyrgyzstan: use by local households, contribution to livelihoods, and influencing factors

Will Fulwider¹, Dietrich Darr¹

¹Rhein-Waal University of Applied Sciences, Kleve, Germany (wmfulwider@gmail.com; dietrich.darr@hochschule-rhein-waal.de)

Much of the literature surrounding the use of the walnut-fruit forests of Southern Kyrgyzstan, a global biodiversity hotspot, has centered on the economically important *Juglans regia*, however the usage of the forests' various other fruit, nut, and medicinal species has received little attention. This article assesses current usage of these underutilized species. To do so, a household survey was conducted (n=307) across 7 villages representing a gradient of forest proximity, climate, and wealth. Furthermore, 78 qualitative in-depth interviews were conducted with selected households and key informants on decision-making criteria driving the collection, processing, and consumption vs. commercialization decision for the 8 most important species. Species use was determined by market pressures and household perception of the health benefits of the species. The economic contribution of underutilized species to annual income (1.8%) while small

compared to employment (43%) and walnut collection (27%), is significant in its timing aspect, providing an influx of cash after the winter months or acting as a coping strategy between harvests. Household value addition was highly dependent on the stability of other sources of income. Factors constraining the use of these species included access to the forest through tenure and proximity, available labor, nearness to local markets, and household age and length of time in the village. While wealthier households exhibiting a diverse array of income sources are best positioned to take advantage of the opportunities presented by these underutilized species, they are less dependent on these species to act as a coping strategy.

Assessment of potential socioeconomic impact of introducing multipurpose trees and agroforestry systems in rural communities of KwaZulu-Natal in South Africa

Sihle Pokwana^{1,2}, Ratsodo Phillip Tshidzumba¹, Paxie Wanangwa Chirwa¹

¹University of Pretoria, Pretoria, South Africa; ²Fort Cox Agriculture and Forestry Training Institute Middelrift South Africa (sihlepoks@gmail.com; phillipmgf@yahoo.com; paxie.chirwa@up.ac.za)

In South Africa, forests benefit rural people in various ways, such as providing various agroforestry systems possibilities and non-timber forest products amongst others. The objective of this study was to identify the potential socio-economic impact of introducing trees and agroforestry in rural areas of KwaZulu-Natal, South Africa. The study was conducted in three purposefully selected communities, which include Mkhoba, Ngubelanga and Kwabase situated in Harding-Weza region. Using the mixed method approach, quantitative data was collected through a means of structured questionnaire, while focus group discussion was also used to collect qualitative data from key members of the communities. The descriptive statistical analysis, including frequencies and Chi-square test of independence to understanding the relationship between respondents knowledge on the benefits of agroforestry in improving the livelihood of the rural communities. Findings revealed that, the household respondents highly accrued non-timber products such medicinal plants, fruits and fodder for their livestock from forests. On the other hand, the results showed that majority of household respondents ranging from 40% to 72.1% were not familiar with agroforestry practice. In the contrary, majority showed interests in planting trees in their homesteads (90.6% to 100%). The introduction of multipurpose trees in these communities has clear potential to improve the household's socio-economic status. However, it would be significant to consider a much-coordinated approach between government and forestry industry stakeholders in order for effective rolling out of impactful agroforestry systems in rural communities of South Africa.

Financial evaluation of Amazonian monocultures conversion to agroforestry systems in Guaviare (Colombia)

Carlos William Rodriguez Contreras¹, Angie Alexandra Vargas Solano¹, Liz Villarraga¹

¹Universidad Distrital Francisco José de Caldas, Bogota, Colombia (cwrodriguez@gmail.com; angie.roglis@gmail.com; lizv@udistrital.edu.co)

In the framework of post-conflict in Colombia, the agroforestry systems (SAF) are an alternative to optimize the land use and improve the economic income of their owners. In Guaviare (Colombia), the Producers' Association for Economic Change of Guaviare (ASOPROCEGUA), is dedicated to the change of illicit activities by the agricultural exploitation and produces pulps of Amazonian fruits in monoculture systems and in some cases in agroforestry. In this study, the financial viability in the conversion of monocultures to agroforestry systems implemented in the farms of ASOPROCEGUA was evaluated, in order to compare the profitability in both systems and be a source of information for farmers who are interested in maximizing their income and benefits with the conversion of monocultures to SAF. For this, semi-structured interviews are developed, based on a systematic sampling with replacement in 20 production farms. Additionally, an analysis of the environmental services provided by the SAF is done. Finally, it was found that the SAFs are more profitable and sustainable in the long term compared to the monocultures, since a product of commercialization is obtained in a short time and also in a period of 20 years a profit is generated by the forest component as well as the environmental services obtained thanks to the change in the productive systems.

A study on community collaboration forest management system of National Forest in Indonesia: its contribution to local economy and environment

Chiharu Maeda¹, Ikuo Ota²

¹Kagoshima University, Kagoshima, Japan; ²University of the Ryukyus, Okinawa, Japan (chiharu.maeda.21@gmail.com; ikuota@agr.u-ryukyuu.ac.jp)

Since 2001, the Indonesian State Forest Company (Perum Perhutani) has cooperated with local community groups for managing National Forests in Java Island. This management program is known as the Community Collaboration Forest Management System (Pengelolaan Hutan Bersama Masyarakat, PHBM). The authors investigated the impacts of the PHBM on local peoples' income, using a case of the Sukabumi Forest District, West Java. Interview surveys were conducted for the staffs of Perum Perhutani and local households participating in PHBM. PHBM in this area divided into two programs: Agroforestry program and resin tapping program. Before 2000, local people occupied the national forest area for illegal cultivation. The PHBM was introduced to Sukabumi in 2007 and local farmers have been allowed to grow agricultural crops on teak (*Tectona grandis*) plantation sites for the first two years. The average income from crop production including upland rice and some beans was Rp 37 million (US\$ 2,600) for year 2013. The Resin tapping program was introduced since 2008 at the pine (*Pinus merkusii*) plantation sites. Perum Perhutani has hired landless farmers and unemployed local people from surrounding communities as resin collectors. The average income of collectors from resin was Rp 9.3 million (US\$ 660) for year 2015, accounting for 70% of their total household income. Forests in Sukabumi has been successfully covered with planted teak and pine, and forest resources are gradually growing. The authors conclude that PHBM has contributed to the local peoples' income and environment on the denuded land.

A1b: AGROFORESTRY IN FOREST LANDSCAPE RESTORATION: TOWARDS A COMPREHENSIVE APPROACH

Social technologies and sustainability's reach into public policies: integrated systems involving crops, livestock, and Forests / Tecnologias sociais e o alcance da sustentabilidade em políticas públicas: o exemplo de ILPS e SAFS

Edson Leite^{1,2}, Ana Maria Junqueira³

¹Embrapa, Brasília, Brazil; ²Ministério da Agricultura, Pecuária e Abastecimento, Brasília Brazil; ³Universidade de Brasília, Brasília, Brazil (edson.leite@agricultura.gov.br; anamaria@umb.br)

A Integração Lavoura-Pecuária-Floresta (ILPF) é uma estratégia de produção sustentável que integra atividades agrícolas, pecuárias e/ou florestais realizadas na mesma área, em cultivo consorciado, em sucessão ou rotacionado, e busca efeitos sinérgicos entre os componentes do agroecossistema. Os Sistemas

Agroflorestais (SAFs) são descritos como sistemas de uso e ocupação do solo em que plantas lenhosas perenes são manejadas em associação com plantas herbáceas, arbustivas, arbóreas, culturas agrícolas e forrageiras, em uma mesma unidade de manejo, de acordo com arranjo espacial e temporal, com alta diversidade de espécies e interações desses componentes. A ILPF e os SAFs contribuem para recuperação de áreas degradadas, manutenção e reconstituição da cobertura florestal, promoção e geração de emprego e renda, adoção de boas práticas agropecuárias (BPA), melhoria das condições sociais, adequação da unidade produtiva à legislação ambiental e valorização de serviços ambientais oferecidos pelos agroecossistemas, tais como: a) conservação dos recursos hídricos e edáficos; b) abrigo para os agentes polinizadores e de controle natural de insetos-pragas e doenças; c) fixação de carbono e nitrogênio; d) redução da emissão de gases de efeito estufa; e) reciclagem de nutrientes; f) biorremediação do solo, ou seja processo nos quais organismos vivos, normalmente plantas ou microrganismos, são utilizados tecnologicamente; e g) manutenção e uso sustentável da biodiversidade A estratégia de ILPF e os Sistemas Agroflorestais contemplam quatro modalidades de sistemas, assim caracterizados: Integração Lavoura-Pecuária (Agropastoril), Pecuária-Floresta (Silvipastoril), Lavoura-Floresta (Silviagrícola) e Lavoura-Pecuária-Floresta (Agrossilvipastoril). Neste trabalho mostra-se como uma política pública bem-sucedida, o Plano ABC, vem dando excelentes resultados.

Agroforestry systems to remediate degraded areas / Sistemas agroflorestais para recuperação de áreas degradadas

Viviane Helena Palma¹, Marcelo Francia Arco-Verde², Martin Ewert³

¹Universidade Federal do Paraná, Curitiba, Brazil; ²Embrapa Florestas, Colombo, Brazil; ³Universidade Federal de Santa Catarina, Florianópolis, Brazil (viviane-palma@outlook.com; marcelo.arco-verde@embrapa.br; nitram.ewert@gmail.com)

Os Sistemas Agroflorestais (SAFs) têm figurado como estratégia capaz de mitigar efeitos da fragmentação florestal, uma ameaça latente em todo o mundo, e ainda unir temáticas ambiental, social e econômica. Resultados expressivos em termos de recuperação de ambientes degradados, conectividade de fragmentos florestais, melhoria de solo e qualidade de água, além de resgate do cultivo de espécies nativas e gêneros alimentícios diversos, têm sido cada vez mais observados e valorizados. No que tange à segurança financeira frente às oscilações de mercado, se bem planejado, o sistema garante resiliência, pois há diversidade de produtos comercializáveis ao longo do ano e durante muitos anos. No Brasil, pesquisa em desenvolvimento com agricultores familiares no estado do Paraná, evidencia que SAFs têm acelerado a recuperação de áreas com histórico de degradação por pastoreio e monocultivos extensivos. A recuperação se dá principalmente por meio de conservação e maior deposição de matéria orgânica sobre o solo, aumento da ciclagem de nutrientes e diversificação da paisagem. Nos casos de maior êxito, além dos benefícios ambientais supracitados, muitos destes agricultores têm garantido aporte financeiro constante. Outro efeito advindo da maior segurança financeira tem sido percebido pela permanência ou mesmo pelo retorno de jovens ao ambiente rural, por vislumbrarem ali uma perspectiva de futuro, garantindo a diminuição do êxodo rural. Portanto, observa-se que um dos principais desafios à maior difusão e adoção dos SAFs ainda é o planejamento, pois quando adequado aos seus atores, este tipo de sistema produtivo integrado pode recuperar ambientes, mudar vidas, fortalecer e diversificar mercados.

Sustainable land management for improved livelihoods and environmental sustainability: the role of agroforestry

Daniel A. Ofori¹, Kouame Christophe², Jeremias Mowo³, Jamnadass Ramni³, Stephen Akpalu¹, Lars Graudal³

¹CSIR-Forestry Research Institute of Ghana, Kumasi, Ghana; ²World Agroforestry Centre, Abidjan, Côte d'Ivoire; ³World Agroforestry Centre, Nairobi, Kenya; (dofori@csir-forig.org.gh; c.kouame@cgiar.org; j.mowo@cgiar.org; r.jamnadass@cgiar.org; sakpalu2@gmail.com; graudal@cgiar.org)

A healthy viable multifunctional landscape has the capability of supporting sustainable agricultural productivity, providing agroforestry and forest products (timber, fuel wood, fruits, medicine, fertilizer, gum etc.) for the sustenance of mankind while providing other environmental services. However these products are increasingly becoming unavailable due to declining soil fertility, climatic extremes, and high costs of inputs. Identifying low-cost, sustainable ways to attain food security and sustainable environment for millions of smallholder farmers in Sub Saharan Africa (SSA) remains a major developmental challenge. The poor performance of the agricultural sector in SSA therefore calls for innovative approaches for sustainable land management and sustainable agricultural productivity. Agroforestry offers an opportunity to meet this challenge. The paper reviews the major challenges confronting the drylands of Western, Eastern and Southern Africa regions with case studies from these regions showing the potential of agroforestry / evergreen agriculture in support of sustainable land management and increased agricultural productivity. This evidence has encouraged development of evergreen agriculture for improved food security, livelihoods and environmental sustainability.

Agroforestry for livelihood revitalization in degraded peat ecosystems as integral part of peat restoration in Indonesia

Endri Martini¹, Subekti Rahayu¹, Sonya Dewi¹

¹World Agroforestry Centre, Bogor, Indonesia; (e.martini@cgiar.org; s.rahayu@cgiar.org; s.dewi@cgiar.org)

Peatland ecosystems in Indonesia have undergone major degradation phases. The impacts of the degradation on increased GHG emission, biodiversity loss, high fire risk, and soaring economic and social costs have been understood. Government of Indonesia has committed to restore degraded peat ecosystems throughout Indonesia with three approaches: rewetting, revegetation, revitalization. Considering the rural communities living within peatland ecosystems, whose livelihoods depend on land-based agricultural activities, the rewetting and revegetation for reforestation potentially reduce their options for livelihoods. Species diversification in agroforestry is expected to enhance options to revitalize livelihoods as well as restore the ecosystems in degraded peatland. However, the success stories are limited due to: (i) less options of economic species that can be productive in water logged areas; (ii) agroforestry technologies for rewetted peat are not widely developed; (iii) limited knowledge exchange on agroforestry technologies between stakeholders. Competing land use options and low government support to market agroforestry products from peatlands also make agroforestry options not interesting. This study in Central Kalimantan and South Sumatra revealed issues at farm level such as the potential species list, agroforestry technologies (including land clearing without burning), and farmers' awareness and interests in maintaining their peat sustainably through agroforestry practices. At landscape level, zonation of peat hydrological unit is important in prioritizing the agroforestry management types. Agroforestry options for livelihood revitalization can be designed by identifying the enabling factors such as market availability, local policies and government support across gradients of peat depths.

Project Cacau Floresta: restoring landscapes and people through biodiverse agroforestry systems in the Brazilian Amazon region / Projeto Cacau Floresta: restaurando paisagens e pessoas via sistemas agroflorestais biodiversos na Amazônia Brasileira

Rodrigo Mauro Freire¹, Thais Ferreira Maier¹, Edenise Garcia²

¹the Nature Conservancy, Belem, Brazil; ²the Nature Conservancy, Brasilia, Brazil (rfreire@nc.org; tferreira@nc.org; egarcia@nc.org)

Os sistemas agroflorestais (SAFs) com espécies nativas em pequenas propriedades rurais podem ser uma solução para o combate ao desmatamento e promoção do reflorestamento econômico na Amazônia. Em 2013 a The Nature Conservancy iniciou o Projeto Cacau Floresta visando à restauração de pastagens degradadas

por meio de SAFs baseados no cacau (Theobroma cacao) em São Félix do Xingu e Tucumã, no sudeste do Estado do Pará. Agricultores familiares foram incluídos de forma participativa no projeto, sendo que atualmente o projeto conta com 130 propriedades, 500 hectares de novos plantios de cacau em SAFs e 70 diagnósticos ambientais realizados para os imóveis rurais que possuem o cadastro ambiental rural (CAR). São produzidos, além do cacau, espécies como mandioca (Manihot esculenta), milho (Zea mays), banana (Musa sp.), açaí (Euterpe oleracea), mogno (Swietenia macrophylla), copaíba (Copaifera spp.), andiroba (Carapa guianensis), taperebá (Spondias mombin), jatobá (Hymenaea courbaril), bacuri (Platonia insignis), castanheira (Bertholletia excelsa Bonpl.), entre outras nativas amazônicas. O projeto vem atuando nos seguintes domínios: produção rural (assistência técnica, garantia de acesso a insumos); socioeconômico (fortalecimento de mulheres, jovens e lideranças locais); organização socioprodutiva (fortalecimento de cooperativas, associações e casa familiar rural); organização de produção e oferta de sementes e mudas florestais) e ambiental (treinamentos em restauração, estabelecimento de acordos de desmatamento zero). Este estudo de caso apresenta uma promissora oportunidade de dinamização da economia local via fomento da cacauicultura em SAFs e restauração florestal, contribuindo para a conservação da biodiversidade e mitigação das mudanças climáticas numa importante fronteira de desenvolvimento da Amazônia.

Growth and production of *Schizolobium parahyba* var. *amazonicum* Huber Ex (Ducke) Barneby as a function of soil management in an agroforestry system / Crescimento e produção de *Schizolobium parahyba* var. *amazonicum* (Huber Ex Ducke) Barneby em função do manejo do solo em sistema agroflorestal

Agust Sales¹, Sílvio Nolasco de Oliveira Neto¹, Haroldo Nogueira de Paiva¹, Helio Garcia Leite¹, Marco Antonio Siviero², Sabrina Benmuyal Vieira³
¹Universidade Federal de Viçosa, Viçosa, Brazil; ²Grupo Arboris, Dom Eliseu, Brazil; ³Universidade Federal do Pará, Belém, Brasil
 (agustsales@hotmail.com; snolasco@ufv.br; hnpaiva@ufv.br; hgleite@gmail.com; m.g@masiviero.com.br; sabrina.benmuyal@grupoarboris.com.br)

Em sistemas agroflorestais práticas de manejo do solo podem ampliar a capacidade de produção. Avaliou-se o crescimento e produção de paricá (*Schizolobium parahyba*) em sistema agroflorestal com práticas de manejo do solo, em Ulianópolis, Pará, Brasil. Implantou-se o paricá no espaçamento 5 x 2 m, consorciado com soja (*Glycine max*), no primeiro ano, e milho (*Zea mays*) no segundo. Avaliou-se os tratamentos T1 = subsolagem, adubação de base, adubação de cobertura, inoculação, consórcio com soja/milho; nos T2, T3, T4 e T5 aplicou-se as mesmas práticas do T1, exceto subsolagem (T2), adubação de base (T3), adubação de cobertura (T4) e inoculação (T5); sendo o T6 a testemunha sem práticas de manejo do solo. Avaliou-se o diâmetro a 1,3 m de altura (dap), a altura total (ht) e a sobrevivência (%) das árvores aos 8, 22 e 36 meses de idade. Aos 36 meses, ajustou-se modelos para estimativas de crescimento e volume de madeira para 48 e 60 meses. Maiores sobrevivências ocorreram em T2, T3 e T4. O crescimento em dap, ht e volume no período com soja/milho foi superior em T2 e T6. Em idades futuras, o dap e volume apresentaram tendências superiores em T6 e recuperação em T1 e T5. Maiores sobrevivências ocorreram em T2, T3 e T4, provavelmente diante maior competição entre plantas que comprometeram o crescimento em dap e volume. Tendências de maior crescimento e produção na ausência de consórcio indicam que a competição exerceu maior influência que práticas de manejo do solo, diante boa fertilidade do solo.

A1c: ASSESSING THE CULTURAL ECOSYSTEM SERVICES FROM FORESTS: CURRENT CHALLENGES AND FUTURE SCOPES

Accounting for cultural ecosystem services: a case of recreation services in Finland

Tuija Sievänen¹, Tuija Lankia¹, Marjo Neuvonen¹, Eija Pouta¹
¹natural Resources Institute Finland, Helsinki, Finland (tuija.sievanen@luke.fi; tuija.lankia@luke.fi; marjo.neuvonen@luke.fi; eija.pouta@luke.fi)

Ecosystem accounting is a coherent framework for integrating measures of ecosystems and the flows of services from ecosystems with measures of economic and other human activity. Ecosystem accounting complements, and builds on the accounting for environmental assets as described in the System of Environmental-Economic Accounting (SEEA) Central Framework. In this study of cultural ecosystem service accounting, the aim was to make a pilot assessment of nature-based recreation in Finland. This presentation describes the methods and data sets used in analyses of indicators, and thoughts of advantages and shortcomings and identification of the gaps in data and methods as the main outcome. We offer a framework for methodology and needed assets, which are suitable to be processed for the accounting system of cultural ecosystem services. The account includes an estimate of the annual volume of recreational visits to nature areas, and an estimate of the value in monetary terms of the recreational use of nature areas and natural resources. We present pilot calculations for accounting. We illustrate how the nationwide data collection that provides the estimate of number of recreational visits in nature areas is a solid base for physical measures, and also for monetary values of the recreational visits. The assessment for the supply of recreational resources is based on land use categories and on data set of public recreation services (LIPAS -Geographic database for sport facilities for Finland). We discuss what improvements of data collection are needed for a functional cultural ecosystem service accounting in Finland.

Replanting life: perceptions of the benefits from forest restoration in resocializing inmates / Replantando vida: percepção dos benefícios da restauração florestal na ressocialização de presidiários

Alan Henrique Marques de Abreu¹, Elton Luis da Silva Abel¹, Alcione Duarte Ferreira¹, Jorge Makhoulta Alonso²
¹Companhia Estadual de Águas e Esgotos - CEDAE, Nova Iguaçu, Brasil; ²Universidade Federal Rural do Rio de Janeiro, Seropédica, Brasil (alan.abreu@cedae.com.br; elton@cedae.com.br; alcione@cedae.com.br; j_makh@hotmail.com)

Ambientes penitenciários são frequentemente sombrios, caóticos, superlotados, e insalubres físico e mentalmente. O trabalho na restauração florestal como forma laborativa, produtiva e terapêutica, aproxima os presidiários da natureza, oferece alívio de ambientes sociais tão duros e promove interação com meio ambiente. Um dos poucos exemplos no Brasil é o Programa Replantando Vida, desenvolvido no Rio de Janeiro pela Companhia Estadual de Águas e Esgotos (CEDAE), que oferece à presidiários capacitação profissional e trabalho em atividades de coleta de sementes, produção de mudas e restauração florestal. Nosso objetivo foi analisar a percepção dos presidiários sobre como as atividades da cadeia produtiva da restauração florestal podem contribuir no processo de ressocialização. Foi aplicado um questionário estruturado à 35 apenados da Colônia Penal Agrícola de Magé que participam do Programa. Os presidiários que participaram da pesquisa possuem em média 35 anos de idade, 80% não terminaram o ensino médio e estão em média a 7 meses no Programa. Os entrevistados declararam que os principais motivos para procurarem o Programa, são a remissão de pena (83%), seguido da oportunidade de aprendizado e capacitação (63%), valorização dos familiares e amigos (51%), além da remuneração (43%). O aumento do senso de responsabilidade foi o benefício mais percebido pelos apenados (66%). O interesse em buscar mais capacitação (48%), melhoria no relacionamento com a família (40%), melhor perspectiva futura (37%), aumento da auto estima (37%) e valorização como ser humano (29%), foram outros benefícios citados. O trabalho com restauração promoveu mudanças significativas na percepção de vida dos presidiários.

Landscape context matters: socio-ecological drivers of woodland recreation

Chloe Bellamy¹ , Rebecca Spake², Mark Atkinson³, David Edwards¹, Kevin Watts³, Felix Eigenbrod¹

¹forest Research, Edinburgh, United Kingdom; ²southampton University, Southampton, United Kingdom; ³forest Research, Farnham, United Kingdom; (chloe.bellamy@forestresearch.gov.uk; r.spake@soton.ac.uk; mark.atkinson@forestresearch.gov.uk; david.edwards@forestresearch.gov.uk; kevin.watts@forestresearch.gov.uk; f.eigenbrod@soton.ac.uk)

There is increasing evidence for the mental and physical health benefits of spending time in woodlands and the wider natural environment, but information on how to manage our landscapes to enhance these cultural ecosystem services is lacking. To develop cost-effective strategies for improving woodland recreation we need a better understanding of where particular management actions will be most successful and why. We applied a statistical framework developed under the SCALEFORES project to identify the factors determining demand for, and supply of, recreation in 15,000 ha⁻¹ National Forest Inventory plots across Great Britain. This comprehensive field survey measures various biophysical and human characteristics of a woodland plot, including its composition, structure, management, condition and social use. These local attributes were integrated with data on the surrounding social and environmental landscape at multiple scales; machine learning was used to identify drivers and their scales of effect. Importantly, by incorporating interactions between variables measured at different scales we were able to investigate how the influence of local features varied according to the landscape context. We demonstrate the usefulness of this spatially-explicit approach for informing the management and restoration of Britain's highly fragmented, sparsely wooded landscape to support social use and highlight its transferability to other regions, environmental contexts and land management challenges.

Assessing social values of urban forest as a key component for urban planning

Sandra Rodriguez-Pineros¹, Nelson Aguilar-Palma¹, Rosalia Sánchez-Basualdo¹, Leonor Cortés-Palacio¹

¹Universidad Autonoma De Chihuahua, Chihuahua, Mexico (sandra_osu@yahoo.com; naguilar@uach.mx; rbasualdo@uach.mx; lcortes@uach.mx)

Urban forests provide several benefits to urban dwellers; they enhance city aesthetics, provide shadow, reduce the amount of greenhouse gases in the air by sequestering carbon dioxide, and help to reduce the amount of energy needed to heat and cool buildings. To understand the effects of climate change to the cities and to develop policies for adaptation it is important to know how stakeholders value the ecosystem services provided by the urban forests. Therefore, urban planning should be based on an integrated approach in which direct and indirect users participate. This study uses Q methodology to assess social values of a forest located in the city of Chihuahua, Mexico, a city that is characterized for being very vulnerable to the effects of climate change due to its geographical location. Seven groups of different stakeholders have been identified, direct users (runners and sport groups), municipal authorities (parks and recreation, municipal maintenance, ecology, library, health department, and planning), vendors, neighborhoods, and non-government organization located inside the park. From the groups of stakeholders thirty individuals were selected to sort a Q-sample of 25 statements that were carefully developed using the quasi-naturalistic approach. At this moment we are collecting the Q-sorts for further analysis, we expect to find two or three factors that reveal how stakeholders value the forest, we also expect to find areas of agreement and disagreement about that valuation. This information is useful for urban planners to develop forestation strategies in the already known hot spots of the city.

Assessing the links among cultural services, future scenarios, and the wellbeing of different cultural groups: an example from Northwestern Australia

Milena Kiatkoski Kim^{1,2}, David Pannell¹, Ken Wallace¹, Jorge Alvarez Romero³, Oliver Knight⁴

¹Centre for Environmental Economics and Policy, School of Agriculture and the Environment, University of Western Australia, Perth, Australia; ²National Environmental Sciences Programme, Northern Australia Environmental Resources Hub, Canberra Australia; ³ARC Centre of Excellence for Coral Reef Studies, James Cook University, Townsville, Australia; ⁴Aboriginal Interpreting WA Aboriginal Corporation, Fremantle, Australia (milena.kim@uwa.edu.au; david.pannell@uwa.edu.au; ken.wallace@uwa.edu.au; jorge.alvarezromero@jcu.edu.au; oknight21@yahoo.com)

Changes in ecosystem services can affect people's wellbeing. Our project uses participatory scenario planning to explore how future environmental changes in the Kimberley region in northwest Australia may affect the wellbeing of different stakeholder groups. The project has two stages: first, future scenarios were developed by a team (~35 people) representing Aboriginal organizations, government, industry and environmental groups. The resulting four spatially-explicit scenarios include 30-year changes in water and land-use, species habitat, and economic indicators. Second, stakeholders were asked to predict the impacts of each scenario on their wellbeing in comparison with their current situation. The cultural benefits of natural forests in the study area included access to: knowledge that comes from nature and special natural places; recreational satisfaction; and spiritual fulfillment. The assessment method uses a classification of wellbeing factors that was translated to work across different cultural groups. In this presentation we show how the method allows for the identification of win-win and win-lose situations associated with future environmental changes between multiple stakeholder groups, and how it could be adapted to different social and environmental contexts.

Public preference for mixed forests: the results of a transdisciplinary research project on ecosystem services in Germany

Iulia Milena Almeida Yakouchenkova¹, Somidh Saha¹, Christine Rösch¹

¹Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany (iulia.yakouchenkova@kit.edu; somidh.saha@kit.edu; christine.roesch@kit.edu)

Mixed forests are known for their higher resilience to climate change impacts such as storms and droughts and superior biodiversity compared to monospecific forests. The supporting (e.g. biodiversity), regulating (e.g. carbon sequestration) and provisioning (e.g. wood production) ecosystem services are well investigated. For cultural ecosystem services such as recreation, tourism and aesthetic experience, however, only few studies are available in Europe. No insights at all exist about the perceptions of stakeholder and citizens for the famous Black Forest Region in South West Germany. In order to close that knowledge gap, a survey was carried out to analyze the views of stakeholder and citizens located in this region on ecosystem services of mixed forests with silver fir and European beech compared to monospecific forests with beech only. Our findings show that people believe that mixed forests provide better regulating, supporting and cultural ecosystem services than monospecific forests. Respondents' perceptions that in mixed forests more large and old trees can be found have a big impact on this rating and the feelings of pleasantness. The only drawback is seen by constraints in provisioning services, which are regarded to be better provided by monospecific forests. These results are surprising since spruces and firs are characteristic for the Black Forest. It can be explained by the change in attitude and behavior of citizens towards the use of the Black Forest. Our insights support the development of political strategies to increase the share of mixed forests for a higher resilience and public acceptance.

Nature's characteristics and benefits influence Latinos environmental responsibility

Jose J Sanchez¹, Netasha Pizano², Anthony Higgins³, David Flores⁴

¹usda Forest Service, Riverside, Usa; ²california State University, Fullerton, Fullerton, Usa; ³california State Polytechnic University, Pomona, Usa; ⁴usda Forest Service, Fort Collins, Usa (jsanchez@fs.fed.us; npizano@csu.fullerton.edu; anthonyhiggins@fs.fed.us; davidflores@fs.fed.us)

While Latinos are the second largest group in the United States contributing to the protection of natural resources, little research has considered Latinos' perspectives on environmental protection. Through quantitative and qualitative analyses, this study aimed to determine Latinos' views on environmental responsibility and the factors that influence such perspectives. Participants were individuals engaged in organized outdoor recreation facilitated by a Latino-led organization. A structural equation model was used to identify potential benefits that recreating in natural settings had on participants' levels of environmental responsibility. Quantitative results indicated that leisurely benefits significantly impacted the perspectives of Latinos. Moreover, personal advancement, such as the gaining of education or inspiration, was negatively related to Latinos reported levels of environmental responsibility. Through qualitative analysis, participants identified additional factors that influenced their levels of responsibility, such as personal health and well-being. Results suggest that Latinos' sense of environmental responsibility may be fostered through recreation that promotes connection and is free from demands. Such results may assist agencies and organizations that seek to build and influence Latinos' conservation practices and beliefs.

A1d: FOSTERING EFFECTIVE AGROECOLOGICAL AND AGROFORESTRY PRACTICES FOR SUSTAINABLE TRANSFORMATION AND FOOD RESILIENCE

Fostering effective agroecology and agroforestry for sustainable transformation

Erin Nelson¹

¹University of Guelph, Guelph, Canada (enelson@uoguelph.ca)

Agroforestry and agroecology are increasingly being recognized as having significant potential for contributing to sustainable development, climate change adaptation and mitigation, and food security. This panel brings together researchers and practitioners working in Brazil, Costa Rica, Mexico, Cuba, and Honduras, to share knowledge and identify common themes related to supporting and improving agroecological and agroforestry practices as a means to ensure community resilience through food security, encourage sustainable production in the face of transformation, and foster intergenerational knowledge sharing. All panel members are currently involved in participatory research and outreach with small-scale farmers and are co-producing transdisciplinary knowledge to ensure policies and practices incorporate local knowledge and realities. Panel members will discuss their current research and a moderated discussion will emphasize common challenges and innovative solutions at the local level, while encouraging audience participation. The goal of the panel is to launch a global north-south knowledge sharing network that will build capacity for farmers to transform their agroecosystems into sites that maximize production of socio-ecological services.

Supporting sustainable communities through erva-mate agroforestry systems

Evelyn Nimmo¹ 

¹Universidade Estadual de Ponta Grossa, Ponta Grossa, Brasil (ernimmo@gmail.com)

In Southern Brazil, traditional agroforestry systems, which include the cultivation of erva-mate (a tea commonly consumed in Southern Latin America), are being threatened by increased pressure on farmers to deforest their lands and move toward monocrop systems. As a result, rates of deforestation in the region have risen dramatically and small-holder farmers are facing issues related to food security, poverty, and loss of traditional knowledge. Our team is working with local community members, government institutions and NGOs to document these traditional life-ways and develop networks of knowledge to support local community members in sharing knowledge about food heritage and culture and supporting sustainable practices that ensure the continuation of traditional food procurement practices and natural forest ecosystems.

The tree species *Cordia allcocca* (L.) and its potential for agroforestry systems in Cuba

Maria Teresa Martinez¹, Mariol Morejon Garcia¹, Angel Leyva²

¹University of Pinar Del Rio, Pinar Del Rio, Cuba; ²Instituto Nacional de Ciencias Agricolas, San Jose de Las Lajas, Cuba (aleyva@inca.edu.cu; morejongarciamariol@gmail.com; luleyva@yahoo.es)

The tree species *Cordia allcocca* (L.), known by the common name ateje, was described in 1953 as a plant of economic interest for Cuba. During the first half of the 20th Century, it was used extensively by campesino communities in the province of Pinar del Rio, primarily for the nutritional value of its fruit for fowl and pig feed. As Cuban farmers gained increased access to imported animal feed, the plant was gradually forgotten. As a result, its current presence in agroecosystems is scarce. In 2013, an in-depth ethnobotanical study of the atejewas begun, and the research found the species to have more than 20 useful properties. It was also found to have a high level of resilience to adverse impacts of a changing climate. Some of its other useful properties include: high growth levels; nutritional value of its fruit; functions as a sanctuary for wild fauna; maintains high quantities of organic material in its leaves. Phytochemical analyses of the tree fruits found high levels of reductive compounds, free amino acids, carotenoids, and flavonoids, of high value for industry. Laboratory testing also found an abundance of reductive sugars and protein in its fruits. Introducing the species to agroecosystems was found to have multiple economic benefits. The research has allowed us to establish as yet unpublished benefits of this species, which have been (and will be) explored through a process of strategic introduction of the trees into local agroecosystems in Pinar del Rio, without reducing land cover dedicated to other crops.

Organic and agroecological orange production: technology diffusion to organized small-scale producers in Veracruz, Mexico

Laura Gomez¹

¹Universidad Autonoma Chapingo, Chapingo, Mexico (gomezlaura@yahoo.com)

Oranges are the most important fruit crop in Mexico, occupying 335, 336 hectares, from which 4.6 million tons are harvested annually, primarily in the state of Veracruz (SIAP, 2017). The majority of the orange production in Veracruz is conventional, using pesticides (primarily Glyphosate), which represents a series of threats to sustainability, fruit quality, and the health of the fruit producers and consumers (Plengue, et. al., 2007). Twelve years ago, one orange farm began

to introduce agroecological practices, innovating various processes, and managing to yield three times more than the average for conventional producers in the region. At the same time, prices for the crop were at least double the conventional price, and costs of production were 22% less. Since 2014, this “mother farm” has served as a base for sharing the technologies used with organized small-scale producers from cooperatives in 10 municipalities. The techniques used include compost, rock flours, reproduction of locally-sourced beneficial microorganisms, mineral washes (e.g ash, lime sulphur), legumes as cover crops, agro-homeopathy, pruning, diversification of non-crop species, living barriers, and farm diversification (e.g. coconut, avocado, noni, other citrus). The Centre for Interdisciplinary Research for Rural Development (CIIDRI) at the Chapingo Autonomous University is leading this process, with a participatory action research methodology that favours knowledge exchange amongst different actors and the development of human resources in the university as well as technicians in the region.

Food systems in Canada’s Northwest territories

Andrew Spring¹

¹wilfrid Laurier University, Waterloo, Canada (aspring@wlu.ca)

Food systems in Canada’s Northwest Territories (NWT) rely on the availability of traditional foods that are harvested, hunted or gathered from the boreal forest. The health of the people is linked to the health of the land, water and forest ecosystem. Climate change is having profound impacts on northern ecosystems and is impacting availability of and access to traditional food sources. For many communities where food insecurity is already an issue, these impacts can further threaten food systems, health and well-being. Many communities, such as Kakisa, NWT, are turning to local food production, or small-scale agriculture, as a way to address these issues and provide fresh, healthy food and avoids the high cost and environmental impacts of purchased food in these remote communities. As climate change continues to impact the NWT, there are opportunities for local food production, as temperature warms and ecosystems shift. It is therefore important to ensure that agriculture is developed in a way that meets the needs of local residents, is culturally relevant, and contributes to the resilience of the boreal forest. Food systems in the NWT already align closely with principles of agroecology, therefore sharing knowledge, research and experiences with partners that practice agroecology can inform how communities such as Kakisa move forward with agriculture in both practice and policy.

Tree-dominated landholdings ensure food and nutritional security

Kamal Melvani^{1,2}

¹Neo Synthesis Research Centre, Polgasowita, Sri Lanka; ²Charles Darwin University, Darwin, Australia (neosynth@slmet.lk)

Food and nutritional security are serious issues in Sri Lanka where assessments mainly focus on per capita availability of staple foods and individual crop yields. Alternately, tree-dominated landholdings covering 22% of Sri Lanka’s land area ensure continuous access to and availability of nutritious food through time and assure livelihood stability. To test this hypothesis, food and nutritional security provided by tree-dominated landholdings were assessed across wet and dry seasons of the reference year and 100 years. Floristic inventories were undertaken in 85 landholdings across the Intermediate zone. Crops harvested in the reference year were classified into Very Short-(vegetables, leafy vegetables, cereals, pulses), Short-(root, herb), Long- (fruit, spice trees) and Very Long-term (fuelwood, timber trees) categories based on times of first return. Crop utilities, nutrient values and phenologies were retrieved from literature. Farmers cultivated various crops for food, fuelwood, timber and income, and most were from the Long-term category. Households were nutritionally secure because 75% of crops provided food with the full complement of macronutrients, while Long- and Very Short-term crops were especially micronutrient-rich. Households were food secure because diverse crop phenologies ensured the availability and access to food and income through wet and dry seasons of the reference year and continuously for 100 years. Consistent revenue lent stability to households and provided purchasing power to buy food when cultivation failed. Crop diverse, tree-dominated landholdings in Sri Lanka provide livelihood stability and alleviate food and nutritional insecurity. They have similar potential in other food and nutrition insecure countries.

Agroforestry adoption as a systems concept: a review

Dagninet Amare¹, Jurgen Pretzsch², Dietrich Darr³

¹Amhara Regional Agricultural Research Institute, Bahir Dar, Ethiopia; ²TU Dresden, Tharandt, Germany; ³Rhine Waal University of Applied Sciences, Kleve, Germany (dagnnet@gmail.com; pretzsch@forst.tu-dresden.de; dietrich.darr@hochschule-rhein-waal.de)

Adoption of innovations is central to improved livelihoods of smallholders and agricultural modernization. Nevertheless, the best suit leading to optimum adoption rates remains blurred amidst several decades of research and development work. The paper employs both qualitative and meta-analysis to summarize the theoretical and empirical studies conducted in the past three decades in agroforestry adoption practice and research. Literature from innovation, social networks, diffusion, and adoption of agricultural innovations are explored to systematically analyze the main outputs of adoption studies. The gaps and progress are then discussed with benchmarks from previous research need recommendations and recent theoretical and analytical propositions. Overall, 23 variables have been often used in 34 econometric models spanning 24 studies to examine the intensity and adoption of different agroforestry innovations. Qualitative and descriptive analysis, however, provided better explanations by exploring additional perspectives away from the overriding socioeconomic variables in econometric models. While risk and uncertainty have been loosely explored by insufficiently defined proxy variables, profitability has not been part of the analysis of agroforestry adoption studies. There is a need to fine-tune the visualization of the adoption concept and adjust analytical defaults to get robust recommendations from agroforestry adoption studies to inform policy and action as well as for designing optimal agroforestry extension interventions.

India’s right to food act: human rights for tribal communities’ forest food

Purabi Bose¹

¹Landing Together, Mumbai, India (purabibose@gmail.com)

India’s National Food Security Act, 2013 marks a historic shift from a welfare-based to a rights-based approach to food security. The importance of ‘wild’ food gathered from landscapes like forests, water, mountains, grasslands – or lack thereof – for food and nutrition security of indigenous peoples and pastoralists remains underexposed. This evidence-based paper examines forest-based food cultures vis-à-vis the Act’s subsidized food grains. This paper proposes a ‘right to forest food’ governance framework to analyse the data. Primary data was collected from 12 distinct indigenous communities living in tribal India. This study result shows that agri-food and not forest food is promoted by the Act’s public distribution system, which is ill suited to ensure indigenous peoples’ food security. The paper highlight implications of ‘cultural acceptability’ and Aadhar - identity card regulations in the human right to food.

A1e: RISING ISSUES IN MOUNTAIN FORESTS AND MOUNTAIN FOREST MANAGEMENT**Global analysis of the share of steep slope in forest land**Mikael Lundbäck¹, Carola Häggström¹, Tomas Nordfjell¹¹Swedish University of Agricultural Sciences, Umeå, Sweden (mikael.lundback@slu.se; carola.haggstrom@slu.se; tomas.nordfjell@slu.se)

There are many different ways of harvesting and extracting roundwood around the world. While analyzing why certain harvesting methods are dominant in certain countries in a bigger context, it became apparent that there are no available statistics of the share of steep slope in forest land that are comparable between countries. At the same time steep slopes have traditionally been a limitation for the cut-to-length harvesting method with rubber wheeled harvester and forwarder, so it was considered as an important variable to control in the larger analysis. A Geographic Information System (GIS) analysis was performed in the open source QGIS software, version 3.2. The core of the analysis is a digital elevation model (DEM) and to cover all 29 studied countries in this case four different DEM:s was used, most commonly with resolution ~90 meters. To convert the DEM data from elevation to slope a built in tool in QGIS was used. All pixel values <20° was set to zero and the rest to one. A raster dataset of land cover was used in combination with the DEM:s to mask away all land other than forest land. The rasters of “slope” and “forest” were combined in the QGIS raster calculator and the resulting raster consisted of forest land with slope > 20°. When that figure was related to the total forest land a percentage was extracted and demonstrated for all countries in a figure. This result can be used as base facts in many contexts where countries are compared.

Forest operations in mountainous areas: a challenging questionRaffaele Cavalli¹  Omar Mologni¹ ¹Dept. TESAF - University of Padova, Legnaro, Italy (raffaele.cavalli@unipd.it; omar.mologni@hotmail.it)

Mountainous forests are crucial sources of wood, especially in an increasingly urbanized world, where the global timber trade is expanding rapidly and around the world the forest industry is facing challenges in accessing wood fibre on steep terrain. Steeper slopes require alternate harvesting systems such as cable yarding, helicopter, and hand falling but these options are more expensive and much more hazardous relative to mechanized ground-based harvesting operations. New machines available today equipped with specialized undercarriages and carriers or with assisted traction devices have been shown to safely access and operate on terrain up to 70-80% slope. With the exponential development of technology, an integrated approach must be developed for conducting productive, injury-free and environmental friendly mechanical harvesting operations on steep slopes. Considering productivity, safety and environmental impacts, two technologies for logging operation in steep terrain forests (i.e. cable logging and ground-based assisted forwarding) will be compared adopting simplified multi criteria analytical procedure. A number of factors, both quantitative and qualitative, will be taken into consideration in order to assess the level of competition between the two technologies and to define the proper field of application. The results will be useful to evaluate the efficiency of the technologies, in the broad sense of the term, and to consider which will be the improvements needed to increase the safety of work and to fit the environmental constraints.

Comparison of erosion potential between manual and cable-assisted mechanized felling on steep slopes: a case study in Southern Oregon, USABrett Morrisette¹, Woodam Chung¹, Kevin Bladon¹, Ben Leshchinsky¹, Jeffery Hatten¹, Joh Sessions¹¹Oregon State University, Corvallis, USA (brett.morrisette@oregonstate.edu; woodam.chung@oregonstate.edu; kevin.bladon@oregonstate.edu; ben.leshchinsky@oregonstate.edu; jeff.hatten@oregonstate.edu; john.sessions@oregonstate.edu)

Cable-assisted logging systems are a relatively new technology being used on steep slopes in the Pacific Northwest, USA. We will present preliminary results from a study comparing traditional manual timber harvesting practices with a cable-assisted, mechanized timber cutting system. Approximately 2 hectares of the 18 hectare harvest unit were manually using a chain saw, and the remaining area was harvested mechanically by a cable-assisted feller-buncher. Timber in both areas was then extracted using the same cable logging system. After cable logging, in late fall 2018, we installed erosion fences in (a) skyline corridors in cable-assisted machine felling areas, (b) skyline corridors in manual felling areas, and (c) cable-assisted machine tracks. Our objectives are to quantify differences in soil erosion and sediment transport between harvest types. We installed 4 pairs of soil moisture probe clusters (10, 20, 30, 40, and 50 cm depth) along machine tracks and minimally disturbed ground in the cable-assisted timber harvesting area to quantify soil water content. We will present preliminary results of overwintering and partial summer erosion, sediment delivery, and soil moisture impacts from the two forest harvesting treatments. To facilitate interpretation of the erosion data, we are also collecting data on post-yarding ground based LIDAR, precipitation intensity and total, and pre- and post-treatment bulk density, soil strength (penetrometer), soil water content, and saturated hydraulic conductivity. This study is expected to provide insights into the relative impacts of steep slope cable-assisted harvesting operations on runoff and erosion compared to the traditional manual timber felling and cable-logging.

Utilization potential of unused broadleaved tree stands harvested with simple rigging cable systems on mountainous areaYasushi Suzuki¹  Tetsuhiko Yoshimura²¹Kochi University, Nankoku, Japan; ²Shimane University, Matsue, Japan (ysuzuki@kochi-u.ac.jp; t_yoshimura@life.shimane-u.ac.jp)

How treat unused broadleaved tree stands have been one of major issues in Japanese forestry sector. Such stands provided fuel woods and non-timber commodity products before modern industrialization. No treatment over some decades degraded the stands, hence it has been said to have fostered oak mortality diseases and invasion of bamboo forests. Recent ecological research achievements have proved that appropriate treatment, i.e., thinning and regeneration cutting, recover such forests to be in ecologically sound condition. However low log price has been an obstacle to conduct such treatment because its cost exceeds income from the harvest in most cases, especially in mountainous area. Recent forest machine development and enhanced technique of forest road construction have improved operational efficiency and cost reduction for harvesting man-made forests, mainly consisted of cedar, cypress, and pine. Application of these developments over the treatments of the unused broadleaved tree stands is one possible answer. The authors have been researched on cable systems with simple rigging methods and found that they especially suitable for small scale harvesting operations combined with appropriate forest road networks. The present study assesses utilization potential of unused broadleaved tree stands on mountainous area by three aspects: 1. resource management, i.e., species and size distribution, 2. operational efficiency and cost of harvesting simple rigging cable systems, and 3. effect of treatment, i.e., harvesting, on remaining stands.

The challenge of sustaining the integrity of forest soils in mountain regions

Klaus Katzensteiner¹

¹University of Natural Resources and Life Sciences (BOKU), Vienna, Austria (klaus.katzensteiner@boku.ac.at)

The sustainable provision of ecosystem services of mountain forests closely depends on the integrity of soils. As soil formation is a slow process, from a human perspective, soils are a non-renewable resource. In many regions, in particular of the Global South, the integrity of mountain forests soils is under threat. The expansion of agriculture by smallholder farmers into steep slopes enhances soil erosion; unregulated cattle grazing causes soil compaction; intensive biomass extraction leads to nutrient depletion and a decrease of humus content of the soil. Moreover, recent climatic changes alter the carbon and nutrient turnover in soil and change the disturbance regime, again causing feedback on soil conditions. On the other hand, financial incentives from offset strategies for greenhouse gas emissions offer chances for improved forest management. Measures for sustainable management and ecosystem restoration have to take into account both, the changing ecological site conditions as well as specific societal demands and economic situations. Communities in Nepal and in the Ethiopian highlands, where carbon offset projects with a strong focus on sustainable management of forest resources have been initiated are our 'living labs'. In the pilot projects, land users are participating at all stages: from research to planning and implementation of measures. It can be demonstrated, that participation is a successful strategy for establishing a certain tree cover: enclosures on erosion prone slopes, selected, afforested and protected by the community as well as on farm trees provide extra resources, thus reducing the pressure on the natural forest.

Tree mortality and recruitment in a high mountain coniferous stand on Mt. Jiri, Korea

Pil Sun Park¹, Jong Bin Jung¹, Hyun Jung Kim², Ahreum Han³

¹Seoul National University, Seoul, Republic of Korea; ²Baekdu-daegan National Arboretum, Bonghwa, Republic of Korea; ³National Institute of Ecology, Seocheon, Republic of Korea (pspark@snu.ac.kr; jb1373@snu.ac.kr; sophie.kim@bdna.or.kr; subalpine@nie.re.kr)

The decline of high mountain coniferous forests has been reported worldwide since 20th century. Global warming and unexpected weather events were suspected to be the major cause of the decline and became one of the important disturbance factors in mountain forests. Diverse disturbances occur on high mountains depending on the region. Windthrow and landslide can result in tree mortality by a discrete event, while drought stress works as a chronic disturbance, resulting in gradual degradation of forests. Individual tree mortality and recruitment were monitored in a Korean fir (*Abies koreana*) old growth stand in 4-year intervals for 12 years. Most species showed fluctuation of mortality, however, the mortality of Korean fir and Korean birch (*Betula costata*) continued to increase, showing the highest mortality among tree species in the study area. The density decrease was 18% for Korean fir and 73% for Korean birch from 2005 to 2017. About 1/3 of dead Korean fir had DBH larger than 20 cm. The ratio of seedling recruitment to tree mortality of Korean fir and Korean birch was about 0.1 and 0, respectively. Most species with seedling recruitment were subtree or shrub species except Korean fir and *Acer pseudosieboldianum*. The stand experienced typhoon almost every year and three to four windthrow events occurred during the study period. Unusual temperature increase in early spring also occurred recently.

The legacy of Pre-Columbian fire on the pine-oak forests of Upland Guatemala

William Harvey^{1,2}, Sandra Nogue³, Nathan Stansell⁴, Gillian Petrokofsky¹, Byron Steinman⁵, Katherine Willis¹

¹University of Oxford, Oxford, United Kingdom; ²St Edmund Hall Oxford United Kingdom; ³University of Southampton, Southampton, United Kingdom; ⁴Northern Illinois University, de Kalb, USA; ⁵University of Minnesota Duluth, Duluth, USA (william.harvey@seh.ox.ac.uk; s.nogue-bosch@soton.ac.uk; nstansell@niu.edu; gillian.petrokofsky@zoo.ox.ac.uk; bsteinma@d.umn.edu; kathy.willis@zoo.ox.ac.uk)

Mountain tropical forests of the Southern Maya Area (Pacific Chiapas and Guatemala, El Salvador and Northern Honduras) predominantly comprise pine and oak formations, which form intricate mosaics and complex successional interactions following large-scale fire. These forests have been transformed by the peoples of the Maya civilization through practices of horticulture, agriculture and architectural developments over thousands of years. In this study we identify: (i) the natural baseline vegetation of the region; (ii) when human impact and agrarian practices began in the Maya uplands; and (iii) what impacts the Maya had on forest structure, composition, and successional regeneration. Past vegetation, anthropogenic use of fire, and faunal abundance were reconstructed using proxy analysis of fossil pollen, macroscopic charcoal, microscopic charcoal, and dung fungal spores (*Sporormiella*). Three phases of forest succession were identified over the past 6,000 years broadly pertaining to the well-defined archaeological periods of (i) the Archaic (10,000-2000 B.C.); (ii) Pre-Classic (2000 B.C. – 100 A.D.); and (iii) Terminal Pre-Classic (100-250 A.D.), Classic (250-950 A.D.), and Post-Classic (950-1522 A.D.). Persistent high intensity burning during the Late-PreClassic to Classic Period resulted in a compositional change of forest structure c.150 B.C. from oak (*Quercus*) dominated forests to pine (*Pinus*) dominated forests. We present the earliest evidence for agriculture within the Southern Maya Area through presence of peppers (*Capsicum*) from 3850 B.C. and the rise of maize cultivation (*Zea mays*) from 970 B.C. The legacy of Pre-Columbian anthropogenically driven fire in these mountain tropical forests demonstrates the resilience and thresholds for fire driven succession.

Assessing ecosystem services from mountain forests

Himal Baral¹

¹Center for International Forestry Research, Bogor, Indonesia (h.baral@cgiar.org)

Mountain forest ecosystems provide a wide range of direct and indirect contributions to the people who live in the mountains and surrounding areas. Occupying steep slopes at high elevation, these ecosystems provide services such as stabilizing slopes, regulating hydrological cycles, maintaining rich biodiversity and supporting the livelihoods of those who are diverse in culture but vulnerable to poverty and food security. To manage these services sustainably, their diverse values must be recognized, assessed and valued. To support this assessment, this paper 1) reviews several tools for assessing the sociocultural, economic and ecological values of mountain forest ecosystem services, 2) demonstrates case studies of tool applications from several countries namely, Bhutan, India, Indonesia, Iran and Nepal, and 3) discusses assessment challenges that should be considered in the application of these tools. Several challenges exist for the assessment of mountain forest ecosystem services and these must be reflected in assessment design. These challenges include the complexity of defining and classifying ecosystem services; limited availability of data on ecosystem services; uncertainties associated with climate change; complex relationships among services including trade-offs and synergies; and limitation of assessments to build successful payments for ecosystem services.

A1f: ASSESSING THE CULTURAL ECOSYSTEM SERVICES FROM FORESTS: CURRENT CHALLENGES AND FUTURE SCOPES

Non-timber forest product as cultural ecosystem services: a case study from the Western Ukraine

Nataliya Stryamets¹, Giulia Mattalia¹, Renata Sökand¹

¹Ca' Foscari University of Venice, Venice, Italy (natastr@gmail.com; juliamattalia@gmail.com; renata.soukand@unive.it)

Forests provide a diversity of tangible and intangible benefits for sustaining local rural livelihoods. The analysis of the intangible benefits provided by forest landscapes have been highlighted as significant research question recently. Within the framework of intimate human-nature interaction, the aim of our research was to analyze the role of non-timber forest products (NTFPs) as cultural ecosystem services for rural residents in the Carpathian Mountains and Roztochya, Western Ukraine. We conducted seventy-two in-depth semi-structured interviews with local rural residents during summer 2018 to understand the role of forest resources as cultural ecosystem services, focusing on spiritual uses of different plant and mushroom taxa. Despite the severe restrictions of performing religious rituals for over fifty years (1939-1991), we found a richness of used rituals and NTFPs. Our results show the celebration of ten religious feasts among Christians in the region, in which 40 wild plant (most important *Salix* sp., *Acorus calamus*, *Armoracia rusticana*) and 12 mushroom taxa (most important *Boletus* sp., *Leccinum* sp.) were employed as ritual food and as ornamental decorations. We discuss the need to maintain cultural use of NTFPs, especially in Western Ukraine. We conclude that the role of NTFPs as cultural ecosystem services for local livelihoods is crucial. Moreover, cultural values and human-nature interactions are irreplaceable and secure the preservation of cultural heritage. This project has received funding from the ERC (grant agreement No 714874 [https://cordis.europa.eu/project/rcn/208447_en.html]).

The LandsCare system: a tool to add value to cultural ecosystem services / Sistema LandsCare: ferramenta para a valorização dos serviços ecossistêmicos culturais

Michele Benetti Leite¹, Pablo Martínez de Anguita^{2,3}

¹LandsCare, Santa Maria, RS, Brasil; ²Universidad Rey Juan Carlos, Madrid, Spain; ³LandsCare Madrid Spain (micheleleit@gmail.com; pablo.martinezdeanguita@gmail.com)

É cada vez maior a pressão sobre os ecossistemas, especialmente os florestais, muitas vezes por falta de alternativas sustentáveis que superem o custo de oportunidade da terra. É preciso encontrar mecanismos pelos quais a sociedade que se beneficia da riqueza natural possa contribuir à sua conservação, apoiando seus proprietários. Uma das alternativas mais utilizadas para fomentar a conservação são os esquemas de pagamento por serviços ecossistêmicos (PSE), que pretendem captar e reverter parte dos benefícios que a conservação do patrimônio natural e cultural geram à sociedade. Entretanto, os projetos são normalmente com foco em carbono ou recursos hídricos, e os serviços culturais são negligenciados. No caso, os PSE por serviços culturais florestais, são sistemas que tentam capturar o valor intangível destes serviços (e que não possuem mercado), para assim compensar aos responsáveis pela sua conservação. Por isso o aplicativo LandsCare surge como uma proposta inovadora de interpretação da paisagem com foco nos serviços ecossistêmicos de beleza cênica (incluindo os culturais) e de biodiversidade, buscando dar visibilidade ao território, agregando valor à paisagem, aos seus valores culturais e a quem torna isso possível. LandsCare é uma ferramenta prática pois auxilia na valoração desses serviços através do método de valoração contingente que está inserido nele, pois cada usuário destina, de forma pessoal, um valor ao micropagamento, que é destinado diretamente ao provedor dos serviços. O usuário do aplicativo tem informação georreferenciada sobre natureza, cultura, trilhas, onde comer e hospedar-se, produtos típicos e guias locais na zona em que se aplica LandsCare.

Forests, people and biodiversity: Chiles national integrated monitoring of forest ecosystems

Sabine Müller-Using¹, Carlos Bahamondez¹, Jaime Valdes²

¹INFOR, Valdivia, Chile; ²FAO, Santiago, Chile (smuller@infor.cl; cbahamon@infor.cl; jaime.valdes@fao.org)

Chile hosts an extraordinary diversity of ecosystems as its natural forests cover 13.6 million ha and possess almost one-third of the world's few remaining large tracts of relatively undisturbed temperate forest; 70 % of these forests are private and were regulated since 2008 by a "Native Forest Law". The government of Chile has developed relevant instruments to monitor these forest ecosystems, namely the Vegetation Cadaster and the National Forest Inventory (NFI), which have led to improved policies and practices stopping overall deforestation. However, two major concerns remain. One is the continuous degradation of forests (an estimated 58⁰44 ha/year according to the national reference level of forest emissions). The second issue is the increasing demand of wood biomass to cover household heating demand, which imply a threat to the forest ecosystem integrity. For adequate monitoring, Chile created the "Integrated national Monitoring System on Forest Ecosystems" in support of policies and Sustainable Forest Management practices incorporating REDD+ and biodiversity conservation. It was built upon a holistic model considering a wide range of socioeconomic and biodiversity variables. The system includes the permanent participation of the society concerned, ensuring a governance model for monitoring at scales from the local to the national. For its implementation, it was necessary to create an inter-institutional coordination and management structure and to free data for its use by national and local policy and regulation formulators. First results show the usefulness of this system to initiate landscape restoration processes with a territory focus in three geographically very different areas.

The Paraná pine (araucária) and the cultural landscape in the colonial center of Paraná, Brazil / A araucária e a paisagem cultural em núcleo colonial paranaense

Janice Bernardo¹, Marcelo Langer¹, Luciane Regina Meira Bastos Camargo², Camila Sanchothene¹, Viviane Gariba³, Marcio Pereira da Rocha¹

¹Eng. Florestal Universidade Federal do Paraná, Curitiba, Brasil; ²Faculdade Estácio Curitiba, Curitiba, Brasil; ³SESI Curitiba, Curitiba, Brasil (janicebs@gmail.com; malanger04@yahoo.es; lucianebastos.psi@gmail.com; camilasanchotene@gmail.com; viviane.gariba@gmail.com; mprocha01@gmail.com)

No final do século XIX imensas florestas da Mata Atlântica, ricas da espécie *Araucaria angustifolia*, cobriam o Estado do Paraná. Na colônia Murici, fundada em 1878, localizada em São José dos Pinhais, a araucária foi a primeira fonte de renda, era picada e vendida como lenha em Curitiba, foi também utilizada para construir pontes, carroças e as casas. Troncos inteiros eram encaixados nas extremidades e constituíam as paredes das "casas de troncos", o trabalho era comunitário e artesanal. Prevaleceu a instalação dos imigrantes poloneses que trouxeram consigo o conhecimento das técnicas agrícolas e das técnicas construtivas, o saber fazer da carpintaria e de outras tradições do país de origem. A madeira obteve importância econômica e social, o pinheiro e o pinhão constituíram os elementos simbólicos do espírito Paranaense alcançando importância artística e cultural. O objetivo do estudo é avaliar a relação da floresta de araucária com a paisagem cultural da Colônia Murici. A

metodologia consiste na aplicação de questionários usando a Avaliação Social do Ciclo de Vida (ACV-S) que define os principais grupos de interesse e as subcategorias de impacto social, entre eles os residentes da colônia e descendentes dos imigrantes, os religiosos, os gestores e os turistas. Busca desse modo analisar o reconhecimento dos valores ambientais e culturais locais. Visa compreender a relação homem natureza e os valores que as sustentam, a fim de viabilizar a motivação responsável da sociedade na promoção da qualidade de vida e das ações de preservação do patrimônio natural, material e imaterial da região.

Alternative management models for addressing emerging demand on forest-based cultural services: a case-study in Northern Italy

Giulia Corradini¹, Mauro Masiero¹, Davide Pettenella¹, Ilaria Doimo¹, Paola Gatto¹

¹University of Padova, Padova, Italy (giulia.corradini@unipd.it; mauro.masiero@unipd.it; davide.pettenella@unipd.it; ilaria.doimo@phd.unipd.it; paola.gatto@unipd.it)

Scientists and practitioners are paying growing attention to forest-based cultural ecosystem services (ES), including Forest Care Initiatives (FCIs). FCIs are organized initiatives supporting active and passive interaction with forests, aiming at increasing human health, wellbeing and quality of life. The use of forests for cultural, recreational and therapeutic uses may represent an opportunity for valuing forest resources and supporting development in marginalized areas. However, this requires new management solutions as well as tailored planning and forest management models (FMMs). The paper analyses the case of the Lowland Forest Association (AFP), a network of forests located in Northern Italy, close to densely populated and touristic sites along the Adriatic Sea. Within the European Union Horizon 2020 project ALTERFOR, current FMMs and stakeholder's ES needs/priorities have been identified via field surveys, meetings and interviews. Data have been then analysed, discussed with experts and modeled to set alternative FMMs and to assess the basket of ES associated to them. It has emerged that cultural ES, including FCIs, are paramount for local stakeholders, however FMMs for promoting them are not limited to technical aspects, rather they shall include mechanisms to enhance governance of forest resources. Alternative FMMs -including group forest management solutions, new investment mechanisms to attract investors, ad hoc initiatives, etc. -shall combine silvicultural choices and arrangements to favor cooperation among different actors. Results from the AFP case study may provide useful insights to inform future policies and inspire research activities on management choices for the provision of forest-based ES.

Tourism in the forested landscape close to urban areas: Parco Regionale dei Castelli Romani case study

Magdalena Pichlerova¹, Roman Sitko¹, Igor Gallay¹, Zuzana Gallayova¹, Andrea Diviakova¹, Hana Ollerova¹, Andrea Zacharova¹, Zuzana Perhacova¹, Adela Wieszikova¹

¹Technical University in Zvolen, Zvolen, Slovakia (magi.pichler@gmail.com; sitko@tuzvo.sk; gallay@tuzvo.sk; zgallayova@gmail.com; andreadiviakova@gmail.com; hana.ollerova@tuzvo.sk; andrea.m.zacharova@gmail.com; zperhacova@gmail.com; a.wieszikova@gmail.com)

Different forms of tourism with properly secured infrastructure can encourage the arrival of tourists to the region together with an economic benefit. Planning is essential to minimize any impact of human activities and to support the functioning of natural processes. Recently the demand for products and services relating more to health and well-being are on rise, especially in forested areas. This is also supported by results of the public survey we carried out in Italy in 2017. It can be stated that forests for people represent especially the source of relaxation and clean air, rather than the source of wood. Our poster represents the case study focused on development of soft (health) tourism in forested landscape close to Roma. Our study area lies within the Parco Regionale dei Castelli Romani and belongs to the Colli Albani volcanic complex. The dominant nature feature of the area is lake Nemi. We focused our attention on its basic natural environment characteristics as well as local features (e.g. exposure of mostly used public areas and trails to direct sunlight). Important input data is on vegetation and quantification of its direct and indirect benefits, as well as determination of possible risks (e.g. allergenic plants, etc.). Introduced is also the Trail assessment decision check-list for measures proposal, to help various subjects to evaluate trails condition. Further, we created land cover and land use characteristics and classification with the use of a very high resolution satellite images, supplemented by assessment of vegetation change over the year 2017.

Economic valuation of remaining carob trees through direct and indirect benefits to conserve the biocultural landscape, a foundation for quality of life / Valoración económica del relicto de algarrobos, por beneficiarios directos e indirectos para la conservación del paisaje biocultural, fundamento del vivir bien

Huascar Camacho¹

¹Universidad Mayor de San Simón, Cochabamba, Plurinational State of Bolivia (huascachoo@hotmail.com)

En la comunidad de Tiataco, municipio de Arbieto, Cochabamba, Bolivia, existe un relicto de 12 hectáreas de algarrobos centenarios que por muchísimos años estuvo haciendo solo presencia paisajística, sin que la comunidad y sus habitantes puedan aprovechar de la diversidad de los servicios ambientales que brinda el bosque. Para demostrar el potencial integral del relicto, se desarrollaron junto a los comunarios, actividades teórico prácticas, que permitieron identificar su valor socio-económico, cultural e histórico. Se aplicó la metodología de valoración contingente con formato binario, entre beneficiarios directos (familias de la comunidad), e indirectos (residentes en la ciudad de Cochabamba, 35 km de Tiataco) obteniendo como resultado, la disposición a pagar por los beneficiarios directos 58,42 Bs/año (8.39 USD/año) y de 105.288 Bs/año (15.12 USD/año) por los indirectos (tipos de cambio septiembre 2018, B.C.B.: 1 \$US = 6,96 Bs). Con los resultados de la valoración económica, se implementaron acciones de conservación y manejo silvicultural, como de recuperación de saberes bioculturales que promueven y dinamizan relaciones de equilibrio y armonía entre el hombre y la naturaleza, junto con la creación de modelos de desarrollo económico local. La recuperación de saberes locales desde el ámbito social y antropológico, permitió implementar actividades de Jornadas turísticas, socio, culturales pedagógicas que recuperan los ritos, costumbres y tradiciones de la cosmovisión andina, practicadas en el Aya Markay quilla (noviembre, mes de retribución con los difuntos) como son La Wallunk'a nativa y el Mast'aku, manifestaciones vivas referentes a la Vida y la Muerte.

AIg: AGROFORESTRY AND PRODUCTION OF NONWOOD FOREST PRODUCTS

Incorporation of non-timber forest products in forest plantation: case study on the growth and yield performance of NTFPS in modified Taungya System

Rita Baaba Abekah¹, Regina Yeboah¹

¹Resource Management Support Centre, Kumasi, Ghana (ritabaabaabekah@yahoo.com; oforiataregina@yahoo.co.uk)

The Forestry Commission of Ghana has adopted forest plantations as a strategy to ensure landscape restoration, enhance environmental quality and develop a sustainable resource base to satisfy future timber demands. Modified Taungya System (MTS) is a co-management system between the Forestry Commission and smallholder farmers that allows inter-cropping of timber and food crops. Practitioners and farmers observed decline in NTFPs from the wild which in recent

times have become a threatening to source of livelihood that often contributes significantly to household incomes. NTFPs were introduced in MTS to engage farmers to protect the forest from wildfire and decrease theft incidences. However, farmers had to leave these lands because their crops were not doing well during canopy closure. Grains of paradise amongst others were found to do well under shade but the best silvicultural practice to apply is indefinite. This study was undertaken to research and determine the best condition (spacing, % of shade, height and yield) suitable for Grain of Paradise cultivation. Primary data was used to gather information. The results show that growth of the Grains of Paradise can grow and yield under both stands (*Teak* and *Cedrela*). However, GoP under *Teak* stand with planting distance of 4X4 and shade cover 84%-86% was found as the suitable condition for GoP productions in terms of growth and yield. Recommended that the Production of GoP should be introduced to other MTS farmers and interested farmers throughout the country as an alternative livelihood.

Bamboo agroforestry in East China: models and their socioeconomic importance

Xiaoniu Xu¹, Qin Wang¹, Jingjing Wang¹

¹Anhui Agricultural University, Hefei, China (xnxu6162@163.com; qlsforest@ahau.edu.cn; forest6211@sina.com)

Bamboo is an extremely versatile plant capable of providing ecological, economic and livelihood security to the people. However, there are limited available data to verify the suitability of the system. In this study, an investigation was conducted in eastern China to analyse the potential socioeconomic and environmental benefits of Moso bamboo (*Phyllostachys pubescens*) based agroforestry and accentuate implications on sustainable rural development in the region. Bamboo forests are a typical forest type in Southern China, representing an area of 6.16 million hectares, and more than 70% of the bamboo forests consist of Moso bamboo. Bamboos play a major role in the livelihood of rural people and rural industry. Results from the investigation showed that there are five models which outmatch most tree species the ability to provide versatility of use. These models include bamboo-tea model, bamboo-medicinal plant model, bamboo-edible fungi model, bamboo-poultry model, and bamboo-tree mixed forest. With comparison to the mono-bamboo system, the economic benefits increased 1 to 4 times for these models. The benefit-cost ratios varied from 2.19 to 3.52. The maximum income in Moso bamboo - *Bletilla striata* (precious Chinese medicine) model reached US\$ 2.32×104/ha/yr. In addition, soil organic carbon, and available nitrogen and phosphorus increased in the intercropping systems. Therefore, bamboo-based agroforestry systems are expected to open new income streams by diversifying agroecosystems and offering multiple economic benefits, which can contribute to rural poverty reduction and improved livelihoods in the hilly area.

Effect of light and nutrient availability and planting methods on the productivity of *Adenophora divaricata* and *Heracleum moellendorffii*

Byung Bae Park^{1,2}, Woo Bin Youn¹, Aung Aung¹, Si Ho Han¹, Huong Thi Thuy Dao¹, Jeong Min Seo¹, Ser-Oddamba Byambadorj¹, Se Bin Kim¹

¹Department of Environment and Forest Resources, Chungnam National University, Daejeon, Republic of Korea; ²Korean Society of Forest Science Seoul, Republic of Korea (bbpark@cnu.ac.kr; younwoobin95@gmail.com; aungaung1361986@gmail.com; bupleurumhan@cnu.ac.kr; thuyhuong.150495@gmail.com; jmseo3@naver.com; seroddamba@gmail.com; sbkim@cnu.ac.kr)

In the agroforestry system, woody plants can affect the quantity and quality of produced herbaceous vegetation. So, the relationship between woody plants and herbaceous vegetation is important. To implement successful agroforestry system, it will be necessary to know the characteristics of plants in the microclimate. For this, we studied the effects of artificial shade and fertilizer on productivity of plants. For this research, *Heracleum moellendorffii* (H) and *Adenophora divaricata* (A) was used. We set the three treatments: shade, fertilization and planting method. For shade treatment, 0%, 35% and 55% shading nets were installed in consideration of different light availability in natural forests. As for fertilization, N, P, K 20-20-20 fertilizer was used. And for planting method, single and mixed planting methods were used with 2 species with the idea of inter and intra-specific relationship in nature. And we replicated them three times. As a result, productivity of H was higher in the 35% shading and fertilization treatment and that of A was higher in the 0% shading and non-fertilization treatment than other treatments. Also, when two different species were planted together, it was found that the competition effect was significant, which greatly influenced the growth of other species. Therefore, the success of agroforestry systems depends on the selection and management of appropriate shade tolerant herbaceous species for optimal productivity and sustainability. So, further studies with each factor would help to clarify the relative importance of each factor as limiting factors of yield in agroforestry systems.

Progress and results of agroforestry in Chile: connecting agriculture to the forests / Desarrollo y resultados de la agroforestería en Chile: conectando la agricultura con los bosques

Alvaro Sotomayor¹, Alejandro Lucero¹, Jaime Salinas¹, Arnoldo Villarroel¹, Bernardo Acuña¹

¹Instituto Forestal, Coyhaique, Chile (asotomay@infor.cl; alucero@infor.cl; jsalinas@infor.cl; arnoldo.villarroel@infor.cl; bacuna@infor.cl)

En Chile durante su colonización, y hasta inicios del siglo XX, existieron Políticas de Estado para eliminar bosques, utilizando sistema de cortas y quemadas, para utilizar estos terrenos en actividades agrícolas y ganaderas. Esta política originó que el 49,1% de los suelos se encuentren erosionados, equivalente a 36,8 millones de hectáreas. Los principales factores responsables de esta erosión ha sido la acción humana. Para paliar lo anterior han existido políticas de forestación con fines industriales desde la década del 70, y programas de recuperación de suelos degradados. En Chile se ha estudiado durante los últimos 20 años un modelo de desarrollo agroforestal alternativo al forestal tradicional con fines industriales, con el objetivo de entregar alternativas a los pequeños productores agrícolas, fomentándose la introducción de especies leñosas en los campos considerando su identidad cultural, sistema productivo, y recuperación de suelos. Con esta forma de reintroducción de especies leñosas bajo sistemas agroforestales, se han verificado disminución de procesos erosivos de hasta 1.700% en terrenos con prácticas para cultivos agrícolas tradicionales; reducción del viento hasta un 200% por el establecimiento de árboles en sistemas silvopastorales, originando a su vez un aumento de la producción praterense; uso de cortinas cortavientos aumentando la productividad praterense y cultivos agrícolas hasta 41%. Esta forma de reintroducir árboles en los campos, bajo ordenación agroforestal, ha tenido mejor aceptación en pequeños y medianos propietarios que plantaciones industriales, donde un 93,1% de estos prefieren establecer árboles en un arreglo agroforestal, versus 27,5% que mostraron disposición a forestar con plantaciones tradicionales

A1p: ECOSYSTEM SERVICES AND AGROFORESTRY SYSTEMS IN SOUTH AMERICA

Application of legislation and public policies related to ecosystem services in the Lujan River basin of Argentina, and connections to levels of perception and educational education / La aplicación de normativa y políticas públicas sobre servicios ecosistémicos en la cuenca del Río Luján, Argentina, y su interrelación con los niveles de percepción y de educación ambiental

¹CONICET, INEDES, Luján, Argentina; ²Universidad de Buenos Aires, Facultad de Derecho, Buenos Aires, Argentina (clara.minaverry@gmail.com; cminaverry@mail.unlu.edu.ar)

Pesq. flor. bras., Colombo, v. 39, e201902043, Special issue, p. 1-768, 2019

La Cuenca del Río Luján es el sistema hídrico más importante de la Región Metropolitana del Gran Buenos Aires (Argentina), posee una superficie total de 2940 km y una longitud de 450 km. Se encuentra dentro de la región pampeana, en la subregión de la pampa ondulada y se caracteriza por la ausencia de árboles, la existencia del pastizal como fisonomía predominante. El régimen hídrico abundante de esta área es ideal para el cultivo de cereales, mientras los suaves valles formados por ríos, arroyos y arroyuelos son indispensables para el ganado. En las áreas rurales, las transformaciones antrópicas han modificado este paisaje original por el de agrosistemas. Dada la relevancia estratégica que posee este ámbito territorial, el objetivo principal de este trabajo es exponer los principales lineamientos de la normativa y de las políticas públicas ambientales vinculadas con la protección de los servicios ecosistémicos en la Cuenca del Río Luján en la Provincia de Buenos Aires, en Argentina, y relevar los niveles de percepción ambiental de la población. La metodología consistirá en realizar un análisis de documentos públicos a través de la aplicación de la hermenéutica jurídica, y también un relevamiento de la percepción ambiental de la población mediante la confección, realización y procesamiento de los resultados brindados por encuestas.

Integrated governance of forests on the Northern Coast of São Paulo, Brazil: the role of the Fazenda and Caçandoca Quilombola communities in protecting ecosystem services / Governança integrada de florestas na região do litoral norte do estado de São Paulo, Brasil: o lugar das comunidades quilombolas da Fazenda e Caçandoca na proteção dos serviços de ecossistema

Gerson de Freitas Junior^{1,2}, Maria de Fátima Pereira Alves^{1,2}, Paula Cristina de Oliveira Castro³

¹Universidade Aberta de Portugal - UAb, Lisboa, Portugal; ²Centro para Ecologia Funcional - CEF Science for People & the Planet, Coimbra, Portugal;

³Universidade de Coimbra - UC, Coimbra, Portugal (gerson.freitas.junior@gmail.com; fatimaa@uab.pt; pcastro@ci.uc.pt)

O processo histórico de criação de um modelo de proteção ambiental na forma de Unidades de Conservação (UCs) no Brasil se desenvolveu sobre um contexto de profundo conflito socioambiental. Criaram-se áreas de proteção em locais habitados por comunidades tradicionais (indígenas, caboclos, sitiantes, seringueiros, caiçaras e, especificamente, quilombolas), de modo que essas populações que organizaram seus territórios, sua cultura e seu modo de vida e construíram os espaços que habitam historicamente, constituindo-os em florestas culturais (e em florestas de memória), tiveram sua mobilidade e sua realização social restringidas pelas diretrizes das UCs. Marginalizadas em relação ao processo de criação das UCs pelos órgãos do poder público e ambientais, essas populações tradicionais resistem, se organizam e buscam garantir seus direitos, como o reconhecimento de sua ancestralidade (em oposição à ideia de terra nullius). Objetiva-se verificar, em abordagem indutivo-comparativa, como as comunidades da Fazenda e da Caçandoca se relacionam com a natureza do ponto de vista da sustentabilidade, contribuem para a proteção dos serviços de ecossistema e desenvolvem sistemas de participação cidadã. Em pesquisa qualitativa recorrendo a entrevistas, pretende-se construir tipologias de governança e níveis de participação destas comunidades.

Financial viability of agroforestry systems using cacao to restore degraded pastures in Southeastern Pará, Brazil / Viabilidade financeira de sistema agroflorestal com cacau para restauração de pastagens degradadas no Sudeste do Pará

Thais Ferreira Maier¹, Rodrigo Mauro Freire¹

¹The Nature Conservancy, Belem, Brazil (tferreira@tnc.org; rfreire@tnc.org)

Os sistemas agroflorestais com cacau (*Theobroma cacao*) têm se apresentado como uma solução para o reflorestamento econômico e social no sudeste do Pará. A The Nature Conservancy vem trabalhando no Projeto Cacau floresta, nos municípios de São Félix do Xingu e Tucumã, utilizando estes sistemas para restauração de pastagens degradadas, gerando renda e aumentando a segurança alimentar dos pequenos produtores. O objetivo deste trabalho foi realizar uma análise financeira de um SAF com cacau e frutíferas para produção de polpas, na região de São Félix do Xingu, PA. A composição das receitas foi calculada a partir da comercialização das amêndoas de cacau, banana (*Musa* sp.), inhame (*Dioscorea* spp. L.), jiló (*Solanum aethiopicum*) e polpas de cacau e goiaba (*Psidium guajava*). Na composição dos custos foi considerada toda mão de obra necessária para implantação, manejo e beneficiamento dos produtos, bem como insumos, equipamentos e infraestrutura utilizados na produção. Como resultados, o modelo se mostrou viável financeiramente a uma taxa de 5,5% ao ano, apresentando taxa interna de retorno (TIR) de 22,04%, valor presente líquido (VPL) de R\$ 43.457,96, relação benefício/custo de 1,7 e payback descontado de 9 anos, em um horizonte de 20 anos de análise. O cacau foi o elemento que mais contribuiu com a geração de renda, sendo complementado pela produção de polpas, seguido da produção de banana. É fundamental encontrar soluções para geração de renda nos primeiros anos do sistema, para que o payback possa diminuir e aumentar a viabilidade financeira ao pequeno agricultor.

Beyond income: motivations for family farmers to incorporate greater diversity of native trees in agroforestry systems in Eastern Amazonia / Para além da renda: motivações para agricultores familiares incorporarem maior diversidade de árvores nativas em sistemas agroflorestais (SAFs) na Amazônia Oriental

Mário Oliveira Neto¹, Livia Navegantes-Alves¹

¹Universidade Federal do Pará, Belém, Brasil (marioneto.eng@hotmail.com; lnavegantes@gmail.com)

Agricultores familiares amazônicos praticam a recuperação florestal de variadas formas, destacando-se os Sistemas Agroflorestais (SAFs) pela intensidade da ação antrópica. Esses sistemas podem apresentar diferentes graus de biodiversidade, conforme a decisão do agricultor. O presente estudo objetiva analisar as motivações dos agricultores familiares para incorporar uma maior diversidade de árvores nativas nos SAFs, no município de Tomé Açu, estado do Pará. Este município foi escolhido por ter um histórico de práticas agroflorestais ao longo de 30 anos, onde foram aplicadas entrevistas semiestruturadas e observação direta com 17 agricultores familiares praticantes de SAFs. As espécies agrícolas e perenes (*Piper nigrum*, *Theobroma cacao*, *Theobroma grandiflorum*, *Euterpe oleracea*) são predominantes nos SAFs analisados, pois, segundo os agricultores, são elas que sustentam as despesas da família. As espécies arbóreas têm como função primordial o sombreamento, tanto para fins produtivos das espécies agrícolas, quanto para o conforto microclimático. Além de geração de renda e qualidade de vida, aspectos morais, religiosos e preocupações sociais, especialmente com as gerações futuras e com os vizinhos, foram referenciados como motivos centrais para integração de maior diversidade arbórea. Três fatores sobressaíram como impulsos para incorporar árvores nativas nos SAFs: mercado e incentivo estatal, e conhecimento das espécies. Em síntese, os agricultores familiares destacaram variadas motivações para incorporação de maior diversidade de árvores nos SAFs, a função das espécies e os impulsos internos e externos também devem ser considerados para compreensão e estímulo à diversificação.

Diversity of agroforestry systems in the State of Bahia, Brazil / Diversidad de los sistemas agroforestales en el estado de Bahia, Brasil

Rozimar de Pereira¹, Gabriel Andrade¹, Thaine Silva¹, Silvanne Santos¹

¹Universidade Federal Rural de Pernambuco, Cruz das Almas, Brasil (rozimarep@gmail.com; andradegabriel@gmail.com; silvathai28@gmail.com; analise.silvane@yahoo.com.br)

Los sistemas agroforestales (SAFs) son un sistema de uso de la tierra con la introducción o retención deliberada de árboles en asociación con otros cultivos perennes o anuales y/ o animales, presentando mutuo beneficio resultante de las interacciones ecológicas y económicas. Así se constituyen en una alternativa para aliar la estabilidad del ecosistema con miras a la eficiencia y optimización de recursos naturales en la producción de forma integrada y sostenida. El objetivo de este trabajo fue evaluar la diversidad de especies arbóreas de los SAFs en los municipios Recôncavo de Bahía - Brasil. Se utilizaron enfoques participativa y multidisciplinario, herramientas del DRP y Diagnóstico Rural Rápido. Los SAF se definieron en 4 tipos. Los datos fueron analizados por la estadística descriptiva y análisis de factores por el índice de similitud. En los SAFs se observó la ocurrencia de especies frutales, madereras, medicinales y ornamentales en las propiedades estudiadas (30), con 98 diferentes especies encontradas, distribuidas en 35 familias botánicas. Las familias Fabaceae y Myrtaceae fueron las más representativas en número de especies. Los modelos SAF1, SAF2, SAF3 y SAF4 presentaron índices de diversidad Shannon (H') de 3,155; 3172; 3135; 2,843 y la equidad (J') 0,906; 0,928; 0,957; 0,949, respectivamente. En cuanto 32,8% de las especies muestreadas son pioneras, el 24,5% secundarias iniciales, el 39,9% secundarias tardías y el 2,8% sin caracterización. El Sistema Agroforestal es de gran relevancia para los remanentes de Mata Atlántica en Bahía, ya que presentan una significativa biodiversidad local.

Food security and income from traditional African oils

Anne Mette Lykke¹ ; Imael Henri Nestor Bassolé², Amadé Ouédraogo³, Elie Antoine Padonou³, Amadou Malé Kouyaté⁴

¹Aarhus University, Silkeborg, Denmark; ²University of Ouaga I, Ouagadougou, Burkina Faso; ³National University of Agriculture, Ketou, Benin; ⁴Institute of Rural Economy, Sikasso, Mali (aml@bios.au.dk; ismael.bassole@gmail.com; amadeouedraogo@gmail.com; padonouelie@gmail.com; amadoumkouyate@yahoo.fr)

Food oil of good quality is important for health, food security and income. Women in rural Africa traditionally extract oil from seeds of numerous native trees, but the potentials are far from fully realized. During two projects, QUALITREE and TREEFOOD, we investigated ethnobotanical knowledge in Mali and Burkina Faso, analyzed physiochemical properties of over 30 native oil trees and made a literature review of native tree oils from West Africa. Local knowledge about oil production is often confined to local areas or specific ethnic groups. Screening of oils from native species revealed very good potentials for ameliorated use, production, sale and export. Examples of highly interesting oil species are *Adansonia digitata*, *Azelia africana*, *Balanites aegyptiaca*, *Carapa procera*, *Lannea kerstingii*, *Lophira lanceolata* and *Pentadesma butyracea*. Few species (mainly *Elaeis guineensis* and *Vitellaria paradoxa*) are highly investigated and used, despite the fact that there is clearly an extraordinary potential for improving health, food security and economic development in poor communities via diversified, increased and improved oil production. Marketing interests of oil includes both local and international markets. However, in many cases tree planting or nature protection in collaboration with local communities are needed to ensure sufficient and continuous oil supplies. Such activities have a potential to improve local biodiversity and give opportunities for carbon certification and sale.

Influence of the tree component in the animal production in an integrated crop livestock system in an environmental protection area in the Brazilian Subtropic

Silvano Kruchelski¹, Thales Baggio¹, Breno Campos¹, Anibal de Moraes¹

¹Universidade Federal do Paraná, Curitiba, Brasil (silvanokr65@gmail.com; baggio.thales@gmail.com; brenomcampos@gmail.com; anibaldemoraes@gmail.com)

This study aimed to compare animal daily gain of beef cattle in four arrangements of Integrated Crop-Livestock Systems. The experiment was carried out at Canguiri Farm of the Federal University of Paraná, located in Pinhais, PR, (25°23'30"S 49°07'30" W), as part of the Technological Center of Innovation in Agriculture protocol. The protocol is located in an Environmental Protection Area with 1400 mm average of total annual rainfall, 12.5 °C and 22.5 °C of mean minimum and maximum temperature, respectively. The design was a randomized block with three repetitions and four treatments, livestock system (LS), silvopastoral system (SS), livestock and crop system (LC) and livestock - crop with tree system (LCT). Plot size was about 1.5 hectares for each experimental unit. The tree species in the SS and LCT systems was *Eucalyptus benthamii* spacing 14.0 m between tree rows, and 2.0 m within the tree row. The average tree height was 13.65 m. The grazing method was continuous stocking with variable stocking rate, to the "put and take" technique. A group of 36 animals (testers) was used on the study. Three animals testers (Angus breed) was taken for each treatment. The experiment was conducted from Jun/2017 to March/2018. The comparison of the mean variables evaluated between LS, SS, LC and LCT was performed by the Tukey test. Daily weight gain was evaluated weighing testers each 28 days during ten months. The daily weight gain did not present significant difference for treatments (LS = 0.82 kg; SS = 0.77 kg; LC = 0.86 kg; LCT = 0.84 kg).

A1q: COMMUNITY INVOLVEMENT IN AGROFORESTRY SYSTEMS AND ECOSYSTEM SERVICES

Towards productive landscapes: trade-offs in tree-cover and income across a matrix of smallholder agricultural land-use systems

Syed Rahman¹

¹Center for International Forestry Research (CIFOR), Bogor, Indonesia (sumonsociology@yahoo.com)

One of the main causes of tropical forest loss is conversion to agriculture, which is constantly increasing as a dominant land cover in the tropics. The loss of forests greatly affects biodiversity and ecosystem services. This paper assesses the economic return from increasing tree cover in agricultural landscapes in two tropical locations, West Java, Indonesia and Eastern Bangladesh. Agroforestry systems are compared with subsistence seasonal food-crop-based agricultural systems. Data were collected through rapid rural appraisal, field observation, focus groups and semi-structured interviews of farm households. The inclusion of agroforestry tree crops in seasonal agriculture improved the systems' overall economic performance (net present value), even when it reduced understorey crop production. However, seasonal agriculture has higher income per unit of land area used for crop cultivation compared with the tree establishment and development phase of agroforestry farms. Thus, there is a trade-off between short-term loss of agricultural income and longer-term economic gain from planting trees in farmland. For resource-poor farmers to implement this change, institutional support is needed to improve their knowledge and skills with this unfamiliar form of land management, sufficient capital for the initial investment, and an increase in the security of land tenure.

Empowering farmers in India through sandalwood cultivation & economic development impact in Rural India

K. T. Chandrashekar¹, Malleshachari Lingachar¹

¹Sandalwood Society of India, Bangalore, India (ktchandrashekar2@gmail.com; mallesh@itrads.com)

Indian Sandalwood is considered as the richest forest species and it was declared as Royal Tree in India. *Santalum album L. is* considered as a premium class which is commercially known as East Indian Sandal wood. Indian Sandalwood is highly prized due to its fragrant wood, oil, which is used as a fixative in world class perfumes, aromatherapy, various pharmaceutical preparations and cosmetics. The oil has an important role in indigenous system of medicinal properties. Every part of the tree is exploitable; sapwood also finds utilization in carving and turnery. Demand of sandalwood is in the tune of 20,000 Metric tons and oil demand estimated at 1000 tons in the international markets. Different agro forestry models introduced are helping farmers realizing higher yield. With other forest species as host plants, the whole eco system of sandalwood clusters is helping in improved soil carbon. This fertile land is becoming useful in growing many high return inter crops. Developed value added products in sandalwood as part of improving farmers revenue. In addition to farmers getting very high economic value, introduction of value added products in sandalwood is helping government in huge revenues. In the next few years, India will see its economic independence by way of empowering rural India. This paper discusses the various agro forestry models introduced, steps taken to improve soil fertility, value added products introduction & yield growth.

Involvement of Tribal Community in cultivation of *Cinnamomum malabratrum* (Burm. F.BI) and *Persea macarantha* (Nees Kosterm) trees across Western Ghats of India as binding material for Agarbhati (incense) industry

K. T. Chandrashekar¹, Malleshachari Lingachar¹

¹Sandalwood Society of India, Bangalore, India (ktchandrashekar2@gmail.com; mallesh@itrads.com)

Burning of incense is a century's old tradition in the religious rites, rituals, and customs of all communities in Asian countries. In India, incense is more commonly known as agarbathi. It is also used as air freshener, disinfectant and masking agent. Indian incense industry is one of the most vibrant cottage industries that employ up to 2 million people who are mostly under privileged in the country. Incense export industry has grown at a CAGR of 15% and is expected to grow exponentially and reach USD 3.5 B (AIAMA) in the next five years. The industry today has scarcity of forest based raw materials like jigat (binding material). The expansion of agarbathi industry has inflated the demand for jigat. These trees are grown in Western Ghats of India where the population of tribal community is highest. These trees have been over exploited and are unable to regenerate themselves as they are unscientifically debarked. It is estimated that approximately 20,000 ha. of captive plantation is required in the next ten years. Cultivation of these trees in different clusters is done in select areas and plans are already drawn for further expansion. In this paper, selection, cultivation of high bark yielding and adhesive property of trees is discussed. This paper also presents structured plans to enrich the livelihood of tribal community by involving them closely in raising the large scale plantation.

Forests for people seen in a national forest inventory (NFI) perspective: experiences and results of measuring cultural ecosystem services in Denmark

Frank Søndergaard Jensen¹ ; Thomas Nord-Larsen¹, Vivian Kvist Johannsen¹

¹University of Copenhagen, Frederiksberg, Denmark (fsj@ign.ku.dk; tnl@ign.ku.dk; vkj@ign.ku.dk)

A number of international processes aim to monitor the forest status, which includes cultural values and services like forest recreation – the question is what role National Forest Inventories (NFIs) can play in this context. The Danish NFI is a continuous sample-based inventory with partial re-placement of sample plots based on a 2 x 2 km grid. A number of recreational indicators is registered as part of the NFI measurement procedures, including: access (forest roads, formal and informal paths), camping (formal campsites, evidence of camping and camp fires), infrastructure (hunting facilities and other visitor facilities) and abuse (littering, vandalism). Danish forests are easily accessible as a total of 70% of the sample clusters were accessible by forest roads or paths. The recreational activity is visible in the forest. On 46% of the clusters, the NFI teams found evidence of camping, camp fires, hunting facilities or other visitor facilities (forest playgrounds, picnic tables etc). The downside to the widespread activity is that litter was found on 20% of the clusters. It is revealed that NFIs relatively simply and cost efficient can be expanded to include a number of recreational/social indicators which generally is not available otherwise. The measurements is a valuable contribution to sustainable knowledge-based management and policy decisions, and may serve as a baseline for monitoring the trend in parts of both the supply and demand of forest recreation – as well as the downside of the activity such as littering or vandalism.

Portuguese regional agroforestry innovation network from the AFINET Project: SWOT analysis after two years of establishment

Joana Paulo¹ ; Raquel Almeida¹, João Palma¹, Ana Tomás¹, Margarida Tomé¹

¹Instituto Superior de Agronomia, Lisboa, Portugal (joanaap@isa.ulisboa.pt; rpalmeida@isa.ulisboa.p; joapalma@isa.ulisboa.pt; anaraquelomas@gmail.com; magatome@isa.ulisboa.pt)

The AFINET project acts in nine European countries aiming at taking up available research results on agroforestry into agricultural practice. Portugal is one of those countries. One of the main tools developed by the project is the creation, at each participating country, of Regional Agroforestry Innovation Networks (RAIN). A SWOT analysis exercise was carried out in order to analyze current results of the RAIN actions. The results show: Strengths – current interest on Agroforestry; – large impact of the available communication channels, in particular social media; – relationship to the EURAF member's community; – high number of agroforestry systems and practices referred by stakeholders; – awareness of relationships constraints between different stakeholder types; Weaknesses – small impact at the national policy level; – practical constraints to increase the implementation of activities covering a broader geographical distribution area; – lack of expertise regarding all of the referred topics, demanding a significant increase of time to tackle them; Opportunities – using the RAIN as the network for future projects related to the Agroforestry topic; – increase communication of scientific knowledge from science to practice; – establishment of new experimental and demonstration trials in collaboration to farmers; – basis for the creation of a national Agroforestry association; Threats – lack of funding for RAIN activities sustainability after 2019; – large scope of subjects approached by the RAIN members, that increase the demand of funding for future activity; – concentration of efforts in already well established and recognized agroforestry systems in Portugal; – lack of institutional awareness to the agroforestry concept.

Urbanisation and implications on norms, taboos and customs in forest governance of Miombo woodlands and implications on forest governance among peri-urban and rural communities

Felix Kalaba¹

¹Copperbelt University, School of Natural Resources, Kitwe, Zambia (kanungwe@gmail.com)

Migration of people in new areas has the potential to change existing norms and customs regulating human-forest interactions. The study aimed at understanding how different cultural institutional settings shape access, use and governance of forest resources. This study was conducted in the Miombo woodlands of Zambia's Copperbelt region. Data was collected using a multiple methods approach combining household interviews with 244 households, focus group discussions and key informant interviews. Findings show that traditional rules regarding harvesting of forest products are prominent in rural settings as opposed to peri-urban areas. Local institutions affect the prevalence of norms and customs that inform resource utilization and management. Communities in peri-urban areas do not engage in protecting forests for any environmental or cultural services. The lack of traditional institutions and diversity of ethnic tribes has led to erosion of cultural norms and practices that regulate forest use. In customary lands, traditional rules on forest use and management exist. Forested areas are important for providing cultural services and norms, taboos and folkways exist that regulate harvesting of products such as barks for medicinal purposes. Traditional governance of forest resources is more likely to provide sustainable management due to adherence to cultural norms, and proximity to decision making structures. Urbanization has the capacity to change local institutional arrangements undermining and eroding customary systems due to diversity of tribes around urban centres. Management of woodlands around urban areas requires deliberate measures to strengthen local authority and promote locally appropriate management actions and plans.

Developing regenerative agroforestry designs to foster gender-responsive forest restoration in the Brazilian Amazon

Mariana Oliveira¹, Paula Costa², Valter Ziantoni²

¹WRI Brasil, São Paulo, Brazil; ²PRETATERRA, São Paulo, Brazil (moliveira@wri.org; paula.costa.agroforestry@gmail.com; ziantoni.valter@gmail.com)

Project entitled Restoration Compatible with Gender Equality and Climate Change, aims to enhance efforts on the link between low-carbon agriculture techniques, forest restoration and sustainable landscape management in Juruti, PA, Brazil. With an HDI of 0.592, the region depends on agro-extractivism and subsistence agriculture based on slash-and-burn cassava cultivation. Fallow reduced from 20 to 2 years, constant growing population, and the increase of wildfires make mandatory creation of new agriculture regenerative models to thrive under climate change conditions. The study aimed to develop participative agroforestry designs as an alternative for slash and burn in the region; prototyping and implementing modular replicable agroforestry units in a successional decision-making logic. During 2018, data collection and pairwise sessions were conducted in 25 communities (157 farmers). The analysis used selected principles, criteria, and indicators. Final adjustments were made merging local ecological knowledge, empirical information and scientific data. Result was a co-created elastic regenerative design, maximizing biomass production and high-value fruit indigenous trees within the system. Estimative annual yield per hectare for cassava is 12 ton; fruits, 24.4 tons and dry biomass, over 3.53 tons, after 4 years, according to farmers' preferences, system can migrate to (1) agrosilvipasture, (2) perennial fruit orchard or (3) biodiverse NTFP forest. Implementation has already started in Nov-2018. With the presented design its expected to drastically improve food resilience while imputing new cash crops and creating an elastic and highly acceptable low-carbon model for amazon cassava-based agriculture, building a new productive paradigm which is sustainable, resilient and long-lasting.

AIr: AGROFORESTRY FOR ENVIRONMENTAL RESTORATION AND CLIMATE MITIGATION

The commercialization of *Adansonia digitata* L. in Malawi: from emergency food to high value market products?

Chifundo Chopi- Msadala^{1,2}, Chimuleke Munthali¹, Kathrin Meinhold², Dietrich Darr²

¹Mzuzu University, Mzuzu, Malawi; ²Rhine -Waal University, Kleve, Germany (chifundochoopi@gmail.com; chimuleke.munthali@gmail.com; kathrin.meinhold@hochschule-rhein-waal.de; dietrich.darr@hochschule-rhein-waal.de)

The baobab tree (*Adansonia digitata* L.) is common in semi-arid sub-Saharan Africa and an important source of Non Wood Forest Products (NWFP). Its fruits contain high amounts of vitamin C, E, calcium and dietary fiber. Other parts of the tree are traditionally used for human consumption, particularly during lean seasons. In line with increasing demand for natural, healthy and nutritious food products in domestic and international markets, the baobab has great potential to address human nutrition and improve rural livelihoods if commercialized properly. In Malawi, where demand for baobab has substantially increased within the last decade, the baobab fruits are being commercialized by both formal and informal processing enterprises to produce fruit juice, cosmetics, ice-lollies and sweets for various rural and urban consumer segments. Yet, information about the sociodemographic background and quality preferences of baobab consumers is scanty. Therefore, a consumer study of 179 juice consumers was conducted in formal and informal retail markets. Qualitative and quantitative data was analyzed by means of cluster analysis and cross tabulation. Results suggest that consumers of baobab and fruit juices in major supermarkets are mostly females between 21 to 40 years old, mainly hold a bachelor's degree and belong to the middle income group. Consumers mostly preferred imported fruit juices over baobab juice due to packaging quality and sweetness. The study concludes that domestic baobab processors should invest in product innovation and process improvements, and quality standards need to be enforced which encourage the positioning of baobab products in higher value segments.

Tree shade control for farming inside Tan Phu Protection Forest of Vietnam: the conflict or new farming technique

Trang Bui Thi Thu¹, Linh Nguyen Thuy My²

¹Vietnam National University of Forestry Southern Campus, Dong Nai, Vietnam; ²Vietnamese Academy of Forest Sciences, Ha noi, Vietnam (trang.bui3282@gmail.com; linh.ntm@rcfee.org.vn)

Agroforestry systems not only play an important technique to minimize negative impacts on biodiversity, human livelihoods, well-being in conservation work, but also create the conflict between conservation and development objectives. In some agroforestry systems in Tan Phu Protection Forest of Vietnam, in order to facilitate coffee and pepper production, local people tend to release *Dipterocarpaceae* tree shade by branch cutting all. This practice is not forbidden in law but has been leading to negative impacts on long-term conservation work: reducing on forest tree foliage, branch production and increment annual stem diameter. Paying farmer to protect forest is minimal in comparison with benefits from their crops, thus it's hard to encourage them cultivating crops without pruning forest trees. This paper aims to provide the view of gaps in relevant policies and how to building on mutually beneficial relationships among farmers and authorities in Tan Phu. The systematic reviews on forestry policies and relevant journal articles are implemented to access the influences of these policies

and law to farmer livelihoods and conservation conflicts. Some studies on specific land-use management and optimal tree shade methods in agroforestry systems are further discussed. The results expect to seek the optimal shade tree density and shade cover for agroforestry systems. And the suggestion to recommend legal and institutional frameworks in agroforestry sector and the options for policy action to support the development of not only improving conservation outcomes, but also respecting and protecting the rights of local people in the use and management of forests.

Interventions for agroforestry and species restoration in Novel Forests of Puerto Rico: enrichment planting success before and after Hurricane María

Génesis Túa Ayala¹, Oscar Abelleira Martínez¹

¹Universidad de Puerto Rico, Mayaguez, Puerto Rico (genesis.tua@upr.edu; oscarj.abelleira@upr.edu)

Much of Puerto Rico is covered by novel forests growing on lands previously used for intensive agriculture, resulting in extreme soil degradation and dominance of introduced tree species. Social-ecological vulnerabilities to extreme events call for interventions to support provision of goods and biodiversity conservation in abundant and idle novel forests. We report on year-one of an experiment to test the suitability of novel forests for agroforestry and species restoration interventions in Puerto Rico, as affected by Hurricane María on September, 2017. We established enrichment plantings of sun (avocado, breadfruit), shade (cacao, coffee) and native (jácana, jagua) fruit tree species to test for effects of dominant canopy tree species traits upon planted tree species growth and survival. Beginning on August, 2017, we planted six individuals of each species on each of 30 sites of which roughly half were dominated by nitrogen-fixing tree species. Ten and 20 sites were planted before and within six months after the event, respectively. We observed high survival rates (80%) of all species across all sites, including those planted before the Hurricane. Planted tree growth was boosted at sites where the Hurricane caused canopy opening or flooding. Results are too preliminary to indicate relationships between planted tree species growth, survival and dominant species traits, yet show the capacity of novel forests for successful establishment of agricultural and extirpated species, protecting plantings from extreme events. Long-term results will aid communities and institutions couple Puerto Rico's forests with provision of goods, biodiversity conservation and resilience to extreme events.

Agroforestry in Southern Africa - new pathways of innovative land use systems under a changing climate (ASAP)

Climate change is already a measurable reality generating significant social, economic and environmental challenges, impacting sustainable development around the globe. The African continent is most vulnerable to the forecasted change in global climate, Southern Africa in particular will face severe challenges within the upcoming decades. Innovative, flexible and improved land use systems are expected to be part of the adaptive solution, mitigating the effects of a changing climate and positively influencing agriculture and food security under altered conditions. The BMBF funded research project 'Agroforestry in Southern Africa - new Pathways of innovative land use systems under a changing climate' (acronym ASAP; grant number: OLL1803) incorporating partners from South Africa, Namibia, Mozambique, Malawi and Zambia alongside researchers from Germany, targets the employment of agroforestry systems (AFS), as an appropriate response to climate change. ASAP aims at investigating ecosystem services as well as socio-economic and environmental benefits of AFS in the southern Africa region. The chosen transdisciplinary approach to investigate the biophysical environment and ecosystem services in conjunction with socio-economic aspects of AFS will help develop a better understanding of a range of possible solutions using AFS for varied agro-climatic zones and landscape scales. The exploration of human-environment interactions within AFS is a major focus with the intention of facilitating a sustainable improvement to rural livelihood utilising AFS. Project outputs will be disseminated to practitioners and researchers through local facilitators in the framework of workshops, lectures and practical guidance in order to establish a paradigm shift.

Tree-based conflict management mechanisms among small land holders in agroforestry systems of Kenya

Pauline Bala¹, Abdalla Kisiwa², Samson Okoth³, Robert Nyambati⁴, Joyce Okumu², Joshua Cheboiwo⁴

¹Kenya Forestry Research Institute -RVERP, Turbo, Kenya; ²Kenya Forestry Research Institute -RVERP, Londiani, Kenya; ³Kenya Forestry Research Institute LVBERP, Maseno, Kenya; ⁴Kenya Forestry Research Institute, Nairobi, Kenya; (paulineballa@gmail.com; abdulkzy@yahoo.com; mcojijosamsa@gmail.com; nyambati@yahoo.com; joyce.okumu@gmail.com; jkchemangare@yahoo.com)

Afforestation programs for adaptation to climate change is challenged by competing land uses. Such conflicts arise whenever there is divergent, incompatible use; access and management of the land resources. Agroforestry is considered an option to reconcile such competition. However, practicing agroforestry on small land holdings remain a challenge due to negative ecological and social impacts of most preferred tree species. Such negative impacts lead to conflict among neighbouring land users and in most instances slow down afforestation efforts. Mechanisms for management of such conflict are not documented. This study intends to explore conflicts arising from tree-planting on farm among different land users, identify the local conflict management mechanism adopted by them and to evaluate effectiveness of the mechanisms adopted. Structured and semi structured interviews were conducted in Kisii County, Kenya. Content analysis was done. Reduction of crop by poorly configured trees on farm and poor choice of tree species were the main sources of tree-based conflicts. Planting of such tree species was mainly driven by the high economic value attached to such trees of negative ecological impact like *Eucalyptus* coupled with small land holdings. Only 36% of the respondents employed co-operative methods of voluntary negotiations such as shared tree ownership, appropriate silvicultural

management and compensation. Some 20% of the respondent adopted third party intervention mechanisms such as Mediation, Adjudication and Arbitration while 10% used avoidance methods. Voluntary negotiations promoted good relations but imposed some cost on livelihood strategies. When involuntary and non-cooperative methods were employed, some land uses were displaced.

Factors affecting the willingness of households to apply HCG technology in black fungus cultivation: an investigation in the forest area of Heilongjiang Province, China

Hongge Zhu¹, Shilei Hu¹, Yue Ren¹, Yukun Cao¹, Xiangyue Liu¹

¹Northeast Forest University, Harbin, China (honggebill@163.com; yiruodongchuan@163.com; ren13199442303@163.com; cykllk@163.com; 1335759586@qq.com)

Hanging-bag cultivation in greenhouses (HCG) of black fungi is a new technology that is being promoted in state-owned forest regions in China. It significantly improves the efficiency of black fungus cultivation; alleviates forested land resource shortages; promotes the smooth transition towards an ecological economy in state-owned forest regions; and promotes the sustainable development of forested areas. However, the effective promotion and application of HCG technology largely depends on the acceptance and willingness of households, who are the final recipients of the promotion of this technology, to engage with it. This empirical study investigated the factors affecting the willingness of households to use HCG technology in the forest area of Heilongjiang Province, using the technology acceptance model (TAM) framework and the partial least squares (PLS) method. The study found that the perceived usefulness (PU) had a significantly positive effect on the willingness to accept the technology. The perceived ease of use (PEOU) affected the willingness to use the HCG technology via the perceived usefulness (PU). Facilitating conditions (FC) not only directly affected the PEOU, but also indirectly affected the PU via the PEOU. The results of the study should provide useful insight into the promotion and application of new forestry technologies.

Neem tree agroforestry practices for degraded soil recovery in tropical areas

Paul Luzuriaga^{1,2}, Monica Gonzalez¹, Cesar Moreira²

¹TeamUp Initiative, Guayaquil, Ecuador; ²ESPOL Guayaquil Ecuador (luzuriagamp@gmail.com; mgonzabur@gmail.com; cemoreir@espol.edu.ec)

Since 2007 several plots of Neem tree (*Azadirachta indica*) and Neem tree plus agroforestry techniques have been tried in the Santa Elena province, a coastal region in Ecuador. The area where the trials took place had eroded soils, highly mineralized because of intensive fertilizer usage and dry weather with precipitations below 300 mm per year. Vegetation was scarce mostly as small bushes characteristic in dry tropical forests. Also, previous owner and local people have tried to produce short term crops with unsuccessful results. The study started by finding endemic species capable to survive in dry weather. Saman, Guayacan and Neem tree were found in the region. Propagation techniques were applied to these species under low irrigation conditions. Neem tree seemed successful with almost 57% survival while others presented 19% for Saman and 33% for Guayacan. After a 7 years adaptation process, Neem tree propagation achieved 73% survival as seedlings, and 64% after planted in the field. Plots developed with agroforestry practices produced micro-climates capable of retaining air humidity and contribute to pasture growth. Cattle was introduced at the fourth year of forestry management. Cattle management started at 0.5 heads per hectare and stabilized at 2 heads per hectare at the tenth year. Other byproducts were obtained with proper forest management, as dry leaves for infusions, bark powder as mild bactericide, Neem seed extract as organic pesticide, and Neem seeds residue as cattle feedstock.

Agroforestry systems in the Atlantic Forest: assessment and proposals for a diagnosis and propositions in the SPVS environmental preserve in the coastal plain of Paraná, Brazil / Sistemas agroflorestais na Mata Atlântica: diagnóstico e proposições em reserva ambiental da SPVS na planície litorânea paranaense

Stefanie Vieira de Albuquerque¹, Rodrigo Condé Alves¹, Ivan Crespo Silva¹, Alessandro Camargo Ângelo¹

¹Universidade Federal do Paraná, Curitiba, Brasil (stefanievieira28@gmail.com; rconde@gmail.com; ivancrespo@ufpr.br; alessandrocangelo@gmail.com)

O presente trabalho foi realizado na planície litorânea do Paraná dentro das reservas ambientais da ONG Sociedade de Pesquisa em Vida Selvagem e Educação Ambiental – SPVS. Esta região possui grande importância ambiental, histórica e econômica para o estado do Paraná. A biodiversidade da Mata Atlântica nesta região em conjunto com a Serra do Mar forma uma das maiores reservas de riquezas naturais de fauna e flora no mundo. A SPVS é uma ONG que atua através de diversos projetos conservacionistas em prol da biodiversidade. Dentre esses projetos, a instituição constituiu três reservas naturais na região: Reserva Papagaio-de-cara-roxa, Reserva Natural das águas e Reserva Guaricica que totalizam 18.722,07 hectares de áreas protegidas. Um dos maiores desafios e prioridades destas áreas é captação de recursos para garantir a sustentabilidade econômica e a relação de desenvolvimento com a população local. Diante deste contexto, os Sistemas Agroflorestais podem ser uma solução. Foram diagnosticados potenciais e desafios locais que orientaram a proposta de futuras ações de implantação de Sistemas agroflorestais nas reservas com base em pesquisas de campo, aplicação de questionários e revisão de literatura. Os diagnósticos aplicados apresentaram resultados positivos em relação a aceitação dos sistemas agroflorestais por parte da instituição e funcionários. Foram apresentadas 24 espécies que cumprem com funções específicas no sistema, focando principalmente frutíferas nativas com potencial de beneficiamento e comércio. E por fim, foi apresentado um arranjo das espécies em forma de croqui agroflorestal.

A2a: SUSTAINING ICONIC AND HIGH-VALUE SPECIES IN NATURAL FORESTS AND PLANTATIONS

Interaction of conservation of genetic resources with forest management for mahogany and Spanish cedar in the Yucatan Peninsula, Mexico

Sheila Ward¹ 

¹Mahogany for the Future, Inc., San Juan, Puerto Rico (mahoganyforthefuture@gmail.com)

Various trials and gene banks have been implemented for ex situ conservation of the genetic resources of the high-value species mahogany (*Swietenia macrophylla*) and Spanish cedar (*Cedrela odorata*) in the Yucatan Peninsula of Mexico. But these trials can be subject to loss from fire, human interference, hurricanes, or disease. Such was the experience with a set of trials established in community forests (ejidos) in 1996 to 1998. In situ conservation of designated seed trees in community forest reserves might be a more practical solution. Stands can be replicated in different ejidos, reducing overall vulnerability to

loss. Mexican forest policy encourages ex situ and in situ conservation of forest genetic resources. But work remains to be done for sufficient protection of populations and genetic resources of species under harvest for their long term sustainability. This presentation reviews long term viability and results for various ex situ trials and seed banks for mahogany and Spanish cedar in the Yucatan, especially for the 1996-1998 trials in Quintana Roo. Of two trials of mahogany and two trials of cedar established on community and private lands, only one remain of each. The remaining trials are being converted to seed orchards in Spring 2020. Also considered is the current status of in situ seed stands for these species, and the relative usefulness of ex situ and in situ strategies for maintaining genetic resources. In addition, current harvest policy and possible modifications for better maintenance of populations and genetic variation are considered.

Management of natural regeneration of *Araucaria angustifolia* in small farms in Southern Brazil: an alternative for the conservation of the species

Denise Jeton Cardoso¹, Maria Augusta Doetzer Rosot¹ ; Marilice Cordeiro Garrastazu¹ ; André Eduardo Biscaia de Lacerda¹, Yeda Maria Malheiros de Oliveira¹ 

¹Embrapa Florestas, Colombo, Brasil (denise.cardoso@embrapa.br; augusta.rosot@embrapa.br; marilice.garrastazu@embrapa.br; andre.biscaia@embrapa.br; yeda.oliveira@embrapa.br)

Araucaria angustifolia (Bert.) O. Kuntze occurs naturally in south and Southeastern Brazil. It has cultural and ecological significance as its seeds are traditionally consumed by local communities and are an important source of food for wildlife. It also has multiple potential uses for timber, paper, and the food industry. Its exploitation is forbidden by law and it is currently listed as critically endangered. Because of legal limitations, regrowth of araucaria trees is seen by landowners as problematic, thus inducing seedling removal. One way to promote its conservation is taking advantage of traditional agroforestry productive systems such as caívas and faxinais that integrate animal husbandry, erva-mate (*Ilex paraguariensis*), and other crop production in forested areas. Under these conditions, araucaria regeneration is abundant and can be managed for productive and conservation goals. We analyzed two examples of such agroforestry systems and confirmed the potential for maintaining high levels of forest diversity, income generation through livestock and erva-mate production, combined with important regeneration of araucaria. In one area we observed a predominance of *Araucaria* (48%) along with 46 other species, and *Araucaria* plants were distributed in various DBH classes. In the second property, we observed that *Araucaria* abundance corresponds to around 13% of the forest with a higher representation in larger DBH classes (up to 86%) while maintaining a diversity of 44 tree species. Overall, despite its economic potential, the species continues to be a poorly understood resource with limited interest in establishing plantations and maintaining natural stands.

From disaster to opportunity: examining the effects of hurricanes Irma and Maria on mahoganies in Puerto Rico and U.S. Virgin Islands, related policy responses, and potential for enhancing long-term sustainability

Kathleen Mcginley¹, Sheila Ward²

¹U.S. Forest Service, International Institute of Tropical Forestry, Rio Piedras, Puerto Rico; ²Mahogany for the Future, Inc., San Juan, Puerto Rico (kmcginley@fs.fed.us; mahoganyforthefuture@gmail.com)

In September 2017, two major hurricanes – Irma and Maria – passed through the Caribbean, resulting in significant loss of life, impacts on local economies, and effects on natural resources. Large areas of forest were nearly to completely defoliated and countless trees were uprooted, snapped, or damaged in natural to urban settings. Tree damage and death occurred throughout the islands, including high-value species, such as big-leaf, small-leaf, and hybrid mahoganies. These species are not native to Puerto Rico or the U.S. Virgin Islands, but have become naturalized with extensive planting since they were first introduced in 1790. Although significant volumes of hurricane-downed mahoganies and other timber species were collected in debris removals as part of the response and recovery efforts in Puerto Rico and the U.S. Virgin Islands, very limited volumes were salvaged for timber and other products, due in large part to limited industrial capacity for wood transformation as well as limited foresight or policy coherence on disturbance-downed wood. The local economic loss has been estimated at millions of dollars. We examine the effects of the 2017 hurricanes on planted and naturalized mahoganies in Puerto Rico and the U.S. Virgin Islands and the related short and long term management and policy responses. We discuss the implications for the sustainable management and use of these high value species, in the context of islands searching for solutions that increase resilience and decrease dependence on imports, including wood products, and which face a likely future of more severe and frequent storms and hurricanes.

Araucaria angustifolia breeding program at Embrapa Florestas

Valderês Aparecida de Sousa¹, Ananda Virginia de Aguiar¹, Miguel Luiz Menezes de Freitas², Alexandre Sebbenn³, Jarbas Yukio Shimizu³

¹Embrapa Florestas, Colombo, Brasil; ²Instituto Florestal de São Paulo, São Paulo, Brasil; ³Autonomous, Curitiba, Brasil (valderes.sousa@embrapa.br; ananda.aguiar@embrapa.br; miguelmfreitas@yahoo.com.br; alexandresebbenn@yahoo.com.br; shimizujy@gmail.com)

Araucaria angustifolia (Bert.) O. Ktze is a native species from Brazil which plays an important social and economic role, especially in the southernmost region of the country. Currently it is threatened on extinction, and consequently its remnants cannot be exploited. Conservation by use is one feasible way to conserve this tree through plantations ensuring adequate variability. However, the seed supply with high physiological and genetic quality to this plantation is a major problem which could be overcome through breeding programs. Embrapa Florestas (CNPq), together with Instituto Florestal de São Paulo (IF-SP) started a breeding program nearly 40 years ago as provenance/progenies tests, covering a wide natural area. As *Araucaria* occurs in an over a wide geographical region, southern and Southeastern Brazil, differences between them must be considered in breeding and conservation programs. The introduced tests were submitted to a thinning of 50 % intensity. From recombining of the remaining trees seeds a second generation provenance/progeny tests were established in Curitiba-SC, Ponta Grossa-PR, Caçador-SC, and Monte Belo do Sul-SC. Consequently, a higher productivity gain is expected in relation to the current seed sources. Moreover a participatory improvement is being considered aiming to promote the increasing of variability and the development and use of adapted germplasm to specific conditions. For this purpose a cooperative araucaria breeding project is being implemented among Embrapa Florestas and partners aiming to develop genetically improved seeds and clones of araucaria, based on a wider genetic base to ensure the potential for genetic improvement for consecutive generations.

Threatened by conservation: addressing policy gaps for the maintenance of high-density Brazil nut tree clumps

Paulo Marcelo Paiva¹

¹Embrapa Amapá, Macapá, Brasil (paulo.paiva@embrapa.br)

Considered a cornerstone species in Amazonian forest conservation strategies, the Brazil nut enjoys a unique status. It is immune to cutting and most of its distribution is under some category of protected area. Nonetheless, both nut-gatherers and researchers consistently report insufficient natural regeneration

levels and the population decline of high-density stands, including at strict nature reserves. The initial hypothesis of seed overharvesting lacks consensus as later studies identified the scarcity of canopy gaps at mature forests as the main cause for the recruitment failure of this gap-loving species. This observation supports the anthropogenic origin hypothesis and is consistent with the abundant recruitment observed in traditional swiddens, where the regeneration density increases with the number of cultivation cycles. This is due to a number of factors, including the scatterhoarder habit of the natural disperser, gap-clearance frequency, species' resistance to fire and remarkable re-sprouting capability. Nut-gatherers intuitively understand the role of swiddens for the maintenance and expansion of high-density Brazil nut stands, and many voluntarily protect their spontaneously enriched fallows from further cultivation cycles. Surprisingly, the very conservation policies end up hindering such traditional management practices. For example, when forbidding nut-gatherers/swidden-farmers from clearing new plots of forest in exchange for those fallows they chose to protect. Expensive, labor-intensive and unpopular recommendations like enrichment planting are puny alternatives for what the ubiquitous swiddens can do, provided revised policies allow them to. Failing that, densities of senescent Brazil nut stands will continue to decrease until hardly justifying the "sustainable alternative to deforestation" discourse.

Morphometry of *Araucaria angustifolia* at different altitudes in Southern Brazil applied in the identification of critical growth points

Pollyni Ricken¹ , André Felipe Hess², Patrícia Póvoa de Mattos³ , Nelson Yoshihiro Nakajima¹, Roberto Tuiyoshi Hosokawa¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade do Estado de Santa Catarina, Lages, Brasil; ³Embrapa Florestas, Colombo, Brasil (pollyni7@hotmail.com; andre.hess@udesc.br; patricia.mattos@embrapa.br; nelson.nakajima@ufpr.br; roberto.hosokawa@pq.cnpq.br)

The aim of this study was to use morphometric characteristics of *Araucaria angustifolia*, as basis to elaborate management plans. Data was collected in three sites of Santa Catarina State: S1 (altitude of 1,350 m), S2 (1,150 m) and S3 (950 m). Random sampling and Bitterlich method were applied using 2 as basal area factor. We sampled 247 individuals (77 at S1, 93 at S2 and 77 at S3). The degree of indexes association was examined by Pearson correlation coefficient. S2 was constituted by larger trees, indicating better growth conditions. S3 presented the highest density of trees (403 trees.ha⁻¹), while at S1 and S2 there were 362 and 188 trees.ha⁻¹, respectively. At S3 most trees had a crown proportion greater than 50% and crown formal smaller than 1, reflecting trees with narrower and longer crowns. The height/diameter ratio was similar among sites (0.4 to 0.5). Diameter correlation with slenderness ratio was negative and bigger than 70%. In all sites diameter at 1.30 m from ground level (DBH) showed positive relation with crown diameter, indicating that as trees increase in DBH, crown diameters also increase. The removal of competing trees becomes essential to increase growth rate by increasing space and light incidence. Morphometric indexes can be used to support sustainable forest management plans, allowing the identification of critical points related to the trees development pattern.

Adapting the Prodan method for sampling species associated with *Araucaria angustifolia* (Bertol.) Kuntze / Adaptação do uso do método de Prodan para amostragem de espécies associadas a *Araucaria angustifolia* (Bertol.) Kuntze

Joelmir Augustinho Mazon^{1,2}, Richeliel Albert Rodrigues Silva^{1,3}, Luciano Farinha Watzlawick¹

¹Universidade Estadual do Centro Oeste, Guarapuava, Brasil; ²Faculdade Guairacá Guarapuava Brasil; ³Universidade Federal do Rio Grande do Norte Natal, Brasil (joelmir23@hotmail.com; richelielufrn@gmail.com; farinha@unicentro.br)

Este trabalho objetivou a adaptação do método de amostragem de área variável de Prodan para o estudo de espécies de porte arbóreo que ocorrem com maior frequência próximas à Araucária (*Araucaria angustifolia*), considerando estas como espécies associadas desta espécie. Para tanto, percorreram-se cinco transectos equidistantes paralelamente em 100 metros, totalizando 1.830 metros de caminhada em um fragmento de Floresta Ombrófila Mista de 22 hectares no Parque Natural Municipal das Araucárias, em Guarapuava, PR. A aplicação do método consistiu na demarcação de indivíduos de Araucária ao longo de cada transecto, utilizando-os como ponto central para a unidade amostral e a cada destes, determinou-se o raio das seis árvores mais próximas, as quais foram identificadas taxonomicamente e classificadas quanto à sua frequência absoluta. Foram mensurados 55 indivíduos de Araucária ao longo de todos os transectos, cujo os diâmetros variaram em média 71,5 ± 26,8 cm, contemplando uma área total amostrada de 0,54 hectares e um total 38 espécies encontradas. As espécies mais frequentemente identificadas consideradas como associadas da Araucária foram: *Campomanesia xanthocarpa* O. Berg, que ocorreu próxima de 51% das Araucárias observadas, *Casearia decandra* Jacq. (34,5%), *Gymnanthes klotzschiana* Müll. Arg. (30,1%), *Araucaria angustifolia* e *Cinnamodendron dinisii* Schwanke (27,3%), *Allophylus edulis* (A. St-Hil., Cambess e A. Juss.) Radlk (20%) e *Matayba elaeagnoides* Radlk. (18,2%). A adaptação do método de Prodan mostra-se uma ferramenta útil para o entendimento da ecologia e fitossociologia da *Araucaria angustifolia*, podendo ser utilizada para projetos de manejo e conservação desta espécie icônica e tão ameaçada no Brasil devido a sua importância econômica.

Genetic analysis of growth curves of individual trees and country-wide provenances of *Araucaria angustifolia* shows huge potential for enhanced domestication, breeding and conservation of this iconic Brazilian conifer

Rafael Tassinari Resende¹, Pedro Tanno², Orzenil Bonfim Silva-Junior³, Ananda Virginia de Aguiar⁴, Valderês Aparecida de Sousa⁴, Alexandre Sebbenn^{5,6}, Dario Grattapaglia^{3,7}

¹Universidade Federal de Goiás, Goiânia, Brasil; ²Universidade de Brasília, Brasília, Brasil; ³Embrapa Recursos Genéticos e Biotecnologia, Brasília, Brasil; ⁴Embrapa Florestas, Colombo, Brasil; ⁵Instituto Florestal de São Paulo, São Paulo, Brasil; ⁶Universidade Estadual Paulista "Júlio de Mesquita Filho", Ilha Solteira, Brasil; ⁷Universidade Católica de Brasília, Brasília, Brasil (rafael.tassinari@gmail.com; tanno.pedro@gmail.com; orzenil.silva@embrapa.br; ananda.aguiar@embrapa.br; valderes.sousa@embrapa.br; alexandresebbenn@yahoo.com.br; dario.grattapaglia@embrapa.br)

Understanding the growth behavior of forest tree species is important for early selection, and to understand ecological patterns, predict future biomass and adaptive tree fitness. We investigated the genetic variation for growth traits of *Araucaria angustifolia* in a trial involving 122 families from 15 provenances from three Brazilian regions. Measurements at ages 7, 24, 32, 33 and 35 were used to adjust continuous growth curves based on nonlinear mixed-effect models for all 2,158 trees, providing estimates for unmeasured ages in the 7-35 interval. Estimated values closely matched observed ones and a reduction of the coefficient of residual variation was observed in the estimated data, possibly due to removal of random error in observed measurements, making the estimated curves more reliable to predict growth patterns. Genetic variation within provenances was greater than between, with a trend of increasing heritabilities over time for most provenances. Growth curves show that trees invest first in DBH and later in height, and even at age 35 *A. angustifolia* does not show biomass growth stagnation. Provenances with great potential for breeding and genetic conservation were identified with variable adaptation to support global climate and landscape change. The data clearly indicate potential for early selection at age 7-10 with 85% accuracy of selection at age 35, and possibility of shortening rotation age to 15-20 years by selecting the best individuals and families. These results underscore the huge potential of expanding investments in breeding and plantation forestry of *A. angustifolia* with a concomitant enhancement of conservation efforts.

Growth of different progeny of *Araucaria angustifolia* (Bertol.) O. Kuntze in Southwestern Paraná, Brazil / Crescimento de diferentes progênies de *Araucaria angustifolia* (Bertol.) O. Kuntze no Sudoeste do Estado do Paraná

Marcos Eduardo da Silva Santos¹, Emanoele Cristina Weiss¹, Wellington Mateus Ribeiro Dzindzik¹, Michel Anderson Masiero¹, Eleandro José Brun¹ 

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (marcoseduardoferraz12@gmail.com; weissemanoele@gmail.com; wellingtondzindzik@alunos.utfpr.edu.br; masiero@alunos.utfpr.edu.br; eleandrobrun.utfpr@gmail.com)

Araucaria angustifolia é considerada uma espécie ameaçada de extinção, devido à exploração indiscriminada e erosão genética historicamente ocorrida. Existe uma grande necessidade de pesquisas e melhoramento da espécie visando conservação e uso sustentável da mesma. Neste trabalho, avaliou-se o desempenho silvicultural de diferentes progênies de *A. angustifolia*, em experimento em delineamento inteiramente casualizado (DIC), implantadas em julho/2016, em 30 tratamentos (progênies) oriundas de Santa Catarina (15) e Paraná (15), com três repetições de cinco mudas cada. Este trabalho apresenta os resultados do inventário realizados aos dois anos de idade, para as variáveis: Diâmetro do colo (D); Altura (H) e Vigor (V), as quais foram submetidas a análise de variância e teste de médias de Tukey a 5% no programa SISVAR v; 5.6. Houve diferença significativa entre as progênies para H e D, onde a maior média para H foi na progênie 957PR (1,54 m) diferindo significativamente de algumas progênies como a 958PR (0,18 m) que obteve a menor altura. No D, o maior valor ocorreu na progênie 963PR (4,2 cm) e a menor foi a 954PR (0,35 cm). Quanto ao vigor (V), 96,6% apresentam o vigor médio, 2,2% baixo e 1,2% alto, mostrando que as plantas ainda estão em processo de adaptação. Ocorreram diferenças significativa entre o crescimento das araucárias, onde as progênies do Paraná (PR) apresentam-se melhor adaptadas que as de Santa Catarina (SC), principalmente as progênies 963PR e 957PR que obtiveram as melhores médias e vigor superior.

Roads with Araucarias: payment for ecosystem services project for small-scale rural producers

Edilson Batista de Oliveira¹

¹Embrapa Florestas, Colombo, Brasil (edilson.oliveira@embrapa.br)

Araucaria angustifolia is the symbolic tree species of Southern Brazil. However, its extensive exploitation over several decades to meet domestic and export market demands for lumber, as well as the expansion of agriculture, has resulted in a significant reduction in the species' population and its inclusion on the Brazilian list of threatened species. Through Payment for Ecosystem Services, the Roads with Araucarias Project encourages the planting of *A. angustifolia* along roadways and property lines on small-scale family farms. Rural producers plant *A. angustifolia* trees on their properties and are remunerated by private companies who use the trees as compensation for greenhouse gas emissions and to promote other ecosystem services, such as roadway landscaping, environmental protection, preservation of the *A. angustifolia* species, environmental education, production of *A. angustifolia* pine nuts (pinhões), benefits for fauna, and shade for cattle. The project also seeks to increase the population size of *A. angustifolia*. Each producer receives R\$ 1,000 (approximately US\$ 300) annually for every 200 trees that he/she plants and maintains along roadways. The project began in 2011 and includes 70 properties in the municipalities of Lapa, Fazenda Rio Grande, and Irati, Paraná, and Caçador, Santa Catarina. In the four municipalities, 20,000 trees have been planted. However, the most positive result is the dissemination of the technique to other rural property owners, particularly those that are not small-scale farmers. Producers have voluntarily adopted the practice of planting *A. angustifolia* along property lines because of the advantages these trees offer, including improved aesthetics.

Overcoming constraints for incorporating valuable-timber native species in the mesoamerican humid lowlands: recent research findings on *Roseodendron donnell-smithii*

Boris Mendez-Paiz¹

¹University San Carlos de Guatemala, Agriculture and Environmental Research Institute, Guatemala, Guatemala (bmpaiz@yahoo.com)

High diversity of tree species is a remarkable feature of humid tropical lowland landscapes; land conversion, forest degradation and overexploitation of wood are reducing populations of native valuable timber producer species. Cultivation of such species is a highly desirable goal in different forestry and agroforestry plantations; however, that is hampered by the scarcity of knowledge on their ecological requirements and feasible silvicultural treatments. This paper describes recent research on the ecology and silviculture of *Roseodendron donnell-smithii*, a valuable timber producer, native of the humid lowlands of Mesoamerica. Species remnant populations are restricted to agroforestry plantations in Guatemala, mostly on Coffee and Silvopastoral Systems due to its value for shade, ornamental and valuable cabinet-timber. Failure of monoculture plantations established in a variety of sites throughout Guatemala with government incentives during the last two decades, raised awareness on needed knowledge of the auto-ecology of the species as the foundation for proper silviculture. Species recent research addressed site requirements, genetic variability and conservation, timber yield potential and stand productivity in mixed stands with other timber species and some permanent agricultural crops as an alternative to monoculture. Research findings for *Roseodendron donnell-smithii* are demonstrating that successful cultivation of valuable tropical native species is feasible for multiple purposes including productive, conservation and restoration, as long as species ecological knowledge support appropriate design and management practices. Long-term research and collaborative efforts among different stakeholders at national and international levels is essential to enhance innovation for increasing the use of such species.

A2p: SUSTAINING ICONIC AND HIGH-VALUE SPECIES IN NATURAL FORESTS AND PLANTATIONS

Effects of the microclimate of different forest community type on the distribution of endangered fern, *Mankyua jejuense* in Jeju Island in South Korea

Younghan You¹, Euijoo Kim¹, Eungpil Lee¹, Seungyeon Lee¹, Yongsik Hong¹, Hyunmo Jung²

¹Kongju National University, Kongju, Republic of Korea; ²National Institute of Ecology, Seochon, Republic of Korea (youeco21@kongju.ac.kr; euijoo@kongju.ac.kr; lyp2279@kongju.ac.kr; ecolee21@kongju.ac.kr; hongfin@smail.kongju.ac.kr; eimple01@nie.re.kr)

Endangered plant, *Mankyua jejuense* (fern), which is distributed only in Jeju Island in South Korea, is one of the smallest one in the world. This species appears to be habitats called Gotjawl where the geology and soil of the basaltic plain are scarcely developed, and temporary seasonal wetlands are often formed by summer heavy rains. In particular, in terms of climate zone, the potential natural vegetation in this area is evergreen broad-leaved forest, but there is almost no *Mankyua jejuense* in this area. Instead, it is distributed mainly in the floor of the deciduous forest, which can be said to be the disclimax forest type of this area. In this study, we monitored and analyzed the microclimate of weather, light and soil factors in two different forests type of Jeju Island. Through this study, we tried to clarify the difference of the microclimatic conditions of the two forests type and attempt to interpret the influence of such microclimate factors on

Mankyua jejuense. As a result, the number of inundation frequency and soil water content were higher in *Castanopsis sieboldii* community (evergreen) than that of *Ulmus parvifolia* community (deciduous), and the inundation level and light intensity were opposite. The average monthly light intensity was higher in *Castanopsis sieboldii* community (evergreen) than of *Ulmus parvifolia* community (deciduous). In conclusion, *Mankyua jejuense* weak against flooding and low light intensity. These microenvironmental characteristics are thought to be derived from two different life forms of woody plant communities in the upper layer. This funded by project of the Korea Research Foundation (No. NRF-2018R1D1A1B07050269) Korea government (Ministry of Education)

Initial mortality in clones of *Ilex paraguariensis* A. St. -Hil (erva-mate) in plantations in Southwestern Paraná, Brazil / Mortalidade inicial de clones de *Ilex paraguariensis* A.St. -Hil (erva-mate) em plantio na região sudoeste do Paraná

Gabriel Michalichen¹, Henrique Ribeiro¹, Débora Kreczkowski¹, Marjorie Eliza Maia Reis¹, Eduardo Pimentel Araldi², Eleandro José Brun¹ 
Ivar Wendling³ 

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil; ²Colégio Estadual Leonardo da Vinci, Dois Vizinhos, Brasil; ³Embrapa Florestas, Colombo, Brasil (gabrielmichalichen@gmail.com; henrique-ribeiro-chap@hotmail.com; debora-kreczkowski@hotmail.com; marjorieeliza99@hotmail.com; edwardmarrola@gmail.com; eleandrobrun.utfpr@gmail.com; ivar.wendling@embrapa.br)

A erva-mate é uma espécie florestal de grande importância não madeireira, tanto economicamente como culturalmente, por ser produtora da matéria prima do chimarrão e de uma série de outros produtos alimentares, cosméticos e medicinais. Estudos estão em andamento com 8 diferentes clones diferenciados em função de características relacionadas a qualidade dos produtos potenciais, em parceria com a Embrapa Florestas. Os mesmos foram plantados em 4 blocos com 5 mudas de cada clone por bloco, em espaçamento de 1,50 m x 1,50 m, com preparo mecanizado do solo (escarificação) e covas manuais de 20 cm de profundidade, com o uso de hidro gel e sombreamento por tabuas do lado oeste, em plantio realizado em Agosto de 2018. Tratamentos culturais de controle de invasoras e formigas cortadeiras vem sendo realizado rotineiramente. Avaliou-se, visualmente, a mortalidade das mudas clonais aos 90 dias após o plantio, onde o clone 3 apresentou porcentagem (%) de mortalidade igual a 0%, clone 12 igual a 5%, clone 81 igual a 5%, clone 82 igual a 5%, clone 1 igual a 15%, clone 101 igual a 15%, clone 83 igual a 30% e clone 84 igual a 35%. Ocorreram grandes diferenças no índice de mortalidade, que variou de 0% (clone 3) a 35% (clone 84), mostrando que o nível de estresse ambiental decorrente da adaptação inicial a área de campo é diferente entre os clones, os quais se comportam de forma variada em sua reação ao clima local.

Spacing patterns for *Araucaria angustifolia* (Bertol.) Kuntze in two management systems for Mixed Ombrophile Forest / Padrão espacial da *Araucaria angustifolia* (Bertol.) Kuntze em dois sistemas de manejo na Floresta Ombrófila Mista

Luciano Farinha Watzlawick¹, Richeliel Silva¹, Joelmir Mazon¹

¹Universidade Estadual do Centro Oeste, Guarapuava, Brazil; (farinha@unicentro.br; richeliel@yahoo.com.br; joelmir23@hotmail.com)

Araucaria angustifolia é um espécie pertencente à família Araucariaceae, nativa do Brasil e em risco de extinção. Objetivou-se neste estudo analisar o padrão espacial da espécie em dois fragmentos de Floresta Ombrófila Mista, sendo o primeiro sob sistema silvipastoril e o segundo uma floresta em processo de sucessão secundária. A amostragem foi realizada em duas parcelas de 1,2 hectares, na propriedade particular Edelweiss, no município de Turvo, Paraná. Para isso, foram registradas as coordenadas (x, y) de cada ponto, com objetivo de testar a hipótese de completa aleatoriedade espacial (hipótese nula), por meio da função K de Ripley, na forma univariada, sendo avaliado o padrão espacial de todos os indivíduos da espécie, como também a distribuição em duas classes diamétricas (5 a 20 cm e igual ou superior a 20 cm), no programa SpPack 1.38. A espécie apresentou distribuição espacial agregada nas áreas de floresta em sucessão secundária e silvipastoril, indicando que as sementes foram dispersas próximas à planta mãe. Em relação aos indivíduos das classes diamétricas de 5 a 10 cm nas duas áreas, o padrão observado também foi agregado. Nas classes superiores a 20 cm, o padrão verificado nas duas áreas foi aleatório. O referido padrão é esperado para as classes com maiores diâmetros, devido à baixa competição e mortalidade, estabelecendo-se assim, os indivíduos mais resistentes. Pode-se concluir que a *A. angustifolia* apresenta o mesmo padrão espacial nos dois sistemas de manejo. Diante disso, os resultados obtidos podem auxiliar no manejo da espécie, contribuindo para sua conservação.

Effects of multi-stem, stand density on cone and timber production of *Pinus koraiensis* in a cone production circle

Hailong Shen¹, Nguyen Thanh Tuan²

¹Northeast Forestry University, Harbin, China; ²Vietnam National University of Forestry, Southern Campus, Dong Nai, Vietnam (shenhl-cf@nefu.edu.cn; tuanvfu2@gmail.com)

Korean pine is an excellent timber and nutritious seed production tree species natively distributed in Northeast China and adjacent areas. Recently, its edible nut production has become a most important issue to the local economic development. During the growth and development of *Pinus koraiensis*, very popular multi-stem phenomenon and stand density has great influence on its timber and seed production. Therefore, four different stand density treatments in a 40-year-old Korean pine plantation were set and an investigation were conducted in a stand with artificial top-pruning 16 years ago to study the effects of multi-stem and stand density on cone production and tree growth in one fruiting circle. The results shown that (1) there was significant positive correlations between natural multi-stem of *Pinus koraiensis* trees and plantation density; both natural multi-stem and top-pruning derived multi-stem were favorable to increase of timber production and cone production of Korean pine in tree level and stand level as well; (2) Korean pine plantations in about 40-year-old at 600-750 trees×hm⁻² and multi-stem occurring position above 8-10 m were favorable to high-quality bole timber production and yield and quality promotion of cones and seeds as well; (3) Double stem trees should be taken as the main cultivation ones because this tree types was the majority in stand, distributed uniformly, had much more contribution to cone production, had better bole production than that of non-multi-stemmed and single-multi stemmed types, and had weak competition and small ecological resource occupancy than that of multiple multi-stemmed type.

Diameter growth of *Retrophyllum rospigliosii* in the Colombian Andes / Crecimiento diamétrico de *Retrophyllum rospigliosii* en los Andes Colombianos

Jorge Ramirez¹ ²; Alejandro Gomez², Adriana Marin³, Jorge Ignacio Del Valle²

¹Universidad del Cauca, Popayan, Colombia; ²Universidad Nacional de Colombia, Medellin, Colombia; ³Smurfit Kappa Cartón de Colombia, Cali, Colombia (j.ramirez@unicauca.edu.co; agomezch@unal.edu.co; adriana.marin@smurfitkappa.com.co; jidvalle@unal.edu.co)

Las plantaciones tropicales con especies nativas se plantean como alternativa al uso de especies exóticas debido a su aceptación en términos ecológicos y sociales. El pino colombiano (*Retrophyllum rospigliosii*) se ha sugerido para la reforestación comercial debido a sus posibles usos para aserrío y pulpa de fibra larga. En plantaciones de *R. rospigliosii* de 20 años en cuatro sitios contrastantes de los Andes colombianos modelamos el crecimiento del diámetro (D)

en función de la edad (t) con la ecuación diferencial de tasas de crecimiento relativizadas de von Bertalanffy mediante modelos mixtos no lineales. Ajustamos un modelo multinivel Bayesiano con dos grupos anidados, sitio e individuo, obteniendo un R-cuadrado Bayesiano de 99 % y cumpliendo los supuestos de la regresión. Nuestros resultados sugieren que esta especie creció hasta $D \approx 30$ cm en $t \approx 18$ años; luego el crecimiento fue casi nulo. El crecimiento medio anual de 1.6 cm año⁻¹, se maximizó rápidamente en $t = 1.2$ años cuando $D = 1.7$ cm. En contraste, otra conífera comúnmente plantada, *Pinus patula* en sitios medios y densidades comparables alcanza en Colombia $D = 45$ cm en $t = 20$ años, y continúa creciendo a altas tasas. *R. rospigliosii* no parece una alternativa atractiva para la producción maderera. Se sugiere su preservación en condiciones naturales, su empleo en restauración y en reconstrucciones climáticas dada su longevidad y la existencia de anillos de crecimiento anuales.

Experiments with mahogany plantations (*Swietenia macrophylla* King) in integrated forest-livestock and agroforestry systems in the Western Amazon / Experiências com o plantio de mogno (*Swietenia macrophylla* King) em SAF e ILPF, na Amazônia Ocidental

Silas Garcia Aquino de Sousa¹, Elisa V. Wandelli¹, João Carlos Matos²

¹Embrapa Amazônia Ocidental, Manaus, Brasil; ²Gardeners Consulting, Manaus, Brasil (silas.garcia@embrapa.br; elisa.wandelli@embrapa.br; joaomatosconsult@gmail.com)

Na Amazônia, plantio de *Swietenia macrophylla* em escala comercial enfrenta grande desafio. Objetivou-se neste trabalho sistematizar experiências com o plantio de mogno, ao longo de 26 anos de pesquisa agroflorestal, na Região Metropolitana de Manaus-AM (RMM). O plantio mais antigo foi realizado em jan/1993, na Estação Experimental da Embrapa (2° 51' 13" - 60° 02' 95"). Os mogno foram plantados conjuntamente com *Inga edulis* e distribuídos em três sítios (1,5 ha), em três condições de plantio e uma testemunha, uma em SAF-multiestratificado, consorciado com *Theobroma gradiflorum*, entre outros nove componentes e duas em ILPF-agrosilvipastoral 1 (altos insumos) e 2 (baixos insumos), consorciado com *Schizolobium amazônico*, pastagem e culturas agrícolas, totalizando 66 mognos/tratamento. Aos 26 anos do plantio, verificou-se no sítio 2 e ILPF 1 indivíduos com maiores DAP (média 48,50 cm), maiores alturas, comercial (média 10,0 m) e altura total (média 19,0 m) e sobrevivência de 75%. No SAF-multiestratificado verificou-se maior índice de mortalidade (95%). Ensaio em outros sítios na RMM, os resultados foram semelhantes. O plantio em ILPF apresentou melhor resultado em DAP, altura e sobrevivência, por causa da adubação periódica com o plantio de *Zea mays* e renovação da pastagem. O plantio sombreado dentro de capoeira ou em agroecossistemas já estabelecidos apresentam severo ataque de *Hypsipyla grandella*. Entretanto, deixar a capoeira ou o ingá crescer junto com o mogno é uma alternativa de menor ataque de *H grandella*. O mogno é uma espécie exigente em solos férteis e apresenta melhor desempenho em ILPF.

Araucaria angustifolia pollen handling and germination

Valderês Aparecida de Sousa¹, Giovana Guimarães², Dayane Tomigian¹, Ananda Virginia de Aguiar¹

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (valderes.sousa@embrapa.br; ggiovanaguima@gmail.com; dayane.tomigian@gmail.com; ananda.aguiar@embrapa.br)

Conservation of Ombrophilous Mixed Forest tree species in Brazil is imperative. *Araucaria angustifolia* (Bert.) O. Ktze is an important tree species over exploited and threatened on extinction. Ex situ conservation through pollen storage, under suitable conditions, could be an alternative to keep male diversity. However an adequate pollen handling methods must be developed specifically. There are critical steps like collection, drying, storage, as well viability estimation. Our goal with *Araucaria* pollen in long term is to keep pollen at deep freezing temperatures as long as possible and evaluate it with appropriate methodology. Here we will introduce results of pollen germination submitted to different freeze drying levels, and culture media regarding medium composition. Germination trials were conducted in randomized complete block design and four replications for treatment. Freeze drying for 15 and 30 minutes; one hour; two hours and four hours has been considered. Germination was leading on a culture medium with agar (0.8 %), sucrose (10 %) and Brewbaker and Kwack (1963) solution for 72 and 96 hours. From these results it was concluded that germination was low both for 72 and for 96 periods affecting conclusions about treatments even with sucrose addition. As a longer period of germination is not possible, due to the contamination, other variables must be considered, as the increase of the re-hydration period before germination, among others, to optimize protocols of pollen germination. On the other hand, the use of specific stain could be also useful to estimate the viability of *Araucaria* pollen in the future.

Benefits from the use and practice of non-timber forest products in Amazonia / Benefícios do uso e costume de PFM da Amazônia

Maria Isabel Araújo¹, Silas Garcia Aquino de Sousa², Evandro de Moraes Ramos¹

¹Universidade Federal da Amazônia, PPGSCA, Manaus, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil; (miar@terra.com.br; silas.garcia@embrapa.br; evandro.ramos@ufam.edu.br)

Os produtos florestais não madeireiros (PFNM) em grande número são utilizados como: alimentícios, aromáticos, artesanais, industriais, medicinais, ornamentais, além disso, configura-se como uma alternativa de renda aos agricultores familiares da região. Objetiva o presente identificar os PFNM, ofertados e demandados nas feiras regional da Agência de Desenvolvimento Sustentável do Amazonas (ADS/AM), em Manaus/AM. Quanto ao método de investigação, utilizou-se a pesquisa-ação, cujo locus da pesquisa compreendeu as feiras semanais da ADS/AM, localizadas na Associação dos sargentos do exército (ASA), Associação dos sargentos da aeronáutica (Cassam), pátio do Comando da Polícia Militar, pátio do Shopping Sumaúma Park, coletados no 2º semestre de 2017. Verificou-se a oferta de uma grande diversidade de produtos e derivados de plantas da floresta e agroflorestal. Estes produtos são bastante demandados pelas populações do campo e da cidade, sendo utilizados como alimento, na medicina popular, cosméticos e demais usos. Observou-se a oferta com registro de 60 espécies, distribuídas em 18 famílias botânica. Destaque para: *Carapa guianensis*, *Protium heptaphyllum*, *Myrciaria dubia*, *Bertholletia excelsa*, *Lecythis pisonis*, *Copaifera officinalis*, *Dipteryx odorata*, *Pourouma cecropiifolia*, *Byrsonima crassifolia*, *Couepia bracteosa*, *Oenocarpus bataua*, *Astrocaryum aculeatum*, *Endopleura uchi*, *Hymenaea courbaril*, *Calycobulus ferrugineus*, *Parahancornia fasciculata*. A comercialização destes produtos nas feiras regionais permite que a população da cidade tenha acesso facilitado destes produtos e derivados, seja na forma in natura ou beneficiados. Conclui-se que, a utilização racional dos PFNM, além de manter a floresta em pé, transforma este grande potencial da biodiversidade Amazônica em vários benéficos tanto às populações do campo como da cidade.

A3a: FOREST OPERATIONS: A TOOL FOR FOREST MANAGEMENT**Assessing the cost and risks of owning and operating used machines**

Dalia Abbas¹, Fulvio Di Fulvio², Enrico Marchi³, Raffaele Spinilli⁴, Mike Schmid⁵, Ted Bilek⁶, Han-Sup Han⁷

¹American University, Washington, DC, USA; ²IIASA, Vienna, Austria; ³UNIFI, Florence, Italy; ⁴IVALSA, San Michele all'Adige TN, Italy; ⁵Self, Moline, USA; ⁶Forest Service, Madison, WI, USA; ⁷Northern Arizona University, Flagstaff, USA (*daliaabbas@yahoo.com; difulvi@iiasa.ac.at; enrico.marchi@unifi.it; spinelli@ivalsa.cnr.it; schmidjamesm@johndeere.com; tbilek@fs.fed.us; han-sup.han@nau.edu*)

The market for used forestry machines is growing. Standard machine costing methods do not account for already depreciated or used machines in a manner that reflects operations run by small-sized firms. This is because the assumptions made for new machines are not very descriptive of the actual conditions of the operations on the ground using used machines – no one size fits all. As a result, these methods alienate this segment of the logging community, because they are not very relevant to what they paid for the machine, nor the actual performance on the ground. To address this issue, this presentation is based on an expert-based understanding developed to integrate operational-economic-market factors in costing used machines. The intent is to help used machine operators more realistically value the cost of their operations in relation to the machines used and their production.

Forest operations for ecosystem services

Yeon-Su Kim¹, Han-Sup Han¹

¹Northern Arizona University, Flagstaff, USA; ¹Northern Arizona University, Flagstaff, USA (*ysk@nau.edu; han-sup.han@nau.edu*)

Forest operations have been traditionally understood as a means of timber harvesting, which is just one of various ecosystem services that forests provide for human well-being. Today, forest operations are an integral part of ecological restoration efforts, which aim to enhance synergic delivery of various ecosystem services, such as healthy watershed and biodiversity, as well as resilience under changing climate. We will present a case of forest restoration activities in American Southwest where overabundant small-diameter trees create high risk of unnatural, mega-fires. Necessary restoration treatments to remove small-diameter trees face challenges due to high costs of harvesting and transportation and low values associated with small-diameter logs and biomass materials. Lack of forest products industry in the region, which makes it difficult to market those materials, is a key barrier to implementing a large-scale forest restoration program. We will present the ongoing efforts to develop innovative forest operations and utilization strategies for promoting forest restoration treatments and assess their impacts on various ecosystem services. This presentation will provide an opportunity for participants to share their own experiences dealing with the challenges that they face and promote the discussions on applying forest operations to maximize the synergic effects of ecosystem services delivery.

Full economic valuation and the case for unprofitable forest operations

Nathaniel Anderson¹, Robert Campbell²

¹United States Forest Service, Missoula, USA; ²University of Montana, Missoula, USA (*nathaniel.m.anderson@usda.gov; robert.campbell@umconnect.umt.edu*)

As described by Marchi et al. (2018), economic sustainability is one of the five pillars of Sustainable Forest Operations (SFO). Historically, the emphasis of operations has been on extracting timber and other market products from a forest, and economic sustainability has been closely tied to profitability. By minimizing unit costs and maximizing productivity and product value, efficient operations ensure that revenues exceed costs. Emissions and site impacts are assumed to be negative, but manageable. Nonmarket ecosystem goods and services are assumed to be byproducts of effective, profitable forest operations. In the public forests of the western United States, this paradigm has been smashed by landscape-scale tree mortality and poor forest health associated with wildfire, insects and disease. Revenues from the low grade and low value products flowing from fuel treatments, salvage harvests, and forest restoration can be far exceeded by the cost of operations. Net positive environmental effects and enhanced ecosystem services are frequently the implicit justification for unprofitable operations, but these benefits are rarely measured at the project scale, and are seldom the focus of engineering optimization in practice. This paper presents a new methodology to more fully integrate the valuation of non-market benefits into the cost and productivity measures of forest operations. Examples from wildfire fuel treatment and beetle kill salvage are presented to illustrate the importance of explicitly accounting for the non-market costs and benefits of such treatments. This has direct implications for decision making in the SFO framework, especially when operations would otherwise be considered unprofitable.

Planning tools for best practice management of threatened species under the Tasmanian Forest Practices System

Dydee Mann¹, Sarah Munks¹

¹Forest Practices Authority, Hobart, Australia; ¹Forest Practices Authority, Hobart, Australia (*dydee.mann@fpa.tas.gov.au; sarah.munks@fpa.tas.gov.au*)

Australia's island state of Tasmania has around 700 threatened flora and fauna species, many of which are found in wood production areas. Tasmania's "clean, green image" relies on well managed forests where native flora and fauna persist. Under current legislation and policy, potential impacts on these threatened fauna species and their habitat must be considered in all planning for forestry activities. Research into flora and fauna species life history, habitat preferences, distribution and threats feeds into a series of planning tools to support decision-making on the appropriate ways to manage each species under different silvicultural systems. Statewide species range boundary maps and specific habitat descriptions are developed, which help forest planners to recognise areas of the state that require more or less intense species management. Species-specific management recommendations are developed to mitigate the impact of forestry activities and delivered in an online tool, then translated by forest planners into on-ground instructions for forest contractors. Management recommendations are designed to be applied at multiple spatial scales, from coupe-level to the broader landscape, and are reviewed whenever new research findings are released. Importantly, implementation and effectiveness monitoring are carried out to support a continually adaptive management approach. This combination of planning tools, science-based management recommendations and regular review contributes to the success of biodiversity management under the Tasmanian Forest Practices System.

Evaluating the exposure of chainsaw operators to wood dust in felling operations

Abdullah Emin Akay¹, Ebru Bilici², Dalia Abbas³, İnanç Taş¹

¹Bursa Technical University, Bursa, Turkey; ²Giresun University, Giresun, Turkey; ³American University, Department of Environmental Sciences, Washington, D.C., USA (abdullah.akay@btu.edu.tr; ebru.bilici@giresun.edu.tr; daliaabbas@yahoo.com; inanc.tas@btu.edu.tr)

The motorized handheld chainsaw is widely used in felling, delimiting, and bucking tasks during forest harvesting operations. The chainsaw operators usually use chainsaw during most of the work hours which potentially leads to various health risks exposures caused by noise, wood dust, exhaust gas, and vibrations. Wood dust particles, in particular, in ambient air may cause occupational lung diseases due to the collection of dust particles on the lung tissues. These particles are divided into two major groups including big particles (PM10) between 2.5 and 10 micrometers in diameter and small or fine particles (PM^{2.5}) 2.5 micrometers or less in diameter. In this study, wood dust particles exposed by a chainsaw operator were measured during a felling operation. In the field, wood dusts with various sizes (0.3, 0.5, 1.0, 2.5, 5.0, 10.0 micrometers) were sampled using Extech VPC300; particulate matter measurement device. After analyzing the particle sizes, it was found that the percentages of particulate matter sizes sampled were 60.71%, 29.29%, 6.99%, 2.80%, 0.16%, and 0.04%, respectively. The results indicate that most of the wood dust (99.80%) that resulted from the chainsaw operations were categorized as fine particles (PM^{2.5}). Based on the analysis using Pearson correlation coefficient, it was found that there was a statistically significant ($p=0.01$) positive correlation between the tree diameter and the amount of wood dust. The results suggest that chainsaw operators are under the risk of fine wood dust exposure, therefore, they should use appropriate personal protection equipment during felling operations.

Short-term effects of forest road construction on bird, mammal, and plant communities: a case study on Forest Road in Minjujisan, Korea

Seung-Woo Han¹, Joon-Woo Lee², Hyoun-Sook Kim², Hakjun Rhee² 

¹Korea Institute of Environment Ecology, Daejeon, Republic of Korea; ²Chungnam National University, Daejeon, Republic of Korea (hanus2000@naver.com; jwlee@cnu.ac.kr; woangsisster@hanmail.net; hakjun.rhee@gmail.com)

Forest road is essential for forest management, but it might cause changes in forest ecosystem. This study investigated the short-term effects of forest road construction on bird, mammal, and plant communities by monitoring a newly-built forest road in Minjujisan, Korea before, during, and after the construction from 2012 to 2015 until the monitoring was interrupted by logging operations. From this period the number of bird species decreased from 34 to 24, but the number of bird individuals slightly increased. The major dominant species and species evenness did not change significantly, but species diversity and richness decreased. The bird community in canopy layer was observed frequently, because large tree canopies were well-connected even after the construction. The inhabited birds, especially summer migratory and resident birds, were affected by road construction in summer, and returned after the construction. Mammals used the forest road more frequently than the control area inside forest according to sensor camera analysis. Large mammals such as wild boar, Korea water deer, and roe deer mainly used the forest road as a passage at night. Therefore, the road use in daytime had no major effects on the movement of nocturnal mammals. The number of species and the growth rates of shrubs and herbs increased after the construction, because it opened the canopy, increased light intensity, and brought herbaceous seeds around the forest road. This study found that the forest road construction disturbed the inhabited bird community, but it might have positive impacts on mammal movement and plant growth.

Comparison of productivity, costs, and effect on the forest soil by four forest harvesting systems in small-scale woodland

Oscar Bustos¹, Carlos Mena¹

¹Universidad de Talca, Talca, Chile (obustos@utalca.cl; cmena@utalca.cl)

A comparison of the productivity, costs and effects on the forest soil expressed in percentage of compaction, when applying four harvesting systems for wood extraction from the forest of small landowners was studied. The systems used in the yarding were a forwarder with harvester, and skidder, a farm tractor, and a bulldozer using chainsaws for felling activities. A statistical design was applied in blocks completely at random, considering the different treatments with its respective replicate assigned to each block. A continuous time and motion techniques in which running times were recorded and the number of stems and volume yarded were determined and recorded for each machines per cycle. Soil compaction was measured on samples in trafficked and untrafficked areas in two general places: skid trail and in the harvested areas. The finding showed a greater productivity in terms of cubic meters per productive machine hour (11.45 m³/PMH), it was reached by the forwarder system, which also caused the smaller effect of compaction on the forest soil (0.86 g/cm³) and its production cost per unit were lowest value among the four harvesting systems (10.03 \$/m³). On the other hand, the system bulldozer caused the greater compaction on the soil (0.97 g/cm³), with a low productivity (4.64 m³/PMH) and production cost (14.10 \$/m³), similar to the skidder and farm tractor systems. The results have a strong implication on the selection of machineries for the planning of the small-scale woodland, as well as, aspect related to sustainability management and conservation of forest soils.

Reducing hazardous fuels with simple biochar kilns

Darren Mcavoy¹

¹Utah State University, Logan, USA (darren.mcavoy@usu.edu)

The Utah Biomass Resources Group (UBRG) introduced simple biochar kilns to Utah in 2017 to reduce hazardous fuels and produce a valuable product. We have conducted seven workshops in Utah to date, educating more than 200 people, and have reduced hazardous fuels by approximately 20 semi-truck loads in the state. More recently, the UBRG received a Public Lands Initiative Grant to scale up this simple approach, from boxes that measure 1.5 meters across, to kilns that can be more than six meters across. Parallel efforts are ongoing in Oregon, Nevada, and North Dakota using a variety of kiln designs that depend on repurposed local materials; several of these approaches will be introduced in this presentation. Advantages of this approach over more high tech machines include significantly reduced cost, increased accessibility, and considerably less cost in feedstock preparation by avoiding the expense and energy necessary for chipping and/or grinding feedstock material. We have safely deployed these kilns in close proximity to heavy fuels loads, urban infrastructure, homes, and ecologically sensitive locations such as within Stream Management Zones. The workshops included a diverse audience of forest landowners and managers; wildland fuels specialists, arborists, gardeners, and city managers. Evaluation results indicate that 80% of the participants were interested in biochar production for its soil amendment properties while 49% of the audience was interested in biochar production as a hazardous fuels disposal method; these results indicate that some were interested in both.

A3b: THE IMPLEMENTATION OF ECONOMICS, FOREST POLICY, FOREST LAW AND GOVERNANCE IN LATIN AMERICA FORESTRY

Forest policy and governance in Uruguay: progress and challenges / Política y gobernanza forestal en Uruguay: avances y desafíos

Virginia Morales Olmos¹, Amalia Stuhldreher¹

¹Universidad de la República, Tacuarembó, Uruguay (vmolmos@gmail.com; astuhldreher@hotmail.com)

Uruguay desarrolló su sector forestal en el marco de una regulación específica que tuvo su origen en la Ley Forestal 15.939 de 1988. Sucesivos decretos han regulado la misma y realizado algunas modificaciones. La mencionada Ley Forestal fue aprobada por unanimidad del Parlamento y, a pesar de la alternancia de los tres partidos políticos mayoritarios en el poder, la política fue mantenida. A 30 años de aprobada la Ley Forestal el país se enfrenta al desafío del desarrollo de un sector industrial diversificado, el cual no se ha materializado. El objetivo de este trabajo es analizar la situación actual de la gobernanza en el sector forestal uruguayo y sus implicancias en términos de su desarrollo. El concepto de gobernanza ha tenido una evolución desde sus orígenes relacionados con la economía institucional (inicios del siglo XX) y también con la escuela de la regulación (década del '70) hasta hoy, donde se lo utiliza en perspectiva multinivel desde lo global, regional, nacional hasta lo subnacional y local, analizando los procesos de desarrollo en su multidimensionalidad. El concepto incluye asimismo relaciones más amplias de aquellas propias del formato político tradicional de gobierno, abarcando vínculos con actores de la sociedad civil y sector privado. En la última década, el gobierno nacional ha realizado diversos esfuerzos para contribuir al desarrollo del sector, en particular, implementado programas. Los resultados han sido dispares: en algunos casos aislados se ha fortalecido la gobernanza y en otros se observa que no existe una coordinación para generar procesos acumulativos.

Willingness to pay for forest conservation in Ecuador: results from a nationwide contingent valuation survey in a combined “referendum” – “consequential open-ended” design

Fernando Gordillo¹, Peter Elsasser¹, Sven Günter¹

¹Thuenen Institute of International Forestry and Forest Economics, Hamburg-Bergedorf, Germany (fernando.gordillo@thuenen.de; peter.elsasser@thuenen.de; sven.guenter@thuenen.de)

Deforestation is a threatening pan-tropical problem. Net deforestation in Ecuador amounts to approximately 500 km² per year for 2008–2014. It represents not only an environmental problem but also a threat to social welfare. As social welfare depends on individual preferences, we examined households' preferences and willingness-to-pay (WTP) for a proposed forest conservation program aiming to avoid deforestation in Ecuador. Our study presents results from a nationwide contingent valuation survey conducted in a geographically stratified random sample of 976 households across the three main geographical regions of Ecuador as well as urban and rural areas. About 98% of surveyed households consider the proposed program worth supporting. For forest conservation, the monthly mean WTP per household lies between \$6.28 (dichotomous choice) - \$3.17 (open-ended) depending on the method of analysis indicating a solid potential for supporting incentive-based conservation programs. Households also expressed their preferences by regions and types of forests but our results are inconclusive in this regard. Methodologically, our study sheds some new light on the causes for the well-known discrepancy between dichotomous-choice and open-ended WTP estimates. Our results may help improving social welfare by incorporating households' preferences into the design of forest conservation programs. Currently realized payments for the Socio Bosque program are based on sound social support which opens doors to discuss amplifying the financial scope of the program by examining the role that households could play in funding forest conservation programs. Our WTP estimates provide aggregate information that could support the design of forest policy instruments.

Multicriterion optimization of livestock and timber production in Uruguay

Adriana Bussoni¹, Valentin Picasso², Frederick Cabbage³, Jorge Alvarez¹

¹Departamento de Ciencias Sociales, Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay; ²Agronomy Department, University of Wisconsin, Madison, USA; ³Department of Forestry and Environmental Resources, North Carolina State University, Raleigh, USA (abussoni@fagro.edu.uy; picassorriso@wisc.edu; cabbage@gw.ncsu.edu; jalvarez@fagro.edu.uy)

The integration of the livestock and timber value chain in Uruguay presents great challenges, including assessing the degree of complementarity and competitiveness in their production, their economic and environmental sustainability, including carbon balance of the system. Despite the fact that demand for wood in Uruguay has grown steadily in the last decade, planted forests still cover a very low proportion of land owned by livestock producers. One problem is the lack of economic valuation of the trade-offs between both activities, and an inadequate ranking of the goals to be achieved. Based on a survey of livestock producers with some afforestation on their farms, preferential weights, hierarchies and productive, economic and environmental targets were established, which are applied using a lexicographic goal programming model. Lexicographic models define a solution subset on which values that conserve or exceed the objectives of the next hierarchy must be based. The results indicate that better livestock economic returns and income stability are achieved when livestock profitability is established as the first priority level, and forest profitability and minimization of income deviations as a second priority level. However, an added environmental carbon goal cannot be met, due to the fact that the pre-established livestock activity cannot be reduced. In spite of this, joint production models can be obtained that improve the environmental goals by establishing another order of priority. This would be possible only if economic or market incentives were applied to achieve the environmental carbon goal as well as livestock production.

Wood yields in native forests and their effects on land opportunity cost for the Arenal-Huetar Norte Conservation area in Costa Rica / Rentabilidad del aprovechamiento maderable en bosque natural y su efecto en el costo de oportunidad de la tierra, para el área de Conservación Arenal – Huetar Norte, Costa Rica

Christian Zúñiga-Méndez¹, Sebastián Ugalde-Alfaro², Víctor Meza-Picado³, Jhonny Méndez-Gamboa⁴

¹Universidad Nacional de Costa Rica, Heredia, Costa Rica; ²Oficina Nacional Forestal (ONF), Heredia, Costa Rica; ³Instituto de Investigación y Servicios Forestales (INISEFOR-UNA), Heredia, Costa Rica; ⁴Comisión para el Desarrollo Forestal de San Carlos (CODEFORSA), Ciudad Quesada, Costa Rica (czunigamendez@gmail.com; sugalde@oficinforestalcr.org; victor.meza.picado@una.cr; jmendez@codeforsa.org)

Esta investigación evaluó la rentabilidad del modelo actual de aprovechamiento maderable en bosque natural y su costo de oportunidad por usos alternativos del suelo, dentro del Área de Conservación Arenal-Huetar Norte, Costa Rica. Se utilizaron 24 sitios con plan de manejo aprobado y ejecutado durante el 2010-2013,

con ello se generaron tres estructuras de costos según el área efectiva de manejo; donde se encontró que la planificación y la formalización del permiso abarcan el 80% de los costos para acceder de forma legal al recurso. Así mismo, la rentabilidad se abordó a través de un modelo microeconómico que utiliza el valor del bosque como indicador, obteniéndose beneficios netos entre \$346,41 ha⁻¹ y \$910,13 ha⁻¹; que no lograron superar el precio del bosque en el mercado (\$3 503,85 ha⁻¹). Con los datos de costo de oportunidad se generó un mapa regional, que señala a los bosques del sur como los más vulnerables a presiones económicas por usos del suelo. Se concluye que, aunque las rentas son positivas, el aprovechamiento de madera no se puede considerar rentable, ya que no logra superar ni igualar el precio del bosque en el mercado; sumado a ello, existen limitaciones por gobernanza que encarecen aún más la actividad, y altas presiones económicas de los usos alternativos. Esta dinámica hace que el aprovechamiento maderable en bosque se restrinja a lugares cada vez más alejados del mercado, y a unidades de manejo superiores a 50 ha; desplazando al pequeño productor.

The probability of default on BNDES funding programs for plantations in legal reserve areas: a case study of Paraíba Valley

Silvana Nobre¹; Marcio Costa², Helena Von Glehn³, Maria José Brito Zakia⁴; Mariana Carvalhaes⁵

¹UPM – Universidad Politécnica de Madrid – ETSI de Montes, Forestal y del Medio Natural, Madrid, Spain; ²BNDES – Nacional Bank of Development, Department of Environment, Brasília, Brazil; ³SMA SP – The Secretariat for the Environment of the State of São Paulo, São Paulo, Brazil; ⁴IPEF – Forestry Science and Research Institute – Silviculture of Native Species Program, Piracicaba, Brazil; ⁵Embrapa, Secretaria de Inovação e Negócios, Campinas, Brasil (silvana.nobre@gmail.com; mmc@bndes.gov.br; hcarrascosa@sp.gov.br; zeze.zakia@uol.com.br; mariana.carvalhaes@embrapa.br)

São Paulo has a legal reserve deficit of 1.7 million hectares that should be regularized by planting native species with economic purposes, especially in underutilized forestry vocation areas. São Paulo State Secretariat of Environment (SMA-SP) identified the Paraíba Valley, as a priority for a multifunctional forest hub due to its relevance for the biodiversity and water conservation, and the low land-use conflicts expectation. SMA-SP led research to create technical recommendation packages for plantations that might adapt to the soil and climatic conditions. Those packages were embedded in open-to-public IT (information technology) tools to support plantation projects. We used the contents of those IT tools to evaluate the BNDES funding programs that might be used to finance legal reserve plantations. This work presents the probability of the default to the BNDES funding conditions applied to the recommendation packages. We used the Monte Carlo simulation methodology to calculate optimistic and pessimistic scenarios for Savana and Atlantic Forest biomes in the context the timber, tropical fruits and pellets industrial hub chains. We evaluated Climate Fund, ABC (Low Carbon Agriculture), and Pronaf (Family Agriculture) funding programs. Results are presented as probabilities of installments non-payment considering revenues from the restoration project. The probabilities vary according to the terms and composition of interest rates; from 2% to 50%. The risk classification that comprises the interest rates is the variable that most influences the default rates. Consequently, if the forest hub is considered a meaningful market risk reduction, the funding programs would have non-significative default rates.

Making forest concessions work for the SDGs and climate change mitigation in Latin America

Thais Linhares Juvenal¹, Baastian Louman², Marco Otarola³, Marcus Alves⁴, Cesar Sabogal⁵, Fernando Carrera⁶, Marco Boscolo⁷

¹FAO, ROMA, Italy; ²Tropenbos International, Wageningen, Netherlands; ³CATIE, Turrialba, Costa Rica; ⁴Servico Florestal Brasileiro, Brasília, Brasil (thais.linharesjuvenal@fao.org; blouman59@gmail.com; marco.otarola@catie.ac.cr; marcus.alves@florestal.gov.br; sabogalcesar10@gmail.com; fcarrera@catie.ac.cr; marco.boscolo@fao.org)

Latin America's 910 million hectares of natural forests have an average carbon content of 119 tonnes per hectare (t/ha) and hosts 40 million forest dependent peoples. Conserving and sustainably managing these forests, therefore, must be a global priority, not only for achieving the Sustainable Development Goal (SDG) 15 – life on land, but also for achieving all other SDGs. About 45 percent of the Latin American natural forest estate is reserved for wood production or has not been assigned a specific use. At least 18.5 million hectares of production forests are managed through forest concessions. This article will build on recent evidence collected in Brazil, Guatemala and Peru to argue that forest concessions, i.e. the allocation of management and utilizing rights of public production forests to non-state agents (private sector, communities, civil society organizations) through contracts establishing clear rights and responsibilities, can be an effective policy instrument to improve forest governance and advance sustainable forest management. Organized around four main sessions, the article will: i) build on the Voluntary Guidelines for forest concessions in the tropics (FAO & EFI 2018) to discuss conditions whereby concessions can be effective policy instruments; ii) assess environmental (deforestation, forest degradation) and socioeconomic indicators (income, employment, access to social services) of forest concessions in Latin America; iii) discuss opportunities and barriers to realize the effectiveness of forest concessions; and iv) present conclusions and recommendations to policy makers on the use of forest concession regimes, as well as the links with developmental and climate change objectives.

Restoration through agroforestry in Brazil: deciphering the forest code to inform policies and practices

Andrew Miccolis¹

¹ICRAF, World Agroforestry Centre, Brasília, Brasil (a.miccolis@cgiar.org)

The new Brazilian Forest Code includes key provisions allowing farmers to perform mandatory restoration of privately-owned protected areas through Agroforestry Systems (AFS), provided they maintain basic ecological functions. The state governments are still in the process of regulating, however, under what conditions this can be done, generating enormous uncertainty among farmers, extension and enforcement agents. This case study discusses how ICRAF and partners have fed into the formulation of policies on agroforestry for ecological restoration so as to fulfill environmental and social functions on Permanent Preservation Areas and Legal Reserves through two examples of pioneering state-level restoration policies in the states of Federal District and Minas Gerais developed through multi-stakeholder and evidence-based policymaking processes. In the Federal District, a multi-stakeholder alliance drafted a policy allowing and encouraging different restoration approaches, including agroforestry systems, to restore these protected areas. A series of indicators and guidelines has brought the focus of restoration to the long-term impacts rather than short-term results, methods adopted, or number of trees planted. In the State of Minas Gerais, a similarly participatory led to the drafting of guidelines for establishing and managing agroforestry-based restoration that tackle some of the key gaps in the national forest law: species selection, systems composition and management practices, including inputs, mechanization, and intensive pruning. Both cases point clearly to paths forward for other states in the process of regulating agroforestry and restoration in Brazil, shedding light on systems and management practices required to achieve ambitious restoration targets.

Analysis of dynamics in production, commerce, and public policies in the Chilean and Costa Rican forest sectors and their impact on competitiveness / Análisis de la dinámica productiva, comercial y de políticas públicas del sector forestal de Chile y Costa Rica y su impacto en la competitividad

Natalia María Chacón Cid¹

¹Universidad Nacional, Heredia, Costa Rica (ncid2213@gmail.com)

El sector forestal muestra serias deficiencias en términos de competitividad sectorial, pero las alianzas con otros sectores productivos son en la actualidad la alternativa para lograr mejoras sustanciales. Las características de las actividades económicas que a él se vinculan muestran opciones para implementar las estrategias regionales y mitigar la variabilidad climática, potenciando el uso de la madera como medio para la captura de carbono y la adaptación de economías verdes (PNUD 2018). Por otra parte, en el sector forestal las tendencias mundiales de comercio de productos de madera responden a un modelo de mercado más consciente de la realidad ambiental y con impactos diferenciados en los grupos generacionales. Actualmente hay quienes buscan alternativas sostenibles o una mayor utilidad y funcionalidad en un mismo producto, por lo que generar bienes mediante procesos de sostenibilidad y que propicien satisfacción por el consumo se vuelven aspectos clave, indispensables para el comercio de productos de madera con miras a la exportación. Los antecedentes sobre las perspectivas del sector forestal en América Latina muestran grandes esfuerzos por afianzar los flujos de comercio de los productos forestales y a su vez generar un mayor aporte a la balanza comercial de cada nación. La información a presentar evidencia los principales factores productivos, de mercado y las políticas públicas que han impactado la dinámica forestal de Costa Rica y Chile, así como el panorama regional en el cual estas dos Naciones han desarrollado la cadena de valor de productos forestales, como una oportunidad para el desarrollo humano.

A3p: THE IMPLEMENTATION OF ECONOMICS, FOREST POLICY, FOREST LAW AND GOVERNANCE IN LATIN AMERICA FORESTRY

Informal markets of forest products: characterization and methods for its analysis

Sergio Molina-Murillo¹  Manuel Guariguata²

¹Universidad Nacional (UNA), Heredia, Costa Rica; ²CIFOR, Lima, Peru (sergiomolina@una.ac.cr; m.guariguata@cgiar.org)

The informal sector is an important source of income for millions of families. It has been estimated that about 60 % of the employed population worldwide are in the informal sector; and specifically, the employment of the informal forestry sector triples the formal one. Multiple countries are taking measures to improve family access to forest resources through sectoral policies, particularly in Latin America. Although there is also pressure through international financing (e.g., REDD+) or trade (e.g., FLEGT) mechanisms, the fact is that there are still no safe and adequate options for those communities that actively participate in informal markets. Understanding adequately the structures and operations of informal markets is a requirement to support and plan the management and conservation of forest resources, as well as to promote the development of local businesses and families involved in them. In this sense, it is not enough to know which species are commercialized and at what prices or in what quantities; it is equally important to know who participates in the — commonly complex — commercial chains, how they are organized and how they evolve. This information is not easily accessible and tends to be of low priority for institutions that collect statistical information. The objective of this review was to explore the role of informal markets in the forestry sector, and explain some of the methods used in their research, citing its main advantages and limitations.

Looking beyond the leaves and understanding the roots: motivations and concerns of farmers planting trees for commercial purposes in Brazil

Manuela Czinár¹, Rocio A. Díaz-Chavez¹

¹Imperial College London, London, United Kingdom (m.czinar@imperial.ac.uk; r.diaz-chavez@imperial.ac.uk)

The Brazilian government has launched in December 2018 its National Plan for Planted Forests setting the goal of increasing the area by 2 million hectares by 2030. In order to understand Brazilian farmers' motivations to plant trees for commercial purposes, a questionnaire was applied to 65 farmers between October 2017 and July 2018. Results show that most of the farmers started planting trees because the prices were attractive by the time of planting. Also, many farmers pointed out that the lack of labour was an important factor in deciding to switch from labour-intensive crops and livestock to forestry. A high number of farmers revealed the possibility of not continuing planting trees for commercial purposes, which could pose a risk to the success of the National Plan. On the other hand, responses indicated that certified farmers are less likely to switch to other crops, suggesting that one less studied impact of certification is the persistence of land use decisions. Other important results were that farmers with less education and income are more likely to be part of associations. However, they do not receive technical support to the same extent than more educated and richer farmers do. This shows that many associations are not providing technical support to their members. In conclusion, by providing more technical support to farmers, the Brazilian government could enhance sustainability practices and expand the adoption of certifications which could help to detain farmers to switching from planted trees to other crops.

Understanding the determinants of technical assistance to support public policy towards planted forests in Brazil

Manuela Czinár¹, Rocio A. Díaz-Chavez¹

¹Imperial College London, London, United Kingdom (m.czinar@imperial.ac.uk; r.diaz-chavez@imperial.ac.uk)

The Brazilian government has launched in December 2018 its National Plan for Planted Forests. The plan consists of various goals, being one of them the expansion of knowledge transfer, training and technical assistance. This presentation focuses on the determinants of technical assistance by analysing data from the Brazilian Census of Agriculture. Data indicated that 78% of farmers in the country do not receive any technical assistance. In order to understand better the variables that determine technical assistance, a logistic model was built using the microdata of the 2006 Brazilian Census of Agriculture. It showed that the probability of farmers in the first quintile of income to receive technical assistance is 88% lower than farmers in the fifth quintile of income. The level of education was the variable with the highest odds: the odds of a farmer with any bachelor's degree to receive technical assistance is 3,128 times that of a farmer without formal education, proving that the farmers with less education have much lower probability of receiving technical assistance. The State in Brazil where the farm is located is not significant for determining technical assistance. Regarding farmers that plant trees for commercial purposes, they are 25% more likely to receive technical assistance than other farmers. By understanding how the coverage of technical assistance differs among the various types of farmers, the Brazilian government can work together with public agencies and the private sector to expand the technical assistance coverage and reach the respective goal set in the National Plan.

Comparing the Brazilian forest concessions model and the FAO voluntary guidelines

Rayssa Yuki Murakami Lima¹, Cláudia Azevedo-Ramos¹

¹Universidade Federal do Pará, Belém, Brasil (rayssa.yuki@gmail.com; claudia.azevedoramos@gmail.com)

Forest concessions in public areas have been used as an instrument to regulate the management of forest resources while protecting the rights of local populations and conserving biodiversity. Nevertheless, international experiences have shown several issues of the forest concession system worldwide. In 2018, the Food and Agriculture Organization (FAO) proposed 8 principles and 39 guidelines to reach the intended scenario for forest concessions in accordance with the UN's 2030 Agenda for Sustainable Development. In this study, we compared the 18 years of Brazilian experience in federal forest concessions with the legal forecast and/or implantation of FAO guidelines by the Brazilian system. As a measure of compliance with FAO guidelines, we use legal framework, concession processes, participation mechanisms and transparency. Each guideline was evaluated in a color system indicating satisfactory, unsatisfactory or non-attendant service. Results indicated compliance with 69% of the guideline. As positive points: transparent forest governance; independent forest audits; social control; indicator system. Among the negatives: intersectoral relationship in the governmental sphere; conflict resolution mechanisms; social inclusion; post contract management; operational complexity; competition with illegal timber; and lack of a specific forest credit system. It is concluded that the Brazilian system adheres to the guidelines of FAO in its majority, but there is still room for improvement, some suggested in this study.

A survey of springs and forest coverage in the municipality of Caxambu, State of Minas Gerais, Brazil, as a strategy for guiding municipal conservation policies / Levantamento das nascentes e área de cobertura florestal do município de Caxambu - MG, Brasil, como estratégia para orientar políticas de conservação municipais

Rodrigo Condé Alves¹, Yohana Cunha De Mello², Ciro Duarte de Paula³, Alexandre França Tetto¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil;

³Neofloresta Serviços Ecosistêmicos, Dois Vizinhos, Brasil (rconde@gmail.com; yoohmello@gmail.com; ciro.floresta@gmail.com; tetto@ufpr.br)

A cidade de Caxambu-MG, Brasil, concentra o maior número de fontes de água mineral carbogásicas no mundo, tendo grande importância turística e cultural. O objetivo deste estudo foi analisar a situação da cobertura florestal das nascentes do município. As áreas florestais foram delimitadas por varredura visual na escala 1:10.000 por meio de imagens de satélite no software ArcGIS com 0,5 m de resolução, datadas de 2016 e 2017. O mapeamento considerou os fragmentos inseridos e contíguos ao limite do município. As nascentes foram determinadas a partir da base de dados do IDE-SISEMA/MG. A área de estudo possui 280 fragmentos que foram classificados como muito grandes (> 100 ha), grandes (50-100 ha), médios (10-50 ha) e pequenos (< 5-0,5 ha). O tamanho do fragmento florestal está diretamente ligado a qualidade e perenidade dos serviços ambientais que a área pode prover, incluindo proteção hídrica e fluxo gênico. Observou-se que das 300 nascentes identificadas 163 não possuem cobertura florestal e das 137 inseridas em áreas florestadas, 37,4% estão inseridas em fragmentos pequenos ou muito pequenos, 22,6% em fragmentos médios e 40,0% em fragmentos grandes ou muito grandes, o que revela a importância das maiores áreas florestais na conservação dos mananciais de água. Políticas públicas municipais, criação de unidades de conservação, assim como diálogo com produtores rurais, podem ser alternativas a proteção dos fragmentos e recuperação do déficit florestal existente, embora sejam necessários estudos futuros para verificação in loco da existência das nascentes identificadas e definição das melhores estratégias para restauração das áreas irregulares.

The technological disaster of the Fundão dam and the (in)experience in the economic valuation of environmental damage in Brazil

Mauro Magliano¹, Humberto Angelo¹

¹Universidade de Brasília, Brasília, Brasil (mauromagliano@hotmail.com; humb@unb.br)

Critical events such as the disruption of the Fundão tailings dam, considered the biggest technological disaster in Brazil and the biggest of its category in the world, test the responsiveness of organizations in charge of protecting the environment. In the process of assign liability for damage, lawsuits initially proposed were replaced by settlements negotiated between companies, state agencies and the Public Prosecution Service, which previously have stipulated amounts for mitigation actions and environmental compensation. The economic valuation of environmental damage, despite being a tool capable of assisting in the quantification of environmental compensation, has not yet been adequately used in the initiatives to hold the Fundão dam case accountable. Preliminary diagnoses of the disaster have not sufficiently detailed the estimated economic values for environmental and socioeconomic repair, nor have they distinguished between the repairable damage and the irreparable ones that must be compensated. Due to the lack of clear definition of who is responsible for the economic valuation of environmental damage, Brazilian environmental protection institutions have not developed standardized procedures for this purpose, except in an incipient, experimental or particular way for certain types of damage. The implementation of civil liability settlements based on inaccurate diagnoses and values can compromise their effectiveness and perpetuate, without compensation, the damage to Brazilian environmental heritage.

Smallholder land clearing behavior and Forest Code enforcement perceptions in the Brazilian Amazon

Stella Schons¹, Eirivelthon Lima², Gregory Amacher¹, Frank Merry³

¹Virginia Tech, Blacksburg, USA; ²Inter-American Development Bank, Washington, USA; ³Conservation Strategy Fund, Washington DC, USA

(szschons@vt.edu; elima@iadb.org; gamacher@vt.edu; frank@conservation-strategy.org)

Small landholder contribution to Amazon deforestation in Brazil has been persistent even after government actions have allowed a steep reduction in the overall annual deforestation area since 2004. We investigate land clearing and the incentives to comply versus not to comply with environmental legislation within the context of the Forest Code in Brazil through a dynamic land clearing model that takes into account smallholder perceptions of the risk of being caught violating the legislation. This model is empirically tested through an endogenous switching regression method applied to data collected from 1,108 households sampled in 2003 and 542 households sampled in 2013/14 in the Transamazon-BR163 region. We show smallholder compliance and noncompliance preferences lead to a selection problem that must be addressed in any land clearing behavior examination. We find greater marginalization, longer land tenure and transitions to cattle grazing, but not agricultural rents, to be major contributors to forest clearance and incentives not to comply with the Forest Code. We also find that higher probability of carrying out forest management leads to lower land clearing behavior and does not contribute to a household's decision to switch from the compliant into the non-compliant group. Our results suggest that the perceived costs of violating the Forest Code are not high enough to surpass the cost of transitioning into more efficient production systems, considering that intensification of smallholder production systems have been prescribed as a solution to reduce deforestation within this group of landholders.

A3q: THE IMPLEMENTATION OF ECONOMICS, FOREST POLICY, FOREST LAW AND GOVERNANCE IN LATIN AMERICA FORESTRY

Assessing the effectiveness of forest closures using the National Forest Inventory, forest management plan records, and reforestation statistics in Nicaragua, Central America / Evaluación de la efectividad de la veda forestal utilizando el Inventario Nacional Forestal, los registros de planes de manejo de bosque y las estadísticas de reforestación en Nicaragua, Centroamérica

¹FAO, Panamá, Panamá; ²Naturaleza para la Vida, Asunción, Paraguay; ³CATIE, Turrialba, Costa Rica (gnavarrom@gmail.com; nestor.sagui@naturalezavida.org; bfinegan@catie.ac.cr; juancarlo.zamora@catie.ac.cr; svilchez@catie.ac.cr)

La investigación analizó el estado de conservación de cuatro especies forestales vedadas por la Ley No. 585 del 2006 en Nicaragua: caoba (*Swietenia macrophylla* King y *Swietenia humilis*), cedro (*Cedrela odorata* Linnaeus) y pochote (*Pachira quinata*) en los paisajes de distribución natural de las mismas. En cada paisaje se determinaron los impactos de la ley de veda en la dinámica de distribución, regeneración y cultivo en bosques naturales, bosques bajo Manejo Forestal Sostenible (MFS) y sistemas agroforestales (SAF). Se analizó la estructura de las poblaciones de cada especie y su distribución actual y cambios potenciales utilizando software MaxEnt. Se determinó la distribución y estructura de las poblaciones empleando análisis estadístico comparativo con el software INFOST. Los análisis se realizaron a partir de los inventarios forestales nacionales del Instituto Nacional Forestal (INAFOR). Para tal caso, se utilizaron dos periodos de comparación: 2008 y 2015. Adicionalmente, se analizaron las bases de datos disponibles de plantaciones forestales establecidas durante el periodo y los planes de aprovechamiento forestal de fincas forestales a nivel nacional. Los resultados se presentan en 11 hallazgos científicos que apuntan a la poca efectividad de la veda forestal como instrumento de política para recuperar y conservar las poblaciones de las cuatro especies vedadas. Particularmente, se identificó que en el largo plazo existe el riesgo de pérdida y degradación de las poblaciones de las especies. Con base en los hallazgos se formularon recomendaciones para revisar y ajustar los lineamientos, estrategias y prácticas de manejo y conservación contempladas en la Ley de veda forestal.

Contributing to forest accounting: valuation of standing wood assets / Contribución a la contabilidad forestal: valuación del activo maderero en pie

Fabiana Ines Molina¹

¹FCE-UNC, Córdoba, Argentina (fabimolina@gmail.com)

En el presente trabajo se analizará la problemática de valuación de la madera en pie, en especial sobre la consideración de los cambios de los activos forestales en la contabilidad de la empresa, para objetivos internos y externos. Se iniciará la presentación con una reseña histórica y actual de diversas metodologías propuestas y las vigentes para la valuación de los activos forestales: Se orientará el análisis tomando como base la información de la literatura europea de IUFRO, en especial de la literatura alemana de los autores Günter Karisch, Hans A. Jöbstl y otros, la literatura americana W. David Klemperer, y autores latinoamericanos como Dr Berger Ricardo y Joao Batista Padilla Junior. Estos desde un punto de vista de la contabilidad interna. Luego se analizará las metodologías propuestas por las normas contables internacionales vigentes NIC 41, Brasil, Argentina, Chile. También se citará la práctica contable de valuación de empresas del país en especial con domicilio de explotación en Misiones, con exposición de problemáticas que se detectan al efecto. Se llegará al final a una conclusión sobre la mejor propuesta en función de los riesgos inherentes que puedan llevar al uso inadecuado de esta información.

Forest policy related to non-timber forest products in Chile / Política forestal en torno al rubro de los productos forestales no madereros (PFNM) en Chile

Gerardo Valdebenito Rebolledo^{1,2} 

¹Instituto Forestal, Santiago, Chile; ²Universidad Mayor Santiago Chile (gvaldebe@infor.cl)

La valoración económica social, ambiental y patrimonial de los PFNM generados por los ecosistemas boscosos es creciente en el mundo. Chile por su geografía y recursos forestales posee ventajas comparativas en este rubro, reflejado en un creciente mercado nacional e internacional, con exportaciones anuales de 90 MMUS\$ y un consumo interno de 370 MM US\$, lo cual contrasta con problemas de sostenibilidad en lo social y ambiental. En este contexto, el Consejo de Política Forestal, organismo con visión de Estado responsable de proponer políticas públicas sectoriales, desarrolló el proceso de planificación, diseño e implementación de programas y acciones público/privadas que permitan en el mediano y largo plazo ampliar significativamente en extensión, calidad y sustentabilidad el rubro de los PFNM en Chile, respetando tradiciones, conocimiento y cultura de los habitantes rurales y pueblos originarios. Utilizando metodologías de levantamiento y sistematización de información de fuentes primarias y secundarias, asegurando una amplia participación y representatividad de actores del rubro de los PFNM, fue posible construir una agenda de política pública que contiene tres ejes estratégicos: productividad y crecimiento económico, equidad e inclusión social, y protección y restauración del patrimonio forestal. Los resultados se materializan en más de 60 acciones de corto, mediano y largo plazo, que hoy se implementan en Chile, las cuales, entre otras, buscan generar bienes públicos, mejorar la asociatividad, agregar valor, fortalecer las organizaciones locales, disminuir brechas, mejorar las condiciones laborales, desarrollar normas de manejo y cosecha sustentable en los bosques y valorar y respetar el conocimiento empírico y ancestral.

Characteristics of companies providing forestry services in Paraguay / Caracterización de empresas prestadoras de servicios forestales en el Paraguay

Pablo Enrique Espínola Ferreira¹, María Laura Quevedo Fernandez¹, William Tomaz Folmann²

¹Universidad Nacional de Asunción, Asunción, Paraguay; ²Independiente, Asunción, Paraguay (pabloespinola744@gmail.com; marialauraquevedo@gmail.com; wfolmann@gmail.com)

Se ha identificado que la mayor parte de las plantaciones forestales en el país son planificadas, implementadas, mantenidas y cosechadas por medio de prestadores de servicios, es por eso que mediante el presente trabajo se ha buscado caracterizar a los mismos mediante la aplicación de un cuestionario; se ha caracterizado a 3 empresas que prestan servicios de consultoría, 7 que prestan servicios de plantaciones y manejo, así como 3 empresas que realizan cosecha y transporte, todas ellas distribuidas en los departamentos de Alto Paraná, Canindeyú, Caaguazú e Itapúa. Los principales servicios de consultoría prestados por las empresas entrevistadas son los de asesoramientos de plantaciones con costos medios de 297US\$ por visita de campo, y adecuación ambiental de la propiedad con un costo medio de 847US\$ por proyecto, en tanto el servicio silvicultura y manejo se da por paquetes que pueden incluir limpieza previa del

terreno, preparación de suelo, canalización, caminos, control de hormigas, análisis de suelo, plantación, reposición, riego, fertilización, enclavado, control de malezas, poda, raleo; se han identificado 11 posibles paquetes y sus costos varían entre 508 a 1.525US\$/ha, mientras que los costos de cosecha van desde 11 a 21,5US\$/ton, que puede incluir destronque, desrama, troceo, carga, descarga, desalijo y chipeado; los costos de transporte van de 11 a 15US\$. En el servicio de consultoría el principal factor crítico identificado fue la disponibilidad de mano de obra calificada, en el servicio de silvicultura la competencia desleal y en el servicio de cosecha y transporte la condición de los caminos.

Situation and perspectives on forest policy and forest governance in post-conflict in Colombia / Situación y perspectivas de política forestal y gobernanza forestal en el contexto del postconflicto en Colombia

José Miguel Orozco¹

¹Universidad Distrital, Bogotá, Colombia (josemiguelorozco@gmail.com)

Entre los años 2015 y 2017 la deforestación en Colombia se incrementó en 77%, pasando de 124.035 a 219.973 hectáreas. Las proyecciones preliminares indican que durante 2018 la pérdida bosques continuó a niveles aún mayores, con una estimación de 270.000 hectáreas de área deforestada, equivalente a un aumento del 117%. Lo anterior confirma los peores temores de expertos que, basados en experiencias internacionales de situaciones similares, advirtieron que de no tomarse las medidas apropiadas por parte de las entidades responsables, habría un alto riesgo de un fuerte incremento de la deforestación en la etapa de posconflicto, luego de suscritos los Acuerdos de Paz entre el Gobierno de Colombia y la guerrilla de las FARC. Si bien este es un fenómeno complejo originado por múltiples causas y agentes, que no es responsabilidad exclusiva del "sector ambiental", obliga a una reflexión sobre los enfoques y logros de la gestión forestal durante la era del Sistema Nacional Ambiental -SINA- (1993-2019), ya que en este periodo han desaparecido alrededor de 6 millones de hectáreas de bosques y, por otra parte, de acuerdo al Segundo Reporte Bienal de Colombia ante la CMNUCC, el 44% de las emisiones de GEI generadas en el país entre 1990 y 2014, se debió a la deforestación y a la mala gestión de los bosques. Para revertir esta situación se propone hacer de la gobernanza forestal el fundamento para orientar una profunda transformación en aspectos estructurales de la gestión: política forestal, ley forestal, administración forestal, participación de actores e incentivos.

The forest sector in Nicaragua in the face of sociopolitical crisis: key reflections for the future / El sector forestal en Nicaragua ante la crisis sociopolítica: Reflexiones claves para el futuro

Ivania Cornejo¹

¹Instituto Interdisciplinario de Ciencias Naturales, Universidad Centroamericana (UCA), Managua, Nicaragua (acornejo@uca.edu.ni)

Nicaragua enfrenta una crisis sociopolítica que estalló en Abril de 2018 afectando a múltiples sectores del país. Previamente la actividad forestal y el manejo sostenible de los bosques y sus recursos representaban ya un reto en Nicaragua principalmente debido a una débil gobernanza. La situación sociopolítica actual afecta al sector forestal pero puede representar la oportunidad para su resurgimiento en un país donde a pesar de que la vocación de los suelos se cuenta hasta en 40% para uso forestal, éste solo representa 1% del PIB. Haciendo uso de cuestionarios, entrevistas a profundidad y fuentes secundarias así como herramientas de pensamiento sistémico para análisis de la información, este estudio presentará: (a) un panorama de la situación del sector forestal a través de la mirada de actores clave (sector pequeña y mediana empresa, empresas high-end, reservas privadas, comunidades indígenas en áreas protegidas, plantaciones forestales, ONGs) y (b) recomendaciones para un futuro escenario postcrisis. Impactos reportados como las continuas invasiones en tierras comunitarias indígenas y reservas privadas, suspensión de actividades de investigación, cierre de proyectos de cooperación internacional y mermada capacidad institucional, derivan en mayores costos de oportunidad y posible aumento de vulnerabilidad de los bosques, biodiversidad y comunidades asociadas ante eventos naturales o amenazas antropogénicas. En el escenario postcrisis nuevas formas de gobernanza basadas en la ciencia y modelos participativos, y recuperación de confianza entre los diferentes actores serán necesarios para un nuevo consenso social que permita hacer del sector forestal un pilar del desarrollo de un país en reconstrucción.

Challenges of governing native forests in South American countries (Brazil and Chile) / Desafíos de la Gobernanza de los Bosques Nativos en dos países de América del Sur (Brasil y Chile)

Liviam Elizabeth Cordeiro-Beduschi¹; Cristina Adams¹; René Reyes²

¹Universidade de São Paulo (PROCAM-IEE/USP); ²Instituto Forestal (INFOR), Valdivia, Chile (liviamcordeiro@gmail.com; cadams@usp.br; rene.reyes@infor.cl)

En las últimas décadas, nuevas formas de gobernanza forestal se han establecido en América del Sur para promover el manejo sostenible de los bosques nativos, a partir de la interacción de diferentes actores sociales. El presente artículo presenta el resultado de una investigación doctoral sobre el modelo de gobernanza forestal en Brasil y en Chile entre 1990-2015. El objetivo de la investigación fue analizar la evolución de la política forestal, los límites y el alcance de las estrategias adoptadas para disuadir sobre la deforestación y la degradación de los bosques nativos. A partir de las corrientes teóricas que contribuyen al análisis de la gobernanza forestal, se analizó el marco institucional competente al manejo de los bosques de cada país y el espacio multi-actores que se establece con base en sus intereses, recursos y poder de decisión sobre los bosques. El estudio se basó en métodos de investigación cualitativa, a partir de la recopilación de datos secundarios y entrevistas con actores involucrados en la implementación de las leyes forestales vigentes, como la Ley de Bosques Nativos (en Chile) y la Ley de Gestión de Bosques Públicos (en Brasil). Los resultados del estudio apuntan al reducido alcance en la implementación de estas políticas y a la necesidad de fortalecer las capacidades de los distintos actores para redefinir el modelo forestal a partir de nuevas institucionalidades que promuevan efectivamente la gestión sostenible de los bosques nativos con base en el desarrollo territorial y comunitario.

Assessment of multi-purpose forests in Paraguay / Diagnostico de plantaciones con fines multipropósitos en el Paraguay

Rodrigo Antonio Burgos Garcete¹, Elias Jose Roman Lozantos¹, Maria Laura Quevedo Fernandez¹, William Tomaz Folmann²

¹Universidad Nacional de Asunción, Asunción, Paraguay; ²Investigador independiente, Asunción, Paraguay (yoyiburgos@hotmail.es; eliasromani94@gmail.com; marialauraquevedo@gmail.com; wfolmann@gmail.com)

Con el objetivo de diagnosticar las plantaciones con fines multipropósitos fue aplicado un cuestionario a 3 empresas y realizado inventario forestal en 2 de ellas. Fueron identificados 8 materiales, entre los que se destacan el I144 plantado en todas las empresas. La habilitación del área para la plantación es realizada en mayor parte con fuego, en cuanto que la preparación de terreno todas las empresas realizan con rastra pesada, estas pudiendo ser combinadas con rastra liviana, con subsolado, taipado y canalización. Los principales los meses de preparación de terreno son de febrero a abril y agosto a setiembre, y los principales meses de plantación de marzo a mayo y setiembre a noviembre, realizada de forma manual con 780 a 1.333pl/ha. El control de hormigas es realizado con fipronil y todas realizan fertilización; en el control de malezas se destacan los métodos químico y manual en la línea de plantación, y mecanico

y químico en la entrelínea. Se realizan entre 7 a 8 podas con alturas máxima entre 9 a 11 m y 2 raleos selectivos o mixtos entre los 3 a 7 años. La cosecha es semimecánica y se destacan como productos la leña y rollos. Con respecto al crecimiento se destaca el I144 en la empresa A con 33,72m³/ha/año. Con relación a la estimación de la viabilidad económica, se puede observar que todas las empresas son viables económicamente. El factor crítico identificado por todas las empresas fue “la falta de normativas que incentiven el uso de plantaciones”

A4a: ARTIFICIAL INTELLIGENCE, MACHINE LEARNING AND KNOWLEDGE SHARING: COMBINING OLD AND NEW SKILLS TO IMPROVE DECISION-MAKING IN FORESTRY

A study on immersion 3D visualization system to promote decision-making of forest management

Huaiqing Zhang¹, Yongliang Li¹, Tingdong Yang¹, Xinjian Tan²

¹Institute of Forest Resource Information Techniques Chinese Academy of Forestry, Beijing, China; (huaiqingzhang@aliyun.com; lyl@ifrit.ac.cn; yangtd@ifrit.ac.cn; bjtan@caf.ac.cn)

Using three-dimensional visualization technology, combining with tree diversity simulation, forest structure and growth interaction models and forest management process models, an immersion virtual forest environment was constructed on the basis of forest resources investigation in Huangfengqiao forest farm, Central South of China. Firstly, a parametric tree modeling based on morphological structure parameters and dynamic self-adjustment was developed using dynamic IFS fractal algorithm, which realized rapid parameterized modeling of different types of tree morphological structure. Secondly, an adaptive three-dimensional visualization simulation method of forest structure based on intelligent model agent and dynamic parameters was established, and a forest growth model was constructed by combination with the environmental factors and the distribution parameters of forest structure, which realized the visual simulation of forest growth dynamics under different structure and environment conditions. Furthermore, a self-defined model simulation method of forest management measures is constructed, which broke through the difficulties of interactive models of forest structure, growth and management. Finally, using the inventory data and plots data from the forest farm, an immersion virtual forest environment was developed with Unity 3D software environment, which ran on VR platform with 320-degree cylindrical structure comprised of tiled stereo-capable displays, tracking system and multi-surround environment. The system provided an ultra-high resolution 2D & 3D visualization systems combined with forest ecosystem models with multi-perception interaction mode and knowledge decision model were proposed to realize immersion three-dimensional feasibility of forest resources status, change, forestry production and management activities, which provided new skills to improve prediction analysis and decision-making in forestry.

X-Stock: a smartphone app for inventory and management of secondary *Nothofagus* forests / X-Stock Una aplicación smartphone de apoyo al inventario y manejo de renovales de *Nothofagus*

Marjorie Martin¹, Sabine Müller-Using¹, Bernardo Pilquinao¹, Carlos Bahamondez¹, Jose Bava², Gabriel Loguercio²

¹Instituto Forestal, Valdivia, Chile; ²Centro de Investigación y Extensión Forestal Andino Patagónico, Esquel, Argentina; (mmartin@infor.cl; smuller@infor.cl; bpilquinao@infor.cl; cbahamon@infor.cl; jbava@ciefap.org.ar; gloguercio@ciefap.org.ar)

El Instituto Forestal ha venido promoviendo el uso de Diagramas de Manejo de Densidad y la Cartilla de Descripción narrativa para el manejo de renovales de *Nothofagus*. Principalmente Roble-Raulí-Coihue (*Nothofagus obliqua*, *N. alpina*, *N. dombeyi*) y para renovales de Lengua (*N. pumilio*), bajo condiciones relativamente homogéneas y coetáneas. Las herramientas propuestas permiten determinar la relación entre tamaño, densidad, competencia, ocupación del sitio y auto raleo. Por otra parte, la “Cartilla de Descripción Narrativa” recoge desde el terreno los aspectos como calidad, sanidad y vigor, entre otros, logrando una mejor caracterización del rodal o bosque y la pertinencia de las futuras intervenciones. Así la definición de un rodal meta y planificación de raleos se pueden enmarcar dentro de los límites de un manejo sustentable, para aproximarse a su valor potencial, sin comprometer su sustentabilidad. Para facilitar el uso en terreno de estas herramientas de apoyo a la toma de decisiones, se desarrolló la aplicación para Smartphone Xstock, que permite utilizar el teléfono como medio de captura de parcelas de inventario y calcular los parámetros que los diagramas necesitan como datos de entrada incluyendo los aspectos cualitativos, para enviar la información vía email cuando la señal de red esté disponible.

Extraction of phenological features using deep convolutional neural networks and random forest models using MODIS EVI time series

Esteban Roitberg¹, Verónica Barraza¹, Francisco Grings¹, Mercedes Salvia¹

¹IAFE - UBA - CONICET, Buenos Aires, Argentina (estebanroitberg@gmail.com; vdbarraza@gmail.com; verderis@gmail.com; mercedessalvia@gmail.com)

Understanding the spatiotemporal dynamics of phenology is critical for forest monitoring and management. In South America, much of the effort in these studies with remote sensing data has been concentrated on tropical rainforests (i.e. Amazonas), while subtropical formations (xerophytic Chaco forests) have been given less attention, although they account for a large fraction of South American forests. In this study, we exploit the 18-year long MODIS EVI data to study time series similarity measures, and to use them to develop a methodology to classify areas with similar phenology over the Chaco Forest in Argentina. The idea to develop a phenology-based classification is not new; several models have been developed to estimate phenology metrics from NDVI time series, from simple linear smoothing methods to more complicated spectral methods (i.e. TIMESAT). Nowadays, machine learning algorithms provide a powerful tool to develop classifiers, even on data sets with poor signal-to-noise ratios or characterized by a high dimensionality. Since we opted for a supervised training approach, we defined six pilot areas inside every major ecosystem, homogeneous in terms of phenology (as seen by MODIS EVI). From each area we extracted EVI time series and used them to train classifiers based on Deep Convolutional Neural Networks and Random Forest. Then, we used these models to classify the whole study area. In this way, we obtained several annual maps of phenologically-similar areas, in which is it possible to study its spatiotemporal dynamics and it is also possible to recognize the anthropogenic impact, mainly related to deforestation.

Comparison of SFM methods on automatic counting of trees in a Brazilian Atlantic Forest restoration area

Rafael Albuquerque¹, Manuel Ferreira², Vanessa Girão³, Cintia Balieiro³, Hendrik Mansur³, João Costa², Maurício Branco⁴, Carlos Grohmann¹

¹Universidade de São Paulo, Instituto de Energia e Ambiente, São Paulo, Brazil; ²Instituto de Estudos Socioambientais da Universidade Federal de Goiás, Goiânia, Brasil; ³The Nature Conservancy Brasil, São Paulo, Brasil; ⁴Instituto Terra de Preservação Ambiental, Miguel Pereira, Brasil (r.w.albuquerque@gmail.com; mferreira.geo@gmail.com; vgrao@tnc.org; cbalieiro@tnc.org; hmansur@tnc.org; joaovsc17@gmail.com; mauricio@itpa.org.br; guano@usp.br)

One of the important parameters measured on areas under Forest Restoration (FR) is the number of trees that are present on the site. Such an important parameter is conventionally obtained by a manual counting process in field works, which takes a significant amount of time and, consequently, increases the project's

costs. Remote Sensing technologies, such as data collected by Unmanned Aerial Vehicles (UAV), provide a panoramic and georeferenced view of whole areas of interest and bring possibilities of automatic data mining processes, such as the automatic counting of trees and therefore reducing FR costs. Two of the most popular Structure from Motion (SfM) software used to process UAV data are Photoscan and Pix4D Mapper. As these software use different SfM methods, they generate slightly different outputs and a possible influence on automatic tree count accuracy should be evaluated. This work aims to compare Photoscan and Pix4D accuracy results on automatic tree counting of a FR area. The automatic tree count was based on watershed algorithm and each identified tree was represented by a coordinate on its highest crown point. Visually, both platforms deliver similar products. But Photoscan presented a better performance than Pix4D, as their general accuracies were equal to 0.938 and 0.105, respectively, suggesting that Photoscan is more adequate to FR monitoring. Although Pix4D, an effective and high quality software, presented poor results, future works should evaluate if high slope conditions, as was found in the study area, influence on the software's automatic tree counting results.

A4b: FORESTS WITHOUT BORDERS: MULTI-NATIONAL FOREST INVENTORY COOPERATION AND HARMONISATION TO ENHANCE SUSTAINABLE DEVELOPMENT

Toward a harmonized regional forest inventory: a need for sustainability in South America

Carlos Bahamondez¹, Marjorie Martin¹, Yasna Rojas Ponce¹, Rodrigo Sagardia¹

¹Instituto Forestal, Valdivia, Chile; (cbahamon@infor.cl; mmartin@infor.cl; yrojas@infor.cl; rsagardia@infor.cl)

Countries which accounts forest resources in South America faces the needs of reporting to the national and international community about the state and condition of their forest periodically. Up to date, countries in the region have made important efforts in planning and implementing national forest inventory initiatives in cooperation with FAO and others relevant institutions. However, countries share similarities, like common biomes, irrespective of national borders, but have differences in species compositions, growing stock, forest structure, industrial and market development and yield, issues that are reflected in their definitions, measurements and methods applied in the national forest inventory. Harmonizing these topics on already existing national forest inventories or standardizing those in new initiatives in the region, will provide a common ground to secure a comprehensive and comparable indicators related to sustainability in the region, will provide a solid framework for policy makers and will produce a consistent and transparent trend on biodiversity, carbon and sustainability indicators.

Challenges and opportunities for the harmonization of national forest inventories in the Amazon Region

Joberto Freitas¹, Doadi Brenna², Sarah Crabbe³, Elvira Gómez Rivero⁴

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²FAO/SFB, Nova Prata, Brazil; ³SBB, Paramaribo, Suriname; ⁴SERFOR, Lima, Peru (joberto.freitas@florestal.gov.br; dabrena@gmail.com; sarah_crabbe@yahoo.com; egomez@serfor.gob.pe)

The extent of forests in the Amazon region was approximately 544 million ha in 2015, of which 21% was assigned to forest production. Most of the eight amazon countries have advanced in the implementation of their national forest inventories (IFN) in the last decade, with the common purpose of producing appropriate information supporting the sustainable management of their forests. Despite similar forest characteristics among countries, since they belong to the same biome, their national forest inventories have different methodologies making the comparison of the acquired results difficult. Within the creation of a common agenda for national forest inventories, that started in 2017 by several Latin American countries, the Amazonian countries prioritized starting a harmonization process focusing on variables related to the estimates of growing stocks of volume and biomass. However, in order to improve the results of this process, it was also identified that a preliminar requirement is to study and compare terminologies and definitions applied in each country, especially related to the forest definition, the forest area estimates, the vegetation classification and the nomenclature of tree species and species groups. The challenges for harmonization are mainly related to the complexity of the forests, especially due to the large number of tree species and their diversity in shape and size. On the other hand, the harmonization of NFIs is certainly an opportunity to improve forest information at a regional level and to promote sustainable forest management.

The North American forest database: successes and challenges in continental-scale forest inventory harmonization into a relational database

Carina Edith Delgado Caballero³, Brad Smith⁵, Joseph Kapron⁶, Juan Carlos Leyva Reyes³, Carmen Lourdes Meneses Tovar³, Mayra Ramirez Salgado³

¹USDA Forest Service, Knoxville, USA; ²Natural Resources Canada, Victoria, Canada; ³Comision Nacional Forestal, Guadalajara, Mexico; ⁴USDA Forest Service, Minneapolis/St. Paul, USA; ⁵USDA Forest Service, Retired, Washington, DC, USA; ⁶Natural Resources Canada, Retired, Ontario, Canada (soswalt@fs.fed.us; graham.stinson@canada.ca; svillela@conafor.gob.mx; rcuenca@conafor.gob.mx; pmiles@fs.fed.us; alex.song@canada.ca; cgodinez@conafor.gob.mx)

Forest Inventory is a fundamental requirement of forest science and policy. Canada, the United States, and Mexico have a legacy of working together on inventory related topics, particularly those in ecological zones that cross political boundaries. Through the North American Forest Commission Inventory and Monitoring working group, the United States, Canada, and Mexico have integrated common forest inventory attributes into an online, user-accessible North American database to provide a borderless assessment of North American ecosystems using a common map developed in conjunction with the Commission for Environmental Cooperation. The first phase of the project is complete and products include a searchable database and an informational ArcGIS Online Storymap, as well as an information brochure and journal publication. Phase two, currently underway, focuses on the expansion of included variables and the addition of a second time step for trend analysis. Here we discuss the successes accomplished in this cross-border effort, as well as the challenges inherent in a project of this magnitude.

The European National Forest Inventory Network ENFIN: achievements, lessons learned and challenges

Klemens Schadauer¹

¹Austrian Research Centre for Forests, Vienna, Austria (klemens.schadauer@bfw.gv.at)

The European National forest Inventory network enfin has been working for more than 15 years on the harmonisation of the nfis. The main driver for its foundation was a lack of comparability of results caused by the variety of national approaches. the 17 member institutions in 2003 where inspired by the idea

of harmonisation in a bottom up process and thus developed basic concepts for the harmonisation of nfis on different levels. Actually enfin has 32 member organisations from 29 countries. so far, the network was successful in developing more than 100 detailed and commonly agreed “reference definitions” based on existing international definitions and a thorough screening of national solutions. ENFIN developed and applied so called “bridging functions” to overcome the gap between national and international approaches. the work also included basics for the harmonisation of modelling approaches. all the work was carried out within 24 international projects and is described in more than 40 publications including 4 books. The main challenges for the future work include the harmonised estimation of changes, the demanding development of remote sensing techniques and a common data policy.

FAO’s initiatives and lessons learned on forestry information harmonization

Carla Ramirez-Zea¹, David Morales-Hidalgo², Rebecca Tavani¹, Anne Branthomme³, Monica Garzuglia³, Leticia Piña³, Anssi Pekkarinen³
¹Food and Agriculture Organization of the United Nations, San Jose, Costa Rica; ²Food and Agriculture Organization of the United Nations, Panama, Panama; ³Food and Agriculture Organization of the United Nations, Rome, Italy (carla.ramirez@fao.org; david.morales@fao.org; rebecca.tavani@fao.org; anne.branthomme@fao.org; monica.garzuglia@fao.org; leticia.pina@fao.org; anssi.pekkarinen@fao.org)

Harmonization of forest-related definitions is a key process for clear understanding of what we are measuring and reporting, as well as to compare data between countries in order to facilitate decisions and agreements at national, regional and global level. Harmonization allows for both temporal and geographical comparability without differences being attributed to subjective definitions. FAO, through the Global Forest Resources Assessments (FRA) is spear-heading such harmonization efforts. Since 1946, each assessment contributed to the improvement of forest-related definitions. Strong efforts have been made to harmonize and streamline reporting with other international forest-related processes within the framework of the Collaborative Partnership on Forest (CPF). The development of the Collaborative Forest Resources Questionnaire (CFRQ), further simplified and harmonized forest-related reporting and allowed joint collection and analysis of forest data. In parallel to these developments, FAO initiated the National Forest Monitoring and Assessment Program (NFMA) in 2000 with the objective of supporting developing countries to enhance the quality of information through designing and implementing continuous National Forest Inventories (NFI). Further promoting the need for well-defined harmonized definitions for REDD+ reporting requirements which call for a comprehensive National Forest Monitoring System (NFMS), which include NFI data amongst other data sets. This document presents a historical analysis of global harmonization efforts, good practices, lessons learned and their influence on the implementation of the NFMS that FAO has supported in developing countries over the years, with the objective of facilitate the production of transparent, reliable, complete and coherent information.

Harmonisation of the estimation of forest available for wood supply in Europe

Wood is currently the main source of financial revenue from forests and its demand is rapidly growing in Europe. It is important to determine whether forest is available or not for wood supply (FAWS and FNAWS) in order to develop forestry related policies with regard to the maintenance and enhancement of forest resources and their contribution to global carbon cycles. The importance of reporting on FAWS and FNAWS is reflected in the agreed criteria and indicators for sustainable forest management assembled in the State of Europe’s Forests and indirectly in the Goals of the UN 2030 Agenda for Sustainable Development. Based on the information provided by the National Forest inventories from 21 European countries, this study aims to quantify the areas of FAWS and FNAWS as well as aboveground dry matter biomass according to national definitions and common reference definitions, and to determine the restrictions and thresholds considered at country level to classify forest into FAWS and FNAWS. Preliminary results indicates that FAWS represents between 80-95% of forest area and AGB in nearly all of the studied countries. A nested restriction list was elaborated, identifying the restrictions considered for the national estimates and those included in the references definition. In Europe, economic and environmental restrictions are the main factors associated with FNAWS, of which profitability, slope and accessibility as economic and protected areas as environmental restrictions are the most frequently considered types of restrictions determining the forests availability for wood supply.

NFI plot based analysis of forest structure in the mountain forests of the Alps

Large parts of the Alpine forest are forest protecting people, settlements and transport routes and industrial installations against natural disasters such as landslides, avalanches, rock avalanches and rock fall. Insufficient utilisation of wood and management causes an imbalanced age structure in forests and compromises the protection against natural hazards. Reliable information on the structure of these forests which are also under considerable use as recreational space and represent valuable landscape elements in a touristic region is of high priority and a precondition for a balanced and efficient management of the functions carried by these forests. In this multi-national forest inventory cooperation, we demonstrate the analysis of the forest structure based on NFI field plots with associated harmonised target variables. At the estimation stage, the NFI plots from Austria, Germany, France, Italy, Slovenia and Switzerland are combined with remote sensing auxiliary data from different sources. Model-assisted GREG regression estimators which optionally borrow strength from outside the estimation region are applied. The analysis software is implemented as a PostgreSQL extension which was assembled within the Horizon 2020 Diabolo project. The system is both generic and flexible: in the handling NFI plot data sampled according to various designs, in the integration of auxiliary data, in the selection of estimators and in the definition of arbitrary trans-national sub-regions of interest. The analysis of forest structures across the Alpine space provides a common information basis for an improved management of the mountain forest in the Alps.

NFIs of Europe towards future: visions and challenges

Annika Susanna Kangas¹ , Kari T. Korhonen¹ , Minna Rätty² , Tuula Packalen¹ 

¹Luke, Joensuu, Finland; ²Luke, Helsinki, Finland (annika.kangas@luke.fi; kari.t.korhonen@luke.fi; minna.ratty@luke.fi; tuula.packalen@luke.fi)

We outline the current challenges of NFIs in the continental and global level assessments. These challenges come from the variation between national NFI designs, measurements and models. While harmonization is necessary to make meaningful comparisons between the countries, there is a tradeoff in the harmonization between introducing additional uncertainty and losing useful information. For instance, harmonization may require using data from other countries in modelling and predicting some required information. This, in turn may introduce bias in the national level results. Harmonization may also require discarding some nationally important data from the harmonized results, for instance when nationally important forest types are combined to broader level classes. An approach of harmonization maximizing the used information content of the national NFIs and minimizing the added uncertainty is therefore required. Especially, the possibility of introducing national or regional level bias in the process of harmonization needs to be addressed. This introduces methodological challenges into the forest resources estimation that can possibly be solved using either hybrid or model-based estimation. These approaches may also be used for calculating accuracy in the continental or global level assessments which are currently lacking.

Synthesis on bioeconomy monitoring systems in the EU Member States: indicators for monitoring the progress of bioeconomy

Markus Lier¹, Martti Aarne², Leena Kärkkäinen¹, Kari T. Korhonen¹, Anja Yli-Viikari³, Tuula Packalen¹

¹Natural Resources Institute Finland (Luke), Joensuu, Finland; ²Natural Resources Institute Finland (Luke), Helsinki, Finland; ³Natural Resources Institute Finland (Luke), Jokioinen, Finland (markus.lier@luke.fi; martti.aarne@luke.fi; leena.karkkainen@luke.fi; kari.t.korhonen@luke.fi; anja.yli-viikari@luke.fi; tuula.packalen@luke.fi)

The urgent need to shift our economy towards a more sustainable, resource-efficient bioeconomy based on renewable resources has been recognized widely by the EU Member States (EU MS). Because the main drivers for the transition towards a bioeconomy often strongly vary from EU MS to EU MS depending on the country-specific economic and ecological settings, legal framework, and social demands, also the national or regional bioeconomy strategies vary in their goals and measures. Consequently, proxies and indicators used to measure the development of a national bioeconomy or the success of a bioeconomy strategy depend on the national goals, and are therefore often not applicable in any other country. Nevertheless, synchronizing the national bioeconomy monitoring activities is necessary to ensure comparability of the results of the national monitoring systems. We identified and compared the different approaches within the EU MS to monitor the progress in a country's bioeconomy. An integrated part was the participatory approach of the project, by direct involvement of ministries and research organizations responsible for developing, assessing and monitoring national bioeconomy strategies. This allowed us to identify- existing national bioeconomy strategies,- industries and activities that are included in the bioeconomy sector at national level,- already existing and desired bioeconomy key indicators and their respective data availability. The identified bioeconomy indicators important and feasible at the national context can contribute to the further discussions when setting the frame for the development of a common EU bioeconomy monitoring system.

The importance of forests for people in the Cerrado: evidences from the Brazilian National Forest Inventory

Raquel Leao¹, David Fagner de Souza e Lira¹, Claudia Rosa¹, Joberto Freitas¹

¹Serviço Florestal Brasileiro, Brasília, Brasil (raquel.leao@florestal.gov.br; liradfs@gmail.com; claudia.rosa@florestal.gov.br; joberto.freitas@florestal.gov.br)

The Brazilian National Forest Inventory (NFI-BR), currently under implementation in 22 states and in the Federal District, has collected biophysical and socio-environmental data based on a systematic cluster sampling with samples distributed every 20km on a regular grid. Biophysical data include information on forest condition. Socio-environmental data provide information on how people use and perceive the forest resources surrounding them. The NFI-BR methodology provides interviews with four people within a radius of 2 km from the cluster's central point. To better understand the importance of the forests to the people living in the Cerrado biome, the categories assessed were (i) the use of forest products and (ii) environmental services. Results were gathered from 10,007 interviews in the states of Goiás, Mato Grosso, Mato Grosso do Sul, Tocantins, Bahia, Piauí, Maranhão and Distrito Federal. For 31.99% of the respondents, the use of forest products contributed to the family income, higher in the northern states of the biome (21.95 - 65.34%). The results indicate that the predominant use of wood are as firewood (42.77%) and stakes (37.26%). The most used non-wood forest products were fruits (46.10%) and barks (33.34%). The NFI-BR's socio-environmental survey results is an important tool to identify productive chains to be strengthened, improve Cerrado's products trade, as well as to identify forest management research priorities. In addition, the results could support the formulation of forest management public policies in a local based approach.

Ecuador's National Forest Assessment: a new cycle of implementation / Evaluación nacional forestal (ENF) del Ecuador: hacia un nuevo ciclo de implementación

Jessica Coronel¹, Leonardo Ayala¹, Miguel Chinchero¹, Ximena Herrera¹, Juan Iglesias¹, Digner Jiménez¹, Carlos Morales¹, Daniel Segura¹

¹Ministerio del Ambiente del Ecuador, Quito, Ecuador (jessica.coronel@ambiente.gob.ec; leonardo.ayala@ambiente.gob.ec; miguel.chinchero@ambiente.gob.ec; ximena.herrera@ambiente.gob.ec; juan.iglesias@ambiente.gob.ec; digner.jimenez@ambiente.gob.ec; carlos.morales@ambiente.gob.ec; daniel.segura@ambiente.gob.ec)

En el periodo 2009 – 2014 el Ecuador desarrolló su primera Evaluación Nacional Forestal (ENF) como una iniciativa liderada por el Ministerio de Ambiente del Ecuador (MAE), con el acompañamiento técnico de la FAO. Este instrumento multipropósito se creó con la finalidad de i) proporcionar datos para la toma de decisiones y desarrollo de políticas para el manejo forestal sostenible (MFS), ii) responder a los requerimientos de información forestal en el contexto climático y, iii) promover periodicidad para el monitoreo a largo plazo. Luego de esta primera experiencia del Ecuador en materia de evaluaciones nacionales forestales (ENF1), el país a partir del 2017 se encuentra en un proceso de tránsito hacia un segundo periodo de evaluación (ENF2), continuando con el desafío de recoger información para fortalecer la gestión forestal en el país, considerando las lecciones aprendidas del periodo inicial e insertándose en la actualidad dentro del Sistema Nacional de Monitoreo de Bosques del Ecuador del MAE. La ENF2 hoy en día, recoge todos los aprendizajes de la ENF1, tomando en cuenta desde las nuevas necesidades institucionales, hasta mejoras en el marco de muestreo y el diseño metodológico, manteniendo la estratificación forestal original, perfeccionando el registro florístico e incorporando ajustes en la captura de datos y otras variables de vinculación con el monitoreo forestal satelital. Este nuevo ciclo de trabajo busca evaluar con mayor precisión el potencial productivo de los bosques, sin dejar de determinar existencias carbono en sus distintos almacenes y la diversidad forestal de los bosques del Ecuador, entre otros.

A4c: MONITORING AND ASSESSING URBAN FOREST SERVICES AND VALUES AT THE NATIONAL TO LOCAL SCALE

National forest inventory for assessment of urban trees in India

Vindhya Prasad Tewari¹, Prakash Lakhchaura², Hirendra Tripathi², Rajesh Kumar³

¹Himalayan Forest Research Institute, Shimla, India; ²Forest Survey of India, Dehradun, India; ³National Sample Survey Office, Dehradun, India (vptewari@yahoo.com; prakash293@gmail.com; tripathi_hk@rediffmail.com; rajsus1@rediffmail.com)

In India, National Forest Inventory also includes inventory of urban trees since 2002 on a two-year cycle by stratifying the country into 14 physiographic zones. The sampling frame for the selection of sampling unit in urban areas is obtained from National Sample Survey office who has prepared sampling frames for each urban area of the country. The surveys in urban areas are carried out by dividing all the urban centers of a district into Urban Frame Survey (UFS) blocks which are of varying sizes. The UFS blocks have well defined boundaries and are formed on the basis of population or number of households and cover the whole area within the geographical boundary of towns including vacant lands. For estimating tree wealth, species name, dbh, crown width etc. are recorded on each tree falling in the selected UFS block. The total tree wealth for a selected district is estimated using value of corresponding parameter from the selected UFS blocks. On the basis of tree wealth of sampled districts, the tree wealth in each physiographic zone is estimated. Aggregation of tree wealth of all the physiographic zones leads to tree wealth estimate of the country. The present estimate is based on 7360 UFS blocks falling in 180 sampled districts across the country which were inventoried during the period spanning from 2010 to 2016. The total urban tree cover of the country has been estimated to be 14,147 sq km, which constitutes 17.14% percent of the country's urban area.

National U.S. urban forest inventories and monitoring

David Nowak¹, Mark Majewsky², Tonya Lister³

¹USDA Forest Service, Syracuse, USA; ²USDA Forest Service, Tofta, USA; ³USDA Forest Service, Newtown Square, USA (dnowak@fs.fed.us; mmajewsky@fs.fed.us; tlist01@fs.fed.us)

The United States Forest Service has been inventorying and monitoring urban forests since the 1990s. These urban forest assessments evaluate and monitor the entire urban forest population, as well as assess their associated ecosystem services and values. The program initially started with developing methods to assess individual city' urban forests, which led to the development of the free urban forest assessment modeling tool suite known as i-Tree (www.itreetools.org [http://www.itreetools.org]). This tool suite can be used globally to inventory and monitor urban forests, as well as assess ecosystem services and values. In addition to i-Tree, the U.S. Forest Service implemented a national urban forest inventory (FIA) program in 2014 (<https://www.nrs.fs.fed.us/fia/urban/> [https://www.nrs.fs.fed.us/fia/urban/]), with a goal to monitor urban forests in the 100 most populated cities, as well as the 68 million acres of urban land nationwide. To date, over 35 cities are being monitored annually. This presentation will discuss the development of the U.S. national urban forest inventory program, the integration of i-Tree within the current urban FIA program, and methods and outputs of both programs. These U.S. based methods and tools can help facilitate the development of urban forest monitoring programs in other nations. Expanded urban forest inventories and monitoring will lead to a better understanding of this important resource and how it is changing, as well as improve forest management to sustain environmental quality and human health in cities across the world.

Chapultepec: old urban park in Mexico City but new information. pioneering the quantification–valorization of environmental services using the i-Tree Eco version adapted to Mexico

Hector M. Benavides-Meza¹

¹INIFAP, Mexico, Mexico (hmb27@yahoo.com.mx)

Chapultepec Forest has been a strategic place for Mexico City for more than seven centuries. In the beginning as potable water source and game preserve for the Aztec emperors. After the Spanish conquest, Chapultepec was declared property of the city (1530) and remained up to the XIX Century as the source of water and the country residence of viceroys, presidents and emperors at Chapultepec Castle. The periurban forest role changed in the early XX Century to an urban park, when the outskirts of the city and the new ways of transportation reached the forest. Urban forestry researchers have studied the benefits–environmental services provided by the urban forest and the important contributions that supplied to city dwellers and the urban environment. Nowadays i-Tree Eco allows the quantification of those environmental services as well as its economic value. Recently this software was adapted for more than 30 Mexican cities where more than 60% of the population lives. Updated tree inventory data from Chapultepec was run in the adapted version and for the first time the environmental services and the economic value of these benefits was determined for any urban green space in Mexico; 21,902 trees were inventoried and the results are presented for

every zone/subzone. The most important environmental services provided by the tree cover of Chapultepec was the carbon reservoir (6,216 Mg) and the capture of air pollutants (9.8 Mg/year), however this environmental service showed the highest economic value of all of them (around \$475,000.00 USD/year).

Urban forests in Latin America: opportunities and challenges

Tahia Devisscher¹, Cynnaron Dobbs², Francisco Escobedo³, Ferreira da Silva Filho Demóstenes⁴, Mariana Baptista⁵, Mónica Nuria Navarro¹, Camilo Ordóñez Barona⁶, Luis A Orozco Aguilar⁶

¹University of British Columbia, Melbourne, Canada; ²Universidad Mayor, Santiago, Chile; ³Universidad del Rosario, Bogota, Colombia; ⁴Universidade de São Paulo, São Paulo, Brasil; ⁵RMIT University, Melbourne, Australia; ⁶The University of Melbourne, Melbourne, Australia (tahia.devisscher@ubc.ca; cdobbsbr@gmail.com; franciscoj.escobedo@urosario.edu.co; desilvafilho@gmail.com; marianadbaptista@gmail.com; nuriannavarropl@gmail.com; camilo.ordonez@unimelb.edu.au; lorozco@student.unimelb.edu.au)

Urban forests in Latin America & the Caribbean (LAC) face several challenges, including socio-economic inequities, scarce resources for management and planning, increased exposure to climate extremes, and new demands for participatory governance processes. Although research on urban forests has expanded in the last 30 years in the US, Canada, Europe, and Australia, it is unclear what this research looks like in LAC, and where it is going. LAC is one of the most urbanized, socially inequitable, and climate-vulnerable regions in the world, and despite the potential of urban forests for alleviating many of these problems, there are no regional-scale assessments on how urban forests contribute to sustainability and resilience in the region. We address this gap by providing a baseline understanding of urban forestry and its potential in LAC. We systematically reviewed the scientific literature on urban forests in LAC, including 182 scientific articles from 13 countries, published from 1970 to 2018 (inclusive) in English, Spanish, and Portuguese. Based on this empirical scientific evidence, and online survey data collected from a wide range of practitioners and researchers working on urban forests in the region, we provide a map of urban forest research, strategies, and practice in Latin America. This presentation will assess current discourses, research directions and needs, capacities, barriers, and opportunities in urban forestry in the region. We discuss these findings in the context of global trends in urban forest research, planning, and management in relation to nature-based solutions and ecosystem services.

Urban greenery variations in 31 main cities and their association with climatic, socio-economic status, and forest attributes: inter- and intra-city comparison

Xingyuan He^{1,2}, Lu Xiao¹, Wenjie Wang^{1,3}

¹Northeast Institute of Geography and Agroecology, Chinese Academy of Science, Changchun, China; ²Institute of Applied Ecology, Chinese Academy of Sciences Shenyang China; ³Northeast Forestry University Harbin China (hexingyuan@iga.ac.cn; xiaolu@iga.ac.cn; wangwenjie@iga.ac.cn)

Urban greenery from street-view image provide new tool for evaluating urban green spaces, their utilization in evaluation at national scale and local scale are scarce. Here, we assess urban greenery, quantified by green view index, variations in 31 provincial capital cities in China, and ask two questions 1) How does urban greenery vary, and 2) how do climatic, socio-economic status, and forest attributes drivers contribute to this variation? We found that Hefei, Chengdu and Chongqing had the best urban greenery, while Shijiazhuang and Lhasa had the poorest greenness on average. Greenery variations, as manifested by standard deviation of total measured data, was lowest in Lhasa and Urumqi, while the largest variations were found in Nanjing. These urban greenery pattern on average was mainly controlled by climatic condition, rather than socio-economic status. The lower sunshine hours, higher MAP and RH, together with higher income and GDP usually accompanied with highest peak greenery. However, we failed to find that higher social development accompanying deduction in intra-city greenery variations, indicating a risk that economic development in China has possibly resulted in even larger inequality of greenery distribution in urban region. By using Changchun as an example, greenery variation in a city and possible reason were also studied, and we found that the urban greenery was mainly driven by green space total area, landscape shape index, and tree diameter at breast height (DBH). Our data in this paper provide a new basis for urban greenspace management from the street scape both in one-city or multiple city level.

Scale issues in remote sensing-based tree cover assessment along the rural-urban gradient of Bengaluru, India: comparing four sensors from 30 m to 30 cm spatial resolution

Nils Nölke¹, Md. Abdullah Al Mahmud¹, Christoph Klein¹

¹University of Goettingen, Dept. of Forest Inventory and Remote Sensing, Faculty of Forest Sciences and Forest Ecology, Goettingen, Germany (nils.noelke@forst.uni-goettingen.de; m.mahmud@stud.uni-goettingen.de; ckleinn@gwdg.de)

In fast developing megacities, the rapid rate of urbanization is leading frequently to drastic changes in tree cover which may follow different patterns along the rural-urban gradient. Monitoring of changes in tree cover may be desired for an assessment of potential ecological functions of these trees. Remote-sensing time series are among the very few data sources that allow such monitoring in an efficient manner. However, estimating tree cover in more or less densely built-up areas is a notorious challenge per se – and sensors of different spatial resolutions may perform differently. This study researches into the question of how sensors of different spatial resolution “see” tree cover of different composition and configuration along a rural-urban gradient. Our study area was the very fast-developing megacity of Bengaluru, India. WorldView-3 imagery of 30 cm resolution served to measure true tree cover on 330 1-hectare square sample plots laid out systematically over a 5 km x 50 km transect extending from the city center to the more rural outskirts. The results illustrate that sensors of different resolution of 30 m (Landsat 8), 10 m (Sentinel-2A) and 5 m (RapidEye) determine tree cover differently- where all 3 sensors underestimate the true tree cover along the rural-urban gradient. This underestimation may also have to do with the overestimation of impervious surface as reported for Landsat. The results of our study are relevant for unbiased and compatible estimation of tree cover in built-up environments and point to the need for suitable calibration approaches.

The pattern of tree species composition changes along the urban-rural gradient in the Indian megacity of Bengaluru

Baragur Neelappa Divakara¹, Chitradurga Umesh Nikhitha¹, Nils Nölke², Vindhya Prasad Tewari³, Christoph Klein²

¹Institute of Wood Science and Technology, Bengaluru, India; ²Georg-August-University, Goettingen, Germany; ³Himalayan Forest Research Institute, Shimla, India (bndsira@gmail.com; thoshitha.cu@gmail.com; nils.noelke@forst.uni-goettingen.de; tewarivp@gmail.com; ckleinn@gwdg.de)

Urban expansion and the corresponding growth in the industrial and economic sector due to construction activities, infrastructure expansion and population inflow has a major impact on biodiversity and ecosystems at various scales. Our study was to elucidate the details of tree composition, density and diversity along the urban-rural gradient in two research transects in the Northern and Southern parts of Bengaluru. Twenty-three and twenty-five plots of 1 ha each were surveyed within the Northern and Southern transects respectively with aid of World View - 3 imagery (0.30 cm). A total of 93 and 83 tree species were observed

in the northern and southern transect respectively. Diversity indices such as Shannon index, Simpson index, Pielou's evenness and Margalef's richness served to analyse how tree species diversity changes along the gradient. Our analysis revealed that tree species are about evenly distributed over all three domain categories for both the Northern and the Southern transect. The diversity index was about constant for the urban domain and the curve decreases as moved towards the transition and rural domain showing less species diversity and dominant species in comparison with urban domain for northern plots, whereas for southern plots no significant trend in the curve were observed as they varied from plot to plot, but decreased towards the transition and rural domain. The overall comparison of northern and southern plots indicated that, the northern plots were more diverse in terms of species richness and total number of trees surveyed i.e 1128 and 1080 trees respectively.

Regulating services from forest tree species in urban park, Bangkok, Thailand

Areerut Yarnvudhi¹, Nisa Leksungnoen¹

¹Kasetsart University, Bangkok, Thailand; (psdaryv@ku.ac.th; ffornsl@ku.ac.th)

Bangkok has been urbanized with rapid growth of population and expected to become one of the world's megacities by 2030 with a population over 10 million. The overpopulation causes an inadequate basic infrastructure and health problem from the pollutions for people. Bangkok has green space only 13 m² per capita which is less than what United Nations (UN) recommends (30 m² per capita); therefore, increase green area in Bangkok is necessarily urgent task. Consequently, Chulalongkorn University Centenary Park was established in central Bangkok. The park is aimed to serve for societies' activities, economic, aesthetic, flood defenses and communities' health. This study was focused on regulating services of urban forest in this park emphasizing on air pollution tolerant index (APTI) and air and soil temperature reduction. Trees in the park consist of 19 species from 17 genera and 10 families with both deciduous (9) and evergreen (10) species. Most species were intermediate tolerance to air pollution regarding to the APTI approximately 11 – 13. Trees in the park could reduce air temperature between 0.60 – 2; 53 oC while the soil temperature was cooler than the concrete pavement by 9.75 – 11.35 oC. Species selection is one the most important processes for ecosystem services. We recommended that the species with thicker leaf and high relative water content tolerate more pollution. Hairy and light-color leaves would reflect more radiation than darker leaves while dense canopy with high leaf area can reduce more air and soil temperature.

A4p: MONITORING AND ASSESSING URBAN FOREST SERVICES AND VALUES AT THE NATIONAL TO LOCAL SCALE

Urban carbon budget for Seoul's community forest landscapes

Hyun-Kil Jo¹

¹Department of Ecological Landscape Architecture Design, Kangwon National University, Chuncheon, Republic of Korea (jhk@kangwon.ac.kr)

Urban forests play an important role in supplying carbon offset and other ecological services in urban landscapes. This study quantified the role of community forest landscapes in urban carbon budget for Seoul, the capital of the Republic of Korea. Urban community forests are here defined as the forests except parks within urban area delimited by zoning regulations. Storage and annual fixation of carbon by the community forests were estimated applying carbon indicators for trees and soils per unit area by forest type and age class. Their carbon offset services were quantified reflecting carbon emissions from energy consumption. Total area of the community forests accounted for about 22% of total study city area. Carbon storage in trees and soils of the community forests was approximately 2,090 kt, and their annual carbon fixation was 116.8 kt. Of all forest types and age classes, broad leaved forests of age class IV (31-40 years) showed the greatest carbon input due to higher carbon estimates per unit area and larger total area. The community forest landscapes annually offset total carbon emissions from residential electricity consumption by 7.3%, and their carbon storage was equivalent to 1.3 times of the carbon emissions. Desirable planning and management strategies should be explored to improve the role for the community forests to contribute to urban carbon budget. This study was carried out with the support of the 'R&D Program for Forest Science Technology (Project No; 2017043B10-1919-BB01)' provided by Korea Forest Service (Korea Forestry Promotion Institute).

Services of particulate matter reduction by urban parks in Seoul

Hyun-Kil Jo¹, Hye-Mi Park¹

¹Department of Ecological Landscape Architecture Design, Kangwon National University, Chuncheon, Republic of Korea (jhk@kangwon.ac.kr; phm2071@gmail.com)

Increasing concentration of fine particulate matter (PM), which negatively affects human health, is a serious environmental concern in the world. The purpose of this study was to quantify PM^{2.5} reduction services by urban parks in Seoul, the capital of the Republic of Korea and to suggest desirable planting strategies to improve the services. A total of 38 parks was sampled applying a stratified random sampling method, and then all the trees planted in each park were field-surveyed including species, stem diameter, and crown volume. These survey data and a dry deposition model were used to estimate annual PM^{2.5} reduction by park trees. Tree cover averaged about 50.9% in study parks. Trees with stem diameter at breast height of less than 30 cm accounted for 81.3% of all the trees. Annual PM^{2.5} reduction per unit area by the trees was approximately 23.1 kg/ha/yr, and total PM^{2.5} reduction of the entire park area in the study city was 102.6 t/yr. Total annual PM^{2.5} emissions from human activities were about 2,580 t/yr in the study city. Seoul's urban parks annually offset the PM^{2.5} emissions by 4.0%. To enhance PM^{2.5} reduction services, suggested are minimization of extensive grass area, full planting in available growing spaces, and multi-layered and multi-aged tree planting. This study could be useful in sharing the role of urban parks regarding PM^{2.5} deposition. This study was carried out with the support of the 'R&D Program for Forest Science Technology (Project No; 2017043B10-1919-BB01)' provided by Korea Forest Service (Korea Forestry Promotion Institute).

Uptake of air pollutants by street trees in Seoul

Hyun-Kil Jo¹, Jin-Young Kim²

¹Department of Ecological Landscape Architecture Design, Kangwon National University, Chuncheon, Republic of Korea; ²Department of Landscape Architecture, Graduate School, Kangwon National University, Chuncheon, Republic of Korea (jhk@kangwon.ac.kr; jykim84@kangwon.ac.kr)

This study quantified uptake of SO₂, NO₂, and O₃ by street trees in Seoul, the capital of the Republic of Korea and explored suitable planting and management strategies to enhance the uptake. A stratified sampling method was applied to select 50 plots and street trees within each plot were field-surveyed to analyze horizontal and vertical planting structures. Annual uptake of the air pollutants was estimated using quantitative models derived from deposition velocity by

pollutant and leaf area by tree species and size. Mean tree density and cover were 5.8 trees/100 m² and 12.1%, respectively. Trees with stem diameter at breast height of less than 30 cm accounted for 66.3% of all the trees. Annual uptake per unit area of the air pollutants by the trees averaged 2.1 kg/ha/yr for SO₂, 7.0 kg/ha/yr for NO₂, and 5.1 kg/ha/yr for O₃. Total annual uptake of each air pollutant for the entire street area in the study city was about 18 t/yr for SO₂, 59 t/yr for NO₂, and 43 t/yr for O₃. Seoul's street trees annually offset total SO_x and NO_x emissions from vehicles by approximately 89.1% and 0.2%, respectively. To improve the offset benefits, suggested are multi-layered and multi-aged tree planting, securing ground and space for normal tree growth, and avoiding excessive tree pruning. Study results could be useful in globally sharing air purification services of street trees and desirable planting techniques. This study was carried out with the support of the 'R&D Program for Forest Science Technology (Project No; 2017043B10-1919-BB01)' provided by Korea Forest Service (Korea Forestry Promotion Institute).

Microclimatic simulation in urban heat island area in Natal, RN, Brazil

Joaquim Custódio Coutinho¹, Flávio Henrique Mendes², Amanda Brito da Silva¹, Wesley Brito da Silva¹

¹Universidade Federal do Rio Grande do Norte, Natal, Brasil; ²Universidade de São Paulo, Escola Superior de Agricultura "Luiz de Queiroz", Piracicaba, Brasil (joaquimcustodiocoutinho@gmail.com; friquemendes@usp.br; amandab_silva12@hotmail.com; wesleybrito.natal@hotmail.com)

The urban heat island is a common problem of large urban centers. As a consequence, it entails higher energy costs due to uncomfortable environments. The objective of this research was to analyze the thermal behavior of a densely urbanized area in Natal/RN/Brazil (city with almost one million inhabitants) and, from this, to identify critical locations regarding air temperature. We used the ENVI-met version 3.1 to perform the microclimatic simulation of an area of 51.8 ha. The software requires two input files: (i) modeling of the area, containing buildings, vegetation and soil and (ii) microclimatic variables, with air temperature (27.24 °C), relative air humidity (76%), wind direction (138 °SE), wind speed (4.4 m s⁻¹) and specific humidity (5.7 g water kg ar⁻¹), with data from the Meteorological Stations of Aeroporto de Natal and the Parque das Dunas, representing a typical summer day (January/2016 - 9:00 p.m., to ensure neutral atmosphere conditions). To obtain stable results, the simulation was done in the cloud and took 104 uninterrupted hours. The results showed that the hottest hour of the day was at 1:00 p.m., with a difference of up to 2 °C within the simulated cutout, with the highest temperatures in places with little or no vegetation. Thus, these areas should be considered as priorities for planning and urban afforestation actions, considering the benefits of vegetation in the amortization of the heat island effect, by promoting better conditions of thermal comfort for the population.

Comparison of two urban heat islands in the center of Natal, RN, Brazil

Joaquim Custódio Coutinho¹, Flávio Henrique Mendes², Amanda Brito da Silva¹, Wesley Brito da Silva¹

¹Universidade Federal do Rio Grande do Norte Natal, Brasil; ²Universidade de São Paulo, Escola Superior de Agricultura "Luiz de Queiroz", Piracicaba, Brasil (joaquimcustodiocoutinho@gmail.com; friquemendes@usp.br; amandab_silva12@hotmail.com; wesleybrito.natal@hotmail.com)

The phenomenon of the heat island is understood by a climatic event occurring in urban centers, expressing a higher temperature when compared to the areas of its surroundings. The objective of this research was to analyze and compare the air temperature for two areas in the urban center of Natal/RN/ Brazil, where the urban heat island occurs. For this, we used the ENVI-met version 3.1 program to perform the microclimatic simulation, one in the East Zone and the other in the North Zone. The program requires two input files: (i) modeling of the area, containing buildings, vegetation and soil and (ii) microclimatic variables, with air temperature (27.24 °C), relative humidity (76%), wind direction (138 ° SE), wind speed (4.4 m s⁻¹) and specific humidity (5.7 g water kg ar⁻¹), with data from the Meteorological Stations of Natal Airport and the Parque das Dunes, representing a typical summer day (January / 2016 - 21 h). The simulation of the East and North Zone clipping was done in the cloud and took 104 and 160 consecutive hours, respectively, with the highest air temperature values in both regions at 1:00 p.m. The difference in air temperature was the same for the two heat islands. However, the Northern Zone presents more points with maximum temperatures when compared with the other urban area studied. Thus, the Northern Zone demonstrates a priority in the increase of afforestation in public roads, parks and squares to soften the effect of the urban heat islands.

Urban green areas and real estate prices in Curitiba, Brazil

Alessandro Panasolo¹, Franklin Galvão¹, Hermes Yukio Higachi², Edilson Batista de Oliveira³, Fernando Campos de Oliveira⁴, Carlos Augusto Wroblewski¹, Tatiana Gadda⁵, Camila Fossa Balbinot⁶

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade Estadual de Ponta Grossa, Ponta Grossa, Brasil; ³Embrapa Florestas, Colombo, Brasil; ⁴Fundação Boticário, Curitiba, Brasil; ⁵Universidade Tecnológica Federal do Paraná, Curitiba, Brasil; ⁶Instituto Capital Natural, Curitiba, Brasil (apanasolo@gmail.com; fgalvao@ufpr.br; hhigachi@uepg.br; edilson.oliveira@embrapa.br; fercampos@gmail.com; carloswroblewski@ufpr.br; tatiagadda@ufpr.edu.br; camilabalbinot@gmail.com)

This research aims to evaluate the impact of urban green areas in the prices of apartments and houses in the city of Curitiba, PR, and to propose a methodology for valuation of ecosystem services generated by urban green areas. The study was based on econometric techniques and Theory of prices provides pleasure, applied in 43 urban green areas, with three units: Private Reserve of the Municipal Natural Municipal Airumã; Teresa Urban Ecological Station; and, refinery President Getúlio Vargas (Repar). Were obtained information about the structural characteristics of 2,832 2,500 apartments and houses. Presented results of exploratory spatial data Analysis (ESDA) and the parameter estimates of the regression models and provides pleasure (theory of prices provides pleasure). The results revealed that these areas contribute to the formation of the final price of the property. Thus, it is concluded that the farther a property located in the commercial and Service Center (CBD) lower your selling price, at the same time that the proximity of the property of green urban areas contributes to the increase in the price of a square meter of housing. However, the real estate valuation should not be interpreted in a linear fashion, as well as, it must be considered that the effects of public and private green areas on the price of residential properties are not homogeneous and stationary along the urban space, and may generate different spatial clusters of real estate prices: high-high and low-bass.

Thermal comfort in the different types of urban forest of Curitiba, Paraná, Brazil

Angeline Martini¹ ; Daniela Biondi², Antonio Carlos Batista², Jennifer Viezzer²

¹Universidade Federal Viçosa, Viçosa, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (martini@ufv.br; dbiondi@ufpr.br; batistaufpr@ufpr.br; jeviezzer@yahoo.com.br)

The presence of urban forest is fundamental for the quality of life in the cities due to its numerous benefits, among which the thermal comfort stands out. Determining how to better plan the cities' vegetation to promote thermal improvement becomes critical in the face of climate change. Thus, the aim of this

research was to analyze the thermal comfort provided by the different typologies of urban forest present in the city of Curitiba. For this, three distinct areas were selected for each type of urban forest (forest fragments, old green area, new green area, street trees, and isolated trees). The variables temperature (°C) and air relative humidity (%) were collected every minute, with a Hobo® model data logger, installed in meteorological mini-shelters for 48 hours during summer. These variables were used to calculate the Human Discomfort Index (HDI). The results showed an average HDI lower for the forest fragments and higher for the isolated trees, with maximum values of 75.8 and 84.9, respectively. In all typologies, the “comfortable” class was predominant for the most part, which proves the benefit provided by the urban forest. The isolated trees presented “discomfort” to the heat only in 8.4% of the analyzed time, and the street trees in 3.5%. For the other typologies, values of discomfort were observed on lower than 0.5% of the time. Therefore, all typologies of urban forest contribute to thermal comfort, with the greatest benefits provided by fragments of forest remains.

Cooling potential of the vegetation in urban squares on their immediate surroundings in Curitiba, Paraná, Brazil

Angeline Martini¹ , Daniela Biondi², Antonio Carlos Batista², Jennifer Viezzer²

¹Universidade Federal Viçosa, Viçosa, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (martini@ufv.br; dbiondi@ufpr.br; batistaufpr@ufpr.br; jviezzer@yahoo.com.br)

The adoption of green areas has been proposed to improve the climatic conditions of cities, making it essential to understand the climatic effect provided by the different compositions of the urban forest. Forest fragments in cities have significant cooling potential. However, these areas are increasingly scarce, making the creation of urban squares with trees in practice more promising. The present study aimed to analyze the air temperature and the cooling potential of the vegetation present in urban squares on their immediate surroundings, comparing their effect with the ones provided by forest fragments in the city of Curitiba. For this, three squares and three forest fragments located in the central portion of the city were selected. Meteorological data was collected using two Kestrel® markings, simultaneously inside the area of interest (urban square or forest fragment) and on a mobile transect through an adjacent street, during summer. On average, the air temperature was 2.4 °C lower in the urban squares than in the transect, and 4.2 °C lower in the forest fragments. Up to 100 m away, the urban squares contributed to reduce 0.6 °C in their surroundings, while the forest fragments contributed to 0.7 °C. The radius of influence of the urban squares on their surroundings reaches approximately 150 m and the forest fragments, 250 m. Thus, even though forest fragments presented a greater effect, we believe that urban squares with trees contribute to the microclimatic improvement of the city, being an efficient alternative for the cooling of their immediate surroundings.

A4q: MONITORING AND ASSESSING URBAN FOREST SERVICES AND VALUES AT THE NATIONAL TO LOCAL SCALE

Effects of wind on trees / Ação do vento em árvores

Raquel Amaral¹, Takashi Yojo¹, Reinaldo Lima¹, Ana Paula Silva¹, Gilder Nader¹, Paulo Jabardo¹

¹Instituto de Pesquisas Tecnológicas do Estado de São Paulo, São Paulo, Brasil (raquel@ipt.br; yojos@ipt.br; reinaldol@ipt.br; apaula@ipt.br; gnader@ipt.br; pjabardo@ipt.br)

A chegada do verão traz também um aumento no número de queda de árvores, causando problemas na circulação de veículos, prejuízos materiais e, o mais grave, riscos de acidentes para a população. Para determinar o risco de queda, utiliza-se um modelo probabilístico e dinâmico que considera parâmetros como: altura total da árvore, diâmetro à altura do peito, porcentagem de deterioração interna e densidade aparente do lenho. Além disso, simula a ruptura da árvore em 12 diferentes velocidades de vento, indicando a probabilidade de rompimento no colo (transição da raiz com o tronco). Devido à variação do coeficiente de arrasto em função da velocidade do vento nas árvores, foram desenvolvidos ensaios com galhos de eucalipto (*Eucalyptus* sp., Myrtaceae) em túnel de vento para determinação destas variações. A partir desses resultados e do comportamento das árvores sob a ação do vento, foi desenvolvida uma metodologia genérica de modelagem numérica de copas de árvores por meio de um modelo de interferência de esteiras para extrapolar os dados de um galho para a árvore inteira. Os resultados obtidos, a partir dos ensaios de galhos de eucalipto, servirão para diminuir as incertezas da análise de risco de queda das árvores na condição urbana e nos plantios homogêneos de eucalipto.

Restoring species using analog forestry techniques in the Gran Parque Metropolitano de La Habana, Cuba / Restauración de especies mediante las técnicas de Forestería Análoga en el Gran Parque Metropolitano de La Habana, Cuba

Ana María Peñalver Jaime¹, Wilmer Toirac Arguelle¹, Orlidia Hechavarría Kindelán¹

¹Instituto de Investigaciones Agro-Forestales, La Habana, Cuba (anamarianalverp@gmail.com; wilmer@forestales.co.cu; orlidia@forestales.co.cu)

El estudio se realizó en el Gran Parque Metropolitano de La Habana perteneciente al municipio Plaza en la provincia Habana en el periodo de febrero – marzo de 2017, empleando las técnicas de Forestería Análoga (FA) se realizó un análisis de la estructura y composición de la vegetación del área. Cumpliendo con los 12 principios que rigen la FA se realizó la valoración ecológica en el área la cual contiene una clave numérica de 1-8 y comprende diferentes indicadores tales como: perfil del suelo, densidad aparente, macro-fauna del suelo, componente vegetal e indicadores de productividad. Además, se plasmó la fórmula fisionómica de la vegetación para obtener una representación en símbolo de la estructura y composición del sitio; se elaboró una tabla de datos de las especies existente y se realiza una propuesta de especies a utilizar en la restauración con objetivo de crear un ambiente recreativo. Para este fin se tuvo en cuenta el tipo de suelo, y las exigencias de cada especie.

Computer machine learning to evaluate the safety condition of urban forest

Luís Miguel Ferreira Martins^{1,2}, Hélder Sousa¹, Tânia Gabirro¹

¹Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal; ²Centre for the Research and Technology of Agro-Environmental and Biological Sciences, Vila Real, Portugal (lmartins@utad.pt; hfps@utad.pt; taniagabirro@gmail.com)

Phytosanitary assessment and tree inventory are important tools to help the management and organization of all activities in order to improve the Urban Forests quality and safety. In Porto city (Portugal), the urban trees, namely in the urban parks, were evaluated in the period of 2016-2017. In the urban parks of Palácio de Cristal, Mata da Pasteleira, Parque da Cidade, Parque Oriental, Quinta do Covelo and Parque de São Roque a total of 24.380 trees were evaluated, considering 42 attributes for each tree (12 quantitative attributes and 30 qualitative attributes). By using those attributes a machine learning (ML) methodology was performed in order to recognize the best variables to explain the health condition evaluated by Visual Tree Assessment (VTA). The ML methods are based

on learning data representations, as opposed to task-specific algorithms. In this study were used supervised, semi-supervised and unsupervised data. First the supervised data was performed using a ML algorithm for a universe of 1600 trees. The model can quantify if the biotic or abiotic injuries in trunk, or principal branches are based in quantified variables. The model can also explain the most important variables related to the safety conditions as well as, recognize the differences between injury dimensions, and the relation between the tree height and the trunk diameter. By using the ML, first tested in a high amount of data, is also possible to predict the risk conditions and reduce the subjectivity of VTA method.

Biotic integrity in urban forests in Southeast Brazil

Vanessa Peixoto Giaccon¹, Ana Paola Di Toro¹, Eliana Cardoso-Leite¹

¹*Universidade Federal de São Carlos, Sorocaba, Brasil (vanessapeixotogiaccon@gmail.com; anapaolagomes@hotmail.com; cardosoleite@yahoo.com.br)*

In southeastern Brazil, forests have been undergoing fragmentation and degradation, causing genetic problems in their populations local extinction processes and reduction of ecosystem services. Thus, it is urgent to monitor the quality of the remaining urban forests, that is, how much they bear with pressure and still manage to maintain their biotic integrity. The objective of this study was to analyze the biotic integrity of forest fragments in the municipality of Boituva (SP), Southeastern of Brazil, and discuss the results comparing them with area size and soil use in the environment. It was used a Biotic Integrity Index (IBB) that is composed of 11 indicators (littler, grass, dead trees, exotic wood, vines, gaps, vascular epiphytes, later species in canopy and in understory, height and diameter of trees) that were applied in 12 areas. The value of IBB can vary from 11 to 55 points. It was observed that the IBB recorded ranged from 31 to 43.5, with 25% of the studied areas showing good integrity and 75% showing regular integrity. The areas with good IBB were the largest (from 75 to 98 there), and most areas with regular IBB were the smallest (from 10 to 62 ha), however a large area (91 ha) also had regular IBB. Most of the areas with urban surroundings presented regular integrity, but one of them presented good integrity, showing that even in urbanized areas the forests can maintain their biotic integrity, and consequently must be conserved to maintain the ecosystem services.

Assessing hurricane impacts on ecosystem services for urban forests in Louisiana, USA

Kamran Abdollahi¹, Zhu Hua Ning²

¹*SU Agricultural Research & Extension Center, Baton Rouge, USA; ²SU Agricultural Research and Extension Center, Baton Rouge, USA (kamran_abdollahi@subr.edu; zhu_ning@subr.edu)*

Hurricane Gustav was the second most destructive hurricane of the 2008 Atlantic hurricane season. In Baton Rouge, Louisiana the wind damage from Gustav was the worst of any storm in memory. Thousands of urban forest trees were uprooted and snapped in half by Gustav's fierce winds. A post hurricane analysis of the Baton Rouge's urban forest ecosystem was conducted using i-Tree Eco software application and based on the Urban Forest Effects Model (UFORE). The analysis revealed that this area has about 1,036,175 trees with tree canopies that cover 44.6 % percent of the city. The analysis reveals a significant tree canopy reduction. The city has more than 45 tree species. Trees currently store about 2 million tons of carbon per year with an associated estimated value of \$ 41 million per year. In addition, these trees remove about 178,354 tons of CO₂ per year with an associated estimated value of \$1.1 million per year. Baton Rouge's trees are estimated to reduce annual residential energy costs by \$8.0 million annually and reduce air pollution (ozone, particulate matter, sulfur dioxide, and nitrogen dioxide) by 860 tons per year with an associated estimated value of \$6.2 million per year. The structural value of the trees is estimated at \$ 6.2 billion. With the increase in climate variability, increased frequency and intensity of storms, and urbanization pressure, more trees need to be planted and maintained to sustain the current level of structural values and ecological services.

Generating a database for forestry management in 6 community organizations of Cochabamba, Bolivia / Generación de una base de datos para el manejo silvicultural en 6 otb's del Municipio de Cochabamba - Bolivia

Alvaro Rico¹, Ana Alvarez², Edwards Sanzetenea³

¹*Universidad Mayor de San Simon, Cochabamba, Plurinational State of Bolivia (alvarorico.bolivia@gmail.com; ¹³¹⁵⁰³anita.aa@gmail.com; e.sanzetenea@gmail.com)*

El Municipio del Cercado en Cochabamba-Bolivia está rodeado de cerros lo que ocasiona que el área urbana este en continuo riesgo ambiental y social debido al rápido crecimiento demográfico, la expansión urbana sin planificación, el cambio continuo de uso del suelo y la expansión de la frontera agrícola. Esto ha ocasionado la reducción en la calidad y cantidad de árboles en el área urbana, el incremento en la temperatura ambiente y la reducción de la calidad de vida de sus habitantes. Sin embargo y a pesar de estos problemas, el Gobierno del Municipio del Cercado no cuenta con una base de datos del arbolado urbano que le permita contar con información real y actualizada para realizar una planificación del espacio urbano y periurbano, así como la confección de políticas y normativa ambiental que contribuya a preservar el arbolado urbano y mejorar la calidad de vida de sus habitantes. El presente estudio es una prueba piloto del desarrollo de una base de datos que contribuye a la realización de mejores prácticas silviculturales y la toma de decisiones técnicas, económicas, sociales y ambientales en 6 Organizaciones Territoriales de Base del distrito 12 y el perímetro de la Laguna Alalay a través del uso de la geomatica con la generación de mapas multitemáticos y el monitoreo del arbolado urbano.

A4r: MONITORING AND ASSESSING URBAN FOREST SERVICES AND VALUES AT THE NATIONAL TO LOCAL SCALE

An evaluation of long-term management efforts for five historic urban forests in the mid-Atlantic Region of the United States

Robert Loeb¹ 

¹*Pennsylvania State University, DuBois, Pennsylvania, USA (rxl5@psu.edu)*

Urban forests provide a variety of services to cities including historical resources. Five sites in the Mid-Atlantic Region of the United States are historic urban forests: Central Park, New York, New York; Fairmont Park, Philadelphia, Pennsylvania; Glenmont – Edison National Historic Park, West Orange, New Jersey; Sagamore Hill National Historic Site, Oyster Bay, New York; and Vanderbilt Mansion National Historic Site, Hyde Park, New York. The landscape designs of all five forests follow the naturalistic landscape design principles of the father of American landscape design - Andrew Jackson Downing. Rehabilitation is the guiding principle for conservation of the forest landscape which involves maintaining and replacing trees planted and present during the time period of historic significance. This evaluation of long-term management efforts is based on reinventory of the forests and comparison to maps of a past inventory of the historic

urban forests. The comparisons of inventories revealed several common patterns of long-term forest changes. The management efforts resulted in extensive non-native tree replacement, sometimes with cuttings from rare specimens being taken to grow the replacement trees. Recent volunteer growth was aggressively removed and dying recent plantings not reflective of the historic context were not replaced. A common problem with trees planted for visual screening is the trees grew far taller and larger than originally intended, especially in the cases of coniferous species. Large size native species predating the historic period, were common outside of the forest core and have not been replaced at rates found for non-native species.

Sustainability indicators for conservations units located in urban concentrations

Guilherme Silva¹, Bruna Branchi¹

¹Pontifícia Universidade Católica de Campinas, Campinas, Brasil (guilherme.silva632@gmail.com; bruna.branchi@puc-campinas.edu.br)

Anthropogenic pressure on the environment and a massive increase in the use of resources during urbanization are two of the most representative and active forces in the 21st century. Although there are many social and environmental problems in the cities, we must know that the process of urban growth is a constant and that its greatest leap has not yet occurred. Therefore, more pressure on the environment must be expected. The need for establishing protected areas rises as one of the most controversial measures in the conservation context. Protection through land acquisition laws and processes does not ensure the preservation of the habitat, however they represent a starting point for the conservation of the environment. Despite the vision of untouched environment held by some sectors of society, these areas are not protected spaces unrelated to the human being. Their goods and services can satisfy diverse needs of the society, including those related to the productive processes. In view of the presented scenario, this study aims to develop indicators that can evaluate the degree of sustainability of protected areas located in urban concentrations. Forests management plans, academic studies published in article and books since 2000 proposing and applying such kind of instruments in Brazil were selected and analyzed. By comparing their methodology, it will be possible to identify strengths and weaknesses and, consequently, propose indicators for protected areas in urban concentrations.

Social participation and environmental policy: cases in urban watersheds within the greater Buenos Aires metropolitan area / Participación social y política ambiental: estudio de casos de las cuencas urbanas de la región metropolitana del gran Buenos Aires

Mariano Ferro^{1,2}; Clara Minaverri^{1,3,4,5}

¹Universidad de Buenos Aires (UBA), Buenos Aires, Argentina; ²CONICET Buenos Aires Argentina; ³Universidad Nacional de Luján (UNLu), Luján, Argentina; ⁴CONICET Luján Argentina; ⁵INEDS Luján Argentina (marianodamianferro@gmail.com; clara.minaverri@gmail.com)

Este trabajo trata sobre la relación entre ciudadanía y política pública ambiental en las cuencas metropolitanas del Gran Buenos Aires desde la perspectiva de la sociología ambiental y de la sociología jurídica. El foco de la indagación se centra en analizar la incidencia de la participación social en la política pública ambiental. Se evalúan los progresos y obstáculos respecto de dos enfoques complementarios y fundamentales para la implementación del paradigma ambiental en el área de estudio: I^a Gestión Integral de los Recursos Hídricos y el enfoque ecosistémico. Se presentan una serie de hallazgos de investigación empírica del análisis comparado de los conflictos ambientales en las tres principales cuencas urbanas del Gran Buenos Aires: Matanza-Riachuelo; del Río Reconquista y del Río Luján. El abordaje diacrónico ha permitido detectar que la incidencia del activismo ambiental en la institucionalización del paradigma ambiental en el área de estudio se dio como resultado de ciertas condiciones facilitadoras para la incorporación de los temas ambientales a la agenda pública, como resultado de un proceso de selección del riesgo, mediados de la década de 2000. Que la modificación que dicho contexto, en la década de 2010, ha comportado una situación desfavorable para la implementación de una gobernanza sustentable del agua en ecosistemas, en nuestro caso de estudio, debido a la inercia de los obstáculos jurídico-institucionales. La metodología utilizada es principalmente cualitativa. Los métodos aplicados son el método de caso (Stake, 2010; Yin, 2009) en combinación con el método narrativo de tópico (Mertens, 2005).

Dynamics of urban forestry in the central area of Imperatriz, MA, Brazil / Dinâmica da arborização urbana da zona central da cidade de Imperatriz, MA, Brasil

Juliana Andrade Pereira¹, Jaqueline Macedo Gomes¹, Dalton Henrique Angelo²

¹Universidade Estadual da Região Tocantina do Maranhão, Imperatriz, Brasil; ²STCP Engenharia de Projetos Ltda, Curitiba, Brasil (juliana_andradep@hotmail.com; jaquelinemacedogomes@hotmail.com; daltonambiente@gmail.com)

A arborização sem planejamento ocorre devido a carência de informações técnicas que podem ser obtidas através de inventários que indicarão a necessidade de poda, plantio, tratamentos fitossanitários, remoção de indivíduos. Neste contexto, o objetivo da pesquisa foi caracterizar a arborização urbana de Imperatriz - MA, fornecendo subsídios para elaboração do plano de arborização da cidade. O estudo foi realizado na Zona Central de Imperatriz (05°31'59,8" S; 47°29'11,2" W) dividida em 86 quadras, compreendendo uma área de 92,87 ha. Foram medidos todos os indivíduos com altura $\geq 1,5$ m nos anos de 2016 e 2018. Analisaram-se a fitossociologia, estrutura horizontal, distribuição diamétrica, ingresso e mortalidade. Registraram-se 700 indivíduos de 20 famílias botânicas e 46 espécies, representando 69,57% exóticas, não recomendadas para arborização e 30,43% nativas. *Licania tomentosa* e *Azadirachta indica* totalizam 49% da abundância do povoamento e os maiores IVI, 20,25% e 13,26%, respectivamente. *Mangifera indica* apresentou maior dominância. A distribuição diamétrica é unimodal, característica de povoamentos jovens e equiâneos. Não houve diferença significativa ($p > 0,05$) entre as distribuições de 2016 e 2018. A mortalidade correspondeu a 27,08% e o ingresso foi 19,55%, observando a substituição ou remoção de alguns indivíduos. *L. tomentosa* teve maior mortalidade (23,90%), seguido pelo *Ficus benjamina* (11,71%) e *A. indica* (9,76%). *A. indica* possui maior ingresso (41,22%), seguido por *L. tomentosa* (12,84%). *A. indica* é preferida na arborização devido seu rápido crescimento e rusticidade, porém não é recomendada, por ser exótica e promover a morte de polinizadores devido suas propriedades bioinseticida e alelopática (UEMASUL, FAPEMA).

Climate-regulation services from riparian preservation areas of Curitiba, PR, Brazil

Jennifer Viezzer¹, Daniela Biondi¹, Angeline Martini²

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade Federal de Viçosa, Viçosa, Brasil (jen.viezzer@gmail.com; dbiondi@ufpr.br; martini.angeline@gmail.com)

Riparian preservation areas (RPA) are established by The Brazilian Native Vegetation Protection Law (n; 12.651/2012) to ensure the provision of ecosystem services, mainly in relation to water resources. However, these forests generate multiple benefits to people besides water protection. Thus, here we discuss the importance of Curitiba's forests on RPA to climate regulation. For this, we used the RPA mapping made by the Brazilian Foundation for Sustainable

Development (FBDS), and the results of previous studies about the cooling effect of vegetal cover. The climate regulation provided by the RPA in Curitiba was calculated relating data of the amount of well-conserved forests on RPA in the city (28,232,089.85 m² - 44.8% of total RPA) with the decrease in average temperature generated by vegetation cover (-1 °C for each 3,381,384.00 m²). We found that the conserved forests on RPA are responsible for reducing 4.055 °C in Curitiba, which means that, without it, the temperature of the city today would be approximately 4 °C higher. This result is significant for a city with 1,751,907 inhabitants, 1,412,917 car fleet, 69.0811% built area and 100% urbanized. If Curitiba maintained the current land use and land cover (LULC) standards, forest restoration on the remaining 55.2% of degraded RPA would contribute to further reduce 4.984 °C. However, with LULC and climate changes scenarios, the effect of RPA restoration on climate regulation may differ, making it necessary to monitor its benefits through time. The results demonstrate the importance of RPA conservation and restoration for climate regulation in Curitiba.

Urban forest spatial indices of Curitiba, PR, Brasil

Mayssa Grise¹, Daniela Biondi¹, Hideo Araki¹

¹Universidade Federal do Paraná, Curitiba, Brasil (mayssamonteiro@gmail.com; dbiondi@ufpr.br; haraki@ufpr.br)

The urban space quality has been estimate by spatial vegetation indices. This study aims to determine and quantify the spatial indices of Curitiba-Paraná-Brazil urban forest (UF) through techniques of high spatial resolution remote sensing, to generate information for the land use planning. To identify the UF (public and private) were used GeoEye-1 images, which were applied enhancement techniques for decision tree classification. Were measured four spatial indices: total UF, private UF, public UF and UF in public green areas. Curitiba showed a high spatial index of total UF with 108.35 m²/inhabitant, however this should be considered with caution as it includes all vegetation (public and private) present in the city. Spatial indices representing the UF that is available for direct use by the population were 22.28 m²/inhabitant public UF (street's trees, urban green protected areas and water bodies) and only 8.01 m²/inhabitant UF in urban green protected areas (woods, parks, squares and public gardens). It was found that the amount of UF covered area by the administrative regions of the city is inversely proportional to its population density.

University/corporate partnerships to preserve urban green space / Parceria entre universidade e empresa para conservação de área verde urbana

Marianna Araujo¹, Helijone Rosa¹, Tomas Domingues¹

¹Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Ribeirão Preto, Brasil (marianna.araujo@usp.br; helijone.rosa@usp.br; tomas@ffclrp.usp.br)

O Centro de Estudo e Extensão Florestal da USP de Ribeirão Preto (CEEFLORUSP) possui um convênio com a Empresa Vila do Ipê Empreendimentos Ltda., com o intuito de desenvolver pesquisas e promover a conservação da reserva legal da empresa, constituída por um fragmento estacional Semidecidual de 20 ha da Mata de Santa Tereza, localizado no perímetro urbano de Ribeirão Preto, SP, e adjacente à Estação Ecológica de Ribeirão Preto. Desde 2005 várias pesquisas sobre estrutura arbórea, influência e manejo das lianas foram realizadas na reserva. No ano de 2014 grande parte da mata sofreu incêndio que destruiu mais de 25 ha. O presente trabalho visa implementar uma metodologia de análise comparativa permanente entre a estrutura arbórea da área intacta com a que foi queimada. Com base nas informações de coordenadas de GPS e bússola de visada, serão estabelecidas 32 parcelas de 20 m x 10 m dispostas em sequência, sendo 16 parcelas em cada área estudada. O critério de inclusão será DAP > 10 cm. Os indivíduos serão identificados com placas de metal numeradas e os dados coletados. Na monografia de Bruno Brazil (2005) os resultados obtidos mostraram que a reserva apresenta valores baixos para a maioria dos parâmetros fitossociológicos analisados, quando comparados com outros fragmentos semelhantes. Com o estudo atual, pretendemos encontrar valores diferentes dos de Brazil, visto que as metodologias usadas são diferentes e pelo fragmento ter sofrido queimada. A importância desse estudo consiste na elaboração de um monitoramento permanente mais preciso, na identificação do estágio de recuperação natural que a mata se encontra e promover sua conservação.

Urban forest study in northeast China, new advances and conclusions

Wenjie Wang^{1,2}, Panli Tian², Xingyuan He^{1,3}

¹Northeast Institute of Geography and Agroecology, Chinese academy of sciences, Changchun, China; ²Northeast Forestry University, Harbin, China;

³Shenyang Institute of Applied Ecology, Chinese academy of sciences, Chinese academy of sciences, Shenyang, China (wangwenjie@iga.ac.cn; 863100147@qq.com; hexingyuan@iga.ac.cn)

Urban forests are important for urban environments, and clarification of their ecological functions are vital for their management. We have studied the urban forest carbon sink, microclimate regulation, biodiversity conservation and soil properties in Northeast China. We found the following conclusion; 1)urban forest could function as carbon sink, and urbanization could result in the accumulation of soil carbon in forests; 2) urban forest could shade the environment, and down-regulate air and soil temperature, humidify air in the semi-arid cities; 3)urban forest is also a biodiversity conservation place for different trees and also birds; 4)various soil nutrient are determined and some place had the risk of soil alkalization; 5) by using ring-road development and urban settlement history, the urbanization effect on various urban forest parameters could be clarified. The data in this paper provide basis for urban forest development and management in China.

A5a: GOVERNING INNOVATION FOR SUSTAINABILITY IN THE FOREST SECTOR - I

Fitting in a local context: local community initiatives in managing and harvesting community forests in Southern Highlands, Tanzania

Numan Amanzi¹

¹Tanzania Forestry Research Institute, Morogoro, United Republic of Tanzania (numansaidi@gmail.com)

In Tanzania, a Forest Management Plan (FMP) is a pre-requisite of transferring power of managing forest to local communities. The FMP entails de jure forest management prescriptions that require local communities to comply with. These include a prescribed burning, restriction of grazing, and harvesting levels of forest products. Undertaking the prescribed activities are costly and some requires a procedural form of knowledge of which the majority of local communities do not possess. This study, therefore, investigate how local community modify the management prescriptions in order to fit in their local context. The study was conducted in four villages owning and managing community forest in Southern Highlands, Tanzania. Primary data were collected through field observations, in-depth interviews with community and forest committee members, and a review of documents on the management plan implementation. The findings show that forest committees were deliberately allow grazing in the community forests as a means of earning incomes to cover management costs, reducing fuel load and thus reducing forest fires intensity and addressing a challenge of grazing land scarcity facing villagers. In addition, committee members did not use the inventory

results to estimate annual allowable cuts as were considered to be not reflecting actual forest condition, instead, they estimated the harvest level of fuelwood based on their practical experiences. In most cases, harvesting levels they estimated were relatively lower as compared to one based on forest inventory. The findings suggest that the practical experience of the local community should also be considered for sustainability of forests.

Forest conservation using market driven mechanisms in Russia

Andrey Ptichnikov¹ 

¹Institute of Geography, Russian academy of sciences, Moscow, Russian Federation (aptichnikov@jgras.ru)

The Strategic Plan for Conservation and Sustainable Use of Biodiversity of the Convention on Biodiversity, the Aichi Biodiversity Targets for the period 2011–2020, envisage the conservation, by 2020, of at least 17% of terrestrial ecosystems, especially areas of high importance for biodiversity and ecosystem services. The main mechanisms for forest conservation in Russia are protected natural areas (PNAs). However, within the protected areas only about 7% of the country forests is protected. About 16% of the forests is located in protective forests, however, the economic management regimes of many categories of protective forests are not in line with the Aichi targets. In recent years, voluntary forest certification in the Forest Stewardship Council scheme has become increasingly important. FSC standards enforce forest companies to maintain high conservation values in forests (HCVF). Around 46 million hectares of FSC certified forests in Russia, of which about 5-6 million hectares of HCVF received additional protection as part of certification. The most important category of HCVF are intact forest landscapes (IFL). As part of the certification, more than 1 million hectares of these priority conservation objects are voluntarily excluded from logging by companies. For 35 certified forest users in the North-West Federal District of Russia, the share of voluntarily maintained HCVF in the lease is comparable to the relative share of protected areas in this region. FSC certification is becoming increasingly important for establishment of an internationally recognized system of forest protection in Russia. Supported by the Institute of Geography RAS state assignment 0148-2019-0006.

Social innovation for sustainable rural communities: overcoming institutional challenges in Serbia

Ivana Zivojinovic¹, Karl Hogl², Gerhard Weiss¹, Alice Ludvig¹

¹Institute of Forest, Environment and Natural Resource Policy, University of Natural Resources and Life Sciences, Vienna (BOKU) and European Forest Institute, Forest Policy Research Network, Vienna, Austria; ²Institute of Forest, Environment and Natural (ivana.zivojinovic@boku.ac.at; karl.hogl@boku.ac.at; gerhard.weiss@boku.ac.at; alice.ludvig@boku.ac.at)

Today's world society is facing a number of longstanding challenges, such as poverty, famine, inequalities, environmental challenges, and migration, which call for new and creative responses that stimulate change and are often lacking in traditional governmental approaches. Social innovations are such responses that can offer social-ecological and economic solutions to mitigate social problems by introducing new practices. They are highly relevant for rural communities for reducing social inequalities and disproportionate resource use, and fostering sustainable development. Understanding the role of social innovation is especially complicated in unstable institutional environments, e.g. in developing, post-war, or countries in transition. This paper, firstly, traces institutional voids related to social innovation in Serbia, such as a relatively poor legitimacy and enforcement of the rule of law, and institutions that fail to address societal needs. Secondly, it analyses ten cases of social innovations in rural areas, related also to forestry sector, based on in-depth interviews and document analysis. The analysis contributes to the understanding of factors that facilitate and constrain social innovations, but also efforts of social innovators to overcome institutional voids. Our results show that some types of social innovation are more likely to fill in institutional gaps and to create social values while others are oriented to secure economic benefits. Furthermore, the need for context-specific structures that enable and foster social innovations is emphasised, including improved legal frameworks (e.g. forestry and rural development related policies), favourable tax regulations and innovative financial mechanisms, which allow implementing social innovations in rural communities.

Assessment of factors affecting participation of community beneficiaries in forest-based land reform public-private partnership models in South Africa

Ratsodo Phillip Tshidzumba^{1,2}, Paxie Wanangwa Chirwa¹, Folaranmi Dapo Babalola^{1,3}

¹University of Pretoria, Pretoria, South Africa; ²Fort Cox Agriculture and Fort Training Institute, Middledrift, South Africa; ³University of Ilorin, Ilorin, Nigeria (phillipmgf@yahoo.com; paxie.chirwa@up.ac.za; folababs2000@gmail.com)

The sustainability of agriculture and forestry production on land subjected to land restitution has been of concern for both government and the private sector in South Africa. The objective of this study was to assess factors that facilitated or hindered participation of the community beneficiaries in forest-based land reform public-private partnership models. The generic structured questionnaire was administered to 140 and 175 randomly selected household beneficiaries in Amabomvini and Cata, respectively. The Amabomvini community managed their claimed land through a Trust's registered contracting company, while the Cata community managed their land themselves under the leadership of the Community Property Association (CPA). The results of the study found that there was a significant relationship with both the level of awareness ($\chi^2=27.026$; $df=3$; $p<0.01$) and participation ($\chi^2=97.278$; $df=1$; $p<0.01$) in the respective partnership arrangements adopted by the community beneficiaries. Some of the factors found to have contributed to low participation in the partnership initiative by household respondents included a lack of transparency, commitment of trustees, lack of technical skills, conflicts over land use priorities amongst beneficiaries, and barriers to markets. Furthermore, research to understand land management priorities desirable to community beneficiaries of land restitution need to be prioritized. Thus, government's role in influencing the participation of the community beneficiaries through provision of necessary governance, technical and financial post-settlement support is critical for the successful management and sustainability of the inclusive project under forest-based land reform public-private partnerships.

Community forest associations: is it far-fetched in Kenya forestry management and forest conservation

Roxventa Ongugo¹, Benjamin Owuor²

¹Kenya Forestry Research Institute (KEFRI), Nairobi, Kenya; ²ACAL, Nairobi, Kenya (rongugo@gmail.com; benjaminowuor@gmail.com)

Community Forest Associations (CFAs) are local based organizations bringing together forest users aim of ensuring sustainable forest utilization. They are formed on the basis of members' proximity to and interest in forest resources contributing to their livelihoods. Under the Kenya's Forest Acts (2005 and 2016), community involvement in management of public forests is provided for through formation of CFAs. In Kenya currently there are about 100 CFAs across the country (Ongugo et al., 2007). While the role CFAs is to participate in public forest management, they have further expanded this to include conflict management, fundraising, and negotiation. Despite their formation, forests have continued to be degraded. Timber harvesting, charcoal production and forest encroachment have increased. Studies conducted by Scientists from KEFRI (Ongugo R. A. et al., 2016 Unpublished) to evaluate the effectiveness of the

CFAs in forest conservation showed that even though CFAs are considered good institutions that give communities a sense of ownership and governance; the communities feel that the full effect and benefits have so far not been felt in the forestry sector. It further shows that forest governance even though devolved through PFM, CFAs are not involved in decision making. As a result, members of the CFAs still feel that they have been left out of decision making structures that affect livelihoods and forestry sector. Therefore, the purpose for which the CFAs were formed still remains a far-fetched dream in Kenya's forestry sector.

Enhancing scientific and social research in landscapes globally through model forests

Leonardo Durán¹, Richard Verbisky², Roger Villalobos³, Fernando Carrera³

¹Universidad Mayor, Santiago, Chile; ²Natural Resources, Toronto, Canada; ³CATIE, Turrialba, Costa Rica (leonardo.duran@umayor.cl; richard.verbisky@canada.ca; rvillalo@catie.ac.cr; fcarrera@catie.ac.cr)

Society has been tackling the concept of managing forests sustainably for many years. In 1992, Canada launched the Model Forest concept internationally as a concrete example of sustainable forest management in practice. By design, Model Forests are inclusive, transparent partnerships with a voluntary governance structure providing a mechanism for long-term engagement in research, programming, and capacity building at a landscape scale. As one of the earth's most widespread ecosystems and as a renewable resource providing a wide range of benefits to society, forests have been at the centre of many recent policy discussions. National and international commitments such as UNFCCC, Convention on Biological Diversity, Sustainable Development Goals, Bonn Challenge, Initiative 20 x 20 and others have signalled a shift towards multi-sectoral and balanced approaches to sustainable development, which include functions and services such as recreation, health and well-being, biological diversity, local livelihoods, equality, climate change mitigation-adaptation. This further supports the understanding that processes in support of sustainable development must include healthy, broad-based partnerships that combine the interests, mandates, and objectives of diverse stakeholders. In this paper, key foundations of sustainable forest management are reviewed, including the balancing of economic and environmental objectives, the concept of landscape management, the role of science and technology, and public participation in decision-making. To examine the practical implications of these concepts, over 600 publications associated with Model Forests as platforms for demand driven research are drawn upon to highlight the benefit and contributions made to integrated natural resource management, knowledge sharing and strengthening local governance.

Creating shared value through group certification for small producers and forestry companies in Argentina / Creando valor compartido a través de la certificación en grupo de pequeños productores y empresas forestales en Argentina

Carolina Isabel Llavallol¹, Florencia Chavat², Roberta Amaral de Andrade³

¹Secretaría de Agroindustria de la Nación Argentina, Buenos Aires, Argentina; ²CERFOAR - PEFC Argentina, Buenos Aires, Argentina; ³Secretaría de Agroindustria de la Nación Argentina, Ciudad Autónoma de Buenos Aires, Argentina (cllavallol@magyp.gob.ar; fchavat@cerfoar.org.ar; betinha.amaral@gmail.com)

La aplicación de la sostenibilidad en la producción ha evolucionado rápidamente desde la superposición de conceptos estancos que tratan por separado lo económico, lo ambiental y lo social - aún vigente en la estructura de ciertas organizaciones -, al de un concepto que se inserta directamente como eje del negocio, tal como expresa el "Valor Compartido" desarrollado por Porter (2011). La certificación forestal es una herramienta que representa la posibilidad de demostrar esta integración en sus procesos productivos para los productores e industriales, lo que se traduce en nuevas oportunidades de mercado, agregando valor al negocio. Como contracara, en un mercado cada vez más competitivo puede convertirse en un factor de exclusión. En Argentina, debido a la falta de recursos económicos y técnicos, los pequeños productores y empresas son los que tienen mayores dificultades para alcanzar los niveles de legalidad y sostenibilidad exigidos en la certificación. Al reducir los costos individuales del proceso y proporcionar escala a la comercialización, la certificación en grupo puede ser una alternativa para esos actores. Sin embargo, muchas veces no están dispuestos o no pueden asumir los compromisos de largo plazo requeridos para la certificación, lo que puede ser solucionado a través de una estrategia de alianza entre proveedores y empresas del "downstream" forestal, para promover el desarrollo mutuo de manera sostenida. En este trabajo mostraremos cómo la certificación forestal en grupo puede crear valor compartido, contribuyendo a los logros individuales y del conjunto e integrándose estrategias de gobernanza para el sector forestal.

Social organization and governance in integrating sustainable use of timber and non-timber forest products, a case study in Mexico / Organización social y gobernanza en la integración del aprovechamiento sustentable de productos forestales maderables y no maderables, estudio de caso en México

Diana Lorena Sánchez Vidaña¹ ; Esteban Valtierra Pacheco¹ 

¹Colegio de Postgraduados, Texcoco, Mexico (sanchez.diana@colpos.mx; evaltier@colpos.mx)

Los bosques son ecosistemas de importancia ambiental, social y económica para la humanidad. México ha sido privilegiado por sus recursos forestales, gran parte de su territorio (71%) alberga vegetación forestal con potencial para generar progreso en comunidades y ejidos, sin embargo, presentan problemas debido a la mala gestión de estos recursos como: sobreexplotación, contaminación, pérdida de biodiversidad, degradación, y en las últimas décadas, deforestación, aunado a lo anterior, se suman pérdidas de empleos por falta de competitividad del sector en un contexto de mercado globalizado. En México, existen cadenas forestales que están emergiendo como empresas exitosas que se organizan y crean instrumentos para gestionar y conservar sus bosques, administrarlos y con ello generar empleos e ingresos en sus comunidades. El propósito de este estudio fue analizar los procesos e instituciones de gobernanza comunitaria en la integración de la cadena de valor maderable y en el aprovechamiento de recursos forestales no maderables en un ejido de la Sierra Norte de Puebla, México. La investigación se realizó a través de entrevistas semiestructuradas dirigidas a actores clave, encuestas estructuradas a trabajadores de la industria forestal y observación directa de las fases productivas. Los resultados muestran que los procesos e instituciones de gobernanza comunal implementados por el ejido han contribuido al manejo sustentable del capital natural y establecido las bases para el desarrollo de sus capitales: social, humano, físico y tecnológico, además de fortalecer su integración a redes de apoyo estatales, nacionales e internacionales.

A5b: GOVERNING INNOVATION FOR SUSTAINABILITY IN THE FOREST SECTOR - II**Determining the collaborative potential in Oregon's forest products industry: a method to foster cross-sector collaboration**

Jose E. Guerrero^{1,2}, Eric Hansen¹

¹Department of Wood Science and Engineering, College of Forestry, Oregon State University, Corvallis, USA; ²Grupo Argos S.A., Medellin, Colombia (jose.guerrero@oregonstate.edu; eric.hansen@oregonstate.edu)

Current global challenges faced by society such as population growth, consumers demand for greener products, and climate change are altering the operational environment of the forest sector. Forest companies are transforming their business through bio-innovations to create value, enhance competitiveness, and replace human dependence on fossil-based products. However, questions remain regarding how can forest companies identify and develop new innovations, capitalize on the business opportunities presented, and achieve a successful transition to the bioeconomy? Research and strategies around the bioeconomy have emphasized cross-sector collaboration as a means for achieving a successful transition via creating new forest-based products. This study aims to assess the potential of Oregon's forest companies to collaborate with companies from other sectors, as well as explore barriers to implementing collaboration with other industries. Personal interviews with top executive members (CEOs, VPs, etc.) of large, Oregon-based companies will be conducted to develop an understanding of their approach to collaboration. An adaptation of the collaborative learning approach, a theory-based framework proposed by Daniels and Walker (2001), will be used to determine company's collaborative potential. Results will help to identify weaknesses, barriers, and feasibility to collaborate across sectors, and provide knowledge-driven recommendations for improving collaborative potential in forest products companies.

A social-ecological-technical analysis framework for forest ecosystem services governance innovations

Carsten Mann¹, Stefan Sorge¹

¹Eberswalde University for Sustainable Development, Eberswalde, Germany (carsten.mann@hnee.de; stefan.sorge@hnee.de)

European forests provide a variety of ecosystem services. Due to the public goods character of many forest ecosystem services, the appearance of externalities, imperfect property rights and insufficient knowledge and information, markets often fail to efficiently allocate natural resources. Ensuring the sustainable provision of the range of forest ecosystem services requires new and unconventional approaches in forest management, business, and in the policies and interventions that govern these. In this talk, we present the conceptual foundation and first empirical application of an analysis framework for explaining the emergence, development of spread of a successful governance innovations for the provision of forest ecosystem services (FES). The framework builds on the idea of complex and interlinked social-ecological-technical-forestry-innovation systems in the context of the H2020 InnoForEst Innovation Action. Studying six governance innovations, payment schemes for ecosystem services (PES) and network approaches, the objective is to gain a solid understanding of what has influenced the governance innovations emergence and development, and what needs to be changed for innovation upgrading and/or upscaling. A wide range of stakeholders are included in the analysis following a multi-actor approach for knowledge co-creation. Through the analysis, interdependencies are revealed and adjustment possibilities of crucial influencing factors are conjointly elaborated for road mapping strategies, depending on the vision and ideas of participating actors. In addition it is shown how the analysis results are integrated with other project findings elaborating on forestry innovation system conditions on EU level, down to local stakeholder visions and interactions.

Conditional incentives: What governance lessons for the design of innovative environmental mechanisms?

Sven Wunder^{1,2}

¹European Forest Institute, Barcelona, Spain; ²Center for International Forestry Research Lima Peru (swunder@cgiar.org)

In recent decades, a greater societal scrutiny of public spending for 'value for money' criteria has also penetrated the forestry and environmental sectors, thus promoting the use of performance-based instruments. Payments for Environmental Services (PES), 'green' production certification, reduced emissions from deforestation and forest degradation (REDD+), and ecological fiscal transfers (EFT) are all examples of 'payments by results', i.e. environmental incentives based on a quid-pro-quo, contractual principle: you only pay for what you get. In what contexts do such instruments provide an adequate governance framework for effective and cost-efficient environmental management between an environmental principal (e.g. a government) and agents (e.g. landowners)? We review meta-studies and systematic reviews related to these four instruments. Our results point to a number of conditions for these instruments to work adequately. For instance, the performance proxy has to be closely correlated to the underlying broader environmental service, and needs to be unambiguously measurable, with a well-defined environmental baseline or standard. Upfront investments for agents need to be either small or externally subsidized. Risks need to be carefully distributed between the two parties for incentive compatibility; agents usually need to be relatively well in control of the outcomes. Transactions costs of monitoring and verifying compliance need to remain manageable. Finally, the principal needs politically to be able to sanction non-compliance, by effectively withholding payments independent of spending pressures. These observations provide some lessons for prospectively using the conditionality principle vis-à-vis other innovative mechanisms, e.g. in managing product markets and value chains.

Policy implications for social innovation in forestry

Alice Ludvig^{1,2}, Gerhard Weiss^{1,2}, Ivana Zivojinovic^{1,2}

¹University of Natural Resources and Life Sciences Vienna, BOKU, Vienna, Austria; ²EFI Research Network, Vienna, Austria (alice.ludvig@boku.ac.at; gerhard.weiss@boku.ac.at; ivana.zivojinovic@boku.ac.at)

Over the last decade, the term Social Innovation (SI) has received increasing attention to address complex global social problems and to add collective values. The forest sector has many potentials for fostering employment, community development and for preventing land flight. It thus appears to be a promising field to investigate modes of SI in terms of collective action and collective benefits through both private and public-private collaborative efforts. One of the main advocates of the concept has formulated briefly that social innovation can be seen as 'new ideas that address unmet social needs – and that work' (Mulgan et al., 2007, p. 2). The paper focuses on examples for new "social practices" that have ultimately become institutionalized and asks the question of how new actors constellations and organizational innovations in forestry have led to innovative business solutions. Methodologically we examine this question with example of qualitative in-depth case studies in different European and Mediterranean countries and study how policies have impacted in fostering these innovations. In conclusion the paper derives the main factors for supportive policy and governance implications and provides an outlook for future governance of SI.

Social innovation: forest owners and their willingness to cooperate

Matthias Sonnhoff¹, Andy Selter¹

¹University of Freiburg, Freiburg i.Br., Germany (matthias.sonnhoff@ifp.uni-freiburg.de; andy.selter@ifp.uni-freiburg.de)

Germany is characterized by a large number of small-scale forest owners. Since more than 50 years they have decided to cooperate in forest owner associations or in community forests to overcome the predominant fragmentation of ownership. Forest owners cooperate to meet the demands of markets, society and environmental influences by a continuous development. Therefore, it is necessary, that innovation takes place. In this context cooperation between forest owners can be defined as social innovation. Forest owner associations are based on this social innovation. The social innovation itself is based on a transfer of knowledge and depended on the context. It is unclear, which factors are adjuvant or obstructive for social innovation. Consequently, we aim to identify the factors that lead to social innovation in the context of forest owner associations. Therefore, the actor-centered institutionalism approach is used, to highlight the abilities and the environmental influences that influence actors and their willingness to cooperate. We have made 25 qualitative interviews with managers of forest owner associations and a quantitative survey directed to 160 forest owner associations in Baden-Wuerttemberg. Preliminary results indicate that forest owners cooperate, if several factors are fulfilled and considered. Especially social needs of forest owners in the context of protecting the independence of their property and the institutional context have to be considered. Furthermore, social demands have also an influence and regulations, organizational structures and natural events are relevant, if social innovation takes place.

Mapping governance of innovations in forest ecosystem service provision

Eeva Primmer¹

¹Finnish Environment Institute, Helsinki, Finland (eeva.primmer@ymparisto.fi)

Scientific and policy interest in ecosystem service provision has consolidated in two major streams: in mapping the spatial distribution of ecosystem service provision and in new income generation mechanisms. In these endeavors, forests represent a key area of practical experimentation, rigorous empirical analysis and prospected application. The two streams of knowledge production have remained surprisingly segregated. The deficient understanding of the spatial distribution of governance mechanisms and the ways in which they match ecosystem service provision is particularly aggravated relative to innovations. Enriching the spatial ecosystem service supply and demand analyses that overlay ecosystem types and recreational use or willingness to pay, this study combines biophysical and institutional analysis to map innovation governance. The talk reports results from a European mapping of forest ecosystem services – representing supply – and forest strategies addressing the same ecosystem services and promoting innovations – representing institutional demand. The hypothesis is that strategies promote innovations for governing such ecosystem services that are either rather scarce or abundant, reflecting the different societal motivations for steering the use of forest. Scarcity would drive policies promoting ecosystem resilience and sustainability of use, while abundance would drive policies boosting market creation, specialization and competitive advantage. The initial document analysis identifying ecosystem services, rights and responsibilities, innovations and governance mechanisms, was carried out in 2018. The completed biophysical and institutional mapping of European forest ecosystem services will allow the evaluation of the role of strategies in the institutional landscape and the ways in which such medium-term policy documents can support innovation.

Devolving community forest commons to smaller, sub-communal user groups: Is it worth the efforts?

Yiwen Zhang¹, Shashi Kant¹

¹Faculty of Forestry, University of Toronto, Toronto, Canada (yww.zhang@mail.utoronto.ca; shashi.kant@utoronto.ca)

Existing research has extensively explored various approaches to enhancing community forest management; however, little research has discussed the feasibility of devolving forests from community-level organizations to smaller, sub-communal user groups (DCFS). Based on a comparative case study of two communities devolving forests from the administrative village to villagers' groups in Western Fujian, China, we explore the effects of DCFS in forest communities specializing in commercial timber production. This study shows that by providing farmers with more forest rights, DCFS increases farmers' representation in managing community forests and makes farmers share more timber revenue. However, the increase in farmers' representation may not necessarily increase the long-run efficiency of timber production. Compared to communal organizations, smaller, sub-communal user groups, which tend to have less capital, technology and leadership, may fail to form collective actions of developing value-added timber production and making long-run investments, which impedes the sustainability of timber revenue generation. Market risks and social changes may also threaten the efficacy of DCFS and bring challenges to commercial timber production of forest communities. Despite these potential problems, sub-communal user groups may develop appropriate institutions to address the problems after DCFS. This research not only presents a new innovative toolkit of enhancing community forest management but also provides insights into certain significant but often neglected issues in managing the commons, such as the correlation between group size and farmers' representation, and trade-off between farmers' representation and the economic sustainability of community timber production.

Science fiction or cutting edge science: How might factory grown wood influence land management?

Jamie Barbour¹, Robert Deal¹

¹USDA Forest Service, Portland, USA (roy.barbour@usda.gov; robert.deal@usda.gov)

Advances in cellular biology have made commercial scale fabrication of plant and animal products a real possibility. The most advanced efforts are with commercial meat production and once this technology is perfected it seems likely that it will also be applied to other cellular materials. At the 2017 IUFRO Division 5 Congress this topic was discussed during brainstorming sessions for the IUFRO Task Force on Foresight for the Forest Sector. Much of the discussion was about the potential to create designer wood products with high value and quality. The question of how large scale fabrication of wood might influence options for land use. If experience gained from the shift of wood production from natural forests to plantation forestry serves as an example, the impact on land management could be substantial by removing an important incentive for keeping forests in forests rather than converting them to agriculture or some other more highly developed use. This could have implications for sustainability of wildlife habitat, recreation, and other ecosystem services. This presentation will explore both the opportunities offered by commercial scale fabrication of wood and the challenges such a technology might present in maintaining other benefits derived from both natural and managed forests.

A5p: GOVERNING INNOVATION FOR SUSTAINABILITY IN THE FOREST SECTOR - I

Characteristics of community housing built in the Western Amazonian city of Pimenta Bueno, Rondônia, Brazil, within the wooden public housing program / *Caracterização de habitações sociais edificadas no município de Pimenta Bueno, estado de Rondônia, Amazônia Ocidental, Brasil, a partir do projeto habitação popular em madeira*

Maria de Fátima de Brito Lima^{1,2}, Cecília Manavella¹, Divino Eterno Teixeira¹, Álvaro Nogueira de Souza², Peter Wimmer¹, Júlio Eustáquio de Melo²

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil (fatima.lima@florestal.gov.br; cecilia.manavella@florestal.gov.br; divino.teixeira@florestal.gov.br; ansouza@unb.br; peter.wimmer@florestal.gov.br; alej@unb.br)

Devido ao grande déficit habitacional brasileiro que atinge especialmente às populações de baixa renda, foram edificadas diversas habitações sociais com madeiras oriundas de apreensões promovidas e doadas pelo Instituto Brasileiro de Meio Ambiente e dos Recursos Naturais Renováveis entre os anos de 2002 e 2003, no Município de Pimenta Bueno, Estado de Rondônia, na Amazônia Ocidental, a partir do projeto “Habitação Popular em Madeira”, desenvolvido pelo Laboratório de Produtos Florestais - LPF, em parceria com a Universidade de Brasília - UnB. Tais moradias foram destinadas a famílias residentes na periferia e em risco de habitabilidade social. O objetivo desse trabalho foi analisar as condições atuais das moradias anteriormente construídas, sob os aspectos de reformas efetivadas, manutenções feitas pelas famílias, resistência do material madeira às intempéries do tempo e conservação geral dos imóveis. Os resultados encontrados, a partir da aplicação às famílias beneficiadas, de questionários socioeconômicos e de habitabilidade, apontaram para que aquelas que tiveram alguma ascensão social através da educação dos descendentes e melhoria da renda familiar promoveram reformas visando ampliação e manutenção dos imóveis, estando aqueles bastante conservados. As famílias que se mantiveram sem nenhuma ascensão social ou que os descendentes não buscaram educação ou melhoria da renda familiar não efetivaram qualquer manutenção ou reforma das moradias e o estado geral de conservação observado se mostrou bastante precário, incluindo risco de desabamento.

Expanding cultivation of peach palm (*Bactris gasipaes*) in Northwestern Paraná State, Brazil / *A expansão do cultivo da pupunheira na região noroeste do Paraná*

Edison Eiti Mikami¹, Sidney Aurelio Valeriano Ramos¹

¹Emater-PR, Cianorte, Brasil (eite@hotmail.com; sidney_valeriano@yahoo.com.br)

Os primeiros plantios foram iniciados na década de 1990 em diversos municípios do noroeste paranaense em pequenas áreas como plantios experimentais e posteriormente houve algumas iniciativas de plantios maiores, porém sem resultados promissores. A partir de pesquisas experimentais do IAPAR, Embrapa, UEM e do Instituto Emater-PR, houve a validação de alguns resultados que permitiram mapear áreas e regiões aptas ao seu cultivo no Paraná e aplicar as tecnologias geradas. O aumento das áreas de cultivo da pupunheira deve ser atribuído a implantação de algumas agroindústrias e a versatilidade no aproveitamento de sua matéria prima, sendo amplamente utilizada na forma in natura. O modelo de produção adotado na região noroeste do Paraná é diferente das técnicas utilizadas nas regiões litorâneas de São Paulo, Paraná e Santa Catarina, caracterizando-se pelo sistema de adensamento e emprego de mecanização agrícola nas áreas de cultivo. Os principais fatores que restringem a expansão da pupunha são o número pequeno de agroindústrias, os custos de implantação, assistência técnica, necessidade de irrigação e crédito.

Tax and environmental control of native timber products: the use of digital technologies / *Controle tributário e ambiental de produtos madeireiros nativos: o uso de tecnologias digitais*

Daniel Teixeira¹, Felipe Vieira², Ítalo Veras³, José Bandeira³, Lucian Stoenica³, Marcello Rangel³, Alexandre Brasil³, Ariel Andrade³

¹Universidade de Brasília, Brasília, Brasil; ²Gestão de Ativos Ambientais e Florestais, Brasília, Brasil; ³Instituto Avaliação, Brasília, Brasil (dnmoura@gmail.com; stockfv@gmail.com; italoverasedu@gmail.com; claudio@avaliacao.org.br; lutisto@gmail.com; marcellorangel@gmail.com; brasil@avaliacao.org.br; arielandrade@yahoo.com)

A participação das florestas nativas na produção primária florestal brasileira tem sido gradualmente reduzida em função de diversos problemas estruturais no setor, com destaque para: a pesada burocracia envolvida na gestão e controle das atividades florestais, levando o empreendedor para a informalidade, e; a fragilidade dos sistemas de fiscalização envolvidos no controle do desmatamento ilegal. A literatura mostra que esses problemas persistem, apesar de haverem normas, ações integradas de combate ao desmatamento ilegal, de constrangimento de mercados consumidores e de promoção ao manejo florestal. As tecnologias da era digital, baseadas em dados, computação e automação se credenciam como uma forma de aperfeiçoar a burocracia e controle da informalidade e ilegalidade da madeira. Assim, as atividades humanas e processos envolvidos na fiscalização seriam criados e recriados com base em volume de dados em escalas antes inexistentes. Portanto, o objetivo do presente estudo foi avaliar, do ponto de vista legal, as potencialidades dos sistemas de controle tributário e ambiental da madeira nativa em absorver as tecnologias digitais. Para isso, realizou-se o levantamento da legislação que rege os sistemas de controle da madeira e distribuiu-se os instrumentos em matrizes analíticas. Os resultados mostraram que a legislação atual já permite que diferentes instituições públicas e privadas possam compartilhar dados não sigilosos. Porém, as normas ainda não expressam as reais possibilidades de incorporação de tecnologias digitais já utilizadas em outros setores da economia, como o de medicamentos controlados.

Rural communities producing wood shingles: an alternative source of income for small forest producers in community and family forest management / *Produção de telhas de madeira (cavacos) por comunidades rurais da Amazônia: uma alternativa de renda para o pequeno produtor florestal no manejo florestal comunitário e familiar*

Ana Luiza Violato Espada¹, Junia Ruggiero², Iran Pires³, Benedito Pacatuba³, Paulo Bittencourt³, Marco Lentini⁴, Ana Luiza Violato Espada^{3,5}

¹Instituto Floresta Tropical, Gainesville, FL, Brasil; ²Instituto de Manejo e Certificação Florestal e Agrícola, Piracicaba, Brasil; ³Instituto Floresta Tropical, Belém, Brasil; ⁴WWF, Brasília, Brasil; ⁵University of Florida, Gainesville, FL, USA (violatoespada@ufl.edu; junia@imaflo.org; iran@ift.org.br; iran@ift.org.br; paulo@ift.org.br; mwlentini@gmail.com; violatoespada@ufl.edu)

Cavacos são telhas de madeira produzidas com técnicas desenvolvidas de forma empírica durante muitas gerações e que ocorrem de forma manual e em pequena intensidade. Paradoxalmente, apesar das vantagens e do baixo custo em comparação às telhas de barro e de fibrocimento, os cavacos raramente são usados. O estudo realizado pelo Instituto Floresta Tropical apresenta as vantagens do uso do cavaco, de forma a resgatá-lo como uma boa opção para a construção civil rural e para a geração de renda, clamando a atenção das agências licenciadoras para a necessidade de regulamentações específicas que simplifiquem o

acesso aos produtos florestais originados tradicionalmente no mercado formal. Apresenta uma análise de viabilidade econômica, de forma a comparar os custos associados à produção e ao uso do cavaco em comparação às telhas de barro e de fibrocimento. Os dados foram coletados no Centro de Manejo Florestal Roberto Bauch, Paragominas. Foram utilizadas duas árvores de *Holopyxidium jarana*. As coletas de dados ocorreram em duas etapas. Em 2009, foram selecionados aleatoriamente 30 cavacos para a mensuração de seu comprimento, largura e espessura. Em 2011, foram sorteados 20% da produção diária e foram medidos produtividade no trabalho e consumo de combustíveis e de materiais. A produção e uso do cavaco apresenta vantagens em relação a produtos alternativos para a cobertura de casas e estruturas rurais, além de ser uma opção de renda interessante para pequenos produtores rurais. Entretanto, tal prática tem sido lentamente abandonada por diferentes razões, e buscamos através deste resumo resgatar o seu uso.

Critiques of the Brazilian national policy on forest biofuels (Project of Law 1291/15) / Comentários críticos sobre a política nacional de biocombustíveis florestais (PL nº 1291/15)

Rafaela Prosdocini Parmeggiani¹, Luiz César Ribas¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil (rafaela.prosdocini@gmail.com; luiz.c.ribas@unesp.br)

A Política Nacional de Biocombustíveis Florestais (PNBF) trata dos combustíveis sólidos, líquidos ou gasosos oriundos da biomassa florestal (lenha e carvão vegetal). Seu objetivo é de ampliar a participação na matriz energética brasileira e o cultivo de florestas plantadas com potencial energético para a produção sustentável de biocombustíveis. Sua implantação dependerá da análise (no qual o custo de oportunidade da terra será uma das variáveis) das alternativas de uso, ocupação e alteração antrópica das áreas rurais (produção alimentar e agropecuária, cana-de-açúcar, soja, carne, reforma agrária e proteção ambiental). Para uma decisão pelos biocombustíveis florestais, os instrumentos (incentivos fiscais, linhas de crédito rural e apoio ao cooperativismo, sequestro de carbono com uma alternativa de pagamento por serviços ambientais, reposição florestal, plantio energético em áreas rurais consolidadas mediante a não destoca da área, etc.) de política florestal, alimentar, agrária, ambiental e energética, devem ser sopesados. Diversos dispositivos da PNBF, portanto, estão justapostos à outras legislações e políticas públicas de cunho nacional e internacional (nova Lei Florestal, Política Nacional do Meio Ambiente, Política Nacional de Florestas Plantadas, dentre outras). A questão da “fiscalização” sempre tem sido o nó górdio de políticas de base florestal, mesmo que se propondo, aqui, mecanismos como o Sistema Nacional de Informações sobre Florestas com Potencial Energético e respectivo banco de dados. O PL 1291-15, inclusive dada a Contribuição de Intervenção no Domínio Econômico, ainda terá que passar por diversas comissões do Congresso Nacional, demandando um acompanhamento mais acurado de seu processo de aprovação, regulamentação e implementação.

The use of participatory approach at the introduction of modern forest harvesting operations with an emphasis on soil protection: project “Links4Soils”

Jurij Beguš¹, Aleš Poljanec¹

¹Slovenia Forest Service, Ljubljana, Slovenia (jurij.begus@zgs.si; ales.poljanec@zgs.si)

Introducing novelties is always accompanied with a certain extent of resistance that can be overcome only by dialogue. Due to close to nature oriented forestry and ecological conditions in Slovenia, modern forest harvesting operations (FHO) have not been always accepted positively. The attitude among different stakeholders towards FHO has been and still is diverse. To overcome differences in attitude and find appropriate solutions, participatory process, consisted of several workshops (WS), has been introduced in 2002 and repeated several times (2010 and 2018). Such uniform approach enabled us to get a systematic view on participants’ attitude towards the use of FHO over the last two decades. Results shows that soil damages caused by FHO are one of the most important issues. Thus, several activities for better integration of soil protection in forest harvesting operations were performed within the Links4Soils project, co-financed by the European Union as part of the Alpine Space Program. Maps showing risks of harvesting operations for soil degradation based on existing soil data were prepared and guidelines for forest operations were upgraded. Important part of the activities was WS (2018) on soil protection for forest experts and practitioners, organized as continuation of participatory process. The results of different activities will be presented and applicability of approaches and methods used will be further discussed.

***Pinus elliottii* Engelm. Resin: a non-timber forest product providing environmental, social, and economic benefits in the coastal grassland region of Rio Grande do Sul, Brazil / Resina de *Pinus elliottii* Engelm.: produto florestal não madeireiro promovendo benefícios ambientais, sociais e econômicos nos campos litorâneos do Rio Grande do Sul**

Samara Lazarotto¹, Rafaelo Balbinot¹, Maria Inez Azevedo Velho²

¹Universidade Federal de Santa Maria, Campus Frederico Westphalen, Frederico Westphalen, Brasil; ²Âmbar Florestal, São José do Norte, Brasil (samara_fk@hotmail.com; rafaelo.balbinot@gmail.com; mivelho@ambarflorestal.com.br)

A extração da resina de árvores é uma técnica antiga e que vem sendo atualizada ao longo do tempo. Atualmente a resina do *Pinus elliottii* Engelm. é retirada de uma maneira mais efetiva e com ferramentas que facilitam o processo. A área de estudo compreende quatro fazendas pertencentes a empresa Florestadora Palmares – Flopal localizadas em Santa Vitória do Palmar, RS, que em um sistema de parceria são resinadas pela Âmbar Florestal. O objetivo deste trabalho é analisar a importância da resinagem para os colaboradores e obter dados socioambientais. A metodologia se resume a entrevistas realizadas por meio de um questionário formulado pelos autores. Foram entrevistados 87% do total de colaboradores da Âmbar Florestal, entre esses a maioria (87,7%) são homens, contudo a representatividade feminina vem aumentando nas atividades a campo. Aproximadamente 63,4% dos entrevistados tem filhos que na sua maior parte são crianças de 10 a 15 anos de idade, faixa etária onde cuidados com educação, escola, saúde e alimentação são essenciais e representam custos para os responsáveis. O maior número dos entrevistados (66,6%) vivem em residências com até 4 indivíduos onde a única fonte de renda provém da resinagem de *Pinus*. A partir destes resultados constatamos a importância da resinagem diretamente na vida do colaborador e indiretamente nas vidas da sua família e na sociedade como um todo.

A6b: BALANCING ENVIRONMENTAL, PRODUCTIVE AND SOCIAL NEEDS TO MEET SUSTAINABLE GOALS IN THE FOREST INDUSTRY: EXPERIENCES OF CROSS-SECTORIAL COOPERATION IN SOUTH AMERICA

Development of a forest sustainable/balance model based on plantations. Perspective of MPC, a private forest company in Chile

Francisco Rodríguez¹

¹CMPC Celulosa, Los Angeles, Chile (francisco.rodriguez@cmpec.cl)

The evolution of this issue within the forest companies in Chile has been very important since the early 90s. The situation of CMPC, although particular, is not far from what has happened in the Chilean forestry sector during the last 30 years. Created in 1920, CMPC is a company whose mission is to produce and market solid wood products, cellulose, paper and tissue products made from plantations. It currently operates in 8 countries in Latin America, providing almost 18.000 direct jobs, with annual sales above 6 billion dollars. It is only in 1991 that CMPC draws up its first Forest Environmental Policy; 8 years later, started a “Good Neighborhood Plan”, oriented mainly to ensure its operational continuity through the establishment of agreements with communities neighboring its operations. These initiatives were finally taken to a higher stage driven by Forest Management Certifications. CERTFOR / PEFC in 2004 and FSC in 2012, unleash a very strong change in the work of CMPC and the entire Chilean forestry sector. Market itself mandates the monitoring of principles and criteria, based on its 3 pillars: economic, social and environmental. As a new link to the aforementioned, multiparty work initiatives have been added including the views of NGOs, local communities, companies and governmental bodies to carry out balanced restoration actions at a landscape level, and to develop their shared governance.

Experiences with conservation and sustainable forest production in Paraguay / Experiencias de conservación y producción forestal sostenibles en Paraguay

Laura Rodríguez¹

¹Fundación Moisés Bertoni, Asunción, Paraguay (mrodriguez@mbertoni.org.py)

Con el desarrollo y la expansión de la actividad agropecuaria, especialmente desde mediados del siglo 20, los bosques en Paraguay han disminuido de manera drástica. El Bosque Atlántico de Alto Paraná sólo mantiene el 13 % de su superficie original (WWF 2017) y actualmente el bosque chaqueño está experimentando el mismo proceso. Siendo un país que basa su economía en los commodities y teniendo un territorio casi en su totalidad apto para la producción, es necesario rescatar experiencias exitosas de producción forestal sostenible que puedan ser replicadas y que ayuden a disminuir el impacto no sólo sobre los bosques, sino sobre otros ecosistemas como el cerrado o los humedales, por lo que esta presentación busca, por un lado, dar un breve análisis sobre el marco legal forestal y ambiental, acerca de las oportunidades que ofrece, y por otro, exponer algunas experiencias de conservación y de producción forestal sostenibles. Las experiencias son desarrolladas en gran parte bajo alianzas entre el sector privado, el sector público, las ONGs y la academia. Las mismas desarrollan distintas estrategias como el desarrollo turístico en áreas protegidas, el manejo de bosque nativo y plantaciones forestales, las dos últimas realizadas bajo diversas certificaciones internacionales. Con estas experiencias, se cuenta hoy con 82.733 ha protegidas bajo la figura de Reservas Naturales Privadas. Asimismo, trabajos con pequeños productores y comunidades indígenas, buscando fortalecer corredores de conectividad a través de la puesta en valor de sus bosques, enriqueciéndolos con yerba mate, logrando la protección de unas 300 ha de bosque.

Environmental, social and economic impacts of forest plantations in Chile

Hans Grosse¹

¹Instituto Forestal, Santiago, Chile (hgrosse@infor.cl)

For decades, Chile’s native forest in the Central and Southern mountain areas where exploited to use the biomass for melting metals of a young mining industry and cleared by fires for giving space to agriculture and livestock, impoverished rural population due reduced soil productivity. Significant environmental, social and economic changes by recovering about 2.5 million ha was the result of a national incentivized afforestation program with well adapted pioneer species. Planted areas stopped erosion and material flow to watersheds was reduced and catastrophic floods regulated. Chile’s forests contribute about 60% of the country’s carbon capture with a significant contribution from plantations. Forest harvest has been concentrated during the last 50 years in planted forests, allowing native forests biomass and biodiversity to recover, being Chile one of the two countries in Latin America where forest cover does not decrease. Taxes payment, considering the complete forest production chain, recovers annually more than the 800 million US\$ the state has invested during 40 years in afforestation incentives. During the same period of time, private investment close to US \$ 20 billion, are currently allowing exports that exceed US \$ 6,000 million yearly. Depressed rural communities 40 years ago, have been able to equal their development to those of suitable agriculture and fishing conditions after afforestation. Increasing forestry activity has a positive impact on employment, to sustain economically at least 9% of Chiles population.

Historical analyses of landscape changes with emphasis on forestry in Mesopotamia, Argentina

Victoria E. Espinoza-Mendoza^{1,2}, Gustavo Adolfo Zuleta¹

¹DECA - CEBBAD, Universidad Maimonides, Buenos Aires, Argentina; ²CONICET, Buenos Aires, Argentina (espinoza.victoria@maimonides.edu; zuleta.gustavo@maimonides.edu)

Commercial tree plantations in Argentina are increasing since 1999, usually motivated by public policies and market forces. The Mesopotamia region currently harbors 79% of plantations. By reconstructing the history of land cover in this region, including analyses of transitions, it is possible to understand the landscape changes. In this research we focus on forestry in Mesopotamia which has a history of timber trade dating to the 1900s. Diverse regulations and policies facilitated a significant growth of the sector, such as government subsidies that encouraged the establishment of paper and cellulose companies. The national policies involve two major goals: (a) the promotion of industrial forestry and (b) the creation of new areas of commercial plantations. The processes are based on commercial industry represented by fast-growing exotic species such as *Eucalyptus* and *Pinus*. Under this context, we did spatial analyses and reviewed historical data derived from scientific literature. We found that (1) the total planted area in Mesopotamia has increased 4000%, from 27.000 ha in 1900 to 1.100.000 ha in 2018, (2) commercial plantation have been concentrated on soils with high suitability and replacing natural forests or grasslands, (3) only one company includes native tree species in its commercial program, and (4) exists a displacement in forestry demands among the three provinces of the region. Besides, we found that (5) the forest transition model can predict some landscape changes in Misiones, whereas in Corrientes and Entre Ríos land uses can be explained by a multiple transition approach.

Factors associated with forest degradation on an Amazonian logging frontier area in Southwestern Pará, Brazil

Danilo Avancini Rodrigues¹, Maria Isabel Sobral Escada¹

¹National Institute for Space Research, São José dos Campos, Brasil (danilo.avancini@gmail.com; isabel.escada@inpe.br)

Forest degradation is a long-term process that reduces forest's biodiversity and impoverishes the ecosystems. Understanding the factors that generates and intensifies forest degradation, and its consequences, allows directing public policies to prevent this process. This study performed a spatial regression analysis between forest degradation intensity (dependent variable), environmental, political and economic variables in Novo Progresso (PA), a logging frontier expansion area in the Amazon Forest, from 2009 to 2011. The independent variables were related to fire occurrence, deforestation, conservation units, indigenous lands, logging poles and roads. The relationship between the dependent and independent variables (R^2 and p-value) was individually tested, and the variables with the highest relationship were included in the regression model. Then, the variables with multicollinearity were excluded from the model with the stepwise backward technique. It was used the Moran test to detect spatial dependency on the data. Spatial dependency was detected with statistical significance ($I = 0,2434$; $p\text{-value} = 0$ e $z\text{-score} = 9,91$), justifying the use of a spatial regression model. The Lagrange Multiplier test pointed out Spatial Lag Model as the best model adjusted to the data. The variables area of deforestation and total edge area explained 40% ($R^2\text{-adj: } 0,4092$) of the forest degradation intensity, indicating that fragmented forest and the forest areas closest to deforested areas are more likely to suffer higher degradation. For further studies, the R^2 of the model can be raised by adding variables related to pasture expansion, forest management, colonization projects and updating the roads data yearly.

Are government incentives effective for avoided deforestation in the tropical Andean forest?

Pablo Cuenca¹, Juan Robalino^{2,3}, Rodrigo Arriagada^{4,5,6}, Cristian Echeverría^{6,7}

¹Laboratorio de Cambio Global, Universidad Regional Amazónica Ikiám, Tena, Ecuador; ²School of Economics, Universidad de Costa Rica, San José, Costa Rica; ³Centro Agronómico Tropical de Investigación y Enseñanza (CATIE), Turrialba, Costa Rica; ⁴Department of Ecosystems and Environment, Pontificia Universidad Católica de Chile, Santiago, Chile; ⁵Center for Applied Ecology and Sustainability (CAPEs), Santiago, Chile; ⁶Millennium Nucleus Center for the Socioeconomic Impact of Environmental Policies (CESIEP), Santiago, Chile; ⁷Laboratorio de Ecología de Paisaje, Facultad de Ciencias Forestales, Universidad de Concepción, Concepción, Chile (pablo.cuenca@ikiam.edu.ec; juan.robalino@ucr.ac.cr; rariagadac@uc.cl; cristian.echeverria@udec.cl)

In order to ensure the provision of goods and services from forests, many governments have promoted less-traditional conservation initiatives such as programs of payments for ecosystem services called, more broadly, direct payments for conservation. The Socio Bosque Program (SBP) is a governmental program in Ecuador that directly provides economic incentives to rural families and local and indigenous communities who have voluntarily agreed to comply with some conservation activities. An impact evaluation method (matching) was used to assess the impact of the SBP between 2008 and 2014. This study revealed that on average, the SBP reduced deforestation by 1.5% in those forests that received the SBP's direct payment. These forests would have been deforested if the SBP had not been implemented. Assessment of the impact of the SBP on individual and collective contracts, using the matching method, revealed that 3.4% and roughly 1% of the forest would have been deforested in the absence of the program, respectively. In other words, the protected area in the collective SBP was 1,247,500 ha and, if the SBP had not been implemented, an area of 11,227 ha would have been lost between 2008 and 2014. The 165,700 ha protected by the individual SBP, it was estimated that 5,733 ha were not deforested due to the implementation of the conservation program. The conclusions are robust, even given potential hidden biases. The present study demonstrated that the SBP serves to mitigate the effects of climate change, especially with those contracts that are intended for individual owners.

Cross-sectorial experiences to meet environmental goals in forestry plantations of Mesopotamia, Argentina

Gustavo Adolfo Zuleta¹, Agustín Guiscafré¹, Victoria E. Espinoza-Mendoza¹

¹DECA-CEBBAD. Universidad Maimonides, Buenos Aires, Argentina (zuleta.gustavo@maimonides.edu; guiscafre.agustin@maimonides.edu; espinoza.victoria@maimonides.edu)

Despite early warnings during the '60s, degradation of natural resources is still a relevant concern worldwide. In 2019, conservation, restoration and sustainable use are still relevant goals to improve ecological conditions but not enough. In Argentina, the forestry sector is increasingly expanding the area planted with commercial trees, but also implementing environmental measures motivated by public policies, eco-demanding customers, and a strong cross-sectorial interaction. The later driver is based on the influence of scientists, consultants, and managers from a wide range of institutions (universities, CONICET, INTA, National Parks Administration, NGOs, environmental firms). As a result, inter-institutional networks were generated, for example a participatory wildlife monitoring program. However, most actions are voluntary and limited to the site or local scale, within the ownership boundaries. To fulfill effective sustainability, regional and multi-scale actions are needed, such as: (1) contribute to establish natural protected areas to preserve at least 17% of each ecoregion historical area (or major ecosystem types), (2) avoid commercial plantations in zones with high conservation values (e.g. riparian habitats, wetlands), (3) minimize new forestry in ecosystems with low legal protection (e.g. grasslands that represent unique habitats for species threatened to extinction, particularly birds), (4) restore or facilitate connectivity at multiple scales, and (5) estimate (and reduce) cumulative and synergic impacts. These measures require forest companies accept that their social and environmental responsibilities are beyond the limits of their properties. In fact, this is also valid for the agriculture and livestock sectors of Mesopotamia.

A6c: CHALLENGES TO SUSTAINABLE FOREST MANAGEMENT TO ENHANCE TRADITIONAL COMMUNITIES AND SMALLHOLDERS' LIVELIHOODS IN THE AMAZON BASIN

Do conservation strategies influence households' land clearing decisions in the Peruvian Amazon? Insights from the Nanay basin

Javier Montoya¹, Aoife Bennett²

¹Australian National University, Canberra, Australia; ²University of Oxford, Oxford, United Kingdom (jmontoya.iq@gmail.com; aoife.bennett@gmail.com)

We combine remote sensing data and household surveys to determine the drivers of land clearing decision making of riverine villagers settled in Protected Areas (PAs) and those not settled in PAs in the Nanay Basin in the Peruvian Amazon. Using empirical data, we ran reduced econometric models both for villages connected to the PAs, and those unconnected to them to determine whether land-clearing decision making was related to PAs. We found that in villages not influenced by PAs, households' land clearing decisions are motivated by market opportunities; meanwhile, in the villages influenced by the PAs (and their

respective conservation projects and initiatives), off-farm incomes, derived mainly from households' participation in Integrated Conservation and Development Projects (ICDP), has resulted in 23% less land clearance overall, with only a marginal difference in land cleared for farm extension. This finding suggests that ICDP interventions have an important inhibitory effect on households' cleared land expansion when they provide high economic returns to village participants. In light of our results, we discuss the limitations to current conservation strategies in the area, and we suggest policy elements that should be in place to strengthen them as soon as possible and going forward. This is critical right now, considering the governments explicit intention for infrastructure development in the region, which will intensify already existing drivers of land clearing, further threatening the socio-environmental integrity of the watershed and nullifying the positive impacts of the ICDP strategies.

From exploitation to management: a review of the context, life history and potential pathways to sustain and increase Brazil nut production

Karen Kainer¹, Lúcia Helena de Oliveira Wadt², Christina Staudhammer³

¹University of Florida, Gainesville, USA; ²Embrapa Rondônia, Porto Velho, Brasil; ³University of Alabama, Tuscaloosa, USA (kkainer@ufl.edu; lucia.wadt@embrapa.br; cstaudhammer@ua.edu)

Brazil nut (*Bertholletia excelsa*) has emerged as a cornerstone species of the Amazonian extractive economy, coinciding with creation of Brazilian extractive reserves. This alternative land use model attempts to balance biodiversity conservation with rural development. Traditional forest residents are assigned legal responsibility to co-manage these reserves and their resources, including Brazil nut, precipitating a shift from general nut exploitation to more conscious, intensive species management. Drawing heavily on our 25 plus years of research in the Brazilian state of Acre and surrounding tri-border region, we ask: (1) Are Brazil nut harvests sustainable in terms of fruit production patterns and resilience to nut (seed) collection? (2) In what ways might production be augmented and nut quality enhanced? We highlight that scientific evidence and local knowledge indicate that restrictions on current levels of nut harvests are not necessary to sustain populations of *B. excelsa* and its key seed disperser, *Dasyprocta* spp. Rather than concentrating on the fate of most seeds produced, the more pressing risk to *B. excelsa* populations is survival of existing large trees. Ample knowledge indicates possible futures to increase productivity by protecting and improving tree conditions: Cutting lianas from host tree crowns dramatically improves productivity; enrichment plantings and tending new recruits, particularly in abandoned agricultural fallows, is an extremely promising way to grow Brazil nut-rich forests. Nut quality and the Brazil nut market also have improved dramatically. Working together, researchers, local communities and progressive industries can promote understanding, sustainable use and conservation of standing Amazonian.

Açaí as a driving force of rural development in the communities of the Amazon river estuary

Ana Margarida Euler¹, Silas Mochiutti¹, Carlos Ramos²

¹Embrapa Amapá, Macapá, Brasil; ²Estuário Consultorias Socioambientais, Belém, Brasil (ana.euler@embrapa.br; silas.mochiutti@embrapa.br; pantojaramos@gmail.com)

The estuary of the Amazon River comprises the area with influence of the tides, where the Marajó archipelago is located with its many islands inhabited by traditional communities that live from agroextrativism. This region has one of the lowest Human Development Index (0.489) in Brazil and 87.28% of the population is vulnerable to poverty. In this context, the açaí (*Euterpe oleracea* Mart.) emerges as a product from the local biodiversity with immense importance in food security, having become the driving force for the Marajó socioeconomic development. Participatory research conducted in 2018, in the municipality of Afuá (Pará), with 135 families of Ilha do Meio Agroextractivist Settlement Project, showed that the açaí constitutes on average 94.5% of the families' income, with an annual revenue of about six thousand US dollars per family. However, 83% of the interviewed families do not have the habit of saving and at the end of the harvest season they are deprived of resources. On the other hand, the açaí economy has generated an improvement in the families' quality of life and consumption patterns. It has also changed their eating habits and the way they use the forest. As a main conclusion, the study points out the need to discuss new market strategies for the diversification of production in order to use other fruits, seeds and oils. Improvement of the financial planning knowhow of the community, by encouraging the habit of saving and creation of community funds is essential to improve the current vulnerability of these populations.

Traditional communities of the Xingu River accessing the timber market: challenges, risks, and opportunity / Comunidades tradicionais no Rio Xingú acessando o mercado madeireiro: desafio, risco e chance

Maximilian K. A. Steinbrenner¹, Iran Paz Pires²

¹Embrapa Amazonia Ocidental, Belém, Brasil; ²Instituto Floresta Tropical, Belém, Brasil (max.steinbrenner@gmail.com; iran@ift.org.br)

O presente artigo relata as experiências com a produção de madeira em tora de seis comunidades na Reserva Extrativista Verde para Sempre, no Rio Xingú, no estado do Pará. Empreendimentos florestais organizados por comunidades rurais com o intento de produzir para os mercados representam um novo ator no setor madeireiro que ainda não aparece em escala, mas tem um potencial importante, já que essas comunidades habitam em 60% das florestas públicas, numa área de 132 milhões de hectares (SFB 2009). Nos casos aqui relatados os comunitários recebem treinamento e capacitação do Instituto Floresta Tropical (IFT), apoiado pela Climate and Land Use Alliance. Adicionalmente, no âmbito do Projeto Bom Manejo, financiado pela Organização Internacional de Madeira Tropical (ITTO) a EMBRAPA Amazônia Oriental e o IFT desenvolvem junto às comunidades uma metodologia de monitoramento de critérios e indicadores técnicos, ambientais, sociais e econômicos do manejo florestal. Esse método deve servir como uma ferramenta de gestão para as comunidades e funciona com a introdução de ferramentas de manejo florestal sustentável desenvolvidas pelo Projeto Bom Manejo na sua primeira fase. Os primeiros resultados do referido monitoramento técnico-ambiental revelaram a vocação das comunidades para o manejo florestal que atende suas tradições. O desempenho produtivo se mostrou promissor e as análises preliminares indicam que os projetos de manejo são rentáveis. Os desafios para assegurar a sustentabilidade dos empreendimentos encontram-se na logística da colheita, na gestão do Plano de Manejo, nas negociações de serviços contratados e das condições de venda e o cumprimento dos contratos.

Management and governance of the use of timber resources by local populations in a floodplain area in Central Amazonia, Brazil / Gestão e governança do uso de recursos madeireiros por populações locais em uma área de várzea na Amazônia Central, Brasil

Caetano Franco¹, Ana Jéssica Silva de Oliveira^{1,2}, Zeneide Damião Silva^{1,2}, Viviane da Silva Marcos¹, Claudio Roberto Anholetto Junior^{1,3}

¹Instituto de Desenvolvimento Sustentável Mamirauá, Tefé, Brasil; ²Universidade Estadual do Amazonas, Tefé, Brasil; ³Universidade de São Paulo, Piracicaba, Brasil (caetano@mamiraua.org.br; ana_jeka@hotmail.com; zeneide.silva@mamiraua.org.br; viviane.marcos@mamiraua.org.br; claudio@mamiraua.org.br)

Na Amazônia, grupos humanos fazem uso direto dos recursos naturais para a reprodução social. Recursos madeireiros são usados para diversas finalidades (embarcações e infraestruturas comunitárias). Populações que habitam áreas de várzea seguem o ritmo da variação do nível d'água, estão sujeitos às alagações anuais. Este ciclo define as variações nos padrões de renda, disponibilidade de recursos naturais e condições de saúde. A legislação ambiental permite que estas pessoas explorem os recursos naturais existentes para manutenção. A Reserva de Desenvolvimento Sustentável Mamirauá (RDSM) abrange 1.124.000 hectares. Este trabalho discute a prática da gestão e governança dos recursos madeireiros pelas comunidades tradicionais residentes da RDSM através de um monitoramento realizado há mais de duas décadas. No período analisado, foram explorados 10,3 mil m³ de madeira não manejada para usos de subsistência dos moradores da RDSM. O Assacú (38,2% - *Hura crepitans* L.) e o Louro Inamuí (21,4% - *Ocotea cymbarum* Kunth) foram as espécies mais exploradas. A Jacareúba (8,02% - *Calophyllum lucidum* Benth.) e o Cedro (2,27% - *Cedrela odorata* L.) estão entre as espécies mais exploradas e são protegidas por acordo local desde a década de 1990. A Castenheira (1,68% - *Bertholletia excelsa* Bonpl.) se encontra nesta lista e é protegida por legislação federal. O monitoramento prove resultados que são parâmetros para o planejamento de uso dos recursos naturais pelos usuários e tomadores de decisões, bem como para a gestão adaptativa e a governança dos mesmos e da área protegida. Isso garante a conservação de espécies biológica e economicamente importantes para a manutenção da floresta e conhecimento tradicional de seus povos usuários.

Logging in protected areas in Amazonia: communities that flourish can inform those that struggle

Ana Luiza Violato Espada^{1,2} ; Natalie Cooper¹, Eduardo Bongioiolo¹, Karen Kainer¹, Lúcia Helena de Oliveira Wadt³

¹University of Florida, Gainesville, USA; ²Instituto Floresta Tropical, Belém, Brasil; ³Embrapa Rondônia, Porto Velho, Brasil (violatoespada@ufl.edu; natalieacooper@ufl.edu; eduardosbongioiolo@gmail.com; kkainer@ufl.edu; lucia.wadt@embrapa.br)

Timber extraction for commercial use has been introduced as a strategy for tropical forest management and conservation. Despite the achievements championed, forest management in the Amazon region has faced a spectrum of challenges, to which forest livelihoods and management stability within protected areas such as extractive reserves are precariously sensitive. However, regional cases of community forestry paired with institutional alliances have emerged with hopeful lessons for the future of forest communities. Communities from three extractive reserves in the states of Pará and Amazonas are thriving since initiating timber management projects, each structured around distinct local needs and visions of community forest management with technical and governance support from government and non-governmental organizations. In contrast, communities in an extractive reserve in the state of Acre are struggling with timber management. To exchange experiences and facilitate a critical link between stakeholder groups (government, universities, researchers and community members) positioned to strengthen community-based forest management, a group of students, faculty, and alumni from University of Florida (UF) and Brazilian partners conducted an information exchange workshop in Acre in June 2017. Key community members and others who have worked to incrementally build community forest management in these Eastern Amazonian reserves shared their experiences with those in Acre positioned to strengthen timber-based community forestry. Based on a social learning framework, we will present lessons learned from different community-based perspectives and experiences as related to forestry operations, financial limitations, partnerships, and collective action that improve community-based timber management, conservation, and development in the tropics.

Organizational arrangements for managing community enterprises in implementing sustainable forest management plans in the Amazon region / Arranjos organizacionais para a gestão de empreendimentos comunitários na implementação de plano de manejo florestal sustentável na Amazônia

Katiuscia Miranda^{1,2}, Manuel Amaral Neto¹, Romier Sousa², Roberta Coelho²

¹Instituto Internacional de Educação do Brasil, Belém, Brasil; ²Instituto Federal de Educação, Ciência e Tecnologia do Pará, Campus Castanhal, Castanhal, Brasil (glaukat2001@gmail.com; manuel@iieb.org.br; romier.sousa.ifpa@gmail.com; roberta.fatimacoelho@gmail.com)

O uso comum de recursos naturais configura uma marcante característica das “populações tradicionais” na Amazônia, reconhecidas legalmente como “povos e comunidades tradicionais”. Estes grupos sociais desenvolvem capacidades organizativas para a gestão de seus recursos florestais com base em suas identidades culturais, adaptados aos ecossistemas em que vivem. Exercem atividades produtivas em várias modalidades fundiárias, sejam em unidades de conservação de uso sustentável, ou assentamentos da reforma agrária. A importância dessa produção tem se configurado cada vez mais estratégica para o abastecimento do mercado. No caso da madeira, o volume oriundo de áreas comunitárias pode chegar a 1/3 de todo volume produzido na Amazônia. Para dar conta desse desafio, as comunidades têm se organizado em associações e cooperativas para fazer a implementação de planos de manejo florestais comunitários (PMFS). Contudo, estabelecer na Amazônia empreendimentos florestais organizados por agroextrativistas que residem em florestas públicas é um desafio. Principalmente, se forem levadas em conta fatores como logística, a baixa escolaridade dos diretores, a complexidade do marco regulatório para a gestão de PMFS, etc. Nesse caso, torna-se central construir estratégias participativas e transparentes para gestão dos empreendimentos. Este trabalho analisa arranjos organizacionais na Reserva Extrativista Verde para Sempre pautados em ações de avaliação e planejamento contínuo e ferramentas simplificadas de sistemas de gestão nos campos da organização, produção e comercialização. Como resultado tem-se obtido um maior empoderamento dos atores sociais envolvidos na gestão e aumento da maturidade organizacional garantindo maior autonomia e rapidez na tomada de decisão dos empreendimentos comunitários na Unidade de Conservação.

Challenges to the policy of supporting plant extractivism by traditional populations in Brazil / Desafios da política de apoio ao extrativismo vegetal praticado por populações tradicionais no Brasil

Mauro Pires¹

¹ICMbio, Brasília, Brasil (mauro.pires27@gmail.com)

O objetivo é refletir sobre desafios, limites e lições das políticas brasileiras do período 1998 a 2018 direcionadas a povos e comunidades tradicionais que encontram no extrativismo vegetal, aliado a outras atividades econômicas, a base de seu bem-viver e de sua identidade. Essas políticas ancoram-se no reconhecimento do papel que os segmentos tradicionais cumprem na conservação ambiental. O trabalho discute as principais políticas, com especial destaque para o programa Bolsa Verde (2011-2018) e o Plano Nacional de Fortalecimento das Comunidades Extrativistas e Ribeirinhas (PLANAFE), instituído recentemente para atender o conjunto das demandas desses segmentos tradicionais. Com especial interesse, o trabalho debate os limites que dificultam a ampliação do escopo, escala e número de beneficiários. Observa que, quando prevalece política econômica de restrição de gastos públicos, maiores são as barreiras enfrentadas por políticas direcionadas aos extrativistas. Constata outros fatores igualmente desafiadores: dificuldade de obtenção de informações para a avaliação do impacto e a necessidade de formação dos servidores públicos para lidar com esses segmentos. Por outro lado, da análise da trajetória das políticas sobressaem lições, principalmente quanto a governança, participação social e tecnologia social, que podem orientar tanto o redesenho na esfera federal quanto ao engajamento de outras esferas governamentais. Conclui apontando que a continuidade das políticas que priorizam segmentos extrativistas depende essencialmente da capacidade de reinvenção de instrumentos e, sobretudo, da formação de alianças com outros setores da sociedade, do ministério público, dos meios de comunicação e mesmo de parceiros internacionais.

Democratizing biodiversity monitoring in actio member countries: collective inputs on the development of a low-cost monitoring tool for Amazonian production forests

Catherine Gamba-Trimino¹, Anders Lindh², Vicente Guadalupe¹, Otavio Marangoni¹, Iran Pires³, Ana Violato⁴, Mariane Nardi⁵

¹Organizacion del Tratado de Cooperacion Amazonica, Brasilia, Brasil; ²HCV Resource Network, Oxford, United Kingdom; ³Instituto Floresta Tropical, Belem, Brasil; ⁴University of Florida, Gainesville, USA; ⁵Universidade Federal do Amapá, Amapá, Brasil (catherinetrimino@gmail.com; anders@hcvnetwork.org; vicente.guadalupe@otca.org.br; otavio.marangoni@otca.org.br; iran@ift.org.br; anaviolatoespada@gmail.com; marianenardi@gmail.com)

One of the principles of adaptive management is to frequently read the environment in order to introduce management changes accordingly. Thus, the ITTO/IUCN Guidelines for biodiversity conservation in tropical production forests (2009) recommend the development of low-cost monitoring programs serving the needs of forest managers, making information on failures and achievements widely available. In the framework of the ITTO/CBD/ACTO International courses in biodiversity conservation through ecologically responsible management of Amazonian production forests, recently implemented in Brazil, Peru and Guyana, a collective exercise on the development of a monitoring tool was proposed to participants and regional training centers. Utilizing the HCVN-Forest Integrity Assessment (FIA) tool, which uses habitats as proxies for biodiversity, and that has not yet been adapted to the Region, as a canvas, around 80 forestry professionals and managers working in different sectors at ACTO member countries provided technical and multi-actor input into this endeavor. Most participants agreed on the importance to make of biodiversity monitoring a participatory exercise, highlighting the benefits for local communities empowerment and to set up feasible conservation goals at the forest management unit scale. Suggestions on adding variables such as soil type, canopy height and forest health indicator species were made and, particularly for forestry operators, the opportunity to look at forest habitats, “rather than just measuring”, and to apply local knowledge was highly appreciated. Some resistance was also encountered, which demonstrates the need to work harder in the diffusion of simpler and more cost-efficient biodiversity monitoring tools, such as FIA.

A6d: COMMUNITY AND FAMILY FOREST MANAGEMENT IN LATIN AMERICA: GUARANTEEING RIGHTS AND CITIZENSHIP WITH SUSTAINABILITY

Public policies and environmental justice: progress and challenges in community-based forest management in the amazon lowlands / Políticas públicas e justiça ambiental: avanços e desafios do manejo florestal comunitário nas várzeas amazônicas

Luciano Regis Cardoso¹, Emanuelle Raiol Pinto¹ ; Elenice Assis do Nascimento¹, Davila Suellen Souza Correa¹, Claudio Roberto Anholetto Junior^{1,2} 
¹Instituto de Desenvolvimento Sustentável Mamirauá, Tefé, Brasil; ²Universidade de São Paulo, Piracicaba, Brasil (luciano.cardoso@mamiraua.org.br; emanuelle@mamiraua.org.br; elenice@mamiraua.org.br; davila@mamiraua.org.br; claudio@mamiraua.org.br)

As provisões de serviços ecossistêmicos da floresta aos povos indígenas e comunidades locais na Amazônia são regidas pela sazonalidade hídrica, clima equatorial e alta diversidade biológica, cultural e étnica, gerando relações materiais e cosmológicas únicas. Composto mais recentemente esta gama de relações, o mercado e o Estado produzem novas dinâmicas monetárias e burocráticas, conduzindo estas pessoas à economia e política ocidentais. O Instituto de Desenvolvimento Sustentável Mamirauá contribuiu na coprodução de conhecimentos entre cientistas, técnicos e populações locais no estado do Amazonas, Brasil, para o manejo sustentável dos recursos naturais com vistas aos direitos humanos, corroborando para que relações mais justas sejam estabelecidas. Esse é o caso do Manejo Florestal Comunitário (MFC), que através de pesquisas científicas e práticas experimentais vêm contribuindo para o fortalecimento dessa atividade econômica na várzea amazônica. Avanços como a promulgação da Instrução Normativa 09/2010/SDS foram essenciais para a adequação da atividade à realidade de áreas alagadas sazonalmente, definindo intensidade, diâmetros e ciclo de corte específicos e diferenciados. Porém, outros desafios obstaculizam o fortalecimento do MFC, como a competição com a madeira ilegal, a instabilidade da cadeia produtiva, a complexa burocracia distante da realidade dos povos indígenas e comunidades locais e os vazios de conhecimento, tanto os técnicos relacionados à ecologia florestal quanto os de caráter social, que avaliam e explicitam as respostas ao bem-estar. Impulsado pelos desafios, o Instituto Mamirauá em seus 20 anos, reafirma sua convicção, estimulando as pesquisas nos manejos madeireiros e não-madeireiros como possibilidades de justiça ambiental com as populações da Amazônia.

Timber-producing forests and biodiversity: environmentally responsible forest management within the focus of the ITTO/IUCN guidelines in the Amazon region / Florestas produtoras de madeira e biodiversidade: manejo florestal ecologicamente responsável sob o enfoque das diretrizes ITTO/IUCN na região amazônica

Otavio Marangoni Souza¹, Erielle Lima Silva², Vicente Guadalupe¹
¹Organização Tratado de Cooperação Amazônica, Brasília, Brasil; ²Gkitaya Socioambiente, Rio Branco, Brasil (otavioflorestal@gmail.com; erillima@yahoo.com.br; vicente.guadalupe@otca.org.br)

A melhoria das práticas e técnicas florestais, com base na incorporação de aspectos teóricos e práticos da conservação da biodiversidade nas diferentes etapas do manejo florestal, pode gerar mudanças positivas nos níveis de biodiversidade e, conseqüentemente, nos meios de subsistência das comunidades e famílias dependentes de florestas, assim como favorecer a manutenção e melhoria dos benefícios oferecidos à sociedade pelos serviços ecossistêmicos. Nesse sentido, foram criadas as Diretrizes IUCN/ITTO, constando de 11 princípios e 46 diretrizes voltados à florestas tropicais de produção, que abordam desde a soberania da sociedade, compromissos internacionais, políticos, educação, manejo florestal, conservação da biodiversidade, entre outros aspectos. A partir destas diretrizes, realizou-se uma análise dos oito países membros da OTCA: Bolívia, Brasil, Colômbia, Equador, Guiana, Peru, Suriname e Venezuela, em duas etapas: a primeira focada na avaliação quantitativa do grau de implementação das diretrizes e a segunda etapa, a qualitativa, composta pelo detalhamento da informação por diretriz e princípio pré-estabelecidos. A análise demonstrou que a média geral de atendimento às diretrizes foi de 2,65, considerado de regular a bom. Com estes resultados pode-se, de maneira abrangente, fornecer informações atualizadas e oficiais relacionadas à conservação de florestas e biodiversidade no âmbito do manejo florestal ecologicamente responsável da região amazônica dos oito países-membros da OTCA, testar a utilidade prática das diretrizes, identificar obstáculos que possam limitar sua aplicação e gerar insumos suficientes para ampliar e diversificar a análise e recomendações para o manejo florestal ecologicamente responsável e conservação da biodiversidade em florestas produtoras de madeira na Amazônia.

Challenges related to the concept of intact forest landscapes (PFI) for developing community-based FSC forest management certification in the Brazilian Amazon / Desafios do conceito de paisagens florestais intactas (PFI) para o desenvolvimento do manejo florestal comunitário certificado FSC na Amazônia brasileira

Nathalia Ribeiro¹, Junia Ruggiero¹, Marco Lentini¹, Vinicius de Faria¹, Leonardo Sobral¹, Edson Vidal²

¹Imaflora, Instituto de Manejo e Certificação Florestal e Agrícola, Piracicaba, Brasil; ²Universidade de São Paulo, Piracicaba, Brasil

(nathalia@imaflora.org; junia@imaflora.org; mwlenini@gmail.com; vinicius@imaflora.org; leonardo@imaflora.org; edson.vidal@usp.br)

Segundo Instituto BVRio, atualmente há 118 Planos de Manejos Florestais Sustentáveis (PMFS) comunitários operando na Amazônia, sendo que cinco possuem certificação FSC. O Manejo Florestal de Impacto Reduzido (MF-EIR) realizado na Amazônia é uma alternativa para valorização da floresta em pé, utilizando técnicas especiais para que árvores criteriosamente selecionadas sejam retiradas (volumetria máxima de 30m³ ha⁻¹), com ciclo de corte que pode variar de 25 a 35 anos. Segundo ICMBio, o manejo florestal comunitário é uma estratégia efetiva de conservação ambiental, otimizando gestão compartilhada da floresta com populações tradicionais beneficiárias de áreas protegidas e possibilitando benefícios diretos e indiretos. A revisão da norma de manejo florestal FSC incluiu o conceito de Paisagens Florestais Intactas (PFI): grandes ecossistemas florestais ou não florestais minimamente influenciados por atividades humanas. A conservação de PFI é um mecanismo robusto para manter a integridade ecológica desses ecossistemas. Entretanto, segundo o conceito incluído no FSC, atualmente 80% de áreas de PFI de comunidades certificadas FSC não podem ser manejadas, mesmo utilizando técnicas previstas no MF-EIR. Os PMFS comunitários em RESEX, FLONA e RDS são o futuro para o desenvolvimento do manejo florestal comunitário, o qual também está intrinsecamente relacionado com a missão do FSC. Dessa forma, foi analisada a dominialidade de PFI do Brasil nos anos 2000, 2013 e 2016 e avaliado como o conceito de PFI pode influenciar o desenvolvimento de PMFS comunitários certificados FSC no Brasil. A maior porção de PFI está em terras indígenas e há PFI em PMFS comunitários certificados e não certificados.

SWOT analysis of the Pae Bacuri I agroextractivist venture in the lowlands of Maranhão, Brazil / Análise SWOT do projeto agroextrativista – Pae Bacuri I na baixada Maranhense

Vera Maria Gouveia¹, Joao Flavio Bomfim Gomes¹, Anida Claudia Dominici Soares², Hulda Rocha e Silva², Tatiana Ribeiro de Santana²

¹Embrapa Cacaos, São Luís, Brasil; ²Incrá, São Luís, Brasil (vera.gouveia@embrapa.br; joaoflavio.gomes@embrapa.br; anida.soares@sls.incrá.gov.br;

hulda.silva@sls.incrá.gov.br; tatiana.santana@sls.incrá.gov.br)

O babaçu representa um expressivo recurso do extrativismo vegetal e a atividade é essencial para as quebradeiras de coco, populações rurais e indústria. Geralmente, a posse da terra não é dos extrativistas cujo acesso é realizado por meio de parcerias com os latifundiários tanto na produção agrícola como na forma de comercialização das amêndoas. Face a essa conjuntura o presente estudo teve por objetivo estudar o Projeto Agroextrativista – PAE Bacuri I cuja comunidade sobrevive do extrativismo e da pesca. Localizado no município de Cajari pertencente ao Hot Spot do extrativismo babaçu no Maranhão, o assentamento está inserido na região da Baixada Maranhense, uma complexa interface de ecossistemas do bioma Amazônia e do Nordeste brasileiro rica em biodiversidade aquática e terrestre. Foi produzido um relatório com a análise SWOT, do inglês, ou FOFA, do português, para o cruzamento das Forças (Strengths), Fraquezas (Weaknesses), Oportunidades (Opportunities) e Ameaças Threats para o gerenciamento sustentável das atividades de uso e ocupação do solo no assentamento. Destaca-se como forças o Cadastro Ambiental Rural com a vegetação nativa que se encontra bem conservada atendendo a legislação florestal e possibilitando atender nichos de mercado para produtos florestais e produção agroecológica. Entre as ameaças identificadas encontram-se a pesca predatória no lago, a caça e o desmatamento de palmeiras de babaçu utilizadas pelas mulheres que vivem no assentamento. Essas ameaças são decorrentes das fraquezas dos assentados como a falta de fiscalização ambiental, acesso a tecnologias produtivas sustentáveis e a falta de organização e articulação para gestão produtiva do assentamento.

Factors in deciding whether to grow trees on subsistence farms in Costa Rica / Factores de decisión que influyen en la adopción del cultivo de árboles en fincas de subsistencia, Costa Rica

Montserrat Romero Mora¹, Víctor Meza Picado¹

¹Instituto de Investigación y Servicios Forestales, Universidad Nacional, INISEFOR-UNA, Heredia, Costa Rica (mariamonse01@gmail.com;

victor.meza.picado@una.cr)

La creciente segmentación de tierras propicia un incremento en el número de fincas pequeñas dedicadas en su mayoría a la producción de subsistencia, esto aunado al retroceso de la producción forestal, mostrado en las tasas de reforestación y del manejo de bosques de la última década, reafirman la premisa de una necesaria transición forestal. A lo que distintas organizaciones han respondido con la generación de proyectos en conjunto con comunidades o productores, sin embargo, no han logrado hacer que permanezcan en el tiempo, ya que al retirarse las organizaciones se da un repetitivo abandono de las actividades forestales. Lo que sugiere que la elaboración de los proyectos y el fomento del cultivo de árboles han sido poco eficientes y evidencia el asistencialismo en su planteamiento, alejándose de la realidad sociocultural y económica de los productores. Por lo tanto, el estudio presenta como alternativa, para enfrentar la tendencia negativa, encausar esfuerzos hacia comprender los factores que influyen en la toma de decisiones del productor, basados en un censo aplicado a 80 fincas de subsistencia ubicadas en dos sitios de Sarapiquí de Heredia, cuyo formulario busca entender los factores vinculados al principal sistema productivo. Mostrando en los resultados preferencias ligadas a actividades tradicionales, facilidad de producción y comercialización, lo que involucra factores como costumbres, rentabilidad, capacidad de venta, entre otros. La aplicación de estos resultados en el ajuste de proyectos forestales mejorara la aceptación de la actividad, aumentando la adopción del cultivo arbóreo y contribuyendo al bienestar de los pequeños productores.

A6e: FORESTS AND HUMAN WELLBEING: LIFE SATISFACTION AND BEHAVIORAL APPROACHES

Planning for green infrastructure in Europe: linking ecosystem services, landscape preferences and human wellbeing

Marine Elbakidze¹, Lucas Dawson², Mykhailo Grodzynskyi³, Diana Surova⁴

¹Swedish University of Agricultural Sciences, Skinnskatteberg, Sweden; ²Stockholm University, Stockholm, Sweden; ³Taras Shevchenko National University of Kyiv, Kyiv, Ukraine; ⁴Universidade de Évora, Evora, Portugal (marine.elbakidze@slu.se; lucas.dawson@natgeo.su.se; mgrodz@ukr.net; dj@uevora.pt)

Green infrastructure (GI) policy encourages the spatial planning of natural and semi-natural areas that deliver biodiversity conservation and a wide range of ecosystem services (ES) important to human well-being. Much of the current literature relies on expert-led, top-down processes to investigate connections

between landscapes and ES. Little is known regarding the preferences of residents, and how they correlate land covers with the delivery of ES important for their well-being. The aim of this study is to identify and locate such land cover types as GI hubs and hotspots that provide multiple ES important for human well-being in different contexts. First, we surveyed 1600 urban and rural residents to identify ES important for personal well-being and the land covers that deliver multiple ES in four European countries – Sweden, Latvia, Belarus, and Russia. Second, to support the inclusion of GI in spatial planning we identified and located spatial concentrations of individual land covers providing multiple ES (GI hubs) and significant clusters of such land covers (GI hotspots). The majority of urban and rural respondents associated their well-being with lakes, old-growth forests, wooded-pastures, mature pine forests and rural farmsteads. There were significant differences in appreciation of GI hubs among different groups of respondents that depended on their education level, gender and urban-rural context. At least three land management strategies are needed to sustain GI hubs: maintenance of the composition, structure and function of natural ecosystems; support for traditional agroforestry and villages as social-ecological systems; and diversification of the current intensive forest management approach.

What do we know about forest health benefits in Europe?

Liisa Tyrvainen¹, Nicole Bauer², Liz O'Brien³

¹Natural Resources Institute Finland, Helsinki, Finland; ²Swiss Federal Institute for Forest, Snow and Landscape Research, Birmensdorf, Switzerland; ³Forest Research, Farnham, United Kingdom (liisa.tyrvainen@luke.fi; nicole.bauer@wsl.ch; liz.o'brien@forestry.gsi.gov.uk)

Health enhancing qualities of forests are a result of multiple benefits such as noise abatement, pollution control and scenic environment that reinforce each other. Key pathways to deliver health benefits are enhanced microclimatic conditions, stress recovery, enhanced social ties/integration, physical activity and strengthened human immune function. This presentation synthesizes knowledge regarding impacts of forests on human health and well-being in Europe with a focus on behavioral aspects. The review was conducted as a part of pan-European expert cooperation Forests Europe serving reformulation of forest policies. The analysis is based on literature reviews and meta-analyses as well as individual peer reviewed studies. There is rather strong evidence that forest visits have positive effects on restoration and psychological wellbeing. Increased evidence also exist that forest visits contribute to beneficial changes in human cardiovascular physiology. The amount of correlational studies analyzing long-term and the curative effect of forests are limited. More studies regarding long-term health benefits and dose-response relationship are needed. Furthermore, information regarding the effect of different type and size of forests as well as effects of their management on health benefits is limited. More scientific evidence is also needed about individual differences in nature exposure. The majority of studies report that forest areas are positively associated with social benefits, but note that the benefits may not be experienced equally by all social groups. The presentation also presents policy implications and recommendations that can strengthen the potential role of forests in health promotion and the preventative aspects of ill-health in Europe.

Spatial behaviour in urban woodlands: mapping pathways and recreational activities using public participation GIS

Tina Gerstenberg¹ ; Christoph Baumeister¹, Ulrich Schraml¹, Tobias Plieninger²

¹Forest Research Institute of Baden-Württemberg, Freiburg, Germany; ²University of Göttingen, Göttingen, Germany (tina.gerstenberg@web.de; baumeister@alumni.ubc.ca; ulrich.schraml@forst.bwl.de; plieninger@uni-goettingen.de)

An increasing number of scientific papers describe and explain the connections between natural landscape features and hotspots of cultural ecosystem services, values, and preferences. The results help environmental planning and decision making with prioritising and balancing management objectives. However, there is a lack of knowledge on associations between physical landscape attributes that characterise used routes and activities of outdoor recreationists (e.g., cycling, dog walking, jogging, walking). In order to address this knowledge gap, we applied Public Participation GIS (PPGIS) to assess spatial behaviour, i.e., way usage, in urban woodlands of city dwellers from three densely populated regions in Germany's Southwest. Respondents also stated their activities for mapped routes, sociodemographic backgrounds, and perceived cultural ecosystem services. In order to characterise each mapped route according to physical landscape features, we used a 50m buffer around each route and measured area sizes (in m²) of landcover classes represented within this buffer, e.g., water bodies, broadleaved, coniferous and mixed species dominated stands, meadows, and human-made infrastructure. Data on these features were derived from OpenStreetMap, inventory maps, high resolution LiDAR satellite imagery, and forest function maps of the provinces' forestry administration. For data analysis, we use the Line Density tool in ArcGIS and linear mixed effects models. We present linkages between visitor intensities and mapped routes' characteristics. If applied in urban forest management, this knowledge may contribute to visitor-centred planning and decision-making as well as development of visitor guidance concepts for urban woodlands.

Form over function? Aesthetic drivers of forest management

Jakob Derks¹

¹European Forest Institute, Bonn, Germany (jakob.derks@efi.int)

Conflicts on forest-related issues are often dichotomised using the same two categories: forestry and nature conservation. Members of these two groups are often perceived as the two main antagonistic factions that set the tone of the debate. This categorical perception often tends to simplify the debate and answers to our innate instinct to classify the environment in which we live. One group uses economic data to back up its viewpoint, the other one fences with biodiversity. These arguments can often be described as a rationalisation of the debate. Indeed, with the same assertion different viewpoints can be defended. It is clear that economic predictions depend on so many variables, many of which are uncertain, that it is hard to produce reliable models for any given case. Similarly, when basing management choices on biodiversity criteria, the choice of the target species is inherently (partly) arbitrary. Every day, forest managers have to make decisions based on incomplete information and unknown future events. How do they do this? A large and often overlooked factor in decision-making relates to emotional choices. Research shows that management choices often relate to the personal history and reference point of the manager and society, and that rational argumentations are interlinked with aesthetic preferences.

Pro-social preferences of first nations people of Ontario, Canada

Shashi Kant¹, Ilan Vertinsky²

¹University of Toronto, Toronto, Canada; ²University of British Columbia, Vancouver, Canada (shashi.kant@utoronto.ca; ilan.vertinsky@ubc.ca)

The characterization of individuals as “rational agents” as a core assumption has resulted in flawed policies. Pro-social preferences towards unknown others in a community is an important determinant of its social capital which influences community development. We develop and test a utility model that captures more fully and accurately the heterogeneity of motives that guide individuals when encountering situations where they are offered the opportunity to display unconditional pro-social preferences to unknown others. We conducted field experiments in a First Nation of Canada using modified Dictators Games (DG)

designed to test the proposed model. Results highlighted strong relationships among expressed motives, social norms and identities, and revealed allocations. The First Nation's culture was manifested by a pattern of more generous giving to elders and women. The provision to dictators of gender or age clues about second players' identities was found to: a) increase average giving; b) shift self-regarding to other-regarding preferences; and c) enable more nuanced allocation decisions. These findings have important implications for forest and other land use policies and management practices.

Bushmeat consumption in Rubi-Tele Hunting domain, DRC

Sagesse Nziavake¹, Mampeta Wabasa¹, Amundala Drazo¹, Sabongo Yangayobo¹, Nathalie Van Vliet²

¹University of Kisangani, Kisangani, Congo, Republic of the Democratic; ²CIFOR, Guiyane, France (sagessenziavake@gmail.com; salomonmampeta@gmail.com; nicaise.amundala@gmail.com; sabongo_prosper@yahoo.fr; vanvlietnathalie@yahoo.com)

African rural communities rely on gathering, hunting and fishing activities for their livelihoods. Wildlife, a renewable biological resource which available quantity is directly linked to previous harvests, contributes to the diet of rural people. Household consumption occupies a prominent place among the major economic aggregates. In DRC, the consumption of wild animals, "bush meat", constitutes in rural forest areas, the main and essential source of protein, given the unfavorable pastoral environment and the under-development of agriculture. Thus this study seeks to determine the supply way of the local communities of the Rubi-Tele Hunting Domain (RTHD). To achieve this goal, we will conduct household surveys through a questionnaire, in 4 localities of the RTHD: Ngbete, Bobonge, Sukisa and Mabanga. Data processing will be performed using R and Excel software. The way local communities of the RTHD are supplied in bushmeat will be determined, as well as the dependency and the species most consumed by local communities will be highlighted. Also, the causes of decline in bushmeat supply in the RTHD will be discussed, as well as the reasons for ineffectiveness of wildlife regulation within these local communities will be determined. As result of these expected findings, strategies for sustainable management of bushmeat in RTHD will be identified.

Method for pricing forest concessions in the Brazilian Amazon: signs of poverty traps in the forest sector / Método de precificação das concessões florestais na Amazônia brasileira: as evidências de armadilhas de pobreza no setor florestal

Daniel Teixeira¹ 

¹Universidade de Brasília, Brasília, Brasil (dnmoura@gmail.com)

A política florestal tem por objetivo prover a combinação de benefícios ambientais, sociais e econômicos que maximize o bem-estar da sociedade de maneira contínua e sustentável no longo prazo. Entre os instrumentos de política disponíveis, as concessões florestais são amplamente utilizadas quando o Estado é detentor de grandes extensões de florestas. Acredita-se que as concessões têm potencial de fomentar o desenvolvimento econômico das regiões em que estão localizadas mediante o manejo florestal sustentável. Contudo, há indícios de que as concessões de florestas nativas têm sido alocadas de maneira ineficiente devido à forma como os preços dos contratos são estabelecidos. Portanto, o objetivo do estudo foi apontar as evidências de como a metodologia de precificação das concessões florestais contribui para o surgimento, nos estados detentores de florestas nativas, de ciclos viciosos de subdesenvolvimento persistente, denominados "armadilha de pobreza". Nesse sentido, foi verificado que os critérios de reajuste dos valores a serem pagos pelos concessionários, baseados no IPCA, gerando um descompasso entre os preços pagos pelos mercados de produtos florestais e o preço das concessões. Considerando os usos alternativos da terra, como a pecuária e a agricultura, o manejo florestal se torna inviável financeiramente, restringindo os investimentos florestais e, consequentemente, o aumento da produtividade do trabalho.

The school basin in Jaguariaíva, State of Paraná, Brazil / Bacia escola de Jaguariaíva, PR

Marilu Mazurechen¹, Samantha Nazaré de Paiva¹, Gilmar Henrique de Oliveira¹, Rogerio Salamuni¹, Uilson Paiva¹, Carolina Bozzeti Rodrigues², Maria José Brito Zakia³

¹Klabin, Telêmaco Borba, Brasil; ²IPF, Jaguariaíva, Brasil; ³Prática Assessoria Socioambiental, Piracicaba, Brasil (mmazurechen@klabin.com.br; snpaiva@klabin.com.br; gilmar.oliveira@klabin.com.br; rogerio.salamuni@klabin.com.br; upaiva@klabin.com.br; cabreuva@gmail.com; zeze.zaquia@uol.com.br)

O abastecimento público do município de Jaguariaíva, PR, é realizado por meio de captações de água em três fontes, sendo uma delas a microbacia hidrográfica Três Bocas, de propriedade da Klabin S/A. A área da microbacia abrange 489 ha, dos quais 287 ha são destinados às florestas plantadas e 119 ha destinados à conservação (vegetação nativa em diferentes estágios de conservação). A localização e as características da microbacia Três Bocas são ideais para a realização do monitoramento hidrológico do PROMAB/IPEF, ao mesmo tempo que reúne condições excepcionais para a implantação do projeto Bacia Escola, levando em conta a proximidade com a cidade e a presença de instituições de ensino, além da atuação da empresa de saneamento do município (SAMAE). O projeto Bacia Escola, inspirado em um trabalho desenvolvido pelo Serviço Geológico Brasileiro no Rio Catu, BA, tem sido uma oportunidade de se gerar conhecimento compartilhado, visto que o conhecimento das relações floresta – água tem ficado restrito a poucos setores. A bacia escola como área de estudo e vivência para diferentes públicos, em especial aos alunos do Ensino Fundamental (com a elaboração de material paradidático e trilhas interpretativas), bem como escolas técnicas e universidades, é uma contribuição para a democratização do conhecimento aliado à geração de valor compartilhado, que é um dos objetivos de empresas na busca pela sustentabilidade.

A6f: GENDER, FORESTRY AND RURAL COMMUNITIES: SHAPING POWER AND AGENCIES IN AN ERA OF GLOBALISATION

Same-same but different: gendering forest ownership in Sweden

Elias Andersson¹, Sabina Bergstén², Carina Keskitalo²

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²Umeå University, Umeå, Sweden (elias.andersson@slu.se; sabina.bergsten@umu.se; arina.keskitalo@umu.se)

As a major feature of the Swedish rural landscape, forests have been shown in studies to reflect pronounced differences and inequalities between women and men with regard to ownership. Employing a more in-depth approach, this study examines how gender construct private forest owners' experiences, perceptions and practices associated with their forests and forest ownership. The gendering, through articulations and meaning making, of forest ownership and its structuring of value and agency is thematically analysed through semi-structured interviews with 25 female and 26 male owners with forest properties located in the South or in the North of Sweden. The findings show a gendering of forest management behaviour and activities, formed by a set of historical and socialisation processes and practices. They suggest a dichotomised understanding of how gender is constructed, whereby specific bodies (male/female) were linked with specific spaces

(forest/household), tasks (manual forest labour/domestic labour), characteristics (strong/caring), and perspectives (economic/ecological). These dichotomies correlate to male forest owners being associated with having more power and more knowledge of forests. Forest values and attitudes connected with values other than production forestry were attributed more to female owners, thereby mirroring the gendering process of doing 'different' as a means of 'othering', but also when perceived as positive and innovative as a way of resisting and negotiating the current gendering of forest ownership and the forestry discourse of production-oriented forestry.

Gender and the inheritance of traditional forest-related knowledge in minority regions in Guizhou Province, China

Juanwen Yuan¹

¹University of Finance and Economics, Guiyang, 550025, China (yuanjuanwen@qq.com)

Women and men play different roles in the inheritance of traditional forest-related knowledge, meanwhile the roles are also changing because of urbanization and rural revitalization in China. However, this research has not attracted much attention by the researchers. This paper aims at understanding the inheritance of traditional forest-related knowledge from gender perspective. The research will employ both qualitative and quantitative to conduct the research in minority regions in Guizhou province in China. The research finds that traditional forest-related knowledge is rich in minority areas in Guizhou. Women are more involved in the inheritance activities relating to time-consuming, while men are more involved in those relating to higher technologies. Men are migrating to cities while women are main labours in the forest management in last three decades. Women are learning more knowledges which are traditionally dominated by men. In recent years, government is promoting rural revitalization and eco-tourism is very popular. Forest plays more important roles. Meanwhile more men are back to the village. The inheritance methods are also changing because of innovative ways are introduced into the village by the in-migrants. Both men and women are important actors and agencies in inheriting traditional forest-related knowledge which promotes sustainable forest management.

Too male, too pale, too stale: dilemmas of public engagement in sustainable forest management in Canada

Maureen G. Reed¹, Jim Robson¹, John Parkins², A John Sinclair³, Solange Nadeau⁴, Amanda Lindgren¹

¹University of Saskatchewan, Saskatoon, Canada; ²University of Alberta, Edmonton, Canada; ³University of Manitoba, Winnipeg, Canada; ⁴Canadian Forest Service, Quebec, Canada (mgr774@mail.usask.ca; james.robson@usask.ca; jparkins@ualberta.ca; john.sinclair@umanitoba.ca; solange.nadeau@canada.ca; amanda.lindgren@usask.ca)

Engaging the public is now a key element of sustainable forest management (SFM). In Canada, "society's responsibility" is one of 6 criteria for SFM, defined through these indicators: Aboriginal and treaty rights; Aboriginal land use and forest-based ecological knowledge; forest community well-being and resilience; fair and effective decision making; informed decision making. The forest advisory committee (FAC) has become the dominant mechanism, located in rural areas, and sponsored either by provincial agencies or forest companies. In 2004 and in 2016, we conducted national surveys of FACs to understand committee demographics, mandates, values, representation, learning outcomes, satisfaction, and effectiveness. Here, we address two questions: (1) How has the representation of people and values on public advisory committees changed since 2004? (2) Are public advisory committees contributing to fair, effective, and informed decision making about sustainable forest management? Our findings from both surveys show that FACs remain dominated by a white, male and aging rural population. This demographic was well satisfied with the achievements of their FACs. Those who are under-represented, in particular, women and Indigenous peoples, were the least satisfied that decision-making was fair and effective. Our findings point to dilemmas of effective and fair SFM governance processes. Given their relative ineffectiveness in representing the Canadian public, if these committees are disbanded, what kind of public oversight might replace them? If committees are maintained, how can they be reformed? We explore options for governance that might allow for more effective engagement of local peoples and more effective practices of SFM.

Gender dynamics in forestry development: experiences from farm forestry in the Kenyan Coast

Leila Ndalilo^{1,2}

¹Kenya Forestry Research Institute, Malindi, Kenya; ²Egerton University, Nakuru, Kenya (leililo@yahoo.com)

Women are disadvantaged by insecure access and property rights to forest, tree and land resources. Discrimination and male bias in land ownership and service provisions like credit and technology and exclusion from policy formulation and decision making at the household, community and national levels have exacerbated the problem. A study was conducted to assess gender participation in farm forestry and the existing mechanisms of benefit sharing amongst tree farmers in the coast region of Kenya. The survey covered Kwale, Kilifi and Lamu Counties, the main tree growing counties in the coast region. Household questionnaires, expert interviews and focus group discussions were conducted to collect data. The study established that women realize only a fraction of the benefits from tree farming and tend to be involved in decision making only when forest and tree resources are already degraded. Moreover, cultural barriers and women's lack of formal education, employment and personal networks inhibits their ability to influence resource allocation and benefit sharing. The study established that gender inclusivity can significantly improve sustainable forest management, and the overall welfare and social protection of families, communities and national economies. There is need to mainstream gender equality at all levels of forestry in order to achieve broader social and economic goals, including the Sustainable Development Goals.

Uncovering the hidden complexities of agency in the rural network of female forest owners

Katri Hamunen¹, Hanna Kumela², Jukka Tikkanen³, Teppo Hujala³

¹Natural Resources Institute Finland (Luke), Joensuu, Finland; ²Natural Resources Institute Finland (Luke), Mikkeli, Finland; ³University of Eastern Finland, Joensuu, Finland (katri.hamunen@luke.fi; hanna.kumela@luke.fi; jukka.tikkanen@uef.fi; teppo.hujala@uef.fi)

Forestry has predominantly been a masculine sphere, providing easy environments for males and more challenging positions for females. Recognition of female forest owners has led to special events and new activity forms targeted for women forest owners both in the USA and in the Nordic Countries. However, responding to the females' suppressed situation with institutionalized tools and technocratic practices carries the risk that females lose the opportunity for political transformation and stay reproducing gendered practices in a niche that the masculine social system has given for them. Therefore, the new task is to enable and reinforce such empowering "doing gender" practices that support female forest owners' agency and escape from the niches. This study analyzed a rural network of female forest owners in Finland (n = 15), data comprising individual and group interviews as well as researcher's observations and participants' feedback from ten forestry learning meetings. The analysis sought a deeper understanding of the owners' perceptions and behaviors as forest owners in general

and in their peer-learning network. The theory-driven qualitative analysis was done with NVivo software employing researcher triangulation. Cognitive, emotional, and motivational difficulties in taking responsibility on forestry decisions were observed. Self-efficacy was often assessed in relation to men. This kind of mirroring was not present in the women-only meetings where they felt less shy to discuss and were not afraid of ignorance. Seeing other female owners' forestry results was empowering. Thus, an appreciating discourse space and a sense of belonging to an actor community fostered female owners' agency.

Rural communities, forestry and women

Peter Edwards¹, Deanna Grant-Smith², Robyn Mayes²

¹Manaaki Whenua Landcare Research, Wellington, New Zealand; ²Queensland University of Technology, Brisbane, Australia
(peter.edwards@scionresearch.com; deanna.grant-smith@qut.edu.au; robyn.mayes@qut.edu.au)

Although forestry has traditionally been constructed as a masculine rural activity, women are participating in increasing numbers and the impact of forestry on women's lives is widely recognised. There is growing interest in gender, forestry and the survival of rural communities in Latin America and Oceania. In these contexts a number of observations have been made around the influence of forestry and gender on the survival of rural communities. Namely, that forestry, on a 30-year harvesting cycle (as compared to other industries), reduces economic opportunities, driving down the population in rural communities and negatively impacting employment opportunities for women (i.e., as teachers in schools and nurses in hospitals) which leads to further depopulation. While in developing countries, this could contribute to the feminisation of poverty, women in developed countries have the ability and capacity to move to larger centres, where employment and services are available. As forestry becomes increasingly important globally for climate mitigation, maintenance of or increasing biodiversity, and sustainability in general, there are likely to be increasing gendered issues emerging from the expansion of forests and forestry. With much of the expansion of forests in Europe, North America, OECD members and high-income countries, we examine the place/role of women in rural communities affected by increasing or decreasing investment in forestry at the local and/or regional level.

A6g: INDIGENOUS AND TRADITIONAL PEOPLES AND THEIR FORESTS: KNOWLEDGE, MANAGEMENT AND GOVERNANCE TOWARDS SUSTAINABLE DEVELOPMENT GOALS

Ethnobotanical assessment of plant species used medicinally / Diagnóstico etnobotánico de uso de especies vegetales como medicinales

Misleidy Gato Hernández¹, Osvaldo Celestino Lupupo Calderín², Magyuri Avila Martínez¹, Hector Barrero Medel¹

¹Universidad de Pinar del Río Hermanos Saiz Montes de Oca, Pinar del Río, Cuba; ²Universidad de Pinar del Río Hermanos Saiz Montes de Oca, Sagua la Grande, Cuba (sheena@upr.edu.cu; avilam@upr.edu.cu; hbarrero@upr.edu.cu)

El siguiente es un estudio etnobotánico fue realizado en diferentes comunidades de la provincia Pinar del Río, con el objetivo de determinar las relaciones etnobotánicas de especies vegetales empleadas en el área de investigación, mediante el conocimiento de los pobladores de las comunidades. En el estudio etnobotánico se recopiló la información de las especies de interés medicinal y el material se identificó por taxones considerando: nombres científicos, nombres comunes, familia, género, especie, autor, endemismo, amenaza, formaciones vegetales, formas de la población de obtener el conocimiento, parte de las plantas que usan, propiedades curativas (atribuidas y comprobadas), preparación y posología utilizada por las comunidades. Se determinó la frecuencia de uso de las especies seleccionadas con el fin de determinarle el valor de uso a cada una de ellas. En esta se mostró que existe una relación entre el género de los encuestados y el conocimiento que tienen estos sobre especies de interés medicinal, existe una gran relación entre los grupos etarios y el conocimiento en cuanto a la diferencia de géneros. Se demostró la pérdida del conocimiento en estas poblaciones. De las especies identificadas en el área de estudio; son de consistencia leñosa el (31%); mientras que el restante (69%) son herbáceas, de estas especies las partes más usadas son las hojas. Se realizó un análisis de todos los padecimientos tratados por las plantas en la localidad y la cantidad de especies que se usan para cada uno de ellos.

Shift in the use of forest and consequences on traditional ecological knowledge among hutsuls in the Carpathians, Western Ukraine

Giulia Mattalia¹ ; Nataliya Stryamets¹, Renata Soukand¹

¹University of Venice Ca' Foscari, Venezia, Italy (juliamattalia@gmail.com; nataliya.stryamets@unive.it; renata.soukand@unive.it)

In the Carpathian Mountains, lives of local dwellers and forests are deeply interweaved. This is especially evident for minority groups such as the Hutsuls, a population living in the Carpathian Mountains. For many centuries, Hutsuls had been working in forest-related activities. However, the economic crises occurred at the end of the XX century caused a sudden abandonment of these forestry activities. This led to a strong emigration and urbanization, but also to an overexploitation of local natural resources. In this study, we aimed at discussing how this economic and social phenomenon affected the knowledge related to use of provisioning ecosystem services among Ukrainian Hutsuls. Specifically, we studied the use of wild taxa gathered in the forest to address the consequences of such a social and economic shift on traditional ecological knowledge (TEK) and local ecological practices (LEP). In summer 2018, we gathered 45 in-depth, semi-structured interviews among Hutsuls regarding the current and past uses of mushroom and plant taxa collected in the forest. We found that TEK and LEP are undergoing a process of erosion due to several factors including traditional livestock breeding abandonment, loss of unintentional contact with natural resources and the commoditization and specialization to few taxa such as *Vaccinium myrtillus* and *Boletus edulis*, which are economically valuable. We discuss that this may lead to severe loss of diversity of the local ecological resources used, which would affect negatively the sustainability and resilience of the local community in case of severe food shortage. (ERC grant agreement 714874 [https://cordis.europa.eu/project/rcn/208447_en.html]).

Role of Mijikenda sacred forests in biodiversity conservation and livelihood improvement: the case of the Kenyan Coast

Leila Ndalilo^{1,2}, Chemuku Wekesa³

¹Kenya Forestry Research Institute, Malindi, Kenya; ²Egerton University, Nakuru, Kenya; ³Kenya Forestry Research Institute, Taita Taveta, Kenya
(lelilo@yahoo.com; chemukufri@gmail.com)

Kayaforests, located in Kenya's coastal landscape, are sacred forests of the Mijikenda people. These forests have been preserved since the 16th century as sacred places where prayers, rituals and sacrifices take place. Protection of the Kayasis deeply entrenched in traditional Mijikenda culture and their integrity and sanctity have been safeguarded by a council of Kayaelders who employ a system of taboos and traditional rules to protect the forests. A study was conducted to assess the role of kaya forests in biodiversity conservation and livelihood improvement among the Mijikenda community in the

Kenyan coast. The study was conducted in Kilifi and Kwale counties of Kenya and the target communities were the Giriama, Chonyi, Rabai, Digo and Duruma sub-tribes of the Mijikenda community. Household questionnaires, focus group discussion and key informant interviews were used to collect data. The study revealed that Kaya forests are facing threats from rapidly changing socioeconomic and ecological conditions leading to a decline in their pristineness. Decline in cultural values attributed to modernity was mentioned by 40% of the respondents as a leading contributor to degradation of the forests. Despite the numerous threats faced by kaya forests, they continue to conserve biodiversity and provide an array of goods and services needed for improving human well-being and livelihood systems, with about 60% of the communities dependent on them for their livelihoods. There is need to protect traditional knowledge and strengthen traditional governance systems which underpin the conservation of Kaya forests for enhanced conservation and socio-economic benefits.

Diversity of local knowledge and use of wild food plants in communities around five biodiversity hotspots in Zimbabwe

Lizzie Mujuru¹, Luke Jimu¹, Admore Mureva¹, Justice Muvengwi¹, Anthony Mapaura², Innocent Nyakudya¹

¹Bindura University of Science Education, Bindura, Zimbabwe; ²National Herbarium and Botanic Gardens, Harare, Zimbabwe (lzmjr2009@gmail.com; jimaldino@yahoo.com; admury@gmail.com; justicemuvengwi@gmail.com; amapaura@gmail.com; pupunege@yahoo.com)

This study documented the use of wild food plants in areas around five biodiversity hot spots in Zimbabwe. Data was collected using semi-structured interviews and focus group discussions in representative communities. Direct matrix ranking, pairwise ranking, and priority ranking methods were used to analyse data. A total of 89 wild food plants were used by communities in the five hotspot areas. Trees constituted 65%, shrubs (11%), tubers/herbs constituted (12%), lianas/ climbers (8%) and succulents (4%). Fruits were the most used parts (52%) followed by leaves (28%), and others (roots/rhizomes/tubers, sap and fibres) (20%). The fruits are mostly consumed raw (96%) whilst others are processed into juices (4%), mostly collected by women and children, but the participation of men was also evident. According to pairwise ranking analysis, fruits of *Adansonia digitata*, *Vangueria infausta*, *Uapacca kirkiana*, *Berchemia discolor/zeyheri*, *Vitex doniana* and the leaves of *A. digitata* were the most preferred plant species because of their taste and availability. However, some fruits such as *Vitex* spp. and *U. kirkiana* were known to have side effects of causing constipation and diarrhoea respectively if consumed in excess. Cultural/Traditional knowledge plays an important role in the value of a species in a particular area and the associated conservation activities of the wild food plants. Biodiversity conservation activities and value addition could help as solution for the conservation and sustainable use of wild food plants in the biodiversity hotspots. Furthermore, more studies are needed to determine medicinal applications of the woodland species around hotspot areas.

Rural communities' local knowledge of forest resources utilization for their livelihoods: a case study in the Katha District, Myanmar

Zar Chi Hlaing¹, Osamu Saito²

¹Forest Research Institute, Nay Pyi Taw, Myanmar; ²United Nations University Institute for the Advanced Study of Sustainability (UNU-IAS), Tokyo, Japan (zarchihlaing08@gmail.com; saito@unu.edu)

Although the application of local knowledge has received increasing attention and became an important role in environmental conservation, the successes, and challenges encountered in the application of local knowledge in managing and governing natural resources. This case study aimed to examine rural communities' applying local knowledge practices related to forest resources for their livelihoods and to understand the role of local knowledge in forest resources management. Data collection was conducted through the face-to-face household interview from 218 households and focus group discussions in four rural communities in the Katha District. The study documented four different types of local knowledge practices such as taboos, custom, norms and other local knowledge related to livelihood activities, and they are acquired and transmitted through family custom, social networks and oral communication including learning from elder people. The results showed that a significantly lower proportion of applying local knowledge when compared to the awareness in each studied community. Household characteristics like length of stay, HHH's age and livestock varieties were found as the influence variables on the awareness and application of local knowledge, and average 85% of local communities showed their agreement on the application of local knowledge. Communities' applying knowledge practices are supporting the forest resources conservation activities directly, and helping to address contemporary livelihood (socio-economic) and environmental conditions. But the vice versa effects like beneficial and detrimental, of local knowledge practices, are observed as one of the attention factors when local knowledge is utilized in forest resource management and livelihood improvement activities.

Chañar (*Geoffroea decorticans* (Gill. ex Hook. et Arn.)): forest heritage and a traditional food from the Atacama region of Chile / Chañar (*Geoffroea decorticans* (Gill. ex Hook. et Arn.)): un patrimonio forestal, agroalimentario y ancestral de la región de Atacama, Chile

Sandra Gacitúa¹, Marlene González², Jaime Montenegro¹, Jose Hernandez¹, Carmen Varela³, Ricardo Muñoz⁴

¹Instituto Forestal, La Serena, Chile; ²Instituto Forestal, Santiago, Chile; ³Consultor Privado, Concepcion, Chile; ⁴Universidad de La Serena, La Serena, Chile (sgacitua@infor.cl; marlene.gonzalez@infor.cl; jmontenegro@infor.cl; jhernandez@infor.cl; varcarmen@gmail.com; ricardo.munoz.cisternas@gmail.com)

Chañar (*Geoffroea decorticans* Gill. ex Hook. et Arn.) es un árbol de la familia Fabaceae que crece en la Región de Atacama, Chile, y en países limítrofes. Produce frutos que han sido fuente de alimento ancestral, constituyendo un importante patrimonio alimentario y cultural, pero de uso y conocimiento restringido. Este fruto tiene un alto potencial nutraceutico aportado por polifenoles y actividad antioxidante, características que favorecen la promoción de su consumo. El estudio se centró en rescatar el conocimiento ancestral y valorar el patrimonio alimentario del fruto y arrope de chañar, con el fin de evidenciar su consumo a través del arrope de chañar como un producto con características especiales para consumidores que buscan lo natural y orgánico, manteniendo y destacando su connotación étnica y ancestral. Para el rescate del conocimiento ancestral referido al uso y proceso productivo se usaron procedimientos metodológicos que se enmarcan en estrategias y técnicas cualitativas, las que fueron aplicadas y trabajadas con comunidades Collas de la comuna de Copiapó. Para la valoración nutricional se determinaron los componentes proximales, antioxidantes y flavonoides de frutos de chañar, específicamente del mesocarpio (pulpa s/cáscara) y su semilla (s/carozo), colectados de diferentes sectores. Los resultados confirman la alta presencia de carbohidratos, flavonoides y antioxidantes, lo que, unido a lo citado en literatura, posiciona los frutos y arrope de chañar como un importante producto, no solamente dirigido al consumo de alimentos en mercados nichos sino también en el ámbito de la medicina popular (producto etnofarmacéutico), mercado que será abordado por la comunidad.

Threats to indigenous beliefs in protection of sacred forests in Southwest Nigeria

Folaranmi Dapo Babalola^{1,2} 

¹Forest Resources Management, University of Ilorin, Ilorin, Nigeria; ²University of Pretoria, Pretoria, South Africa (babalola.fd@unilorin.edu.ng)

Sacred forests play a central role in the cultural and livelihoods of indigenous people. Despite the vital roles of sacred forests, declines in the areas of the forests have been reported. The consequence of this is that many indigenous knowledge systems built over the years toward protection of the endemic forest diversity are being abandoned due to civilization and pressing land demands. The study investigated the indigenous beliefs used in conserving sacred forests as well as the challenges facing the beliefs. The respondents include people living adjacent to Igbo Igunnko (meaning Igunnkosacred forest) and Igbo Oro (Orosacred forest) located in Ogun State, Southwest Nigeria. The forests form part of the history upon which the surrounding villages were established. Among the taboos supporting existence of the sacred forests, prohibition of fishing in Oso'ro River (that links the two sacred forests) is the most effective. At the local scale, factors such as demand for farmlands, firewood collection and poaching constitute threat to the sacred forests. However, emerging issues such as infiltration of factors like modern civilization, western cultural diffusion and foreign religion are contributing to the neglect of cultural beliefs that are in support of the sacred forests. There is need for proper demarcation of the boundary of sacred forest for protection against pressing land uses and over exploitation. Also, the current traditional knowledge and beliefs in support of sacred forest should be properly institutionalized and strengthened.

Conditional cash transfers to indigenous societies and the long-term impacts on Amazonian deforestation: a case study of Bolsa Família Program to the Kĩsêdjê indigenous people

Priscila dos Reis Cunha¹, Camilo Rodrigues Neto¹, Carla Morsello¹

¹Universidade de São Paulo, São Paulo, Brasil (priscila.cunha@usp.br; camilorneto@gmail.com; cmorsello@gmail.com)

Indigenous territories correspond to ~23% of the Brazilian Amazon, which implies they are essential for the fate of forest conservation. Evidence indicates the traditional natural resources use by Amazonian indigenous societies produces low environmental impacts. However, increased access to the market economy is likely to raise negative environmental impacts produced by these groups. Currently, Conditional Cash Transfers (CCTs) affect indigenous societies worldwide and increase their exposure to the market economy. Even so, few studies investigate their long-term impact on natural resources and, when they do, depart from models which assume people's decisions on time use follow the principles of Rational Choice Theory. Yet, unlike proposed by the Rational Choice Theory, evidence suggests that people do not think about time fungibly, but tend to mentally divide time in different accounts (e.g., "work" and "non-work"), such as expected by the Mental Accounting model. Changing people's decisions rules might lead to different predictions of CCT long-term impacts, because the time dedicated likely affects the expected size of the crop area and, consequently, deforestation. Therefore, we investigated in this study the CCTs effects on the area deforested for agriculture, and if/how the adoption of alternative decision theories (Rational Choice and Mental Accounting) changes the predictions. To do that, we investigated CCTs from the Bolsa Família Program to the Kĩsêdjê indigenous people, through an agent-based model, described using the ODD + D protocol and parameterized with empirical data obtained through a survey based on interviews, time allocation, weigh day and farm area measurement.

Forest holdings, food security, and ways of life in native communities in loreto and Madre de Dios, Peru / Tenencia forestal, seguridad alimentaria y medios de vida en comunidades nativas de loreto y Madre de Dios, Perú

Zoila Cruz-Burga¹ ; María de los Ángeles La Torre-Cuadros^{1,2} ; Iliana Monterroso³ ; Anne M Larson³

¹Grupo Sistemas Socioecológicos y Servicios Ecosistémicos, Facultad de Ciencias Forestales, Universidad Nacional Agraria La Molina, Av. La Universidad S/N Lima 12, Peru; ²Facultad de Ciencias Ambientales, Universidad Científica del Sur, Av. Panamericana Sur km 19, Villa, Lima 42, Peru; ³Center for International Forestry Research, Av. La Molina 1895, Lima 12, Peru (zcruz@lamolina.edu.pe; mlatorrec@ucientifica.edu.pe; i.monterroso@cgiar.org; a.larson@cgiar.org)

En Perú, durante los últimos 40 años, se han titulado más de 1300 comunidades nativas en la Amazonía peruana. Sin embargo, quedan desafíos importantes para cerrar la brecha en la formalización de las áreas reclamadas aún por los pueblos indígenas. Según la Asociación Interétnica para el Desarrollo de la Amazonía Peruana, AIDSESP existen reclamos sobre 20 millones de hectáreas de tierra y bosque. Este trabajo analiza los impactos de la formalización de derechos colectivos a la tierra y el bosque (titulada y no titulada) en relación a los cambios en la seguridad alimentaria y medios de vida en 22 comunidades de la Amazonia en dos regiones, Loreto y Madre Dios. A partir del análisis de datos cuantitativos (1006 encuestas intrahogar) y cualitativos (44 grupos focales y 52 entrevistas en profundidad) se encontró que existe una tendencia a que las comunidades tituladas tengan menos problemas para satisfacer las necesidades alimentarias en la familia que las no tituladas a un 90% de confianza y se encontró que la comunidades no tituladas nativas tienen menores patrimonios agropecuarios que las comunidades no tituladas campesinas con relación a los medios de vida. Estos resultados demuestran que el reconocimiento de derecho colectivo sobre tierras forestales y la seguridad de tenencia contribuyen a la diversificación y mejora de los medios de vida de las comunidades nativas en la Amazonia peruana.

How can traditional knowledge for managing forests be legally ensured by government? Collecting *Styrax benzoin* tap and conflicts of land tenure in customary forest in North Sumatra, Indonesia

Kazuhiro Harada¹, Wiyono Putro², Yumi Sakata¹

¹Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan; ²Faculty of vocational school, Gadjah Mada University, Yogyakarta, Indonesia (harada@agr.nagoya-u.ac.jp; wiyono.putro@gmail.com; ta72483@yahoo.co.jp)

Collecting *Styrax benzoin* tree tap in customary forest is a sustainable way of life inherited for generations in North Sumatra. Customary forest has had traditionally individual land holdings, in which collecting tree tap is a significant means of livelihood. The government partially entitled a pulp company to the concession to cut the trees and plant first growing trees as *Eucalyptus*, which evoked conflicts between local people and the company. This study investigates; 1) how local people may collect the tap, 2) how much money they can earn from the activity, 3) how conflicts evoked between the two parties and been solved with new government forest law. Household survey and interviews with local people and NGOs revealed that local people had approximately 1 ha of customary forest and collected tree tap mainly twice a year, which is their daily subsistence and main income source. While customary forest traditionally owned by them have been partially deprived by the government with the juridical land classification, the forest environment changed badly, induced the reduction of the amount of the production and jeopardized the traditional property right of local people. The

situations has been changing after the issue of new forest law in 2015, in which customary forest was recognized to have communities' property right, separated from state forest. The customary forest in North Sumatra has been in the process of being recognized as property forests after intensive negotiations and discussions between local people and central/local governments under the support of local NGOs.

The role of international law in the protection of traditional forest-related knowledge (TFRK) of Amazonian indigenous peoples

Siu Lang Carrillo Yap¹

¹*Göttingen University, Göttingen, Germany (siulang.muchik@gmail.com)*

The growing value of forest resources has produced an increasing regulation of the use of forest resources in the national States of the Amazonian region. The new generation of forest norms has established a standardized system for the utilization of forest resources based on two main aspects: the elaboration of forest management plans for ordering the extraction of forest resources, and the granting of forest licences by the State's authorities before the implementation of the forest management plans. While this system has improved control over the extraction of forest resources in concessions and private lands, it has produced a number of conflicts in indigenous lands. One of the claims of indigenous peoples is that there are increasing barriers for the application of TFRK in their lands because the current forest norms consider neither their knowledge, nor their customary law, nor their values. Then, national norms are in disagreement with the customary law of indigenous peoples, when it comes to regulating the use of TFRK. This situation implies the breach of international agreements which order the protection, promotion and further development of traditional knowledge. In view of this problem, this research identifies the gaps and opportunities of three international agreements, namely CBD, UNDRIP and the ICH Convention for the protection of the TFRK of Amazonian indigenous peoples, considering the national legal frameworks of Bolivia, Brazil, Ecuador and Peru.[1] [#_ftn1] [1] [#_ftnref1] The four countries account for approximately 80% of the Amazonian region.

A6h: PATHWAYS TOWARDS SUSTAINABLE RESOURCE USE FROM AFRICAN SUDANIAN AND ZAMBEZIAN WOODLANDS: RESOLVING CONFLICTING POINTS OF VIEW

Effectiveness of woodland management to meet local need in fuelwood in Sudanian zone

Eméline Sèssi Pélagie Assède¹ ; *Fortuné a. Azihou², Sayuni b. Mariki³, Samadori S. H. Biaou¹, Coert j. Geldenhuys⁴, Paxie w. Chirwa⁴, Brice Sinsin²*

¹*Faculty of Agronomy, University of Parakou, Parakou, Benin;* ²*Faculté de Agronomie Science, University of Abomey-Calavi, Abomey-Calavi, Benin;* ³*Sokoine University of Agriculture, Morogoro, United Republic of Tanzania;* ⁴*University of Pretoria, South Africa (assedeemeline@gmail.com; fazihou@gmail.com; zion²⁰⁰⁰tz@gmail.com; hbiaou@gmail.com; cgelden@mweb.co.za; paxie.chirwa@up.ac.za; bsinsin@gmail.com)*

Woodlands in Sudanian zone are under different management regimes, including total protection to controlled use. However, the intensity of tree harvesting mainly for fuel wood does not meet local need and thereby threatens the biodiversity. This study implemented in Sudanian zone of Benin aims to access the effectiveness of Sudanian woodlands to meet local population needs in term of biomass productivity. Three vegetation units of about 80 m x 80 m each were identified, representing the three development stages of the study area. Three random blocks (repetition) of 20 m x 20 m each were demarcated per unit in homogeneous stands. Blocks were divided into four treatment plots of 10 m x 10 m each. Treatments were randomly allocated and consisted in i) no thinning and no pruning, ii) 30% thinning and pruning, iii) 60% thinning and pruning iv) 100% thinning. Tree growth in height of individual ≥ 1 m were measured every 6 months between 2015 and 2016. The need of local population for fuelwood was estimated at 9,515,850.22 kg biomass/year. The influence of thinning and pruning on biomass production was positive. The best biomass production (3,018,736.25 kg/year) was obtained with 30 % thinning and pruning. A long term experimentation (≥ 10 years) is crucial to confirm these results.

Disturbance impacts on the composition and diversity of the *Baikiaea-Guibourtia-Pterocarpus* woodlands of North-western Zimbabwe

Angella Chichinye^{1,2}, Coert J Geldenhuys², Paxie W Chirwa²

¹*National University of Science and Technology, Bulawayo, Zimbabwe;* ²*University of Pretoria, Pretoria, South Africa (angiechichinye@gmail.com; cgelden@mweb.co.za; paxie.chirwa@up.ac.za)*

Variation in floristic composition of recovering *Baikiaea-Guibourtia-Pterocarpus* woodlands was studied in four different development stages and utilization systems in Gwaai and Tsholotsho areas in north-western Zimbabwe; 150 nested concentric circular plots were sampled. Diameter at breast height (DBH) and tree height were recorded by species for all trees with DBH ≥ 15 cm and 5.0 – 14.9 cm trees were measured in a 30 m radius concentric plot (0.283 ha) and 11.3 m radius concentric plot (0.04 ha) respectively. Stems < 5 cm DBH were counted in an inner sub-plot of 5.65 m (0.01 ha) radius. Tree data (stems ≥ 5 cm DBH) and regeneration data (stems < 5 cm DBH), were used separately to run TWINSpan ((Two-way Indicator Species Analysis) classifications. Importance values were calculated for all tree species per community. Shannon Weiner diversity indices were tested for differences using the One-Way ANOVA in SPSS Version 21. Detrended Correspondence Analysis (DCA) in the CANOCO ordination programme was used to determine the extent of variation amongst the identified communities. The classification identified 12 tree and 13 regeneration communities. *Baikiaea plurijuga* was the most important tree in all tree and most regeneration communities. *P. angolensis* showed low importance in most communities, except for communities from undisturbed sites and abandoned fields (mostly young trees). Species diversity differed significantly ($p < 0.05$) amongst tree communities. The DCA ordination showed little variation amongst the tree communities with a cumulative contribution of 22.6% and 26.1% for regeneration communities, suggesting that disturbance is the main driver of changes in species composition among other factors.

Assessing dependence and pressure on forest resources in Limpopo National Park (Mozambique): the case of Mopane woodlands

Vilela de Sousa¹, Cristiano Pires¹, Coert J. Geldenhuys², Albano Figueiredo³

¹*Universidade Pedagógica, Campus de Lhangue Faculdade de Ciências Naturais e Matemática - Biologia, Maputo, Mozambique;* ²*Forestwood, Pretoria, South Africa;* ³*University of Coimbra, Coimbra, Portugal (vilelasousa2@gmail.com; cristo.pires@gmail.com; cgelden@mweb.co.za; geofiguc@gmail.com)*

This study forms part of a larger study in mono-specific Mopane woodlands (dominated by *Colophospermum mopane*) within the Zambeian Region, conducted in the Limpopo National Park, Mozambique. The aims are to correlate the dependence of local communities for mopane woodland resources with the composition and structure of mopane woodland, as a basis for sustainable use management and conservation of Mopane woodland. The dependence of communities on Mopane woodlands was estimated through a survey to qualify and quantify the main sources of income, dominant

housing type, and shape, type and attributes of building materials, seasonality of resource collecting, the replacement rate of materials used in types of infrastructure. A current Mopane woodland status was assessed through forest inventory within 2 land use and land cover systems (woodland with tree harvesting, woodland in recovery stages after abandoned crop cultivation and people resettlement) compared with intact woodland structure and composition. Plots were sampled in each land use zone to collect information on Mopane stand development stage, type of disturbance, recovery period, and stem diameter and height, by species. Preliminary results show that construction materials and firewood contribute to community income although leads the reasons to disturbance of Mopane woodland with tree harvesting, that influencing the structure and composition. The outcome of this study will indicate what are the human impacts on Mopane woodlands sustainable resource use, and how this could be improved through guided sustainable uses.

Zambeian woodlands: matching resource use needs of people with the ecology of these woodlands to sustain their biodiversity, productivity and resource use products, values and services

Coert J Geldenhuys¹

¹Department of Plant and Soil Sciences, University of Pretoria, Pretoria, South Africa (cgelden@mweb.co.za)

Zambeian dry, deciduous woodlands cover 11 countries in southern Africa, where millions of rural people rely mostly on subsistence use of products and services obtained from them. Miombo woodland (largest area), Undifferentiated woodland and Mopane woodland are the main woodland types. Most of their tree species developed unique underground rootstocks to survive browsing by fire, wildlife and people, and are strongly light-demanding for good regeneration, mainly vegetative regrowth. The main causes of their perceived degradation/deforestation are cultivation of crops and harvesting poles and fuelwood by rural societies. Current policies of agriculture, woodland timber concessions, plantation forestry, biodiversity conservation, REDD+ strategies and rural development are not aligned with the woodland ecology; generally following a protectionist approach of protecting mature tree stands, and maintaining minimum stem diameter cutting limits. Slash-and-burn traditional agriculture and charcoal production are condemned; plantation forestry is considered a viable alternative for wood production. Recent studies in all three systems showed that slash-and-burn agriculture and charcoal production provide for fast recovery of plant diversity and productivity through vegetative regrowth from the rootstocks, and maintain the diverse woodland use value. An integrated, multiple-use approach based on selective stem thinning in stand development stages, branch pruning of retained good trees, and group-felling of mature stands, is promoted. It will maintain the supply in fuelwood and poles, maintain plant diversity, improve woodland condition and productivity, increase carbon stocks and sequestration rates; all to the direct benefit of rural small-scale farmers; in sharp contrast to the moribund old-growth stands in protected areas.

Drivers of change in Sudanian woodlands and potential management strategies for a sustainable use

Samadori Sorotori Honoré Biaou^{1,2}, Sèssi Pélagie Eméline Assédé^{1,2}, Jesugnon Fifamé Murielle Féty Tonouéwa², Shegoun Eudes Idjigbérou^{2,3}, Armand Kuyema Natta^{1,2}

¹Faculté d'Agronomie, Université de Parakou, Parakou, Benin; ²Laboratoire d'Ecologie, de Botanique et de Biologie Végétale (LEB), Université de Parakou, Parakou, Benin; ³Communauté Forestière du Moyen Ouémé (CoForMO), Tchaourou, Benin (hbiaou@gmail.com; assedeemeline@gmail.com; tonouewam@gmail.com; shegounes@gmail.com; armand.natta@gmail.com)

Sudanian woodlands belong mostly to the *Isobertinia* woodland type, which is typical of Africa northern hemisphere and forms a large and almost continuous strip extending from Mali to Uganda. In this study, we discuss the importance, drivers of change, and potential management strategies of Sudanian woodlands. Woodlands structure and species composition are strongly influenced by disturbances such as fire, grazing regimes and tree removal. The underlying mechanisms are complex and include a multitude of resource gradients (e.g. soil or climate driven stress) which potentially interact with or modify the importance of the disturbances. Woodland is also the most abundant vegetation type having significant woody cover in the Sudanian region. As such, a great number of people depend on them for their livelihoods, including for food, medicine, fuel wood, charcoal, construction and furniture woods, and cash income. An increasing pressure on woodlands should be expected in the future due to the depletion of traditional timber "hard wood" species and increased demand for "soft wood" tree species such as *Isobertinia* spp. The dangers that would result from the destruction of Sudanian woodlands include the extension of savannas, an increase in fire damages, the denudation and drying up of soils, the reduced wood production and loss of tree species diversity. With regards to these threats, relevant management strategies, accounting for local needs, could ensure a sustainable use of woodlands.

Socio-economic contributions of chainsaw milling enterprise to rural development in Ogun State, Nigeria

Ismail Azeez¹, Akeem Abibu¹

¹Department of Social & Environmental Forestry, University of Ibadan, Ibadan, Nigeria (ismail.azeez@mail.ui.edu.ng; besomeoneinlife@gmail.com)

Despite the prevalence and increasing activities of Chainsaw milling (CSM), its unapproachable nature tends to limit study on its economic and livelihood implications, which could serve as basis for policy review on the enterprise. This study reports the contributions of CSM to socio-economic development in the cities of Ago-iwoye and Isara Remo, Ogun state, Nigeria. Data were obtained from community residents using simple random sampling procedure through questionnaire administration. Results were subjected to descriptive and Chi-square test statistics at $\alpha=0.05$. The study was based on responses from 61.5% male respondents with age distribution cutting across those less than 20 years to those above 50 years. Chain sawmilling enterprise was positively associated with employment (81.7%), women participation (76.7%), coordinated activities (74.2%) and poverty reduction (85.8%) in the study area. Also, cohesion between associations, designation of key responsibilities to women and revenue generation for the community are open opportunities that will significantly complement the socio economic contributions of the enterprise. However, age and occupation of practitioners have the most significant effects on the enterprise while CSM operations was confirmed as negatively impacting the study area environment. Meanwhile, the negative impacts on agricultural production could be abated by ensuring that farmers get their due compensation to crop damage. The study also explicates the prospects of CSM enterprise in the study area provided learning the art of chainsaw machine handling is enforced before issuance of permit for CSM operation.

A6i: SOCIAL AND ECONOMIC BENEFITS IN PROTECTED AREAS: PARTNERSHIPS AND CONCESSIONS FOR LOCAL DEVELOPMENT

Community engagement in tourism concessions in parks

Lucas Milani Rodrigues¹, Moema Pauline Barão Septani¹, Camila G. de Oliveira Rodrigues², Teresa Cristina Magro Lindenkamp³, Victor Eduardo Lima Ranieri¹

¹Universidade de São Paulo, São Carlos, Brasil; ²Universidade Federal de Rio de Janeiro, Rio de Janeiro, Brasil; ³Universidade de São Paulo, Piracicaba, Brasil (rodrigues.milani@gmail.com; moema@usp.br; camirural@gmail.com; teresa.magro@usp.br; victor.ranieri@gmail.com)

Twelve parks within the State of São Paulo, Brazil, ruled by its government, had the concession of their tourism services approved by State Law nº 16.260/2016. In a previous publication, we verified that Consultative Councils (CC) of those Parks did not conduct a substantive discussion prior to the approval of the Law. In this work, through documentary analysis of meeting and public hearing minutes, the community involvement in discussions about the concession in Jaraguá State Park (PEJ) was analyzed. It was found that the indigenous community living in PEJ was informed about the concession only after the approval of the law, and there was no previous discussion in the village about new possibilities of tourism arrangements. The analysis of meeting minutes shows that the indigenous community of Jaraguá objected the new proposal, participated in a public hearing after the approval of the law in the Legislative Assembly of São Paulo State and brought to the public its dissatisfaction with regard to the new law. It can be concluded that the top-down approach adopted, without prior discussion with the community directly affected by the change, was rejected by local residents, resulting in potential future conflict in the development of activities under concession.

Impact of state forest concession revenues on municipalities of the Eastern Amazon

Jime Rodrigues Ribeiro¹, Iranilda Silva Moraes¹, Claudia Azevedo-Ramos¹

¹Núcleo de Altos Estudos Amazônicos, Universidade Federal do Pará, Belém, Brasil (engenheirajime@gmail.com; iranilda.ideflor@gmail.com; claudia.azevedoramos@gmail.com)

The forest concession is one of the main instruments for public forest management in Brazil. However, the effective social benefits of Amazon forest concessions still raise concerns. In 2011, Pará state had its first state concession contracts signed on 151 thousand hectares of native forests in the region of the Glebas Mamuru-Arapiuns, comprising three municipalities (Aveiro, Juruti and Santarém) in northwest of the state. In order to evaluate the forest concession revenue transferred to these municipalities and its use, this study analyzed financial reports from the state environmental agency and the municipalities. By 2016, the State Fund for Forest Development - Fundeflor - transferred approximately R\$ 3.2 million royalties to the three municipalities: 15.4% (R\$ 507,169.63) for Aveiro, 35.1% (R\$ 1,156,865.28) for Juruti and 49.5% (R\$ 1,629,427.04) for Santarém. The financial reports of Aveiro reported that the 2014 and 2015's economic resources were applied in infrastructure and purchase of supplies. Santarém reports revealed that most of the 2014 to 2016 resources were spent on travels, staff, supplies and equipment. Juruti did not present a report. The use of these resources in activities unrelated to those predicted in forest policies (or the lack of accountability) reveals the need for greater monitoring of the distribution state forest concession revenues in order to increase local benefits.

The impact of forest concessions on deforestation in protected areas of Brazilian Amazonia / Concessões florestais afetam dinâmica de desmatamento nas áreas protegidas na Amazônia brasileira

Roberto Palmieri^{1,2}, Vinicius Faria², Felipe Cerignoni², Mateus Batistella^{1,3}

¹Universidade Estadual de Campinas, Piracicaba, Brasil; ²Imaflora, Piracicaba, Brasil; ³Embrapa Informática Agropecuária, Campinas, Brasil (palmieri@imaflora.org; vinicius@imaflora.org; felipe@imaflora.org; mateus.batistella@embrapa.br)

Cerca de dois milhões de hectares de Áreas Protegidas (APs) na Amazônia brasileira foram concedidas para manejo florestal por empresas privadas. Alguns atores envolvidos com as concessões apontam preocupações quanto ao interesse econômico das empresas sobrepor-se aos interesses públicos de proteção ambiental. Esse estudo contribuiu para avaliar o impacto das concessões florestais no desmatamento. Foi utilizada a série histórica dos dados sobre desmatamento do PRODES/INPE de 2000 a 2016. Também foram realizadas entrevistas com atores relacionados às concessões. Optou-se por considerar as APs com assinatura de contrato da concessão até 2014. Cada AP foi comparada com duas APs similares em tamanho, formato, fitofisionomia e declividade, porém sem concessões florestais (grupo controle). As cinco APs concedidas analisadas tiveram menores taxas de desmatamento em comparação com as APs similares interpretadas estatisticamente ao nível de 5% de significância evidenciando a contribuição das concessões florestais para manutenção da cobertura florestal. Isso pode estar relacionado ao fato das empresas que se instalam em uma UC terem inibido invasores e atividades predatórias na área protegida devido à corresponsabilidade contratual sobre essas áreas e pelo seu interesse em manter o estoque de madeira para posterior manejo pela própria empresa já que são contratos de 40 anos. Continuar monitorando essas APs por mais tempo, assim como incluir outras APs concedidas mais recentemente, evidenciarão as interferências das concessões na atividade madeireira local. Efeitos inesperados, tal como o aumento da pressão de desmatamento para áreas próximas também devem ser avaliados para o entendimento sobre as mudanças nas paisagens.

Planning concessions for support services related to visiting Brazilian Federal Conservation Units, 1998–2018 / Ações de planejamento de concessões dos serviços de apoio à visitação em unidades de conservação federais brasileiras entre 1998 e 2018

Moema Pauline Barão Septani¹ , Victor Ranieri¹

¹Universidade de São Paulo, São Carlos, Brasil (moema@usp.br; vranieri@sc.usp.br)

Concessões dos serviços de apoio à visitação em áreas protegidas têm sido defendidas como uma forma de aprimorar o uso público e contribuir para um aumento dos recursos financeiros arrecadados. Países como Brasil, Estados Unidos, Canadá, África do Sul, Nova Zelândia, entre outros, têm experiências de concessão em áreas protegidas e estudos apontam uma tendência de ampliação dessa prática. Neste contexto, o presente estudo buscou identificar as ações de planejamento das concessões em Unidades de Conservação (UCs) federais brasileiras desde 1998. Para isso, foram buscados dados sobre Leis, Decretos, Instruções Normativas, Editais, Políticas, Planos, Programas, Estratégias, e notícias e publicações do Ministério do Meio Ambiente e do Instituto Chico Mendes de Conservação da Biodiversidade sobre o tema, onde foram identificadas 25 ações. Destas, seis ocorreram entre 1998 e 2002, todas sobre concessões no Parque Nacional do Iguazu, nenhuma entre 2003 e 2009, e nove entre 2010 e 2017. Para 2018, dez ações foram identificadas relacionadas à assinatura de dois contratos e à elaboração de dez projetos. Percebe-se que houve aumento nos esforços de planejamento durante o período analisado, entretanto as informações identificadas não permitem compreender como este planejamento foi ou

está sendo realizado. Não foram encontradas Políticas ou Planos sobre o tema. Há menção sobre um Programa a partir de 2017, porém não há esclarecimentos a cerca de seus objetivos, metas e cronogramas de execução, e sobre uma Estratégia em 2018, onde apenas são apresentadas as UCs onde os projetos de concessão estão sendo desenvolvidos e quais os serviços concessionados.

Private conservation in indonesia: Is it possible? A comparative study from Bukit Barisan Selatan National Park, Indonesia and Kruger National Park, South Africa

Adi Gangga¹, Jeni Pareira², Matthew Leggett²

¹University of Florida, Gainesville, USA; ²Wildlife Conservation Society (WCS), Bogor, Indonesia (gangga.gangga@gmail.com; jpareira@wcs.org; mleggett@wcs.org)

Prioritization of economic growth and development goals at the national level contributes to the long-standing natural resources management conflict between human-wildlife and human-human at the local level. As part of a global issue, conflict in national park management has always been an obstacle in the protected areas system in Indonesia. Recognizing the importance of a bottom-up approach, privately managed conservation area as the devolvement of management role has been acknowledged and encouraged for effective and sustainable forest management. This literature review was designed to evaluate how private conservation has been implemented in Indonesia. Bukit Barisan Selatan National Park (BBSNP), home for three flagship wildlife species - *Panthera tigris sumatrensis*, *Elephas maximus sumatranus*, and *Dicerorhinus sumatrensis*, provides substantial materials for forest-dependent communities living in and around the Park. With high interest in utilizing the Park for multi-purpose at multi-level, engaging private sectors including individual(s) and group(s) to collaborate in the Park management can be a strategic approach. Learning from existing initiatives in Indonesia and other countries such as South Africa, a success story is feasible to create only with the consideration of the needs of the Park. Legal regulations, bureaucracy, and stakeholders' commitment are the key factors in the implementation of private conservation yet remain challenging. By understanding its specific context and addressing potential challenges, private conservation could work successfully to mitigate the trade-offs between conservation and development.

An analysis of hut and shelter management in mountain national parks of Japan Alps

Taiichi Ito¹, Shoma Jingu¹

¹University of Tsukuba, Tsukuba, Japan (ito.taiichi.ft@u.tsukuba.ac.jp; jinguu.shoma.xa@alumni.tsukuba.ac.jp)

Japan's national park system started in the 1930's, and the roles of concession was stipulated in the national parks law of 1931. However, the concessionaire has not developed in Japan's national parks because the park authorities did not own any lands in the park, and because the mountain huts and trail to them were already developed before park designation by local entrepreneurs. The increasing demand for outdoor recreation after the Second World War brought over-use problems in the national parks of Japan Alps since the park authorities could not regulate the number of huts and their guest capacities. The private hut managers increased the hut numbers and their capacities by incorporating personal business to accommodate more trekkers in the northern Japan Alps, while in the less-popular southern Japan Alps, local government installed shelters along the trails systematically intervals and then asked local hiking club or forestry companies to manage them. Now, Japan's population is rapidly aging and decreasing especially in rural areas. To cope with reduction of local staff and of guests, the hut-managing companies recruited urban or foreign staff and then attracted group tours including foreign visitors. In the southern part, hut managing companies supplied shuttle bus to and from the trail-heads to bring more guests. In both areas, the quality of food and other service has improved, and the environmental impacts reduced. However, the resulting rise of accommodation fee kept less affluent trekkers away from huts and mountains. This is a dilemma common to ecotourism.

Forest conservation and socio-economic benefits through community forest concessions: evidence from the Maya Biosphere Reserve in Petén, Guatemala

Dietmar Stoian¹, Aldo Rodas², Iliana Monterroso³

¹World Agroforestry Centre (ICRAF), Montpellier, France; ²Ministry of Agriculture and Livestock, Petén, Guatemala; ³CIFOR, Guatemala City, Guatemala (d.stoian@cgiar.org; aldorodasc@gmail.com; i.monterroso@cgiar.org)

With an extension of 2.1 million ha, the Maya Biosphere Reserve (MBR) in Petén, Guatemala is the largest protected area in Central America. To reconcile forest conservation and socio-economic development, community forest concessions were created in its Multiple Use Zone (MUZ) in the late 1990s and early 2000s. Operated by a community forest enterprise (CFE), and with a cycle of 25 years, the concessions grant usufruct rights to local communities on an area of about 400,000 ha. Currently, nine concessions are active, while the contracts of two concessions were cancelled and the management plan of another suspended. Our study of the 12 CFEs and associated member households (n=292) shows that the community concessions have largely been successful, both in terms of forest conservation and socio-economic development. Between 2000 and 2013, deforestation rates in the nine active concessions were negligible (0.1% p.a.), as opposed to the core (1.0% p.a.) and buffer zone (5.5%) of the MBR. In terms of socio-economic development, we found asset building both in the CFEs and their member households. At enterprise level, forest revenues have been reinvested in physical infrastructure, machinery and equipment for higher value adding; and business management skills have improved, as has working capital and degree of indebtedness. At household level, forest income has allowed to enhance nutrition, education and health, and to invest in vehicles, home appliances, and livestock. The findings support the communities' claim for concession renewal, which is due over the next years, and have broader implications for natural resource governance.

An environmental multipurpose project at Soforestal, Tuluá-Colombia

Fernando Velez Escobar¹

¹Independent professional, Medellín, Colombia (fernando.velez52@gmail.com)

A pine plantation forest project was established at the Central Mountain region in 1980s, altitude range 1.500-3.050 m.a.s.l., lower-montane and montane moist and wet Holdridge's life zones, steep terrain, whole area of 5.811 ha, conserving 1.984 hectares of natural forest and 3.282 hectares of pine plantation. Due to difficult accessibility and financial constrain, now there are 808 hectares of pine plantation left, and 2.474 hectares of wild vegetation succession or pine natural regeneration. A multipurpose environmental proposal is therefore presented, giving a regional example of forest conservation with economic social options: Water capture, regulation and quality control of about 100 million m³/year, usefull for human consumption, and water supply to coffee and sugar cane farmlands. Ecological tourism, education, environmental culture programs, for about 12.000 potential visitors per year, will be possible with the establishment

of 20 local rural families as hostels and guides. Biodiversity conservation: equivalent natural reserves declare about 350 animal and 725 flora species. This will help to contrast neighbor's land use of cattle grasslands and intensive bare land crops. Pine plantation stumpage volume of 310.000 m³, that is possible to harvest at a rate of 20.000 m³ round wood per year, to industrialize it locally, and then replant the area, also gather for labor offer to 62 rural workers. After a forest management program for 16 years it will then offer a sustainable wood production of 8.000 m³/year. Existing carbon retention is closed to a 1,8 million CO₂-eq, and carbon caption to 18.000 CO₂-eq ton/year.

A6J: STRENGTHENING COMMUNITY AND SMALLHOLDER FORESTRY FOR SDGS AND OTHER FOREST-RELATED GOALS

Assessing the status of community-based forestry at national levels and building a framework for a global comparison

Andrew Taber¹, Jean-Claude Nguinguiri¹, Safia Aggarwal¹, Didier Habimana¹

¹UN Food and Agriculture Organization, Rome, Italy (andrew.taber@fao.org; jean-claude.nguinguiri@fao.org; safia.aggarwal@fao.org; didier.habimana@fao.org)

The extent of the world's forest estate under community-based forestry (CBF) regimes, including both collaborative and smallholder forestry, and related tenure transformations is growing. Evidence indicates that transfer of forest management rights to communities can improve the sustainable use and resilience of forest resources, social and economic conditions of impoverished rural populations, and prospects for attaining various SDG targets. Potential beneficiaries are 100's of millions of forest people, including many indigenous communities, and the large proportion of the world's population that depend on forest products and ecosystems services. However, standardized tools are lacking to undertake national-level assessments of the extent and effectiveness of CBF regimes. Understanding the factors contributing to the success and failure of different CBF regimes is crucial to ensure that they fulfill their promise in securing forest resources while delivering a wide range of environmental, social and economic benefits. This talk builds on a process to develop a standardized CBF assessment framework facilitated by FAO. We will present results of the application of a draft framework in 15 countries in Latin America, Asia and Africa. The impacts of different CBF regimes will be reviewed along with requirements to ensure their environmental, social and economic effectiveness. Building on lessons learned, we will launch framework tools for national assessments of CBF and forest tenure with the goal of improving effectiveness at country levels, and to inform comprehensive Global comparisons.

Smallholder forestry and Sustainable Development Goals: from knowledge gaps to Global collaborative research

Markku Kanninen^{1,2}, Maarit Kallio^{1,2}

¹University of Helsinki, Viikki Tropical Resources Institute (VITRI), Helsinki, Finland; ²University of Helsinki, Helsinki Institute of Sustainability Science, Helsinki, Finland (markku.kanninen@helsinki.fi; maarit.kallio@helsinki.fi)

Trees in farms managed by smallholders in diverse systems (e.g. tree stands, agroforestry systems, home gardens, living fences, managed secondary forests) are becoming increasingly important in increasing need for sustainably produced food, fodder and wood. Trees grown by smallholder-managed systems can contribute towards many of the Sustainable Development Goals by providing vital ecosystem services and by supporting smallholder livelihoods. To set up realistic expectations of such a win-win approach, and to design meaningfully measures to support smallholders in their tree growing initiatives, it is necessary to generate a more comprehensive understanding on the real scale and impacts of trees planted or managed by smallholders in the tropics and subtropics. Furthermore, there is a lack of recognition, understanding and data on the enabling environment of such incentives, such as on markets, logistics, risks and opportunities enhancing or preventing smallholder tree growing from becoming an attractive livelihood option. This paper addresses the above-mentioned challenges and assesses current state of knowledge, knowledge gaps, and bottlenecks. It also examines opportunities for filling the above-mentioned research gaps e.g. through collaborative multidisciplinary research efforts.

Forest: the important support to end poverty

Choiriatun Nur Annisa¹

¹Independent Forestry Consultant, Jakarta, Indonesia (c.nur.annisa@gmail.com)

Approximately 820 million people in tropics live in and around forests and 40% of them are living below US\$1.25/day (FAO, 2018; Chomitz et al., 2007). Up to one-fifth of the world's population get direct and indirect forest benefits with approximately 9% of the rural populations are lifted above the extreme poverty level with resources from forest (World Bank Group, 2016). Thus, forest is potentially significant to alleviate global poverty. Understanding the underlining cause of poverty in forest communities is important to formulate suitable approaches to eliminate it. Lack of necessary major capitals is one of the reasons (Sachs, 2005). Forest is usually remote that often found in rural areas with minimum facilities. Most of the forest areas are also publicly owned (UNFF, 2011). People are landless and most likely have no access to finance mechanism, therefore they are 'forced' to "live on common property resources" (Dasgupta, 1993). Forest is not the panacea, but rather it is an important support. Ending extreme poverty is our common agenda that is stated in SDGs. Forests can be the intersection to achieve multiple goals that leads to reducing poverty. There are at least three priorities to make forests worth contributing to eradicate poverty (particularly for forests communities): (i) Open the Access and Management to Community – Accelerating sustainable and inclusive economic growth; (ii) Capacity Building – Investing in people to build human capital; and (iii) Improve Forest Governance – Fostering resilience to global shocks and threats.

Assessing and communicating benefit sharing best practices to achieve sustainable land management at the jurisdictional scale

Lauren Cooper¹, Emily Huff¹, Dietmar Stoian²

¹Michigan State University Department of Forestry, East Lansing, USA; ²World Agroforestry Centre, Montpellier Area, France (lcooper@msu.edu; ehuff@msu.edu; d.stoian@cgiar.org)

Benefits are an important incentive for actors who would otherwise not reduce greenhouse emissions, namely by way of deforestation. However, sharing schemes must be transparent, legitimate, and fair; especially challenging because payments are often based on avoided actions rather than tied to specific goods. Earlier approaches focused on financial returns, but new thinking encompasses a broader set of 'monetary' and 'non-monetary' benefits, including tenure reform, local climate regulation, and community resilience. There is precedent for programming at various jurisdictional (geo-political boundary) levels, and multi-year efforts at different scales have highlighted both the great potential for this type of approach, as well as associated challenges. However, there is a

gap in understanding best practices for benefit sharing at the jurisdictional scale, which is reflected in the limited guidance for jurisdictions to develop such plans. This study aims to address this gap by assessing, compiling, and communicating best practices across the spectrum of data currently available in multiple programs, supplemented with a case study approach in two focal countries (Peru and Indonesia) using sound scientific methods including semi-structured interviews, surveys, strengths weakness opportunities and threats (SWOT) analysis, Q-sorting, and statistical analysis. To reduce conflation between familiarity with common practices and the identification of best practices, the study undertook a specific data collection and analysis approach; these findings are used to highlight knowledge transfer opportunities. Further analysis assessed how information was deployed and closes with recommendations to increase uptake of the best practices identified.

External factors contributing to customary forest formation and recognition in Jambi, Indonesia

Yumi Sakata¹, Kazuhiro Harada¹

¹Nagoya University, Nagoya, Japan (sakata.yumi@e.mbox.nagoya-u.ac.jp; harada@agr.nagoya-u.ac.jp)

Customary forests (CFs) have been managed by local/indigenous people for a long time. While CFs had been included in state forests, the status of CFs was changed by the constitutional court decision No 35/2012, which ruled that CFs are excluded from state forests. A ministerial regulation was stipulated as an enforcement regulation of CFs in 2015 and recognition of each CF by the central government started; 34 CF units covering 23,000 ha have already been recognized by the central government by the end of 2018. Out of 34 cases, 20 cases are located in Jambi Province, even though Indonesia has 34 provinces. Then this study investigated why formulation and recognition of CFs have proceeded in Jambi. Establishment of Kerinci Seblat National Park (KSNP) in 1990s was a start of recognition process of CFs in Jambi. During a project for KSNP, World Wildlife Fund (WWF) found existence of CFs on borders of the KSNP and asked local governments to recognize them to secure rights of local people. In 2000s, forest area in Jambi began to be under development pressure of timber production, palm oil plantation and mining, which triggered claims of CF rights by local people. There are also some CFs which were formulated by top-down approach by means of dissemination by a forest management unit (KPH). Cases in Jambi shows that CF recognition is important for forest conservation and security of local life, however, continuity of management of CFs certified by policy-based top-down is still questioned.

Evaluation of involvement of local stakeholders in sustainable management of state forest reserve under concession in Kwara State, Nigeria

Folaranmi Dapo Babalola^{1,2} 

¹Forest Resources Management, University of Ilorin, Ilorin, Nigeria; ²University of Pretoria Pretoria South Africa (babalola.fd@unilorin.edu.ng)

In implementing Sustainable Forest Management, there has been shift from sole ownership of forests to participatory forest management. Odun Forest Reserve (OFR) is located in Kwara State, Nigeria. It comprises about 203 ha plantations of *Tectona grandis* and *Gmelina arborea* established through Taungya System. The plantation was established by a private investor in 1976, but later transferred to the state forestry Department and then gazette into forest reserve. Currently, exploitation in the reserve is based on concessions through payment of levy to the state forestry department. The reserve has provided employment for about 43.8% households in the adjoining community. However, only 18.8% of the interviewed rural dwellers have paid levies to collect products from the reserve, while 26.3% and 26.3% have collected firewood and leaves respectively for free in the reserve. Majority (95.0%) of the rural dwellers did not participate in the management of the reserve with education significantly ($t = 2.736$, $p = \text{value} = 0.008$) contributing to this. Timber contractors working in the reserve carry out pruning and coppice management, while only 35.0% participated in voluntary fire control. Less than half (45.0%) of the contractors have been invited by the state forestry department in decision making process on the reserve. Other than revenue generation from exploitation in the reserve, participation of the stakeholders in management of the reserve from the contractors and rural dwellers is inadequate. There is therefore, the need for proper engagement of the stakeholders to facilitate sustainable management of the reserve.

Contributions by forest concessions in Guatemala toward fulfilling Sustainable Development Goals / Contribución de las concesiones forestales en Guatemala al cumplimiento de los Objetivos de Desarrollo Sostenible

Fernando Carrera¹, Aldo Rodas²

¹CATIE, Turrialba, Costa Rica; ²MAGA, Petén, Guatemala (fcarrera@catie.ac.cr; aldorodasc@gmail.com)

Las concesiones forestales en Guatemala fueron otorgadas como estrategia, por parte del Consejo Nacional de Áreas Protegidas (CONAP), para frenar el avance de la deforestación en la Zona de Uso Múltiple de la Reserva de la Biosfera Maya (RBM). Se trata de cerca de medio millón de hectáreas otorgadas a grupos comunitarios organizados e industriales de la madera donde uno de los requisitos para su funcionamiento era la obligatoriedad de obtener la certificación forestal del FSC a más tardar el tercer año de adjudicada la concesión y mantenerla vigente durante todo el periodo del contrato estipulado en 25 años prorrogables. El estudio se fundamenta en una evaluación realizada bajo la metodología de FAO, enmarcada en las Directrices Voluntarias para el Manejo de Bosques Públicos de Producción, el análisis de informes de auditorías de certificación y de varios estudios científicos y socioeconómicos realizados al proceso concesionario. Los resultados revelan que el proceso de manejo forestal en las concesiones en Guatemala no solo logró frenar el avance de la deforestación, en contraste con lo sucedido en las áreas protegidas aledañas, sino que además están contribuyendo a cumplir con varias de las Metas de los Objetivos de Desarrollo Sostenible (ODS).

A6k: THE BIOECONOMY: A SUSTAINABLE WAY FORWARD?

The SDGS, bioeconomy and forests: a nexus for Global sustainability?

Peter Edwards¹, Helga Püzl^{2,3}

¹Manaaki Whenua Landcare Research, Wellington, New Zealand; ²University of Natural Resources and Life Sciences, Vienna, Austria; ³European Forest Institute, Vienna, Austria (edwardsp@landcareresearch.co.nz; helga.puezl@boku.ac.at)

Nearly 1/3 of global land area is currently forested. Due to the upcoming “bioeconomy paradigm” the transition of current economies to one where materials, chemicals, and energy are derived directly from renewable (forest) resources or based on biotechnological processes may result in more intensified use and/or expansion of forest areas. The bioeconomy is also framed as a transformative way to achieve a low waste/carbon bio-based economy. Many bioeconomy policies however display technocratic or efficiency-oriented approaches, where the idea of sustainable development is narrowed. The globally agreed Sustainable

Development Goals (SDGs) encourage global transformation to sustainable use & management of resources along 17 goals including ending poverty, hunger & climate change, encouraging wellbeing, clean water, energy, gender equality & economic growth, with forests specifically addressed in goal 15. SDGs promote a shift to integrating economic and social development with environmental sustainability, providing a holistic view of sustainable development. The ambition is to overcome disconnected approaches & silo thinking. Applying a nexus approach and integration theory to bioeconomy policies & SDGs the paper aims to understand how both are connected & (not) governed in a way to achieve societal transition. Based on an analysis of bioeconomy strategies and SDG policies in forested and low-cover forest countries we aim to determine the ways in which the bioeconomy and SDGs are (dis)connected, and thus the role of forests in contributing to the SDGs plays out.

Roadmap to competitive circular bioeconomy: from challenges to solutions and strategy

Janni Kunttu¹, Diana Tuomasjukka¹, Jo Van Brusselen¹, Hans Verkerk¹, Michael den Herder¹, Mercedes Rois¹, Pekka Leskinen¹, Cleo Orfanidou¹, Yitagesu Tekle¹, Xiaoqian Chen¹

¹European Forest Institute, Joensuu, Finland (janni.kunttu@efi.int; diana.tuomasjukka@efi.int; jo.vanbrusselen@efi.int; hans.verkerk@efi.int; michael.denherder@efi.int; mercedes.rois@efi.int; pekka.leskinen@efi.int; cleo.orfanidou@efi.int; yitagesu.tekle@efi.int; xiaoqian.chen@efi.int)

Circular bioeconomy is a wide concept based on goods and services from renewable, agriculture and forest, or aquatic bio-based resources, aiming to keep the materials in use through re-use and recycling for as long as possible. Despite the massive research and innovation creation around the topic, there are still many knowledge gaps to overcome, such as barriers in cascade use or new business creation. One reason for this is, that the findings often lack information of how to implement the changes in practice, and what are the synergies between those changes. Also, they often do not reach the real actors. We aim at developing a detailed roadmap to strengthen circular bioeconomy in Nordic regions. We will i) create a network model on the circular bioeconomy key influence factors to overcome the barriers, and ii) utilize research and other stakeholder partners including Nordic research institutes and circular bioeconomy actors to develop a step-wise strategy to realize the actions needed. This is carried out in a KETSO workshop, which is also the first step towards change, as we directly transfer knowledge to the key audience. The 'roadmap to competitive Nordic circular bioeconomy' will be an actual example of the outcome of this participative strategy creation method, which connects knowledge and the key audience. In our presentation we will also discuss how to apply this method to other regions and purposes.

Assessing the sustainability of the German bioeconomy – the primary timber footprint

Vincent Egenolf¹, Stefan Bringezu¹

¹University of Kassel, Kassel, Germany (vincent.egenolf@usf.uni-kassel.de; bringezu@uni-kassel.de)

The increased use of biogenic resources is linked to expectations of "green" economic growth, innovation spurts through biotechnology, development options for rural areas and an increasingly regenerative resource base that is also climate-neutral. However, since several years the signs for unintentional and unwanted side effects are increasing. A comprehensive framework for the evaluation of the sustainability of the bioeconomy based on the three pillars of sustainability concept was developed. A special focus is set to the intersection area of the pillars where the particularly important integrative key objectives "food security, sustainable consumption, production and infrastructures" and their assigned indicators apply. The scale of the consumption of natural resources and GHG emissions determines the bundle of environmental impacts caused by human activities at national and foreign territory. The use of footprint indicators (agricultural land, primary timber, water, material and climate) is a viable tool to quantify the resource and climate impact of the German production and consumption system and to highlight the share the bioeconomy has. We calculated the primary timber footprint of the German bioeconomy. However, the quantification of a resource footprint does not allow statements about the change in sustainability performance. It is necessary to put the respective footprint in relation to orientation values in a meaningful reference system (global, regional, local). One example is the comparison to net the annual increment of forest biomass at national and global level to calculate the self-sufficiency rate and global supply rate.

Policy narratives regarding the growth of wooden multi-story construction (WMC) and sustainability transformation in the society: the case of Finland

Heini Vihemäki^{1,2}, Ritva Toivonen^{1,2}, Anne Toppinen^{2,3}

¹Department of Forest Sciences, University of Helsinki, Helsinki, Finland; ²Helsinki Institute of Sustainability Science, Helsinki, Finland; ³Department of Forest Sciences, University of Helsinki, Helsinki, Finland (heini.vihemaki@helsinki.fi; ritva.toivonen@helsinki.fi; anne.toppinen@helsinki.fi)

Wooden Multi-story Construction (WMC) is often considered as a way to promote socio-economic transformation, and shifting toward sustainable bioeconomy or low-carbon economy. The goal to increase industrial wood construction has thus gained much political support and public interest, but the market share of WMC has increased only slowly. This paper addresses the dynamics of policy efforts to transform the construction sector towards increased WMC in urban contexts, using Finland as a case. We approach the topic by exploring narratives of national level policy-makers and other key actors involved in the policy processes, and in shaping related agendas. The actors' conceptualizations of the WMC and its relationship with socio-economic transformations, including policies to support such transformation, were explored using a discursive approach. Sixteen thematic interviews of policy-makers, business and third sector actors were conducted in 2018, and complemented with analysis of policy programs and participatory observation. In the analysis, four partly competing, partly over-lapping policy narratives regarding WMC and socio-economic change were identified, including (1) a shift toward bioeconomy, (2) sustainable and low-carbon development, and (3) (forest and wood) industry development. The preferred policy solutions varied from bottom-up to top-down approaches, whereas the fourth narrative was generally critical about the agenda to promote wood in construction, seeing it as "unsustainable". The results highlight the diversity of actors and interests involved in the policy debates at the nexus of bioeconomy and sustainable development. The findings indicate need for well-coordinated efforts to effectively support the growth of WMC.

A plantation boom and structural change: the impact of the Indonesian palm oil expansion on manufacturing firm TFP

Nicolas Koch¹, Sebastian Kraus¹, Sabine Fuss¹

¹MCC, Berlin, Germany (koch@mcc-berlin.net; kraus@mcc-berlin.net; fuss@mcc-berlin.net)

For many tropical countries, the prospect of advancing a bio-economy has been attractive from the perspective of economic development. Brazil's bio-economy is already thriving and Indonesia has experienced a palm oil boom that has turned it into the biggest producer of the commodity. However, while the palm oil expansion has reduced poverty, it has also led to deforestation, so it stands to question whether this is a sustainable way forward. This paper investigates whether the palm oil boom has also created positive spillovers on the industrial sector empirically. We combine digitized archive data on district-level oil palm area and

remote-sensed and crowdsourced maps on palm oil plantations with all available waves of the Indonesian manufacturing census in an instrumented long-difference and difference-in-differences design to estimate local firm-level Total Factor Productivity. A land suitability instrument is derived from a global spatially explicit model on crop-specific soil and climatic conditions.

Beyond bioproducts production: enhancing bioeconomic value from forests

Karen Bayne¹, Robert Radics¹, Carel Bezuidenhout², Peter Edwards³

¹Scion, Christchurch, New Zealand; ²Toi Ohomai, Tauranga, New Zealand; ³Scion, Wellington, New Zealand (*karen.bayne@scionresearch.com; robert.radics@scionresearch.com; carel.bezuidenhout@toiohomai.ac.nz; edwardsp@landcareresearch.co.nz*)

Increased recognition of the need to reduce dependence on non-renewables has seen a renewed interest in bio-based products and their markets. Globally, New Zealand has a strength in natural biological resources, particularly in agriculture, and forestry, and more latterly, growth in horticulture and marine production. Despite this strong resource base and supporting infrastructure, New Zealand remains largely in pathway 'lock-in' around intensive production, low-value production and an innovation system that supports the existing food and fibre-based sectors. Allowing niches to break into the mainstream through infrastructural and institutional remodelling remains challenging. New Zealand forest business is somewhat restricted from taking full advantage of the innovative opportunities due to difficulty in attracting finance, and a lack of government policy. Drivers for change in the traditional forestry products model, or even in enhanced wood production, is largely economic. To fully embrace the opportunities provided by a 'newer' bioeconomic model, New Zealand will need a different model of diversification, innovation, and marketing, rather than reliance only on enhanced technology, and refinement of current processing pathways. We examine the drivers for enhancing the 'new' bioeconomy in New Zealand, both at the niche and regime levels, and provide examples and evidence for mechanisms to build additional value through leveraging forest-based products' services, bi-products, credence attributes and brand story.

Enabling a sustainable bioeconomy through wood value chains

Pierre Bouillon¹, Thais Linhares Juvenal¹, Anastasiia Kraskovska¹

¹FAO, Roma, Italy (*pierre.bouillon@fao.org; thais.linharesjuvenal@fao.org; anastasiia.kraskovska@fao.org*)

Food, agriculture, wood-based industries and forestry are the biggest components of bioeconomy. A first assessment by the European Union (EU/JRC) in 2016 showed that EU bioeconomy represented 4% of EU value-added. While representing only 0,8% of value added to total economy, the wood-based industries and forestry represented 19% of EU bioeconomy and 15% of EU bioeconomy jobs. Based on global evidence, this article will: i) lay down the current status of wood value chains contributions to the bioeconomy, from the forest to the mills and end markets, establishing the link with the Sustainable Development Goals and climate change objectives; ii) discuss their high suitability to circularity and cascading; iii) assess the barriers and opportunities for enhancing wood value chains' contributions to sustainable bioeconomy; and iv) outline some policy recommendations to enhance such contributions.

Existing National C&I Systems used for monitoring of forest-based bioeconomy related SDGs in selected Countries

Markus Lier¹, Stefanie Linser²

¹Natural Resources Institute Finland, Joensuu, Finland; ²EFI Forest Policy Network and University of Natural Resources and Life Sciences, Vienna (BOKU), Vienna, Austria (*markus.lier@luke.fi; stefanie.linser@efi.int*)

A circular and sustainable bioeconomy is the pathway to achieve the UN Sustainable Development Goals (SDGs) by 2030. The forest-based bioeconomy contributes particularly to a number of SDGs. Our interest is focusing on how these SDGs are taken into account in the formulation of a national bioeconomy strategy and how the indicator-based progress monitoring could be improved. Our study focuses on 10 countries which have already elaborated national bioeconomy indicator sets within their bioeconomy strategies. As these countries are from all over the world, the sets have different country-specific-socio-economic, ecologic and cultural settings. We analyse if and how forest-based SDG targets are taken into account in the formulation of the national bioeconomy strategy, and compare and analyse the different national indicators used to monitor the progress of forest-related SDGs and of the bioeconomy. Our material and methods are based on literature study, qualitative analysis and a questionnaire sent to the ministries responsible for national bioeconomy strategies. Against this background, we compare if the different national bioeconomy indicators used are similar to the respective intergovernmental forest-related regional or international C&I for SFM sets and derive recommendations for the further development of the national SFM and bioeconomy indicators.

Measuring the value of forests in a green economy

Alicja Kacprzak¹

¹UNECE/FAO Forestry and Timber Section, Genève, Switzerland (*alicja.kacprzak@un.org*)

Forests are of essential importance in the transition to a green economy and to the implementation of the 2030 Agenda for Sustainable Development. However, assigning a value to forests as natural capital and the environmental and social services provided by forests, which could help assess the role of forests in this transition, remains a major challenge. This paper presents green economy related definitions and concepts, as well as internationally developed assessment methods for measuring the progress in transition to a green economy, green growth and sustainable development as well as natural capital and ecosystem services valuation methodologies. It also takes stock of assessment systems, including criteria and indicators, developed by the forest sector to measure sustainable forest management (SFM). It analyses the complementarity of present forest sector valuation systems with approaches developed by other sectors in the context of the green economy. The paper explores alignment of forest sector measuring approaches of SFM to those being used in wider economy contexts and explains how they could be adapted to measure progress of the forest sector towards a green economy. Building on the Rovaniemi Action Plan for the Forest sector in a Green Economy, it proposes a new specific approach on how the forest sector's contribution to a green economy could be measured. Among others, the following approaches have been taken into account in the analysis: OECD Green Growth Indicators, UNEP Green Economy Progress Index, natural capital accounting approaches and Sustainable Forest Management Criteria and Indicators (Forest Europe and Montréal Process).

A61: INDIGENOUS AND TRADITIONAL PEOPLES AND THEIR FORESTS: KNOWLEDGE, MANAGEMENT AND GOVERNANCE TOWARDS SUSTAINABLE DEVELOPMENT GOALS - 2

Corporates-communités economic relations: creating a dialogue between indigenous people and the forest industry in Canada

Helin Dura¹, Jean-Michel Beaudoin¹, Thierry Rodon¹

¹Université Laval, Québec, Canada (helin-subhi.dura.1@ulaval.ca; jean-michel.beaudoin@sbf.ulaval.ca; thierry.rodon@pol.ulaval.ca)

Creating a fair share of the benefits from forest-based development between the industry and the Indigenous communities is an important concern in Canada and many other countries. This can be done by building Corporate-Community economic relations (CCER). A strategy based on corporate-community economic relations has several advantages: socio-economic improvement, fairer participation in benefit sharing, availability of workforce while simultaneously reducing operating costs. Yet, CCER face a range of challenges: unfair power sharing, difference between the partners' visions, and communications gap between what the community needs and what the industry wants. However, available information on this topic is scarce and outdated. We use a qualitative approach and a comparative case study method to address the following question: How to design a Corporate-Community economic relations model between Indigenous communities and the forest industry to better address and target the needs and goals of both parties? We identified a based model that take into account decision-making and management processes that fit Indigenous culture and expectations, strategies for recruiting and retaining Indigenous employees and adaptive learning approaches where partnership members share a common understanding and engage in the cocreation of knowledge and practices. Our study provide information to develop better-adapted interventions to help Indigenous communities and the forest industry to work together more effectively in improving the quality and reliability of their mutual relations.

Challenges to environmental management in indigenous lands / Desafios à gestão ambiental em terras indígenas

Elke Costanti¹, Jorge Nogueira¹, Cloude de Souza Correia²

¹UnB, Brasília, Brasil; ²Instituto Internacional de Educação do Brasil, Brasília, Brasil (e.costanti@terra.com.br; jmn0702@unb.br; cloude@iieb.org.br)

O papel fundamental dos povos indígenas em gerir e preservar as florestas tem sido reconhecido em estudos recentes que mostram uma relação positiva entre a regularização de terras indígenas e o menor desmatamento na floresta Amazônica brasileira. Atualmente, há cerca de 1.180.000 km² de terras indígenas estabelecidas no Brasil, equivalentes a 14% do território nacional, e 24% da região Amazônica brasileira. Realizar uma eficiente gestão ambiental e territorial dessas terras é fundamental para o desenvolvimento sustentável do País. A Política Nacional de Gestão Ambiental e Territorial (PNGATI), lançada em junho de 2012, estabeleceu os planos de gestão ambiental e territorial como a principal ferramenta de gestão das terras indígenas. Essa política inclui ainda a questão do uso sustentável, do monitoramento e proteção, e das alternativas econômicas de desenvolvimento para os povos indígenas. O artigo irá mostrar experiências exitosas de gestão territorial e de produção sustentável das terras indígenas, bem como os principais desafios e obstáculos para a comercialização e valorização de seus produtos. Ademais, mostrará uma análise custo-benefício econômica e social que aponta serem os custos de proteção ambiental muito menores do que os custos de recuperação. Mostra também que os benefícios para a sociedade como um todo derivados dos serviços ecossistêmicos são maiores do que os advindos da exploração de seus recursos naturais "business-as-usual", opção que leva a benefícios privados mas, apesar do efeito distributivo dos tributos para a sociedade, consome capital natural, com diminuição do bem-estar futuro.

Forest land for oil palm plantations? A case about indigenous peoples in Northeast India

Purabi Bose¹

¹Landing Together, Mumbai, India (purabibose@gmail.com)

Mizoram state of Northeast India is referred to as 'Bamboo Queen' for its largest bamboo forest. It is becoming famous for country's first commercial oil palm plantations. The state's 90% of the population are diverse ethnic minority tribes otherwise identified as indigenous peoples, traditionally practicing or shifting cultivation. In 2011, Mizoram implemented New Land Use Policy (NLUP) to formalize forestland titles that has been till date decentralized and managed by traditional laws. How the centralized NLUP brings change by replacing shifting cultivation in customary forest through settled farming is examined here. The paper analyzes the NLUP using empirical data collected from focus group discussions and interviews of diverse stakeholders, including indigenous peoples of two districts: Kolasib, and Lai Autonomous District Council of Lawngtlai. The study result indicates even after the NLUP the bamboo forests are allocated for shifting cultivation. These abandoned forestlands are then promoted by the Agriculture Department for palm oil plantations. Gender dynamics is observed wherein women's roles become 'submissive' in settled cultivation of oil palm as compared to their contribution in shifting cultivation. Private palm oil companies do not collect fruits from farmers living away from motorable roads, which pushes men to do daily-wage labour work, and women to do artisanal palm oil extraction at home. The key recommendations for implementing the NLUP are (a) introduce the RSPO sustainable certificate, (b) acknowledges indigenous system of land-use for conservation and gender equity, and (c) prioritizing household land titling as well community land tenure.

Combining environmental policy with indigenous rights and knowledge: a practical perspective to forest conservation in Acre, Brazil

Ane Schjolden¹

¹Rainforest Foundation Norway, Oslo, Norway (ane@rainforest.no)

The Brazilian state of Acre has collaborated with local communities to find workable forest management strategies, with an aim to safeguard the Amazon rainforest's ecosystem services and simultaneously secure forest peoples' rights and livelihoods. This resulted in various "florestania" policies, shaped by and adapted to the history, culture and identity of the different local and indigenous communities involved. To assess how the interaction between policy and practice has influenced the situation for forest dependent peoples, Rainforest Foundation Norway undertook case studies with interviews on experiences and management strategies in two different indigenous territories, that of the Ashaninka of the Amônia river and the Huni Kuin territory Colônia 27. In both cases, the recognition of territorial rights over a fixed area has been essential for the investment in both environmental qualities and the improvement of livelihoods. Further, the usefulness of government policies really depends on the continuous participation and involvement of the local communities. Letting traditional knowledge and culture form the basis for e.g. management plans, has increased identity, pride and sense of community, and spurred an increased interest in the passing on of traditional culture. Food security has been improved both by changing management practices and by supporting the advantageous participation in local and regional markets. While many of the policies have rendered success, there is need for greater coordination between the different policy instruments and better law enforcement, particularly to improve the security situation in this border region with Peru, plagued by illegal logging and drug trafficking.

Forest governance and indigenous peoples: the case of prior consultation of forest policy in Peru

Cristina Miranda¹

¹PUCP, Lima, Peru (cristinamirandabeas@gmail.com)

In Latin America, a region that is half tropical forests, has a third of freshwater reserves, the quarter of the world's potentially arable land, and indigenous peoples who represent 8% of the South American population, social changes are intimately related to the governance processes of natural resources. In 2015, 185 people died from extractive conflicts in the world, two-thirds were Latin American and about half were indigenous. From this perspective, this research analyzes the political and technical changes that characterized the process of a Peruvian forest policy that was submitted to prior consultation of indigenous peoples during the years 2014 and 2015, this happened as a result of one of the most serious socio-environmental conflicts in the country in Peru, "Baguazo", which caused the death of 33 people. Indigenous peoples occupy almost 30% of the extension of Peruvian forests that represent 56% of the territory. The indigenous demanded the right to use the forest resources and their territorial rights, therefore the Peruvian State was forced to establish spaces for dialogue and agreement. This process generated structural changes in the governance of natural resources that in this research is called Relational Capacity, composed of four elements: relationship and articulation of actors, formal and informal rules of the game, provision of human and financial resources and leadership. The consensus reached between public and private actors, as well as the development of the relational capacity, generated changes in the decision making on forest resources and the design of policies on Peruvian forests.

Social and environmental governance in extractive reserves: a strategy for collective management of conservation units in the Amazon region / Governança socioambiental em reservas extrativistas: uma estratégia para a gestão coletiva de unidades de conservação na Amazônia

Ana Carolina Vieira¹, Ana Luiza Violato Espada^{1,2} , Elias Serejo¹

¹Instituto Floresta Tropical, Belém, Brasil; ²University of Florida, Gainesville, USA (carolina@ifft.org.br; violatoespada@ufl.edu; elias@ifft.org.br)

Com a implementação das Unidades de Conservação de Uso Sustentável, criadas para conciliar a conservação da natureza ao uso sustentável dos recursos naturais por populações que tradicionalmente residem nesses territórios, houve uma mudança no paradigma da natureza intocada. A partir de então, a gestão seria compartilhada e, governo, comunidades locais e sociedade civil organizada passaram a dividir direitos e responsabilidades sobre o uso do território e recursos naturais associados. A gestão compartilhada é um reconhecimento político do protagonismo social na conservação da biodiversidade, e para isso é necessário um olhar que integre indicadores sociais vinculados às estratégias de uso e conservação da natureza. Desde 2012, o Instituto Floresta Tropical (IFT) tem atuado com o fomento ao manejo florestal comunitário em seis reservas extrativistas da Amazônia. Na perspectiva de gerar indicadores sociais e operacionais para a governança socioambiental nesses territórios, o IFT tem monitorado, por meio de observação participante e entrevistas individuais, como as comunidades e seus parceiros têm atuado de forma coletiva, considerando a ação colaborativa para a conservação e melhoria da qualidade de vida. A participação de diferentes atores dos três setores: órgãos públicos, empresas privadas e organizações da sociedade civil é chave para que se estabeleçam relações que promovam: a criação de um ambiente de parceria interinstitucional capaz de definir acordos, negociar interesses e definir estratégias; o diálogo constante entre os parceiros; a transparência de informações e interesses entre os parceiros; a construção coletiva das estratégias; um ambiente favorável à resolução de conflitos e flexibilização de interesses.

Respect, on whose terms? Collaborating with Asheninka and Yine Peoples in the Peruvian Amazon

Andrea M Vásquez Fernández^{1,2,3}, María Shuñaqui Sangama⁴, Raúl Sebastián Lizardo⁵, Miriam Pérez Pinedo⁶

¹UBC, Vancouver, Canada; ²PUCP, Lima, Peru; ³Unión Regional de los Pueblos Indígenas de la Amazonía de la Provincia de Atalaya, Atalaya, Peru;

⁴Asheninka, Atalaya, Peru; ⁵Yine, Atalaya, Peru; ⁶Federación de Mujeres Indígenas de la Provincia de Atalaya, Atalaya, Peru (ecomundo.andrea@gmail.com)

Amazonian Indigenous Peoples have said they are disrespected. Their accounts of exploitation and violent dispossession of their territories at the hands of outsiders include the rubber boom in the 19th century and current contexts in which oil, gas, minerals, and timber exploitations occur. In these contexts, the rhetoric of "development" is used to push the agendas and values of the outsider proponents of resource exploitation practices over the Indigenous Peoples' own desired futures. National and international policies encourage "mutual respect" as the most important practice to have a peaceful coexistence in culturally diverse scenarios. However, can this respect really be "mutual" if Amazonian Indigenous sets of subjectivities, sensitivities, and practices of what they translate from their own languages into the colonial/imperial language as "respect" are either not known and/or neglected by outsiders' praxis? German philosopher Immanuel Kant continues to be the main reference for definitions of respect in the world. Asheninka and Yine Peoples argue that their conceptions and practices of "respect" exceed those articulated in hegemonic spheres. How do Asheninka and Yine perspectives of "respect" inform and transform hegemonic conceptions and practices of "mutual respect" when the latter is heavily based on euro-western perspectives of respect? The purpose of our research is to build from Asheninka and Yine perspectives an "intercultural respect" model instead of "mutual respect" with the Peruvian central government in the context of industrial "natural resource" extraction. This project was initiated at the invitation of Indigenous community members, and uses decolonizing and Indigenous approaches.

Building trust during collaborative natural resource governance

Ngaio Hotte¹, Stephen Wyatt², Robert Kozak¹

¹University of British Columbia, Vancouver, Canada; ²Université de Moncton, Edmundston, Canada (ngaio.hotte@alumni.ubc.ca; stephen.wyatt@umoncton.ca; rob.kozak@ubc.ca)

In Canada, an estimated 490 bilateral and trilateral agreements have been established between Indigenous organizations and governments and provinces regarding lands, resources and economic development. This reflects a broader global trend toward implementation of collaborative natural resource governance to resolve conflicts, generate social and ecological benefits and increase implementation of decisions. Several studies have identified the importance of trust in the context of collaborative natural resource governance. Lack of trust between collaborators, and the absence of processes for building trust, are barriers to collaboration and natural resource governance outcomes, including those related to sustainable development. Insights into how trust is created during collaborative natural resource governance have the potential to improve processes and outcomes. This research tested a theoretical framework for building trust in the context of collaborative natural resource governance in Canada using a survey of representatives from Indigenous, federal and provincial governments. The theoretical framework focused on three types of influences on trust that are identified in the literature: individual

influences, interpersonal influences and institutional influences. Institutional influences are further divided into institutional characteristics and trust in institutions. Research results identify the relative weight of each of these influences on collaborators' decisions to trust others, as well as the degree to which these variables interact and contribute to mutually beneficial solutions. Results of this research can be used to inform the establishment of collaborative governance protocols based on trust that are more conducive to successful and sustainable outcomes.

Leveraging conflict and cooperation: indigenous strategies to achieve both transformational and incremental change in governing Quebec's forest lands

Stephen Wyatt¹, Martin Hébert², Jean-Francois Fortier²

¹Université de Moncton, Edmundston, Canada; ²Université Laval, Québec, Canada (stephen.wyatt@umoncton.ca; martin.hebert@ant.ulaval.ca; jean-francois.fortier.1@ulaval.ca)

First Nations in Quebec, Canada, like most Indigenous peoples elsewhere around the world, find themselves on the margins of governance arrangements for forests on their traditional lands. While Indigenous rights are increasingly recognized, Indigenous peoples typically face considerable barriers in transforming these rights into meaningful governance arrangements, improved access to forestlands, and an equitable share of the economic benefits of forestry. Governments and the private sector are proposing collaborative mechanisms to incrementally develop forestry opportunities for Indigenous peoples, but some groups consider that such proposals remain insufficient. This disconnect creates situations in which conflict or opposition come to be seen as necessary means to achieve significant transformational change. This study presents a longitudinal analysis of the experiences of the Atikamekw Nehirowisiwok, Huron-Wendat and Mi'gmaq nations in Quebec, Canada over more than thirty years. Examining the numerous and diverse processes used by each nation to expand their engagement in forestland management, we sought to determine if these represented a broader strategy. All three nations made use of both conflictual processes (road blockades and legal actions) and collaborative arrangements (round tables, consultations, business partnerships, etc.), sometimes sequentially, but also simultaneously. Considering the history of different processes and the connections between these, we conclude that each nation has developed a distinct strategy to use different opportunities to change an existing situation, and then to build upon this change through collaboration with other actors. Accordingly, First Nations should be seen as strategic actors who seek to enhance their roles in forest management.

A6m: WOMEN AND FORESTS: PROMOTING GENDER EQUALITY CONNECTING RESEARCH, PUBLIC POLICIES AND FOREST MANAGEMENT IN THE TROPICS

The challenges of female extractivist leadership in constructing public policies for community forest management in the Amazon / Os desafios de uma liderança feminista extrativista na construção de políticas públicas para o manejo florestal comunitário na Amazônia

Maria Margarida da Silva¹

¹Cooperativa Mista do Rio Arimum, Porto de Moz, Brasil (margarida.florestal@gmail.com)

A história do manejo florestal comunitário na Amazônia brasileira é uma história de luta pelo direito a terra, pelo reconhecimento dos territórios de uso comum, e por políticas de promoção do uso dos recursos naturais. Há 30 anos Chico Mendes, um dos principais líderes do movimento extrativista, foi assassinado por defender a floresta e os direitos das populações tradicionais. Desde então, 27 milhões de hectares de florestas comunitárias foram destinadas em diferentes categorias (RESEX, PAE, RDS, PDS, PAF). A gestão destas áreas é compartilhada entre governo e organizações sociais. E é neste contexto que apresentamos a experiência e lições aprendidas de uma liderança feminista na Resex Verde para Sempre (Pará). Agroextrativista, mãe de três filhos, militante do movimento de mulheres, da juventude e sindical. Como Presidente da Associação Comunitária do Rio Arimum aprovou o 1º plano de manejo florestal comunitário em Unidade de Conservação no Brasil. Teve atuação decisiva na proposição das políticas estadual e nacional de manejo florestal comunitário. Em 2014 participou da criação da Cooperativa Mista do rio Arimum que implementa sete planos de manejo florestal. Atualmente trabalha na formação de novas lideranças. Por suas realizações, em 2017 foi vencedora do Prêmio Wangari Maathai. Acredita que a mulher é capaz de fazer gestão florestal em todas as etapas desta cadeia produtiva, desde o inventário, exploração, romaneio, comercialização. Sendo o principal desafio promover o acesso a um modelo diferenciado de educação para os jovens extrativistas, desde o ensino básico ao superior, com foco no uso da floresta.

Women and forests: progress and challenges in recognizing the role of women in forest governance in the Amazon region / Mulheres e floresta: avanços e desafios para o reconhecimento do papel das mulheres na governança florestal na Amazônia

Ana Luiza Violato Espada^{1,2} ; Ana Carolina Vieira²

¹University of Florida, Gainesville, USA; ²Instituto Floresta Tropical, Belém, Brasil (violatoespada@ufl.edu; carolina@ifl.org.br)

São nos ambientes rurais que as desigualdades de gênero ficam ainda mais evidentes nas relações familiares e comunitárias. Por exemplo, o manejo florestal foi, por muitos anos, visto como uma atividade masculina e machista, tanto entre produtores florestais familiares, como profissionais da engenharia florestal. Esse cenário vem mudando, comunidades tradicionais e seus parceiros estão se empenhando para estimular o envolvimento das mulheres na tomada de decisão referentes às melhorias das cadeias de valor de produtos florestais. Desde 2012, o Instituto Floresta Tropical (IFT) tem atuado com o fomento ao manejo florestal comunitário em seis reservas extrativistas da Amazônia. Na perspectiva de aumentar a participação das mulheres, o IFT tem monitorado, por meio de observação participante e entrevistas individuais, como as comunidades estão incorporando conceitos de participação de gênero nas atividades produtivas locais. Participação assume, pelo menos, três dimensões: acesso à informação e preparação em pé de igualdade para a tomada de decisão que reflete na vida da família e da comunidade; direito de ser ouvida nos encontros e momentos chave de tomada de decisão; boa vontade dos demais participantes em ouvir, discutir e deliberar as e alternativas propostas pelas mulheres. As funções executadas pelas mulheres refletem diretamente na qualidade e entrega da produção ao comprador. As mulheres estão envolvidas desde a preparação para a colheita ao beneficiamento dos produtos florestais. Mas é preciso se esforçar ainda mais. É evidente que a mulher tem papel importante nas atividades produtivas, mas é o homem que ainda aparece como o protagonista.

Model forests: regions in search for equity and gender equality / *Bosques Modelo: territorios en búsqueda de la equidad e igualdad de género*

Maria Ximena Campos Bustos¹, Fernando Carrera², Richard Verbisky³

¹Red Latinoamericana de Bosques Modelo, Jamundí, Colombia; ²Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba, Costa Rica; ³Servicio Forestal Canadiense, Ottawa, Canada (maria.campos@catie.ac.cr; fcarrera@catie.ac.cr; richard.verbisky@canada.ca)

La Red Latinoamericana de Bosques Modelo (RLABM) promueve un modelo de gestión territorial que se centra en las alianzas de las personas con una visión común hacia el desarrollo sostenible, sin embargo, se ha identificado que en los principios y en los criterios de evaluación de un Bosque Modelo no se plantea claramente la equidad e igualdad de género, siendo éste un eje transversal necesario para lograr realmente el desarrollo sostenible. Por lo anterior, la gerencia de la RLABM, abordó la elaboración de una propuesta de estrategia de equidad e igualdad de género adaptada al contexto de los Bosques Modelo. La propuesta fue elaborada bajo una metodología participativa que involucró al equipo gerencial de la RLABM, a organizaciones y personas aliadas y a representantes de los Bosques Modelo. La propuesta se validó de manera presencial en el Bosque Modelo de Pichanaki y se presentó en la reunión anual del 2017 del directorio de la RLABM. Se espera que la estrategia desarrollada contribuya a institucionalizar o transversalizar el enfoque de género en la RLABM y en cada uno de los Bosques Modelo, con el propósito de examinar las implicaciones de las acciones emprendidas para los hombres y mujeres, y hacer que todas las necesidades, intereses y experiencias de mujeres y hombres sean parte integral del diseño, ejecución, monitoreo y evaluación de políticas, programas y proyectos.

The perception of female forest engineering students about gender devaluation in the profession

Ana Caroline Oliveira da Silva¹ ; Andressa Ribeiro¹

¹Universidade Federal do Piauí, Bom Jesus, Brasil (anacarol.ctbj@gmail.com; andressa.florestal@ufpi.edu.br)

The struggle for gender equality has intensified in recent decades, highlighting the academic, science and technology fields. Historically these areas have been predominantly occupied by men, but the number of women in courses such as engineering have increased in the past years. The objective of this work was to evaluate the perception of female students of the forestry engineering course of the Federal University of Piauí about gender devaluation in the profession. For this a survey with 12 questions was answered by 35 students. The course has a total of 254 students, being 41% women. The results showed that 65.7% have been discouraged by someone to become a forester, 54.3% felt devalued regarding to the profession by colleagues and/or professors and 48.6% witnessed one of these situations with other women. A total of 51.4% felt less capable than their male counterparts, being the feeling of insecurity, sense of devaluation, constant criticism and manual labor regarded as work for men the principal reasons cited; 17.1% of the students believe that this devaluation occurs equally in other institutions, while 14.3% believe that it manifests with more force locally. To change this scenario, the suggestion of engagement of women in groups to discuss their role in the space they are occupying, by discussion circles for example, are fundamental to break this paradigm.

The presence of women in the Brazilian forestry sector / *A presença das mulheres no setor florestal brasileiro*

Fernanda Rodrigues¹, Maria Harumi Yoshioka¹, Patricia Nazario¹, Vitor Afonso Hoeflich² 

¹Rede Mulher Florestal, Curitiba, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (fe.rodrigues.1412@gmail.com; mhyoshioka@gmail.com; pattynipa78@gmail.com; vitor.ufpr@gmail.com)

O setor florestal brasileiro tem grande relevância para a economia nacional. Em 2017, contribuiu com cerca de 6% do PIB e foi responsável por 91% de toda a madeira produzida para fins industriais. As mulheres já são a maior parte da população brasileira representando 51% desta conforme demonstrado no último censo em 2010, todavia o País não tem estatísticas precisas sobre a participação das mulheres no setor florestal. De acordo com a Organização Internacional do Trabalho os últimos vinte anos foram positivos para a situação das mulheres no mundo do trabalho e da igualdade de gênero na sociedade. O levantamento deste estudo abrangeu formados do curso de Engenharia Florestal da Universidade Federal do Paraná entre 1964 e 2016 apresentando que nos primeiros anos da criação deste curso no Brasil, praticamente homens se formaram engenheiros. Esta realidade vem gradualmente se modificando. Apenas em 2004 houve um número maior de mulheres do que homens formados(as) na UFPR neste curso. Em 2017, dentre as pessoas empregadas na área florestal no Brasil considerando o setor de plantações e florestas nativas das empresas certificadas pelo FSC, as mulheres representavam em média 8%. Apesar de existir uma tendência apresentada pela maior participação no número de mulheres formadas em engenharia florestal, no campo as mulheres ainda têm baixa representatividade na força de trabalho. Espera-se que, a partir da implementação da Agenda 2030 da ONU no setor florestal, se alcance o ODS 5 quer almeja alcançar a igualdade de gênero e empoderar todas as meninas e mulheres.

Building partnerships and strengthening social capital in community forest management: the case of the Tapajós National forest in the Amazon region of Brazil / *Construindo parcerias e fortalecendo capital social no manejo florestal comunitário: o caso da Flona do Tapajós, Amazônia*

Ana Luiza Violato Espada^{1,2,3} ; Mário Vasconcellos Sobrinho³

¹University of Florida, Gainesville, USA; ²Instituto Floresta Tropical Belém Brasil; ³Universidade Federal do Pará, Belém, Brasil (violatoespada@ufl.edu; mariovasc@ufpa.br)

Parceria pode ser importante estratégia para a implementação e o aprimoramento de atividades produtivas sustentáveis em florestas públicas da Amazônia. Em Unidades de Conservação de Uso Sustentável, o manejo florestal comunitário é prática que pode gerar benefícios socioeconômicos, tais como trabalho e renda, além de promover a conservação ambiental. O objetivo do artigo é compreender como as parcerias, enquanto instrumento da governança ambiental, podem contribuir para a promoção de atividades sustentáveis e para o desenvolvimento local. Os conceitos teóricos que fundamentam a discussão são da governança ambiental e capital social, ao considerá-los processos construtivos que envolvem diferentes atores atuando de forma sinérgica para a promoção da melhoria da qualidade de vida e uso sustentável dos recursos naturais. Estudou-se o caso de uma cooperativa comunitária que executa manejo florestal na Floresta Nacional do Tapajós, oeste paraense. Os resultados revelam que o manejo florestal comunitário nessa floresta pública foi implementado e aprimorado a partir de uma rede de parceiros envolvendo comunidades tradicionais, governo, sociedade civil organizada e setor privado. Essa rede de parceiros contribui para a formação da gestão coletiva dos recursos florestais, a qual se mostra eficiente e qualificada, ao permitir a geração de trabalho, renda e aperfeiçoamento técnico e profissionalizante dos moradores da floresta. Atualmente, o modelo de gestão do manejo florestal na Floresta Nacional do Tapajós é referência nacional e internacional, sendo fruto da atuação de diversos parceiros que promovem, cada um com sua expertise, as bases para o desenvolvimento local e sustentável do oeste do Pará, Amazônia.

A6p: WOMEN AND FORESTS: PROMOTING GENDER EQUALITY CONNECTING RESEARCH, PUBLIC POLICIES AND FOREST MANAGEMENT IN THE TROPICS

The more the merrier? The perspectives of female college student leaders on gender aspects in the forest sector

Pipiet Larasatie^{1,2}, Taylor Barnett¹, Eric Hansen¹

¹Oregon State University, Corvallis, USA; ²LPDP, Jakarta, Indonesia (larasatp@oregonstate.edu; barnett@oregonstate.edu; eric.hansen@oregonstate.edu)

Continuous efforts to increase gender diversity result in some good news such as more women in education, paid employment, and top management positions. However, women still suffer greater economic exclusion with an average of 15-20 percent less earnings than men. This study utilizes interviews to explore the perspectives of female college student leaders on gender aspects in the forest sector. Our respondents are 28 female student leaders in the top four forestry universities in the world based on The Center for World University Rankings: Swedish University of Agricultural Sciences, Oregon State University, University of British Columbia, and University of Helsinki. The research questions are (1) What are perceptions of female college student leaders on the current situation with respect to gender diversity in forest sector education? (2) What motivates female students to enter forest sector education and industry? (3) In what ways do gender stereotypes and expectations influence the experiences of being a collegiate forest student organization leader? and (4) In what ways do female college student leaders think the forest sector education and industry could be made more attractive to young females?

Forests for people

Joyce Ofori Kwafu¹

¹Forestry Commission, Accra, Ghana (afuakwafu2000@yahoo.com)

Forests play an important role in the lives of people and how people can ensure their sustainable use. "Forests are for people and people are for forests". Forests are sources of income for people through the collection and sale of non-timber forest products (NTFPs), the Modified Taungya System (MTS), which is a system of intercropping foodstuff with trees until such a time that the trees form canopy, then the foodstuffs are harvested and the trees are allowed to grow. People get income from forests through the hunting and selling of "bushmeat". Timber sales on the local market and export markets and tourists visitations to wildlife protected areas and national parks for nature based - tourism, creates income for people. Community Resource Management Areas (CREMAs) concept where indigenous people are trained and engaged in forest management provides alternative sources of livelihoods to communities while improving their well - being. The National Forestry Development Plan birthed the Youth in Afforestation Programme which has engaged over 70,000 youth to plant trees on degraded forest areas.

The role of women in extraction pracaxi nut oil in the Limão do Curuá community of the Bailique Archipelago, Amapá in the Brazilian Amazon / O protagonismo feminino na exploração de óleo de Pracaxi da Comunidade do Limão do Curuá, Arquipélago do Bailique, Amapá, Amazônia, Brasil

Ana Cláudia Lira-Guedes¹ ; Ranielly Coutinho Barbosa², Isabelly Ribeiro Guabiraba³, Ana Margarida Castro Euler¹ 

¹Embrapa Amapá, Macapá, Brasil; ²Projeto Bem Diverso, Macapá, Brasil; ³Universidade do Estado do Amapá, Macapá, Brasil (ana-lira.guedes@embrapa.br; raniellycb@gmail.com; isabellyguabiraba@gmail.com; ana.euler@embrapa.br)

Algumas atividades de uso da biodiversidade na Amazônia são culturalmente desenvolvidas por mulheres, como a extração artesanal de óleos de sementes florestais. Essa cultura está relacionada ao conhecimento tradicional sobre o uso de plantas medicinais, principalmente por parteiras e/ou benzedadeiras. A comunidade do Limão do Curuá - Ilha que compõem o Arquipélago do Bailique, costa leste do Amapá - vem ganhando destaque, no Estado, nos últimos anos, devido à extração artesanal de óleo de sementes de pracaxi (*Pentaclethra macroloba* (Wild.) Kuntze), realizada por, aproximadamente, 70 mulheres. Esse óleo é um produto fitoterápico conhecido localmente por seu poder antifidico e de cicatrização, e vem recebendo notoriedade nas indústrias de fármacos e cosméticos. As mulheres do Limão do Curuá, têm adaptado métodos para a extração do óleo, não cozinhando as sementes e usando um triturador e uma prensa artesanal de madeira. Com essas adaptações, as extratoras conseguem produzir grande quantidade de óleo (em média, meia tonelada em 2017 e uma tonelada em 2018), com boa qualidade (odor agradável). No entanto, ainda é necessária a adoção de boas práticas, desde a coleta até o envasamento do óleo, para aumentar a qualidade do produto. Também é urgente a organização dessas mulheres para que tenham maior alcance de mercado e poder de negociação. É notório que essa atividade tem potencial de crescimento e pode se consolidar, como um dos principais empreendimentos femininos do Arquipélago do Bailique, potencializando a economia da biodiversidade da Amazônia.

Constructing an integrated approach to gender in a restoration project using agroforestry systems in Southeastern Pará, Brazil / Construção de abordagem integrada de gênero em projeto de restauração com sistemas agroflorestais no Sudeste do Pará

Thais Ferreira Maier¹, Edenise Garcia¹, Rodrigo Mauro Freire¹

¹The Nature Conservancy, Belem, Brasil (tferreira@tnc.org; egarcia@tnc.org; rfreire@tnc.org)

O Projeto Cacau Floresta, conduzido pela The Nature Conservancy, tem como objetivo a promoção da restauração de pastagens degradadas por meio de sistemas agroflorestais com base no cacau (*Theobroma cacao*) junto a pequenos agricultores, no sudeste do Pará. Atualmente, o projeto tem foco numa abordagem integrada de gênero para aumentar a eficiência das ações, a sustentabilidade e a equidade do mesmo. Iniciado em 2013, o projeto conta com 130 propriedades e tem atraído cada vez mais mulheres agricultoras, que demonstram aptidão e interesse por temas ligados à produção, segurança alimentar, gestão financeira da propriedade e beneficiamento de produtos agroflorestais. Em recentes oficinas sobre a gestão financeira da propriedade, as mulheres representaram 44% dos participantes. Outras oficinas sobre biodiversificação da produção, transição agroecológica e beneficiamento de produtos agroflorestais estão previstas. Também serão realizadas oficinas participativas para diagnóstico de oportunidades e desafios do maior protagonismo feminino, bem como coleta e análise de dados desagregados sobre esta temática. A desagregação constitui basicamente na separação de dados de mulheres e homens, tais como participantes do projeto, uso de mão de obra, participação em treinamentos, tipos de tarefa que executam, entre outros. Desta forma, é possível obter análises diferenciadas, com maior riqueza de informações em relação ao gênero e apoiar numa melhor gestão em termos de promoção da equidade de gênero. Trata-se de uma perspectiva pioneira para a restauração que tem por objetivo empoderar as mulheres e melhorar suas habilidades para gerenciar as propriedades rurais.

Beekkeeping and community honey production: a project to develop strategies for conservation of natural ecosystems in the Juan de Mena district of Paraguay through a comprehensive approach / *Apicultura y meliponicultura comunitaria – Proyecto para el desarrollo de estrategias para la conservación de ecosistemas naturales en el Distrito de Juan de Mena, Paraguay a partir de un enfoque integral*

Samara Lazarotto¹, Carolina Blanca Alvarez Fretes², Carmen Monges², Fabiana Maria Benitez Popoff²

¹Universidade Federal de Santa Maria, Campus Frederico Westphalen, Frederico Westphalen, Brasil; ²Universidad Nacional de Asunción, Carrera de Ingeniería Forestal, San Lorenzo, Paraguay (samara.fk@hotmail.com; alvarezfretes10@gmail.com; aracelymonges@gmail.com; fabibenitez0927@gmail.com)

La polinización es uno de los procesos más importantes para la manutención de la biodiversidad de ecosistemas naturales terrestres y las abejas son una de las principales responsables de este proceso, ya que se encargan de la dispersión de polen. Las mismas visitan las flores en busca de néctar y polen que más tarde convertirán en miel, su principal alimento. Este proyecto busca instalar un modelo de producción orgánica de miel con abejas nativas y comerciales, y de esta manera promover la ecología integral con un enfoque ecosistémico. Por medio del empoderamiento de un grupo de mujeres, asentadas en una localidad rural del distrito de Juan de Mena, Paraguay. De manera a mejorar sus ingresos económicos y contribuir a la conservación de la biodiversidad de flora y fauna. La metodología a emplear para el desarrollo de este proyecto se dividirá en 3 etapas: 1ª Aplicación de herramientas de diagnóstico rural participativo con enfoque de género, que permita un intercambio horizontal de saberes con miras a que las mujeres se sienten aptas para discutir y construir su propia visión y capacitación; 2ª Realización de cursos y talleres sobre apicultura y meliponicultura; 3ª. Desarrollo, gestión y puesta en marcha de una propuesta de empresa comunitaria de productos obtenidos de la apicultura y meliponicultura. Al final del proyecto esperamos que el grupo de mujeres se apropien y desarrollen de manera integral las actividades de producción y comercialización de miel con propósitos a la conservación de la biodiversidad de flora y fauna local.

Productive social inclusion of rural women through sustainable forest management of natural resources in the Amazon region / *Inclusão sócio produtiva das mulheres rurais por meio do manejo florestal sustentável dos recursos naturais na Amazônia*

Katiúscia Miranda^{1,2}, Manuel Amaral Neto¹, Marcos Silva¹, Waldileia Amaral¹

¹Instituto Internacional de Educação do Brasil, Belém, Brasil; ²Instituto Federal de Educação, Ciência e Tecnologia do Pará, Campus Castanhal, Castanhal, Brasil (glaukat2001@gmail.com; manuel@iieb.org.br; marcos@iieb.org.br; walamaral2013@gmail.com)

A Amazônia brasileira se estende por uma área de aproximadamente cinco milhões de km², possuindo aproximadamente 63% de sua extensão coberta por florestas nativas. A mesorregião do Marajó, localizada no estado do Pará, congrega parte deste potencial florestal com destaque para a região de Portel com uma área territorial de 25.384,960 km² e uma população de 57.205 habitantes. Em que pese sua importância estratégica para o desenvolvimento da região por conta de seu potencial social, produtivo e ambiental, o Território Marajoara vem sofrendo grande pressão por conta da exploração ilegal de madeira e pela desordem na exploração dos seus recursos naturais e a disputa pelo território. Buscando superar esses desafios, nos últimos anos, o município de Portel tem sido foco de ações governamentais e da sociedade civil com o objetivo de promover a produção sustentável, o qual tem se dado, principalmente pelo enfrentamento feito pelas comunidades extrativistas contra a exploração predatória da madeira e seus impactos sobre o meio ambiente e a vida das comunidades. Os resultados aqui apresentam a experiência de constituição de uma cozinha agroextrativista na comunidade de Santo Ezequiel Moreno, em Portel, onde ações solidárias e de inclusão sócio produtiva sustentável das famílias agroextrativistas são protagonizadas por um grupo de mulheres, que buscam estratégias para potencializar a diversidade da produção e o acesso à mercados mais justos e solidários. Atualmente, a cozinha agroextrativista fornece aproximadamente 80% da merenda escolar na comunidade com uma variedade grande de produtos da culinária regional, garantindo segurança e soberania alimentar à comunidade.

A6q: SOCIAL ASPECTS OF FORESTRY

Impact of forest concessions on local jobs in Central Amazon

Jime Rodrigues Ribeiro¹, Cláudia Azevedo-Ramos¹, Ricardo Bruno Nascimento dos Santos²

¹Núcleo de Altos Estudos Amazônicos, Universidade Federal do Pará, Belém, Brasil; ²Departamento de Economia, Universidade Federal do Pará, Belém, Brasil (engenheirajime@gmail.com; claudia.azevedoramos@gmail.com; ricardobns@gmail.com)

In the humid tropics, forest concessions have become the main mechanism for accessing public forest resources. In Brazil, the forest concession was established in 2006 and had as one of its assumptions the generation of local jobs. In order to assess whether this impact has been effective around the first Brazilian forest concessions established in a National Forest in 2010, the municipality of Itapuã do Oeste in Rondônia state was used as a case study. The impact of the public policy on jobs was verified through the Synthetic Control technique between the period 2002-2015. The impact on forestry jobs start in 2014, four years after the beginning of forest operations. This fact may be related to the emergence of new concession areas in Rondônia, contractual changes through federal resolution and compliance with local workers' qualification requirements by concessionaires. Itapuã do Oeste benefited from an increase in forestry jobs by concentrating timber processing from local and neighboring forest concessions. It can be concluded that local development in the Amazon region may be benefited from forestry if the planning of forest concessions combines jobs in forest and industry. This would need the support of broader and integrated national and state policies than those under the responsibilities of the environmental agencies that manage the concessions today.

Local initiatives for strengthening community forest management in Jigme Dorji National Park in Bhutan

Kazuhiro Harada¹, Sonam Phuntsho², Om Katep²

¹Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan; ²College of Natural Resources, Royal University of Bhutan, Lobesa, Bhutan (harada@agr.nagoya-u.ac.jp; som¹⁰finso@gmail.com; om@cnr.edu.bt)

Community forestry (CF) has been recent forest management trend in Bhutan. CF was firstly introduced in 1979 by National Royal Decree and became popular in 1990s. The purpose of CF is to put management initiative of state forests to local people, some parts of which used to be customarily managed. This study tries to investigate how local people have management initiatives of CF under the supports of national park authorities in Jigme Dorji National Park. The village which acquired CF prepared 10 year forest management plan under the guidance of the national park authority, and based on it, CF members in the village voluntarily managed forests. In the management plan, usage of all resources including building materials and fuelwoods was only allowed for village members and strictly managed to keep sustainability. In case of fuelwood, for example, members were permitted to cut one or two pieces of trees and take them from CF once a year. Members and park officers inspected the site together and checked the trees preferred by members, and then the officers stamped on the trees

decided to cut. After the process, members paid royalties to the CF committee and cut down the trees within a certain period of time. Strict forest management by CF members and the park authority made it possible to prevent invasion of outsiders in CF as well as to achieve both forest conservation and local utilization in a good balance, realizing SDGs targets.

Three perspectives to assess and foster sustainable wood: global, landscape, value chain

Vincent Gitz¹, Alexandre Meybeck²

¹CIFOR, Bogor, Indonesia; ²CIFOR, Rome, Italy (v.gitz@cgiar.org; a.meybeck@cgiar.org)

Wood is, by definition, a sustainable material: it is renewable and biodegradable. It has, however, to be produced at least at the same rate as it is consumed, while accounting for competing demands on land, and for all environmental, economic and social potential benefits and trade-offs. This presentation aims to provide a framework for the sustainable development of wood production and consumption along three perspectives: global, landscape and value chain. From a global perspective, wood is to be considered as a renewable material to be compared to other materials. It invites to analyze its use to growth time ratio, how it can be recycled and its final use for energy production, with corresponding contributions to climate change mitigation through carbon sequestration and substitution to other materials. At landscape level, sustainable forest management calls for an integrated landscape approach, taking into account, along with wood production, all potential impacts on natural resources and human well-being, including remote effects. Value chains can enhance the sustainability of wood by improving resource efficiency, reducing waste, facilitating the use of less valued species and parts as well as recycling and final use for energy production. It is along value chains that are distributed economic and social benefits and that sustainable consumption and production can be linked. Such a framework is effective to assess the sustainability of wood in all its dimensions while facilitating the consideration of synergies and trade-offs in order to design appropriate institutions and policies to enhance bioeconomy and sustainable development.

Fuels, food and forests: fathoming bioeconomy's 3 Fs

Valny Giacomelli Sobrinho¹, Eva Cudlínová²

¹Universidade Federal de Santa Maria, Santa Maria, Brasil; ²University of South Bohemia, České Budejovice, Czech Republic (giacomelliv@yahoo.com.br; evacu@ef.jcu.cz)

Within the strategy of substituting renewable energy inputs for fossil fuels to curb greenhouse gases, bioeconomy stands out as an option to reduce the harmful effects from these emissions. Bioeconomy from this perspective is seen as a sustainable solution for global problems, yet we suppose it cannot be considered as self-evidently sustainable. The emissions reduction effect will only take place if neither does biofuel production spread over forestland, thereby causing deforestation, nor does it displace food production to areas previously covered with forests. Bioeconomy, and particularly biofuel, production is related to food and forest outputs, where the relationship between biofuel development and tropical deforestation is a complex problem in terms of biodiversity and carbon sequestration. Although its 3F-grounded (fuels, food and forests) decarbonization thrust resembles the 3R-based (reduce, reuse and recycle) dematerialization one in waste management, the reduction of fossil fuels, the reuse and recycle of food and forest wastes claimed by the bioeconomy strategy stumble on two opposite stances. Biofuels are said to be grown on degraded agricultural and pastureland, not driving deforestation. But the practice of their expansion causing the threatening of standing forests, either directly, through land-grabbing and deforestation, or indirectly, by displacing farmland onto forestland. This paper seeks to estimate how strong the connection among deforestation, biofuel (sugarcane ethanol) and food production in Brazil is. Brazil case was chosen because of the institutional framework set down in the 1970s (e.g. Proalcool) for producing biofuels, which turned the country into the second world's largest producer.

Impacts of earthquake on community forest and livelihoods: perspectives from the community forest user group members of Sindupalchok District, Nepal

Sudha Adhikari¹, Kazuhiro Harada¹, Yumi Sakata¹

¹Nagoya University, Nagoya, Japan (adsudha21@gmail.com; harada@agr.nagoya-u.ac.jp; sakata.yumi@e.mbox.nagoya-u.ac.jp)

Community forests are the crucial component of farming systems and people's livelihood in rural middle-hills of Nepal, as they depend upon forest for fuelwood, fodder, and leaf litter for their daily needs. Almost two and half years have passed since the massive earthquake of April 2015 and the forest-dependent communities in hilly Nepal are still in the process of the recovery phase. The study aims to assess the community forest users group's perception on community forest products supply and local environmental condition as well as their livelihood capitals. In addition to open-ended interviews with 68 earthquake-affected households; extensive visits to the study area, key informants interviews and focus group discussions were carried out. The study showed that the community forest user group perception towards community forest products supply was decreased, the local environmental condition was degraded and livelihood capitals were negatively affected. Out-migration, inflow of remittance, manpower shortage and reduced dependency on forest were also observed leading to the risk of passive participation in community forestry. The recovery activities carried out by community forest user group members were based on traditional knowledge, skills and practices. Policies should thus be implemented to support livelihood options which are sustainable such as agriculture and livestock in rural hilly areas of Nepal with new technologies and access to productive resources. There is a need to strengthen local institutional policy and mechanism to provide the communities with knowledge, skills and practices for smoother and effective post-disaster recovery.

Politics of transition in the New Zealand bioeconomy

Peter Edwards¹, Anita Wreford², Karen Bayne³, Alan Renwick²

¹Manaaki Whenua Landcare Research, Wellington, New Zealand; ²Lincoln University, Lincoln, New Zealand; ³Scion, Christchurch, New Zealand; (edwardsp@landcareresearch.co.nz; anita.wreford@lincoln.ac.nz; karen.bayne@scionresearch.com; alan.renwick@lincoln.ac.nz)

New Zealand is currently struggling to transition/transform from an 'old' bioeconomy based on the provision of food and fibre to a 'new' bioeconomy. The underpinning economic and political foundations remain largely the same – using market forces to maintain or add value, increasing capital accumulation for businesses. Because the free-market foundations remain unchanged, the vision of the 'new' bioeconomy is not heavily or directly promoted or adopted by the government or overtly political forces, but are solidly entrenched in sectorally-based industry bodies. Without a coherent national strategy and a foundation maintaining capital accumulation, there is limited opportunity to link the bioeconomy to achieving the Sustainable Development Goals (SDGs) in New Zealand. The pervasive neoliberal philosophies are an indication of the political (and economic) forces at play in New Zealand with respect to the bioeconomy, and appear conflict with social and environmental targets in the SDGs. The potential turn to a bioeconomy through more intense utilisation of natural resources using biotech and other bioprocessing is not necessarily an answer to environmental and social sustainability issues. A central question we examine is what

economic and political practices or changes are necessary to develop a nexus approach to the bioeconomy and SDG attainment? We examine the bioeconomy in New Zealand in the context of its underlying neoliberal economic and political environment, and potential conflict between changing land uses, and social and environmental outcomes in New Zealand.

Tropical forests and people in the Asia-Pacific Region

John Herbohn¹, Jack Baynes¹, Nestor Gregorio¹, Liz Ota¹, Kurt von Kleist¹, Kanchana Wiset¹

¹University of the Sunshine Coast, Sippy Downs, Qld, Australia (jherbohn@usc.edu.au; jbaynes@usc.edu.au; ngregori@usc.edu.au; lizsota@gmail.com; kurtvk3@gmail.com; kanchana.wiset@gmail.com)

Despite the recent economic growth of countries in the Asia-Pacific region, poverty rates are still high in rural areas, especially in areas with dense forests (Sunderlin et al; 2008). The degradation and loss of these tropical forests are a threat to the more than 450 million people for whom forests are essential to their livelihoods (RECOFT, 2013). The Tropical Forests and People Research Centre (TFAP), of the University of the Sunshine Coast in Australia, undertakes research and development in south-east Asia and in the Asia-Pacific Region. The purpose of this research is to ascertain how to establish, restore or manage forests while improving the lives and livelihoods of local communities. For instance, in Papua New Guinea, our focus has been to assist farmers to grow seedlings and establish woodlots for firewood and timber. These woodlots may also be used as a shade crop for cacao. Research into the sustainable harvesting of native forest is continuing. In the Philippines, a pilot watershed rehabilitation project with local communities has demonstrated how social preparation is critically important for engaging and motivating community members. This project has also identified several challenges for watershed rehabilitation and forest and landscape restoration, including: lack of institutional support, limited human capital, high vulnerability to natural disasters, high discount rates of rural people, among others. The poster brings a synthesis of major findings of over 18 years of forest-related research in the Asia-Pacific Region by TFAP members and the implications for practice.

Gender and NTFPs: case study in Putao District, Kachin State of Myanmar

Ei Ei Swe Hlaing¹, Zar Chi Hlaing¹, Chan Nyein Kyaw¹, Thaug Naing Oo¹

¹Forest Department, Naypyitaw, Myanmar (eieiswehlaing@gmail.com; zarchihlaing08@gmail.com; channyinkyaw.cnk1990@gmail.com; tnoo71@gmail.com)

This study examines gender differentials in collecting, processing and marketing of non-timber forest products (NTFPs) in Putao District which is a home to three major ethnic groups: Lisu, Shan and Yawan. The specific objectives are to identify the NTFPs extracted from natural forests and to assess the resource availability. Field-based quantitative and qualitative data collections were carried out in June, October and December 2018. Data were obtained from seasonal market survey, focus group discussions and face to face interview with 36 women and 50 men. Respondents were selected by using snowball sampling method. Participatory assessment of the identified NTFPs and scientific inventory of Rattan (15 circle shape sample plots of 78.5 m² were randomly selected in the natural forests where women collect Rattan) were conducted to estimate the distribution area of resources. A total of (56) species of NTFPs used by the local people were documented including edible plant products (32 species) collected by men and women for food source; medicinal products (18 species) and non-edible plant products (6 species) collected and processed by men for livelihood. Study shows that NTFPs provide not only production function but also buffer function in times of scarcity of staple food and social function. It is found that unsustainable harvesting and insecure marketing were the major constraints for sustainable utilization of the products. We suggest supportive policy for secure marketing and sustainable management of NTFPs for income generation and livelihood improvement of forest-dependent communities.

A6r: SOCIAL ASPECTS OF FORESTRY

The wood-resource-balance as monitoring tool to estimate wood-processing-residues in Brazil

Emilin Joma da Silva¹ , Udo Mantau² 

¹University Hamburg, Hamburg, Germany; ²INFRO, Informationssysteme für Rohstoffe, Hamburg, Germany (emilin.joma.da.silva@uni-hamburg.de; udo.mantau@iufro.eu)

Resource monitoring tools supports the development of public policies aiming the achievement of circular economy. The forestry sector integrates the bioeconomy, hence the recommendation to periodically monitor forest production and further wood consumption to assure its sustainability. The wood-resource-balance (WRB) developed by Mantau (2009) consist of a method to record information related to wood consumption. Furthermore, it takes into account the recycling potential of wood-processing-residues (WPR). According to the Brazilian Forest Service (SFB), in 2017 around 85% of the wood consumption in Brazil had been supplied by planted forest. Therefore, the Brazilian WRB calculation consulted official statistics and carried out a primary survey exclusively related to planted forest round wood. The selected enterprises informed besides wood production and consumption, the amount and type of occurred residues. The potential WPR volume was estimated to be greater than 70.0 million cubic meter of round wood. In 2017, the majority of wood secondary resources were utilized for energy purposes. However, WPR were also demanded for material uses at panel factories, pulp mills, livestock, gardening and for wood-plastic-composites (WPC) production. Knowledge about WPR availability helps to promote recycling and the cascade use of secondary resources. Integrated inventories about forest production and wood consumption are essential to satisfy the need for wood and add value on WPR, as well as to develop knowledge about recycling potential of secondary resources.

Contributions from a public forestry incentive program to developing a biomass energy production chain in Dois Vizinhos, Paraná, Brazil / Contribuição de um programa de fomento florestal público para o desenvolvimento da cadeia produtiva de energia de biomassa no município de Dois Vizinhos, Paraná, Brasil

Anathan Bichel¹, Eleandro José Brun²

¹Engenheiro Florestal, Londrina, Brasil; ²Universidade Tecnológica Federal do Paraná, Campus Dois Vizinhos, Dois Vizinhos, Brasil (anathan_sulina@hotmail.com; eleandrobrun.utfpr@gmail.com)

Para suprir a falta de madeira para fins energéticos e a pressão de uso irracional sobre as florestas nativas, sistemas de desenvolvimento socioeconômicos sustentáveis, como programas de incentivo aos plantios florestais vêm ganhando força, tanto no setor público como privado. O fomento florestal é um instrumento estratégico que promove a integração dos produtores rurais à cadeia produtiva e lhes proporciona vantagens ambientais, sociais e econômicas. Desta forma, objetivou-se com o presente trabalho avaliar a contribuição de um programa de incentivo ao plantio de *Eucalyptus* spp. para o abastecimento da cadeia produtiva de energia no

município de Dois Vizinhos, Paraná. O trabalho foi elaborado por meio do banco de dados dos projetos: “Metodologia de monitoramento do programa de fomento ao plantio de eucalipto do município de Dois Vizinhos: ferramenta de gestão florestal municipal” e “Demandas e oportunidades de mercado para o setor florestal/madeireiro de Dois Vizinhos, PR”, ambos realizados pela Universidade Tecnológica Federal do Paraná (UTFPR), Campus Dois Vizinhos e apoiados por outras instituições. Os resultados mostram que a maioria dos plantios florestais provenientes do incentivo são para o segmento de energia. A visão dos participantes do programa sobre o uso do eucalipto apresenta diversos elementos positivos, entre os quais, a contribuição das áreas plantadas em benefícios socioeconômicos e ambientais, autoabastecimento e segurança energética, perspectivas para um equilíbrio nos mercados consumidores da região, principalmente no segmento de biomassa energética.

National forests: an essential organizational chart for staffing / Florestas nacionais: organograma de pessoal, fundamental na estruturação.

Trajana Gracia Neto¹

¹MMA/ICMBio, Fernandes Pinheiro, Brasil (trajanogracioneto@gmail.com)

As florestas nacionais fazem parte no Brasil do Sistema Nacional de Unidades de Conservação da Natureza (SNUC), classificadas na condição de uso sustentável, contando com precursores como o Instituto Nacional do Pinho (INP) nas décadas de 40 até a de 60, o IBDF nas décadas de 60 até a de 80 e agora inseridas no Instituto Chico Mendes de Conservação da Biodiversidade (ICMBio), na Diretoria de Criação e Gestão de Unidades de Conservação (DIMAN). Essas unidades de conservação encontram-se com seus quadros de pessoal extremamente defasados em relação a um quadro de pessoal básico e mínimo, ainda agravados pela falta de diversificação de atribuições, principalmente no tocante a formação acadêmica para os setores básicos técnicos e científicos. Essas limitações implica em não ter condições de resolutividade em vários campos de ação da gestão, monitoramento e proteção da biodiversidade com isso deixando essas áreas protegidas em parte de cumprir com seus objetivos. Como alternativa para solucionar esse cenário de carência estrutural apresento a implementação de um quadro de pessoal permanente e básico com enfoque pluritemático, ou seja, multidisciplinar e integrando áreas de conhecimentos próximas e afins. A setorização de pessoal pelas principais áreas de conhecimentos aplicados em recursos naturais proporcionam segurança e resolutividade, complementada.

The observatory for community and family forest management: a strategy for inter-institutional connection with civil society to promote public forest policies in the Amazon region / Observatório do manejo florestal comunitário e familiar: estratégia de articulação interinstitucional da sociedade civil para promoção de políticas públicas florestais na Amazonia

Manuel Amaral Neto¹, Katiúscia Miranda^{1,2}, Milton Kanashiro³

¹Instituto Internacional de Educação do Brasil, Belém, Brasil; ²Instituto Federal de Educação, Ciência e Tecnologia do Pará, Campus Castanhal, Castanhal, Brasil; ³Embrapa Amazônia Oriental, Belém, Brasil (manuel@iieb.org.br; glaukat2001@gmail.com; milton.kanashiro@gmail.com)

As florestas públicas comunitárias no Brasil representam grande potencial de dimensões social e econômica no país. Essas florestas comunitárias tem demonstrado eficácia em resistir às pressões do desmatamento no Brasil. Estes territórios ocupam, aproximadamente, 136 milhões de hectares envolvendo um contingente de mais de dois milhões de pessoas, compostas por povos e comunidades tradicionais, agricultores familiares e assentados da reforma agrária (SFB, 2010). Por conta disso, constituem-se territórios estratégicos nas negociações internacionais celebradas pelo governo brasileiro relacionadas à manutenção do clima. Contudo, as florestas comunitárias no Brasil são alvo de pressão de setores da indústria florestal para exploração ilegal e predatória. Visando articular o engajamento de atores sociais e promover o Manejo Florestal Comunitário e Familiar (MFCF) por meio de políticas e implementação de planos que viabilize a produção sustentável das florestas, geração de renda e defesa de seus territórios surge, em 2017, o Observatório do MFCF. O Observatório é uma articulação interinstitucional composta por 32 instituições, entre organizações associações comunitárias, ONGs e entidades de ensino e pesquisa voltada para a produção de conhecimento aplicado com atuação sociopolítica em torno de uma agenda comum de fortalecimento comunitário na implementação de planos de manejo, proteção ao território, sistemas de produção sustentáveis e agroecológicos, a inclusão e fortalecimento de mulheres e jovens, em ações de advocacy que reforcem a influência em formulação e acesso a políticas públicas por parte das organizações comunitárias. Trata-se de uma iniciativa inovadora de grande potencial para o protagonismo da sociedade civil na agenda florestal.

Governance of forest resources in communities within the Verde para Sempre Extractivist Reserve / Governança de recursos florestais em comunidades da RESEX Verde para Sempre

Marlon Costa de Menezes¹, Suzana Ligoski Zeferino¹, Natally Celestino Gama¹, Saymon Roberto Pontes da Fonseca², César Augusto Tenório de Lima³

¹Universidade Federal do Pará, Altamira, Brasil; ²Comitê de Desenvolvimento Sustentável de Porto de Moz-CDS, Porto de Moz, Brasil; ³Universidade Federal Rural da Amazônia, Paragominas, Brasil (marlon@ufpa.br; suzanaligosk@gmail.com; natallygama28@gmail.com; saymonpontes21@gmail.com; cesar.tenorio@ufra.edu.br)

A Reserva Extrativista Verde para Sempre criada em 8 de novembro de 2004 para assegurar a proteção da população extrativista e a conservação dos recursos naturais, vem fomentando a utilização da madeira através do Manejo Florestal Comunitário (MFC). Essa pesquisa tem como objetivo demonstrar a importância do fortalecimento do MFC em comunidades da RESEX Verde para Sempre, possibilitando a melhoria da governança local. Está localizada entre os rios Xingu e Amazonas, município de Porto de Moz-PA, com 1.288.717,00 hectares. Atualmente 6 comunidades extraem madeira orientadas pelas diretrizes do MFC, sendo precursora a comunidade Arimum, em 2007 através do IBAMA e em 2016 as comunidades Arimum, Por tí meu Deus, Paraíso, Ynumbi, Itapéua e Espírito Santo via ICMBio. Os principais resultados de um conjunto de ações implementadas são apoio interinstitucional através do Comitê de Desenvolvimento Sustentável de Porto de Moz (CDS), da Universidade Federal do Pará (UFPA), do Serviço Florestal Brasileiro (SFB), do Instituto Internacional de Educação do Brasil (IEB) e do Instituto Floresta Tropical (IFT), fortalecimento das associações comunitárias e criação de cooperativas para a gestão florestal, regularização da produção madeireira e incremento da renda das famílias nas comunidades Arimum, Por tí meu Deus, Paraíso, Ynumbi, Itapéua e Espírito Santo com receitas anuais de R\$ 642.485,34, R\$ 141.129,42, R\$ 255.053,67, R\$ 207.384,01, R\$ 408.407,78 e R\$ 323.006,00, respectivamente. A criação da RESEX trouxe segurança jurídica para os extrativistas utilizarem seus recursos florestais, regularizando sua produção através da formalização de planos de manejo, conservando a floresta e gerando renda para as famílias.

Challenges in selling palm hearts from management of açai palm groves in Federal Conservation Units / Desafios para a comercialização do palmito oriundo de manejo de açazais em Unidades de Conservação Federais

Simone Rabelo¹

¹ICMBio, Breves, Brasil (simone.rabelo@icmbio.gov.br)

A Ilha do Marajó/PA, apesar de possuir uma elevada biodiversidade, é uma das áreas mais pobres no Brasil, nessa perspectiva as Unidades de Conservação (UCs) possuem papel fundamental na mudança desse cenário. Como a ilha é conhecida pela sua abundância em açazais nativos, o ICMBio, desde a criação das Reservas Extrativistas, vem trabalhando, em parceria com a Emater/PA, o manejo de açazais, especialmente porque o manejo é visto como principal substituto à exploração madeireira ilegal. Mas, apesar dessa atividade ser fortemente incentivada pelo ICMBio, ainda há alguns desafios a serem superados. Atualmente, os extrativistas que possuem áreas de manejo de açazal dentro de UCs federais enfrentam uma legislação pesada no que tange à burocracia e viabilidade econômica, que impossibilita a comercialização do palmito. Apesar de haver uma legislação no Pará que simplifica e libera de onerações o comércio de palmito, IN9/2013 da Sema/PA, esta não é válida para os extrativistas de UCs federais. Então, todos os extrativistas que hoje trabalham de forma legalizada, veem-se obrigados a transformar o palmito em adubo, ração ou alimento próprio. O ICMBio, na tentativa de minimizar os trâmites burocráticos em apoio aos extrativistas, publicou a IN16/2011, no entanto ainda deixou algumas questões não resolvidas, especialmente, no caso em questão, o documento não isenta o extrativista da emissão do DOF, à exemplo da IN9/2013 da Sema/PA. Portanto, o aproveitamento financeiro da etapa de desbaste/limpeza do açazal, executado no processo de manejo, é juridicamente impraticável pelos extrativistas de UCs federais marajoaras.

Similarities and differences between the Environmental Reserve Quota (CRA) and tradable permits: potential for the new instrument and recommendations / Semelhanças e diferenças entre a Cota de Reserva Ambiental (CRA) e as Licenças Negociáveis: potencialidades do novo instrumento e recomendações

Maria Luiza Almeida Luz¹

¹Universidade de Brasília, Brasília, Brasil (marialuizaluz@gmail.com)

Em fevereiro de 2018, o Supremo Tribunal Federal tornou constitucional a compensação ambiental por Cotas de Reserva Ambiental (CRA) como prevista no Novo Código Florestal. Apesar da constitucionalidade da compensação, quando da votação do instrumento, o STF alterou o texto, acrescentando que a área cadastrada para compensação ambiental deve guardar relação de “identidade ecológica” com a ARL desmatada. Assim, estabeleceu-se um cenário de insegurança jurídica, porque faltam definições do que se entenderá por “identidade ecológica”, que não é um termo reconhecido pelo direito ou pela comunidade científica brasileiros. Esse estudo teve dois objetivos: levantar semelhanças e diferenças das CRAs com as licenças negociáveis, instrumento econômico consolidado, e analisar a relevância do conceito de “identidade ecológica” para os objetivos de implementação das CRAs. Os resultados corroboram que a CRA tem potencial, mas ainda carece de melhor regulamentação, principalmente para sanar as inseguranças jurídicas relacionadas a situações de adicionalidade de proteção e cancelamento e reversibilidade de áreas adicionais de ARL após o vencimento da CRA. Quanto à utilização do termo “identidade ecológica”, rigorosamente, seria necessário avaliar os benefícios, custos e resultados ambientais que seriam alcançados ao se adotar diferentes abordagens de classificação de áreas equivalentes para a compensação ambiental. Considerando escassez de recursos e tempo como fatores limitantes, fica a recomendação da adoção do conceito de “equivalência ecológica” para áreas de compensação ambiental, em especial às CRAs. Isso porque esse já é um conceito consolidado na esfera jurídica e científica e, portanto, retira a insegurança jurídica trazida pelo termo “identidade ecológica”.

A6s: SOCIAL ASPECTS OF FORESTS AND FORESTRY

Deployment of integrated silvopasture systems in rural properties near Cianorte, in Northwestern Paraná state, Brazil / Implantação de Sistemas de Integração Lavoura, Pecuária e Florestas (SIPAS) em propriedades rurais da Região de Cianorte, noroeste do Estado do Paraná

Sidney Aurelio Valeriano Ramos¹

¹Emater-PR, Cianorte, Brasil (sidney_valeriano@yahoo.com.br)

A Região de Cianorte juntamente a Paranaíba e Umuarama compreendem a Região Noroeste do Estado do Paraná. De acordo com os dados de 2013 do Departamento de Economia Rural (DERAL), 50% da receita da região provém da agricultura, sendo 49% da pecuária e 1% das florestas plantadas. Utilizando-se do modelo agrícola existente, a implantação de sistemas de integração lavoura pecuária e florestas (SIPAS) tem o propósito de assegurar benefícios econômicos ao produtor de gado de corte e de leite além benefícios ambientais a região, associados ao bem-estar animal por meio do conforto térmico. A sensibilização do produtor para adesão ao SIPAS se dará por meio de visitas técnicas a propriedade e repasse das experiências de sucesso e das dificuldades encontradas, por meio dos dias de campo e reuniões técnicas com depoimento dos produtores já adeptos do SIPAS. Os resultados esperados dizem respeito a ampliação da renda da propriedade sem aumentar o volume das atividades já existentes; produção de madeira de qualidade a baixo custo; impactar positivamente a sucessão familiar; agregação de valor ao produto por meio do marketing ambiental; estreitamento do vínculo entre pesquisa e extensão rural, atuação desde a produção das mudas até o manejo dos resíduos industriais.

100 Years of National Park Management: determining best practices for moderninternational application

Kalifi Ferretti-Gallon¹, Guangyu Wang¹

¹The University of British Columbia, Vancouver, Canada (kalififg@mail.ubc.ca; guangyu.wang@ubc.ca)

National park systems worldwide are changing. For over a century, national parks have played a critical role in ensuring the protection of natural landscapes worldwide. Parks have functioned to protect the world's biodiversity, conserve carbon stocks, and ensure food security to local communities. The introduction of an applied national park framework to countries rich in biodiversity but without a current system, therefore, is crucial. The concept of what a national park is and how it should be managed has been in development since the late 19th century. In 1872, the world's first national park, Yellowstone National Park, was established as a recreational area, in the United States. Within the decade, similar systems were adopted in Australia, Canada, and New Zealand. While all four countries have unique experiences specific to their distinct landscapes and species allocation, they share a wealth of knowledge on how to effectively introduce and sustain a long-term national park system. With over 100 years of experience in national park management each, Australia, Canada, New Zealand, and the United States can offer invaluable lessons on lessons learned and best practices. This project seeks to review the evolution of park development in all four countries, synthesize available expert opinion, and establish guidelines on how to best introduce and effectively manage national parks. This will greatly benefit countries in emerging economies, lacking relevant expertise.

Strategic planning for the Latin American Model Forest Network (RLABM), 2018–2022 / *Planificación estratégica de la RLABM para el periodo 2018-2022*

Maria Ximena Campos Bustos¹, Fernando Carrera^{2,3}, Roger Villalobos Soto^{2,3}

¹Red Latinoamericana de Bosques Modelo, Jamundí, Colombia; ²Red Latinoamericana de Bosques Modelo, Turrialba, Costa Rica; ³Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba, Costa Rica (maria.campos@catie.ac.cr; fcarrera@catie.ac.cr; rvillalo@catie.ac.cr)

La Red Latinoamericana de Bosques Modelo (RLABM) se define como una alianza voluntaria entre los Bosques Modelo de Latinoamérica, respaldados por representaciones gubernamentales de cada país miembro, organizaciones internacionales de investigación, de cooperación y organizaciones privadas. Los Bosques Modelo se pueden definir como plataformas neutras para la gobernanza participativa que agrupan un amplio rango de organizaciones y personas que se asocian voluntariamente y trabajan conjuntamente hacia una visión común para la gestión sostenible de sus recursos naturales. La Planificación Estratégica de la RLABM define los principales ejes temáticos reconocidos por los diversos miembros de la organización para su crecimiento y consolidación en el mediano y largo plazo. El proceso de Planificación Estratégica de la RLABM para el periodo 2018-2022 se realizó de forma participativa y constó de 4 pasos fundamentales: la identificación y establecimiento de la plataforma de participación, el análisis de situación, una planificación preliminar y una planificación final. Como resultado se definieron tres tipos de objetivos estratégicos: para los Bosques Modelo, para el equipo de Gerencia y para las instituciones socias, reconociendo como principales ejes temáticos la implementación de buenas prácticas de conservación y producción, la equidad e igualdad de género y la comunicación interna y externa de la organización.

Evaluation of plantation establishment and livelihood improvement scheme as method for raising forest plantations in Kenya

Joram Kagombe¹, Mercelyne Khalumba²

¹Kenya Forestry Research Institute, Nairobi, Kenya; ²Kenya Forest Service, Nairobi, Kenya (jokagombe@gmail.com; khalumbamercelyne@yahoo.com)

Plantation establishment has incorporated communities and had changed over time from shamba system, Non resident cultivation and presently plantation establishment and livelihood improvement scheme (PELIS). Success of PELIS varies from region to region. The case study evaluated PELIS in Mau, Eastern, Nairobi, North Rift and Central highlands conservancies. A socioeconomic survey was conducted followed by visit to the site. Total area under PELIS in Kenya was 18,932.63 ha distributed in six forest conservancies. The overall seedling survival rate was 67% with Nairobi leading with 78% followed by Central Highlands conservancy with 74% and North Rift with 65%. Main cause of low survival was poor seedling quality. Most farmers (91%) got their household food requirements from crops grown in PELIS plots and this contributed to household food security. The PELIS rules were abused by 55% and 33% of the respondents in Bahati and Dunderi respectively. Most farmers (70%) paid rent for the first year but this reduced to 10% in the third year. The level of satisfaction with PELIS depended on how community members were involved, plot allocation methods and methods in place for solving conflicts. Results suggest that PELIS is suitable practice in which both the Kenya Forest Service and the farmers benefit. For the farmers, the food crop yields and financial earnings realized are sufficient to attract their participation. Therefore the PELIS qualifies to be sustained. KFS PELIS rules need some adjustment, especially on type of food crops, plot allocation, and collection of revenue.

Mapping communities: putting the concept of impacted parties into practice / *Mapeamento de Comunidades: operacionalização do conceito de partes afetadas*

Uilson Paiva¹, Pricilla Soltovski¹, Andreia Pimentel¹, Neri Pires de Lima Filho¹, Darlon Orlamunder de Souza¹, Marciano Souza de Oliveira Silva¹, Clewerson Scheraiber¹, Maria José Brito Zakia²

¹Klabin, Telêmaco Borba, Brasil; ²Prática Assessoria Socioambiental, Guararema, Brasil (upaiva@klabin.com.br; psoltovski@klabin.com.br; anpimentel@klabin.com.br; nfilho@klabin.com.br; dosouza@klabin.com.br; marciano.silva@klabin.com.br; cscheraiber@klabin.com.br; zeze.zakia@uol.com.br)

A matriz de aspectos e impactos sociais é um instrumento para balizar a tomada de decisão em uma empresa, visando minimizar os impactos que podem ser causados por suas operações. Na Klabin S/A, a construção da matriz envolveu diretamente cerca de 250 funcionários e consultas à sociedade. Para minimizar impactos das operações florestais evoluindo de uma ação corretiva para atuação mais proativa, todas as comunidades foram mapeadas e classificadas conforme os critérios: a) Casas Isoladas I: até 10 casas - menos de 30 pessoas; b) Núcleo II: 10 a 20 casas - de 30 a 50 pessoas; c) Vila III: 20 a 100 casas - mais de 50 e até 300 pessoas; d) Distrito IV: mais de 100 casas - mais de 300 e até 3000; As rotas (estradas) foram classificadas de acordo com o fluxo e intensidade de tráfego, também quanto à duração da operação (permanente/temporária). O impacto mais percebido está relacionado ao transporte de madeira, em função da poeira gerada. Com base no monitoramento das informações, foram direcionadas ações de mitigação, como: mudança de itinerário, utilização de caminhões pipas; alteração de posição do escapamento de veículos, revestimento das estradas. São atendidos sete dos 17 ODSs da ONU: 8. Trabalho decente e crescimento econômico; 9. Indústria, inovação e infraestrutura; 11. Cidades e comunidades sustentáveis; 12. Consumo e produção responsáveis; 13. Ação contra a mudança global do clima; 15. Vida terrestre; 17. Parcerias e meios de implementação.

Determining tourist load capacity on the cascata trail in Desengano State Park, Rio de Janeiro, Brazil / *Determinação da capacidade de carga turística na trilha da cascata do Parque Estadual do Desengano, Rio de Janeiro*

Thamires de Souza Carvalho¹, Marcello Pinto de Almeida¹, Gumercindo Souza Lima¹, Angeline Martini¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (dsc.thamires@gmail.com; marcello.efl@gmail.com; gumercindo.ufv@gmail.com; martini.angeline@gmail.com)

O uso público nas áreas naturais protegidas, se mal conduzido, pode representar uma ameaça para a proteção dos recursos naturais existentes. Dessa maneira, uma boa estratégia é a implantação de um sistema de monitoramento e gestão dos impactos da visitação. Considerando a importância da conservação e proteção da natureza e o desenvolvimento do ecoturismo no Parque Estadual do Desengano, o presente trabalho buscou determinar a capacidade de carga turística de uma das trilhas mais visitadas, a Trilha da Cascata, utilizando-se a metodologia proposta por Cifuentes. Tal método leva em consideração fatores biológicos, físicos e a qualidade da experiência da visitação para estimar a quantidade máxima diária de visitantes que uma determinada área pode receber sem apresentar danos ao meio ambiente. A capacidade de carga física (CCF) estimada foi de 14.067 visitantes por dia. A capacidade de carga real (CCR) encontrada foi de 9.969 visitantes por dia, sendo obtida a partir da CCF depois de submetida a fatores de correção. Por sua vez, a capacidade de carga efetiva (CCE) calculada, que considera além dos fatores de correção a capacidade de manejo (CM), foi de 6.879 visitantes por dia. A CCF sofreu uma redução de 29% após aplicação dos fatores de correção selecionados para este trabalho, enquanto a CCR foi reduzida em 31% em função da CM estimada para o parque. Os resultados obtidos permitiram determinar que a capacidade de carga turística para a Trilha da Cascata é de 6.879 visitantes por dia.

Social forests: planning sustainable properties / Matas Sociais: planejando propriedades sustentáveis

Wilson Paiva¹, Sabrina Bicca¹, Marcos Alexandre Danieli², Emilio Ribas³, Joel Franzim Junior³, Rosana Silva³, Suelen Pavanelo³, Giovana Baggio⁴, Paulo Santana⁴
¹Klabin, Telêmaco Borba, Brasil; ²Apremavi, Atalanta, Brasil; ³Sebrae, Londrina, Brasil; ⁴TNC, São Paulo, Brasil (upaiva@klabin.com.br; sbicca@klabin.com.br; marcos@apremavi.org.br; emilio@apremavi.org.br; jfranzim@pr.sebrae.com.br; rosilva@pr.sebrae.com.br; susilva@pr.sebrae.com.br; gbaggio@tnc.org; psantana@tnc.org)

Com o objetivo de estimular a economia local em uma das regiões mais pobres do Paraná, bem como valorizar o trabalho e o protagonismo dos pequenos e médios produtores rurais, aliando desenvolvimento sustentável à preservação da biodiversidade, a Klabin S/A promove, desde 2015, o programa “Matas Sociais”. A iniciativa incentiva a agricultura familiar e auxilia pequenos produtores rurais dos municípios de Ortigueira, Imbaú e Telêmaco Borba em todas as etapas de produção. Em três anos de trabalho, 334 produtores rurais receberam assistência técnica, tiveram acesso a novas tecnologias e mercados, receberam capacitações, participaram de rodadas de negócios e oficinas para novas alternativas de cultivos agrícolas. Os benefícios do programa também se refletem na reconstrução da floresta, de sua função ecológica e dos serviços ambientais associados. Exemplos são os mais de 60 hectares de áreas de preservação permanente restaurados, 17 nascentes protegidas e mais de 136 mil mudas plantadas. Além disso, foi realizado o Cadastro Ambiental Rural (CAR) de 690 propriedades em Imbaú e 1.888 em Ortigueira. O programa contribui ainda no atendimento de 11 das 17 Metas do Milênio, os ODSs da ONU: 1. Erradicação da pobreza; 2. Fome zero e agricultura sustentável; 6. Água potável e saneamento; 8. Trabalho decente e crescimento econômico; 10. Redução das desigualdades; 11. Cidades e comunidades sustentáveis; 12. Consumo e produção responsáveis; 13. Ação contra a mudança global do clima; 14. Vida na água; 15. Vida terrestre; 17. Parcerias e meios de implementação;

Benefit distribution among smallholders in large-scale forestry projects: the case of *Camellia* in China

Jia Li¹, Bettina Bluemling², Zuomin Wen¹

¹Nanjing Forestry University, Nanjing, China; ²The University of Queensland, Queensland, Australia (lijiahy@hotmail.com; b.bluemling@uq.edu.au; zmwen@njfu.edu.cn)

While internationally, large-scale forestry projects have gained importance for local livelihoods, and the implementation of such projects faces various obstacles. Hereby, the equity of benefit distribution is generally considered vital to support a balanced socio-economic development in poor rural areas and guarantee long-term project success. China presents an especially interesting case of smallholder forestry. *Camellia* is a typical Chinese perennial oil-producing wood species, providing non-wood products in sub-tropical areas. Using two cases of (inter)national camellia plantation projects, this research analyzes the distribution of benefits under different so-called forestry project implementation regimes. Empirical research was undertaken in thirty villages in two counties of Jiangxi province, China, applying a survey among over 308 smallholders in 2010, and semi-structured stakeholder interviews in 2010 and 2017. Results show that five implementation regimes of *Camellia* plantations can be distinguished, i.e. individual, partnership, collective-individual, collective, company, each having their own specifics of project access and benefit distribution among smallholders. Collective-individual, collective, and company forest implementation regimes perform better in terms of program access and equal benefit distribution than individual and partnership regimes. But also for the former three regimes, village leaders and companies may seize substantial project benefit reducing the benefits to and marginal smallholders. Finally, some individual and partnership are still continuing the program. Company and collective-individual are searching for new management schemes and technology to solve the problems in the program. These conclusions are policy relevant as in formulating (inter)national forestry projects the local implementation regimes need to be taken into account.

A8a: ECOLOGY, SILVICULTURE AND MANAGEMENT OF TROPICAL DRY FORESTS

Ecology and silviculture of dry forests in the tropics: where we are and where we go

Sven Günter¹, Carlos Ivan Espinosa Iñiguez², Mehdi Pourhasemi³

¹Thünen Institut, Hamburg, Germany; ²Universidad Particular de Loja, Loja, Ecuador; ³Research Institute of Forest and Rangelands, Teheran, Islamic Republic of Iran (sven.guenter@thuenen.de; ciespinosa@utpl.edu.ec; pourhasemi@rifra-ac.ir)

Seasonally dry forests are heavily threatened by human disturbances and climate change. They are particularly affected by fuel wood extraction, exploitation of high value timber species, browsing, and conversion into agricultural land. Additionally they are heavily threatened by fires, with an increasing trend due to climate change. In this presentation we aim to give an introduction to the state of the art of research on dry forest silviculture and management in the tropics. A central issue is to identify ecological research gaps which are of importance for improving the potential for sustainable use. Further on, we discuss future challenges for science and practice which are rooted in the ongoing trends of deforestation, degradation and climate change. Emphasis is set on contributing to the development of management systems and silvicultural tools for sustainable provision of multiple ecosystem services, including fuel wood, timber, biodiversity conservation, and control of soil and water fluxes. By means of a short participatory exercise we invite the audience and participants of the session to identify needs for future research as well as strengths and research foci of the participants. This can be the basis to reinstate the IUFRO working group “Ecology, silviculture and management of tropical dry forests”. You are cordially invited to join the group.

Sustainable Caatinga forest management in NE Brazil: state of the art

Frans Pareyn¹, Enrique Riegelhaupt¹

¹Associação Plantas do Nordeste, APNE, Recife, Brasil (franspar@rocketmail.com; riegelya@yahoo.com)

Caatinga native forest was used since Portuguese colonization for cattle raising and extraction of wood and non-wood forest products. From 1980, wood fuel demand for domestic and industrial use rose sharply. The first research plots on caatinga management were installed in the 80's. The Caatinga forest Management Network was established in 2003: about 185 permanent plots were monitored every 3 years, in more than 85 ha. The network includes seven federal universities, federal and state research organizations and is coordinated by APNE (Associação Plantas do Nordeste), which carried out additional research on commercially managed forests. This study presents some of the main results and conclusions obtained from the experimental areas and commercial stands. Tree diversity is very much site-dependent and it can increase after the forest is cut. After 10-15 years of harvested, no differences are found between clear cut and diverse selective cuttings. Forest growth after harvest follows similar patterns at each site, whichever the cutting regime. Variability between sites and plots can be very high but growth patterns along time are very similar in different plots. Growth rates are mainly defined by

rainfall and can be efficiently predicted by growth equations based on mean annual rainfall as independent variable. The soil properties have almost no effect on the growth after harvest. These results should be urgently considered in forest management regulations and should guide all involved stakeholders (foresters, land owners, environmental agencies and researchers).

Understanding regeneration mechanisms of the Southern African Savannah: the pathway towards developing sustainable Silvicultural systems for the Zambezi woodlands

Annie Namuyya Sikanwe¹, Stephen Syampungani¹

¹The Copperbelt University, Kitwe, Zambia (anniesikanwe@gmail.com; ssyampungani@yahoo.com)

Most African savannas tree species are capable of regenerating both sexually and asexually. However, specific studies on regeneration mechanisms of species of woodland savannas are limited yet integrating the knowledge of regeneration mechanisms of the woodland savannas is a pre-requisite for developing appropriate silvicultural management regimes for this woodland ecosystem. We therefore examined the different regeneration mechanisms of the Miombo woodland tree species in the Zambian forest reserve of Mwekera on Copperbelt Province by excavating the ground and assessing the aerial and basal sprouts within 66 plots along transects of different ages of charcoal abandoned sites. The results show that coppices/sprouts were predominant (77%) compared to true seedling (22.9%). Among the 63 species studied 41 were observed to regenerate through coppicing while others regenerated from both seed and root suckering. Twenty-nine species among which were of the genera *Brachystegia*, *Albizia* and *Julbernardia* were observed to regenerate from both seeds and root suckering. *Brachystegia* species, *Julbernardia paniculata* and *Diospyros kirkii* were observed to develop from all the regeneration mechanisms. Significant difference in terms of the influence of regeneration mechanisms on shoot collar diameter and height development were observed with coppicing ($p < 0.001$) and true seedlings ($p < 0.01$). The variation in regeneration mechanisms and associated influence on shoot development has a direct implication on developing a suitable silvicultural system for Miombo woodlands. Management of Miombo woodland would require a strategy that considers the regeneration mechanisms of major species if we are to sustain the woodlands.

Drivers of land use change: effects on forest structure in Miombo woodlands and implications for sustainable forest management

Christina Jany¹, Jobst Michael Schroeder¹, Davison Gumbo², Moses Kazungu¹, Tiza Mfuni², Sven Günter¹

¹Thuenen Institute for International Forestry and Forest Economics, Hamburg, Germany; ²Center for International Forestry Research (CIFOR), Lusaka, Zambia (christina.jany@thuenen.de; jobst.schroeder@thuenen.de; d.gumbo@cgiar.org; moses.kazungu@thuenen.de; t.mfuni@cgiar.org; sven.guenter@thuenen.de)

In Sub-Saharan Africa, dependency on forests and woodlands is high as people use these as sources for timber and non-timber products for a multiplicity of daily needs and as assets. One of the most important types are the Miombo woodlands. In Zambia, they make up about 80% of the volume of the growing stock. Although studies have attempted to assess the extent and causes of deforestation and forest degradation of the Miombo woodlands, much is still unknown or lacks sufficient data. In our study, we analyse forest structural data, tree species' composition and the regeneration potential on basis of 144 plots in 12 landscapes throughout Zambia, comparing old-growth forests with post extraction and swidden-fallow forests under different use regimes. The inventory data are compared with forest use patterns of the inhabitants living in or near the respective forests on basis of 100 household interviews for each landscape. Emphasis is on tree species with high local demand, including *Pterocarpus chrysothrix*, a tree species, which faces extinction in Zambia. The results of this study will enable us to draw conclusions on current use trends on the assessed landscapes and to develop recommendations for sustainable forest management strategies in the Miombo woodlands and tropical dry forests in general.

Sustainable forest management plans as a tool for sustainable use of the Caatinga: past, present and future / Planos de manejo florestal sustentável como ferramenta de uso sustentável da Caatinga: passado, presente e futuro

Frans Pareyn¹, Enrique Riegelhaupt¹, José Luiz Vieira¹, Mário Marques¹, Elcida Araújo^{1,2}

¹Associação Plantas do Nordeste, APNE, Recife, Brasil; ²Universidade Federal Rural de Pernambuco, Recife, Brasil (franspar@rocketmail.com; riegelya@yahoo.com; jlvieira@gmail.com; mariowm@gmail.com; elcida.araujo@ufrpe.br)

A implementação do manejo florestal da caatinga teve início na década de 80, visando principalmente atender a demanda de biomassa energética. O seu instrumento principal consiste em um Plano de Manejo Florestal Sustentado (PMFS) que contém o inventário florestal e as propostas técnicas de intervenção, licenciado pelos órgãos ambientais. Desde 2005, a APNE vem construindo um banco de dados sobre os PMFS para monitorar a dinâmica do manejo na caatinga. Este estudo objetiva apresentar as principais tendências dessa dinâmica nos últimos 15 anos e as perspectivas futuras. Embora o número total de PMFS tem aumentado, nos últimos três anos observa-se uma queda significativa e preocupante dos PMFS ativos (50% do total). A distribuição dos PMFS concentra-se no Ceará; 40% dos PMFS são pequenos (< 250 ha) e 5% são grandes (> 2.000 ha). Os PMFS pequenos, embora muitos, contribuem pouco para o volume anual autorizado; 15% dos PMFS ocorrem em projetos de assentamento. Atualmente, 59% dos PMFS tem até cinco talhões explorados e apenas 18 dos 473 planos ativos tem mais de oito talhões explorados. O ciclo de corte adotado nos PMFS é definido em função da normativa existente e não baseado em critério técnico. A lenha é o principal produto do manejo oferecendo apenas 0,4 milhões de tMS/ano de uma demanda industrial crescente (atualmente 6,5 milhões de tMS/ano). Perante a necessidade de evitar emissões de Gases de Efeito Estufa, é fundamental identificar os problemas que desestimulam o manejo para reverter o cenário de decadência do manejo na região. (Financiamento CNPq-441310/2017-6).

The role of fire in regeneration of a Colombian tropical dry forest

Angela Parrado-Rosselli¹, Anghy Gutiérrez-Rincón¹, Alejandro Hernandez Cobos¹

¹Facultad del Medio ambiente y Recursos Naturales, Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (aparrador@udistrital.edu.co; anghyforestal@gmail.com; jalhercobos@gmail.com)

In fire-influenced ecosystems some plant species have the ability to germinate and establish after a fire; however, their proportion varies between sites. Currently, there is a debate on the influence of fire in Colombian tropical dry forests (TDF) and if the vegetation has the capacity to regenerate after fire. In that way, in a TDF of the Upper Magdalena River Valley in Colombia, we characterized natural regeneration following a fire and the effect of heat shock on seed germination of dominant legume trees. All seedlings and saplings of woody species were recorded 1.5 years after a fire in 75 2 x 2 m plots installed in burned and unburned sites. Additionally, we exposed seeds of five dominant legume species to nine experimental heat shock treatments (i.e; 80 °C, 100 °C and 140 °C for 1, 3 and 5 minutes). Seeds were then incubated in an acclimatized germination chamber. Regarding natural regeneration following fire, species richness was lower in

burned sites, but the number of individuals was higher than in unburned areas. *Casearia corymbosa*, *Machaerium capote* and *Astronium graveolens* were highly abundant in the burned plots, while poorly represented in the unburned ones. Regarding legumes, *Chloroleucon mangense* and *Enterolobium cyclocarpum* showed heat-tolerant germination while *Pseudosamanea guachapele* was heat stimulated. In contrast *Albizia niopoides* and *Piptadenia* sp were heat sensitive. Our findings indicate that some tropical dry forest species have fire-tolerant traits that should be considered in restoration programs in light of future and more frequent forest fires due to climate change.

Priority areas for conserving biodiversity and ecosystem services in dry tropical forests in the Upper Magdalena river basin (Colombia) / Áreas prioritarias de conservación de la biodiversidad y los servicios ecosistémicos del bosque tropical seco en la cuenca alta del río Magdalena (Colombia)

Luz Piedad Romero-Duque¹ ; María Fernanda Batista Morales¹, Jessica Alejandra Vargas González¹, Patricia Balvanera Levy², Víctor Jaramillo Luque²
¹Universidad de Ciencias Aplicadas y Ambientales, Bogotá, Colombia; ²Instituto de Investigación en Ecosistemas y Sustentabilidad, Morelia, Mexico
 (luz.romero@udca.edu.co; mfbatistam@gmail.com; alejavargas@gmail.com; pbalvanera@cieco.unam.mx; luque@cieco.unam.mx)

Uno de los aspectos más importantes para tener en cuenta en el ordenamiento territorial es la conservación de bienes y servicios ecosistémicos. Esto se puede hacer mediante la identificación de áreas prioritarias. Estas áreas surgen cuando están en riesgo o son vulnerables a cambios que disminuyen su capacidad para proveer el servicio o actividad considerada. El área de distribución del Bosque tropical seco (BsT) de la cuenca alta del río Magdalena en Colombia ha disminuido un 87% y se encuentra amenazado por proyectos viales. Para identificar áreas prioritarias de conservación de este ecosistema 1) caracterizamos la diversidad y estructura de 12 parches de bosque, 2) establecimos la variación espacial de la diversidad, su magnitud y estado de conservación e 3) identificamos la variación espacial de servicios de regulación climática, retención de agua y prevención de la erosión. La diversidad, estado de conservación y prestación de servicios ecosistémicos del BsT son mayores en los departamentos de Tolima y Cundinamarca. La superposición la información espacial indica que el 20% de los 2018 km² de BsT son de alta prioridad de conservación y se distribuyen en su mayoría en Tolima (407.6 km²) y Cundinamarca (142.9 km²), mientras que en el Huila se presenta baja prioridad de conservación. Por ello, en Tolima y Cundinamarca el ordenamiento debe apuntar a la conservación y, en Huila debe apuntar a la restauración y la recuperación de este ecosistema. Esto teniendo en cuenta la tenencia de la tierra, la accesibilidad y las presiones o amenazas.

Ecological vulnerability of *Anacardium excelsum* caused by climate variability in areas of dry tropical forest in the Magdalena Valley, Tolima, Colombia / Vulnerabilidad ecológica de *Anacardium excelsum* causada por la variabilidad climática en áreas del bosque seco tropical, valle del Magdalena, departamento del Tolima. Colombia

Luis Alfredo Lozano Botache¹, Omar Aubrelío Melo Cruz¹, Miguel Ángel Quimbayo Cardona¹
¹Universidad del Tolima, Ibagué, Colombia (llozano@ut.edu.co; omelo@ut.edu.co; miguelq@ut.edu.co)

En el bs-T del departamento del Tolima, la demanda del maderable *Anacardium excelsum* ha conllevado a su disminución poblacional. Un estudio previo determina que su distribución poblacional es aleatoria y que se requieren 80 años para conseguir dimensiones de corta comercial. Este hecho se suma al cambio de uso de áreas de bosques hacia la ganadería y la agricultura, y al riesgo por variación climática. Para evaluar la vulnerabilidad ecológica de la especie ante la variación climática, se tomaron tres sitios de muestreo al norte del Tolima, con mediciones semestrales de crecimiento diamétrico y la homogeneización de mediciones climáticas de 52 estaciones meteorológicas en torno y con influencia en el área de estudio. Con ello, por modelo determinístico, se contrasta el crecimiento diamétrico de *A. excelsum* versus los extremos de temperatura y lluvia causados por el fenómeno del niño, durante los últimos ocho años. Se estiman rangos de tolerancia climática y plasticidad para adecuarse a las nuevas condiciones ambientales y la capacidad para mantener su población en su área de distribución del bs-T. Los resultados son evidencia científica que aporta a las decisiones de la gestión de los recursos naturales en el departamento del Tolima. Esta investigación será modelo para estimaciones similares en otras especies forestales.

The role of stem traits in *Cordia alliodora* survival after a fire in a Colombian tropical dry forest

Angela Parrado-Rosselli¹, Laura Carolina Segura¹
¹Facultad del Medio Ambiente y Recursos Naturales, Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (aparrador@udistrital.edu.co; lauraseguratrana@gmail.com)

Plant species exhibit fire resistance and tolerance traits in fire prone ecosystems that allow them to survive or to generate new individuals after a fire. For instance, bark thickness protects trees and epicormic buds from fire, while stem height may allow apical buds to escape being scorched after a fire. Currently, there is a debate on the influence of fire in Colombian tropical dry forests (TDF) and if the vegetation has the capacity to regenerate after fire. Therefore, we evaluated whether bark thickness, stem height and diameter of *Cordia alliodora* (Boraginaceae), a representative tree species of these forests, was associated with stem survival and resprouting. In that way, 149 *Cordia alliodora* individuals were sampled, after a fire, in a Tropical Dry forest in the Upper Magdalena Valley Colombia. The number and type (epicormic or basal) of resprouts per individual, bark thickness, tree height and DBH were recorded for all individuals in a 2 ha plot. Results showed that most trees (66%) survived after the fire. Stem survival was positively correlated to stem height and bark thickness. Epicormic resprouting was more common than basal resprouting, and was positively associated to height and bark thickness. Stem diameter was not a strong predictor of stem survival or resprouting. Our results suggest that *Cordia alliodora* has both fire resistance and tolerance traits, as the species avoids fire-death by a combination of stem-height and bark thickness, as well as most of the surviving individuals exhibited either (or both) epicormic or basal resprouting after fire.

Changes in soil hydraulic properties, soil moisture and water balance in *Acacia senegal* plantations of varying age in Sudan

Wafa Abaker¹, Frank Berninger², Mike Starr³
¹University of Khartoum, Khartoum, Sudan; ²University of Eastern Finland, Kuopio, Finland; ³University of Helsinki, Helsinki, Finland
 (wafaadam59@yahoo.com; frank.berninger@uef.fi; mike.starr@helsinki.fi)

We investigated the effects of *Acacia senegal* trees on soil moisture (SM) and hydraulic properties in relation to plantation age (7 to 24 years) in two semi-arid sites in Sudan. Adjacent grasslands at the two sites were used for comparison. Profiles of SM contents were measured for two years (2011-2012) using Time Domain Reflectometry (TDR). Daily water balances of the plantations and grasslands were computed using a simple water balance model and temperature and rainfall data nearby meteorological station. The TDR SM data was used for model calibration purposes. Hortonian runoff was calculated using the SCS runoff curve number (CN) method and evapotranspiration calculated using Jensen-Haise global radiation reference crop evapotranspiration, seasonal crop coefficients

derived from MODIS NDVI values, and a soil water availability index. Soil hydraulic parameter values were derived using pedotransfer functions based on measured soil texture and soil organic carbon (SOC) contents. Measured SM contents in the plantations were lower than in the grasslands, but increased with plantation age, reflecting a similar trend in SOC contents and related plant available water holding capacities. Annual runoff was lower from the plantations because of increased infiltration, while evapotranspiration was higher which resulted in reduced drainage and lower SM contents, as shown by measurements. Greater SM contents in the grasslands were attributed to the lower evapotranspiration and resulted in the greater drainage fluxes compared to the plantations. The study highlighted the need for more empirical studies on the effect of trees on the water balance of savanna woodlands in Africa.

A8b: FORECASTING THE EFFECTS OF LAND-USE ON WILDLIFE COMMUNITIES AND CONFLICT AT HUMAN-WILDLIFE INTERFACE

Stable isotope niche segregation and overlap amongst rare antelope and other sympatric bulk grazers from a West African Savanna

Chabi Djagoun¹, Nicole Wrage-Mönnig²

¹Laboratory of Applied Ecology/University of Abomey Calavi, Calavi, Benin; ²Grassland and Fodder Sciences, Agricultural and Environmental Faculty, University of Rostock, Rostock, Germany (dchabi@gmail.com; nicole.wrage-moennig@uni-rostock.de)

Understanding the mechanisms of species coexistence within local assemblages can play a crucial role in conservation of a species. There is little understanding of how large mammalian bovid species from West Africa partition diet resources, and to what extent the rare antelope and other sympatric bulk grazers can cope with this co-existing system. Using teeth stable isotopic composition data we studied an assemblage of three sympatric grazers (topi, hartebeest and roan) with different population density. We find little evidence for diet niche overlap between rare antelope with bulk grazing species. The sizes of the dietary isotopic space was higher in hartebeest ($1.30 \pm 1.14 \text{‰}^2$) and roan ($1.86 \pm 0.88 \text{‰}^2$) compared to topi ($0.26 \pm 0.19 \text{‰}^2$) with a significant variation at individual scale. This high variation of isotopic niche at individual level in hartebeest and roan species revealed that within species variation of stable isotope ratios explained the isotopic niche breadth of the study species better than between-species variation. The isotopically partitioning of dietary niches at individual scale may facilitate coexisting in rare and high density ungulate community.

The “Bird Detectives” environmental education program / O programa de educação ambiental “Detetives de Aves”

Lilly Briggs¹

¹Cornell Lab of Ornithology, Ithaca, USA (lpb29@cornell.edu)

Detetives de Aves é um programa de educação ambiental que foi criado pelo Laboratório de Ornitologia da Universidade de Cornell, que pretende ampliar os conhecimentos das crianças sobre ciência e meio ambiente através das aves. Ele também busca desenvolver a capacidade de os estudantes participarem ciência cidadã, observando aves e inserindo os dados no site do eBird (www.ebird.org [<http://www.ebird.org/>]). Nesta oficina, os participantes vão obter experiência com o uso do programa, e como podem engajar seus estudantes na ciência cidadã do eBird para poderem apoiar os esforços de conservação.

Forest structure modulates the response of wildlife to human recreation

Veronika Braunisch^{1,2}, Coppes Joy¹, Rudi Suchant¹, Ursula Nopp-Mayr³

¹Forest Research Institute of Baden-Wuerttemberg, Freiburg, Germany; ²University of Bern, Bern, Switzerland; ³University of Life Sciences and Natural Resources, Vienna, Austria (veronika.braunisch@iee.unibe.ch; joy.coppes@forst.bwl.de; rudi.suchant@forst.bwl.de; ursula.nopp-mayr@boku.ac.at)

Outdoor recreation activities in forest ecosystems are growing in popularity, causing increasing pressure on wildlife. There are various ways in which wildlife reacts to recreation activities, ranging from behavioural to physiological responses, with regional variation in response-intensity within the same species. We tested whether negative effects of human recreation on wildlife are modulated or even mitigated by habitat suitability, i.e. forest structures providing food and cover. Based on radio-telemetry and a systematic, plot-based survey of species presence and forest structure over 13 years in 13 study regions across central Europe, we studied how recreation infrastructure and habitat suitability interact and affect local habitat use and population densities of an endangered model species: the Western Capercaillie (*Tetrao urogallus*). Radio-telemetry revealed the species avoidance of recreation infrastructure with seasonal differences in avoidance-distances. Moreover, avoidance was stronger under poor habitat conditions, while it was mediated by high habitat suitability. Population densities varied greatly between study years and regions and were mainly determined by habitat suitability. However - independently of habitat conditions - densities dropped markedly when more than 50% of the area was influenced by human recreation. Our results indicate that negative effects of recreation activities can to some extent be mitigated by forest management measures improving habitat suitability; however this has limits because it only affects local habitat use but not regional population densities. For the latter, we stress the importance of recreation-free areas in human-dominated landscapes which act as refuges for wildlife.

Sustainable collection of *Bertholletia excelsa*: coexistence between humans and dispersers

Lúcia Helena de Oliveira Wadt¹, Camila Lima Faustino², Christina L. Staudhammer³, Karen A. Kainer⁴, Joziane Silva Evangelista⁵

¹Embrapa Rondônia, Porto Velho, Brasil; ²Instituto Federal de Educação, Ciência e Tecnologia do Acre, Tarauaca, Brasil; ³Universidade do Alabama, Departamento de Ciências Biológicas, Tuscaloosa, USA; ⁴Universidade da Florida, Escola de Recursos Florestais e Conservação, Gainesville, USA;

⁵Universidade Federal do Acre, Rio Branco, Brasil (lucia.wadt@embrapa.br; camila.faustino@ifac.edu.br; cstaudhammer@ua.edu; kkainer@ufl.edu; joziane.gestorambiental@gmail.com)

We tracked whole fruits of *Bertholletia excelsa* during primary (fruitfall) and secondary mammalian fruit dispersal. *Dasyprocta* spp. is particularly important for *B. excelsa*, because it is the main disperser and often buries *B. excelsa* seeds, facilitating seed germination and early seedling establishment. We asked: (1) Given a short and synchronous fruiting period, what patterns of primary and secondary fruit dispersal emerge? (2) Do rainfall and local vegetation affect dispersal? We monitored date of fruitfall and condition of individual fruits from 20 trees over a 20 ha area, sequentially visiting each study tree on average every 3-4 days. As expected, primary dispersal was fairly synchronous over 3-month period. While 6855 observed fruits were falling, scatterhoarders were removing some to outside tree crown projection (4.1%) and opening a much smaller proportion (0.5%) under mother trees. Approximately ¼ fruit opening or removal occurred within 5 days of fruitfall. More fruits were opened or removed when subcanopy vegetation had higher bamboo density or lower densities of saplings and trees. While humans directly compete with native dispersers/predators for *B. excelsa*'s seeds, our results revealed that prior to human collection in mid-January, 94%

of fruits had fallen, and mammal dispersers had already accessed (moved beyond the canopy, consumed or buried) 197 fruits (2.9%) or approximately xx seeds. Considering our dispersal findings, cumulative research and collective understanding of the *Bertholletia-Dasyprocta-Homo sapiens* interactions, we conclude that Brazil nut harvests boost rural incomes and in our study site, likely do not threaten Brazil nut recruitment or maintenance of agouti populations.

Consultations between forestry and reindeer husbandry in Sweden: history, status and possibilities for a land-use partnership and an inclusive co-management process

Ulrika Roos¹

¹Department of Forest Resource Management, Umea, Sweden (ulrika.roos@slu.se)

Functioning coexistence between different land users is usually a central part of sustainable resource management. In Northern Sweden, forestry and reindeer husbandry are the two major land use practices that overlap spatially. Thus, sustainable forestry is greater than the sum of its parts and requires implements for coexistence. To facilitate the coexistence, consultations between forest land owners and reindeer herders has been carried out since 1954. However, long lasting conflicts indicate that the consultation procedures have not been satisfactory and also that the purport of the consultations is unclear to the participants. Drawing on Arnsteins (1969) ladder of participation and Wandéns (1997) classification of different conflicting goals, this paper address the concept of consultation and participation in relation to how it has been carried out in this particular context. Relevant literature will be reviewed, together with an in-depth analysis of the process based on protocols from consultations and notes from meetings of the Central Advisory Group for Reindeer Husbandry and Forestry, as well as observations during ongoing consultations. Identified problems and opportunities will be used towards an improved and more inclusive co-management process.

Changes in conservation values in modified forest: Does human involvement affect its land use pattern and wildlife presence?

Shoma Jingu¹, Keisuke Sakata², Taiichi Ito²

¹Division of Appropriate Technology and Sciences for Sustainable Development, Graduate School of Life and Environmental Sciences, University of Tsukuba, Tsukuba, Japan; ²Faculty of Life and Environmental Sciences, University of Tsukuba, Tsukuba, Japan (s1730263@s.tsukuba.ac.jp; sakata.keisuke.gn@u.tsukuba.ac.jp; ito.taiichi.ft@u.tsukuba.ac.jp)

Conservation of biodiversity is an important issue not only in protected areas but also in secondary natural environments which have been modified by many years of human use. One typical example in Japan is a “satoyama” forest. Satoyama is considered symbolic of human-nature coexistence as it is a forest based on traditional, sustainable use of natural resources. The government is putting its efforts in conserving the satoyama which is decreasing in coverage. However, it is questioned whether conservation of present state satoyama can play a similar role of traditional human-nature coexistence. Here we show the historical change of satoyama through satoyama-related land use and wildlife presence. In Tsukuba city, located 50 km North East of Tokyo, we found that many satoyama remnants have undergone various changes in its land use and have equally affected wildlife presence. Some areas have changed far enough to question the human-nature coexistence conservation value of satoyama. Although largely changed satoyama may retain wildlife conservation value through provision of habitats, we found changes in observed wildlife. While we agree that human-modified forests are important for conservation, change in usage patterns result in varied environmental outcomes. This study provides an example that traditional human-nature coexistence should not necessarily be the primary conservation value in secondary natural environments which are subject to change in human involvement.

Community forestry and crop raiding: understating feedback effect of community-based forest policy in Nepal

Rajesh Bista¹

¹University of North Carolina at Chapel Hill, Carrboro, USA (raaj@live.unc.edu)

Community forestry (CF) in Nepal has improved forest condition significantly and has become a key source of rural livelihood. As a result, Nepal’s forest cover increased from 37% in 1986 to 45% at the present. Approximately 30% of Nepal’s forest is under community management. However, there is no empirical study that assessed impacts of wildlife on crops/livestock with increase in forest cover and improvement of habitat quality because of CF. We adopted the coupled natural-human systems framework to examine the feedbacks to the human from natural systems. We carried out a survey with 215 households in 2018 across seven CF in the Kavrepalanchok, Nepal. We found that crop-raiding is one of the main reasons for agriculture-land abandonment. Study shows that 16% of cropland abandonment were solely caused by crop-raiding by wildlife; 39.9% of cultivated land-parcels have suffered damage from wildlife (monkey, wild-boar, porcupine), though the intensity is different among communities. More than 88% of the farmers perceived that the increase in forest stock in CF is the major reason behind increasing incidences of crop-raiding. Farmers from higher caste suffered most as they have comparatively higher amount of land holdings. Though Nepal government has formulated Wildlife Damage Relief Guideline 2069, none of the farmers have claimed for compensation for the crop-damage due to lengthy bureaucratic procedure. Moreover, monkey is not included within the government relief scheme. These findings suggest addressing these issues from policy level as well as recommends introducing wildlife conflict management measures in operational plan of CF.

Human-primate conflict in Brazilian pine plantations: linking production and conservation through research

Sandra Bos Mikich¹, Dieter Liebsch², Edilson Batista de Oliveira¹, José Mauro Magalhães Avila Paz Moreira¹

¹Embrapa Florestas, Colombo, Brasil; ²Dieter Liebsch Consultoria Ambiental, Curitiba, Brasil (sandra.mikich@embrapa.br; dieterliebsch@yahoo.com.br; edilson.oliveira@embrapa.br; jose-mauro.moreira@embrapa.br)

Capuchin monkeys (*Sapajus nigritus*) saw part of their native habitat replaced by other land uses as pine plantations in South Brazil. With the gradual reduction in food (mainly fruit and insects) supply, they have included pine sap in their diets giving rise to a conflict with the wood industry. Our multidisciplinary team have been studying this sensitive issue since 2003 as the impact on production is significant but capuchins are native protected species and provide important ecological services. One of the outcomes of this research is that, contrary to everybody’s expectations, we have found that capuchin populations are quite low, preventing any direct management. Additionally, we have established procedures, variables and parameters to evaluate capuchins’ damage translated into a computer tool that allow us to forecast impacts on production. We have also classified subtropical and tropical pine species based on the preference of this primate. As a result, depending on the degree of damage we might indicate the management of the pine stand, the replacement of *Pinus taeda* (preferred species) by *P. patula* (avoided species) and/or native forest enrichment using fruit species that are important in the capuchin’s diet based in local long-term studies. This way we expect to reconcile wood pulp/timber production and conservation.

Understanding the livestock depreddations pattern by sympathetic carnivores in tropical deciduous forest of Western India

Randeep Singh¹

¹Amity University, Noida, India (rsingh18@amity.edu)

We investigated the influence of environmental and socio-ecological factors on livestock depredation by carnivores in pastoral villages conflicts pattern in pastoral villages adjacent to Ranthambhore Tiger Reserve (RTR), Rajasthan, India a protected area situated in tropical dry deciduous forest and characterized and examined the causes of conflicts. Both leopards (*Panthera pardus*) and tiger (*Panthera tigris*) are sympatric and involved in depredation and responsible for 81 %, and 19 %, of attacks on livestock, respectively. Examination of cattle kills indicate that leopards killed a significantly greater proportion of smaller livestock (e.g., goats and calves), whereas tigers killed a significantly greater proportion of larger livestock (e.g., cows and bulls). The livestock depredation was 44% in summer and 56 % in winter by both felids. Of the depredation on livestock by leopard was majority (81%) were goats, sheep, and calves (72%) and where as 28% cow and bull. Information-theoretic evaluation of models found that leopard kills livestock inside villages during night time, while tiger kills livestock outside villages. Even leopard attack caused the greatest overall financial loss to villagers, which negatively affected local tolerance towards carnivores. To improve both large carnivore and local livelihood prospects, conservation and development projects should be trailed as conflict mitigation strategies.

A9d: COMMITTED AND HELD ACCOUNTABLE? EXPLORING ACCOUNTABILITY RELATIONS OF STATE, BUSINESS AND CIVIL SOCIETY ORGANISATIONS IN MULTI-LEVEL FOREST GOVERNANCE

The politics of designing accountability in REDD+ benefit sharing

Grace Wong¹, Maria Brockhaus^{2,3}, Moira Moeliono⁴, Thu Thuy Pham⁴

¹Stockholm University, Stockholm, Sweden; ²University of Helsinki, Helsinki, Finland; ³Helsinki Institute of Sustainability Science, Helsinki, Finland; ⁴Center for International Forestry Research, Bogor, Indonesia (grace.wong@su.se; maria.brockhaus@helsinki.fi; m.moeliono@cgiar.org; t.pham@cgiar.org)

Benefit sharing mechanisms (BSMs) related to forest exploitation and conservation has long been an area of contestation. Conflicts have arisen over perceived injustices in how and what benefits and burdens are allocated between the State, private or non-governmental entities and forest communities (Myers and Muhajir 2015), around inclusion and exclusion in decision-making processes, and in the inadequacies of benefits relative to burdens (Luttrell et al; 2017). These conflicts are often exacerbated by a lack of accountability and transparency in the design and implementation of benefit sharing mechanisms, and can lead to risks of elite capture, perceived inequity and illegitimacy of the policy process, and dis-incentivizing behavior to reduce deforestation (Loft et al; 2016). Accountability would have to include an assessment of the interests and biases of state, private sector, international and non-governmental institutions (Kramarz and Park 2016) in the design of BSMs, which would determine what to account for and to whom. In this paper, we focus on the relational aspect of accountability: who are held accountable to those who have the right to hold to account (Biermann and Gupta 2011). We draw on data from a global comparative study to assess the stances of different groups on who should benefit from REDD+, how these influence the design of REDD+ BSMs and hence, identify what REDD+ is accountable for and to whom. We draw on environmental governance practices ranging from safeguards, grievance mechanisms, anti-corruption mechanisms and transnational legal instruments to identify potential accountability structures for design of REDD+ BSMs

Certification in the Brazilian palm oil production chain: A case of socioenvironmental responsibility? / Certificação na cadeia produtiva de óleo de palma no Brasil: Um caso de responsabilidade socioambiental?

Susane Ferreira¹, Claudia Azevedo-Ramos¹

¹Universidade Federal do Pará, Belém, Brasil (susane_cristini@hotmail.com; claudia.azevedoramos@gmail.com)

Empresas de óleo de palma (dendê) têm procurado a certificação por exigências mercadológicas. Dentre os vários disponíveis está o da “Round Table on Sustainable Palm Oil” – RSPO, que dita os padrões do óleo de palma sustentável. No Brasil, o grupo Agropalma é um dos maiores produtores de óleo de palma e, portanto, tem grande visibilidade. Este estudo revisou os compromissos de sustentabilidade declarados pela Agropalma, sua inserção no sistema de certificações e comparou com os estudos recentes que avaliam seu desempenho socioambiental. A Agropalma tem declarado compromisso com o desmatamento zero e a conservação de florestas nativas. Tem, ainda, demonstrado interesse na melhoria de seu desempenho, comprovado pela conquista de 12 selos de qualidade e certificação de acordo com os padrões RSPO. No entanto, vários estudos criticam sua responsabilidade socioambiental atribuindo ao grupo empresarial a subordinação dos agricultores familiares à empresa, êxodo rural, ameaças ao sistema de produção local, pressão sobre a mata secundária, tratamento inadequado dos resíduos agroindustriais, com contaminação de rios, e preservação inadequada do capital natural e de seus serviços ecossistêmicos. Embora a Agropalma tenha demonstrado ações em direção a uma produção mais sustentável, ainda há críticas quanto ao seu desempenho. Conclui-se que a sustentabilidade na produção do óleo de palma ainda depende de um aperfeiçoamento na interação empresa-órgãos certificadores- pesquisas para garantir um progresso contínuo nos padrões exigidos e na sua conformidade.

Transparency and accountability in monitoring national scheme on payment for forest environmental services-lessons learnt from Vietnam

Thuy Pham Thu¹, Tien Nguyen Dinh¹, Long Hoang Tuan¹, Chi Dao Thi Linh¹, Thang Le Manh²

¹Center for International Forestry Research, Hanoi, Vietnam; ²Son La forest protection and development fund, Son La, Vietnam (t.pham@cgiar.org; ndtien.up@gmail.com; bberviet@gmail.com; chi.daolin161194@gmail.com; thanglnsl@gmail.com)

Payment for forest environmental services (PFES) is seen by Vietnamese policymakers as one of breakthroughs in forestry sector. PFES is run and managed by state agencies but there is a lack of rigorous and scientific assessment on actual impacts of PFES on environment and local livelihood. Moreover, legal framework on monitoring and evaluation of PFES in Vietnam is still at infant stage. Public and private sector who have paid PFES fee through water and electricity bills have raised concern on transparency and accountability of the schemes in the absence of no available data on effectiveness of PFES schemes. This paper investigates enabling and hindering conditions for transparency and accountability in monitoring and implementing PFES policy in Vietnam as well as draw out lessons learnt for improved forest governance. We found that PFES has enhanced transparency and accountability in forest monitoring as it creates additional funding and independent agencies to verifying government forest inventory results. However, transparency and accountability of government reporting on PFES results are impeded by political interests and political missions of governmental agencies to only report

on program positive outcomes, conflicts of interests and unclear responsibilities amongst government agencies, elite capture in natural resources and information, and the lack of political space given to local communities and non-state actors to take part in monitoring and evaluation process. Our paper suggests that enhancing transparency and accountability in monitoring and implementing PFES requires not only application of advanced technology but also to address underlying politics of numbers.

Lessons from land management platforms: model forests in Latin America / Lecciones aprendidas de las plataformas de gestión territorial: caso de los bosques modelo de Latinoamérica

Fernando Carrera¹, Roger Villalobos¹, Leonardo Duran², Claudia Rojas¹

¹CATIE, Turrialba, Costa Rica; ²Universidad Mayor, Santiago de Chile, Chile (fcarrera@catie.ac.cr; rvillalo@catie.ac.cr; leonardo.duran@umayor.cl; claudia.rojas@catie.ac.cr)

Los Bosques Modelo son plataformas de gobernanza para la gestión territorial que vienen operando en Latinoamérica desde hace dos décadas. Estas plataformas están enlazadas a través de la Red Latinoamericana de Bosques Modelo (RLABM) que reúne a 33 territorios de incidencia en 14 países y el apoyo de organizaciones internacionales como FAO, CUSO, CIFOR, CIAT y CATIE. La RLABM es parte de la Red Internacional de Bosques Modelo (RIBM) que aglutina a más de 70 plataformas en 30 países a nivel global. La investigación sintetiza las principales lecciones aprendidas de estos procesos de gestión territorial en Latinoamérica, mismos que son reconocidos como un espacio que favorece la articulación de actores del ámbito público, privado y de la sociedad civil para responder a las oportunidades y desafíos del desarrollo sostenible en un territorio de interés común. Estas lecciones fueron obtenidas con base en entrevistas, revisión de documentación y visitas de campo. Entre los aprendizajes se destacan la necesidad de involucrar a los gobiernos locales e instituciones académicas en la gestión de estas plataformas; la conveniencia de que organizaciones locales asuman con mayor peso el liderazgo; la importancia de contar con personal y un mínimo de recursos físicos y financieros; el peligro que representan los cambios en las políticas gubernamentales en la continuidad del proceso; la conveniencia de contar con planes estratégicos participativos; lo determinante del liderazgo social, el compromiso de los socios y la identidad territorial. Se resalta que el establecimiento de alianzas estratégicas desde la acción favorece la sostenibilidad de la gobernanza.

Interests and conflicts in forest management: Who possess power in Slovakian forest governance?

Yvonne Brodrechtova¹, Róbert Sedmák¹, Ján Bahyl¹, Michal Bošela¹, Ján Ján Tuček¹

¹Technical University in Zvolen, Zvolen, Slovakia (yvonne.brodrechtova@tuzvo.sk; robert.sedmak@tuzvo.sk; jan.bahyl@tuzvo.sk; michal.bosela@tuzvo.sk; jan.tucek@tuzvo.sk)

The actor landscape in Slovakian forestry has become more diverse since the early 1990s due to the transition from planned to market economy. This has led to various conflicts among actors concerning forest management and its output: ecosystem services (ES). Who are the relevant actors and what power resources they possess to act in forest management today? Based on the actor-centered power approach the actors' interests in ES and power to drive forest management were assessed based on the ability of actors to apply the mechanisms of coercion, incentives, and dominant information. The results of 38 in-person interviews and participatory observations revealed that both actors both inside and outside of the forestry arena drive forest management in Slovakia. However, governmental actors in forestry, environment (with various interests in ESs) and agriculture are still the most powerful and have the highest impact on forest management. Moreover, the governmental actors are often influenced by businesses rather than politics. The power is increasingly being taken by businesses, which either formally (e.g., associations, (environmental) non-governmental organizations) or informally (e.g., media, lobbying) influence forest politics. In contrast to actors representing the environment via various non-governmental organizations that exercise medium power in the forest arena, the actors in forestry represented via various associations have a rather low impact. As a result, forest management research should focus more to power resources and relations of actors acting on forest management. If not, powerful actors driving forest management may use conflicts for their benefit and avert balanced ES trade-off.

Puzzle pieces or poker chips? How citizens use multistakeholder forums to hold government and NGOs accountable

Anne Larson¹, Juan Pablo Sarmiento Barletti¹

¹CIFOR, Lima, Peru (a.larson@cgiar.org; j.sarmiento@cgiar.org)

Greater coordination and collaboration among actors – particularly across governance levels and sectors – is one of the main strategies proposed to support the achievement of climate goals regarding land and forest use. Such strategies have recently been referred to as landscape approaches, multistakeholder initiatives or jurisdictional approaches, but they emerge from a history of similar efforts at participatory processes, integrated conservation and development initiatives or co-management arrangements. To what extent have these past experiences informed current efforts at collaboration? How are new initiatives addressing power relations and inequity in order to assure legitimacy and accountability in processes and outcomes? This paper is based on the comparative analysis of 14 multistakeholder forums (MSFs) established to conserve forests and/or improve land use, primarily in subnational jurisdictions. We focus on four countries - Brazil, Peru, Indonesia and Ethiopia – and specifically on forums that bring together subnational (and sometimes national) government, NGOs, grassroots organizations and private sector stakeholders in a specific geographical location. Data were collected through 30 to 40 structured, in-depth interviews for each MSF, with organizers, participants and non-participants, as well as with key informants who have knowledge and firsthand experience on the context of forest management in each region. In four cases, focus groups were conducted with rural communities. This article analyzes approaches to addressing power differences and inequities across the MSFs and, specifically, the obstacles and opportunities for actors from marginalized groups (indigenous people, peasants, women) to voice their concerns and to influence the forums' agenda and outcomes.

A9e: FORESTRY IN TRANSITION? FOREST POLICIES IN CHANGING SOCIETIES. PART 1: EUROPE

Evolution of Estonian forest policy during and after transition

Paavo Kaimre¹

¹Estonian University of Life Sciences, Tartu, Estonia (paavo.kaimre@emu.ee)

The presentation covers the most important forest policy decisions in Estonia during and after transition period. Forest policy is observed in interaction with country's development and general economic policy. Forestry related legislation has played a major role in the policy implementation. Consequently, remarkable number of changes and completely new versions of Forest Act have been passed by the Parliament. For example, one of the main goals of the 1993 Forest Act was to create a basis for private forest ownership; Forest Act passed in 1998 focused on the reform of public forest management; changes in legislation in the 21st century are mostly related to the principles and rules of forest management. Another very important document influencing the whole forest sector is the Estonian Forestry Development Program. The first national program was approved by the Parliament in 2002, the second in 2011, and the preparations for the third one were started in 2018. The most important goals and measures listed in the development programs have been shortly analysed. The policy formulation process has been changed remarkably within decades, from the decisions made by public administration to the open debate and participation of stakeholders. At present, the public interest and expectations on forestry are higher than ever, therefore the involvement of interest groups and scientific expertise into the policy making is crucial.

Good-bye to command-and-control in forest governance? A critical analysis of two countries after socio-economic transition

Ekaterina Makrickiene¹, Vilis Brukas², Yvonne Brodrechtova³, Gintautas Mozgeris¹, Róbert Sedmák³, Jaroslav Šálka³

¹Vytautas Magnus University, Kaunas, Lithuania; ²Swedish University of Agricultural Sciences, Alnarp, Sweden; ³Technical University in Zvolen, Zvolen, Slovakia (ekaterina.makrickiene@asu.lt; vilis.brukas@slu.se; yvonne.brodrechtova@tuzvo.sk; gintautas.mozgeris@asu.lt; robert.sedmak@tuzvo.sk; jaroslav.salka@tuzvo.sk)

Sharing similar socialistic past and almost three decades of transition from planned to market economy, Lithuania and Slovakia had to cope with the legacy of command-and-control approach in forest governance and management. Our study is aimed to theorise on criteria suitable to judge the degree to which forestry in a given country is steered by command-and-control as opposed to the more adaptive forms of governance and to apply the devised analytical framework for the selected case countries. The analysis involves five criteria, four of which - efficiency, equity, transparency and participation - stem from the framework of good governance. The fifth criterion - adaptiveness - corresponds to the concept of adaptive governance. The analysis was based on desktop research, expert opinions and stakeholder interviews. Both countries perform rather well in transparency, not least in terms of comprehensive data on forest resources. The performance for all other criteria is poor: economic efficiency is low, forest owners lack decision freedom and face injustice, wide public participation is weak, and the adaptive capacity of forest management low. This leads to the conclusion that, despite the economic and societal transition, the command-and-control forest governance is still in full effect in Lithuania and Slovakia. There is a long way to go towards more adaptive governance characterised by flatter hierarchies, lighter regulative load and bigger decision freedom.

Is there a transition towards participatory forest governance in Ukraine?

Maria Nijnik¹, Simo Sarkki², Mariana Melnykovich³, Ivana Zivojinovic⁴

¹James Hutton Institute, Aberdeen, United Kingdom; ²University of Oulu, Oulu, Finland; ³Ukrainian National Forestry University, Lviv, Ukraine; ⁴BOKU, Vienna, Austria (maria.nijnik@hutton.ac.uk; simo.sarkki@oulu.fi; mariana.melnykovich@ukr.net; ivana.zivojinovic@boku.ac.at)

Is there a transition in forest governance in Ukraine? What are the pathways to change? How do people see the future? What are the dominant public attitudes concerning the transition? What policies can be designed and operationalised using socially innovative tools, strategies and adaptive management practices? We conducted a national level survey on forest governance, and complemented the use of participatory methods with the application of Q-methodology on public attitudes towards forestry-in-transition. We analyzed the results by discourse analysis and inductive content analysis. The findings indicate that deliberative governance systems can enhance collective agreement on: (i) how to achieve desirable trade-offs between non-marketed and provisioning ecosystem services and (ii) which strategies, policy instruments and management tools to use to promote sustainable forestry. Results suggest that participatory decision-making processes and collaborative networks, involving scientists and other relevant stakeholders can assist in the development of a better understanding of the drivers and pathways of change, and demonstrate how these drivers may affect the forestry sector and local communities, residing in wooded areas. The findings indicate that tuning of participatory processes is often insufficient to achieve transition from authoritative state to democratic and participatory forest governance. This is due to institutional inertia and unwillingness to decentralize decision-making power. Our results offer some useful insights into innovative responses to addressing the challenges faced by the sector and forest-dependent communities, specifically through the promotion of social innovation and linked novel governance mechanisms. Acknowledgement: The project on Social Innovation in Marginalised Rural Areas (SIMRA) is supported by the European Commission (GA 677622).

Professional forest manager - as an instrument for sustainable forest management in private forests

Zuzana Sarvašová¹, Vilém Jarský², Jaroslav Šálka³, Zuzana Dobšínská³, Milan Sarvaš⁴

¹Department of Forest Policy, Economics and Forest Management, National Forest Centre - Forest Research Institute, Zvolen, Slovakia; ²Department of Forestry and Wood Economics, Faculty of Forestry and Wood Sciences, Czech University of Life Sciences Prague, Praha, Czech Republic; ³Department of Forest Economics and Management, Faculty of Forestry, Technical University in Zvolen, Zvolen, Slovakia; ⁴National Forest Centre - Institute for Forest Consultancy and Education, Zvolen, Slovakia (zuzana.sarvasova@nlcsk.org; jarsky@fld.czu.cz; salka@tuzvo.sk; dobsinska@tuzvo.sk; sarvas@nlcsk.org)

Sustainable forest management as a key approach in European forestry is ensured by several policy instruments. This presentation compares findings of implementation of the institute called Professional Forest Managers (PFM) that is applied in the forest law in the Czech Republic and Slovakia. The main role of the PFM is to organize and direct forestry management. Because PFM's rights and obligations are directly determined by forest act, it can be stated that PFM can be considered as a tool of the state forest policy. Surveys among private forest owners as well as interviews with PFM confirm the necessity to have such kind of professional advice. On the other hand, our results have shown that in many cases, especially in the case of small or fragmented private property, the PFM does not fulfil its function adequately. There are gaps in communication, lack of finances, different attitudes of forest owners and PFM etc. Nearly 30 years

of newly implemented PFM in private forests after the restitution processes, call for changes based on an evaluation research studies. Presented findings are based on the evaluation of data received in frame of national projects NAZV QK1820041 in the Czech Republic and project APVV IMPEVALES in Slovakia.

Tools for professional forest management in central and Southeast Europe

Vilém Jarský¹, Zuzana Sarvašová², Marcel Riedl¹, Michal Hrib¹, Martin Flora¹, Jiří Oliva¹, Luděk Šišák¹

¹Czech University of Life Sciences Prague, Prague, Czech Republic; ²Department of Forestry and Wood Economics, Faculty of Forestry and Wood Sciences, Czech University of Life Sciences Prague, Praha, Czech Republic; ³Department of Forest Economics and Management, Faculty of Forestry, Technical University in Zvolen, Zvolen, Slovakia; ⁴National Forest Centre - Institute for Forest Consultancy and Education, Zvolen, Slovakia (jarsky@fld.czu.cz; sarvasova@nlcsk.org; riedl@fld.czu.cz; hrib@fld.czu.cz; flora@phpartners.cz; oliva@fld.czu.cz; sisak@fld.czu.cz)

The aim of this presentation is to describe the tools how the sustainable forest management is secure in selected Central (CZ, SK, PL, HU, AT) and Southeastern European counties (SI, RO, BIH, HR, SRB, MN). We are focusing on the analysis of the role of so called Professional Forest Manager (PFM) which is described in several countries as a person with forestry education and praxis who helps forest owners to manage their property. Methodically the data for the analysis were obtained in two ways. The first way was the text analysis of national forestry legislation (forest act). The second approach was based on common terms of reference filled by national experts due to lack of available English texts of forest acts. The results of the analysis of the legislation show that in the Czech Republic, Slovakia, and Hungary there it is obligation of the forest owner to have (or follow the opinion according to) a PFM and its duties and competences are very similar. On the other hand, other countries are using different approaches, e.g. state forest administration, experts from state forests, extension service or contracts with private associations to ensure professional forest management in private forests. Presented findings are based on the evaluation of data received in frame of national projects NAZVQK1820041 in the Czech Republic and project APVV IMPEVALES in Slovakia.

Forest ownership changes in ECE region and policy responses

Ivana Zivojinovic^{1,2}, Gun Lidestav³, Gerhard Weiss^{1,2}

¹Institute of Forest, Environment and Natural Resource Policy, University of Natural Resources and Life Sciences, Vienna, Austria; ²European Forest Institute, Forest Policy Research Network, Vienna, Austria; ³Swedish University of Agricultural Sciences, Department of Forest Resource Management, Umeå, Sweden (ivana.zivojinovic@boku.ac.at; gun.lidestav@slu.se; gerhard.weiss@boku.ac.at)

Multiple changes in forest ownership structures have been observed worldwide, e.g. emergence of new ownership types, denationalisation and restitution of state forests, fragmentation and urbanisation of private forest ownership. Forest policies are often struggling to respond adequately. In our paper we assess these forest ownership changes and their drivers in the ECE region during the last 25 years, by conducting a two-stage expert assessment of the changes in each country, mapping geographical patterns, and discussing policy implications. The analysis shows that the share of the main ownership categories (public/private) remained fairly stable in the ECE region, however, significant qualitative changes deserve attention. The main change has been the restitution of forestland to private owners in transition countries in central and southeast Europe. Change in the owners' motivations, lifestyle and attitudes is the second important trend, particular in Western and Northern Europe.

Forestry in transition or in opposition? Muddling through the societal transformations

Vilis Brukas¹

¹Swedish University of Agricultural Sciences, Alnarp, Sweden (vilis.brukas@slu.se)

Societies in the Baltic, Central and Eastern European region underwent radical transformations in early 1990s, the pace of social changes is increasing in any country across the globe. How do such changes affect the forestry subsystem is a crucial question, however, forest policy scholarship struggles with providing reasonable answers. Different studies examine selected bits and pieces, often without attempting a more holistic understanding of the intricate relationships between society and forestry. Based on critical analyses of forest governance, this presentation attempts to shed light on these inherently complex developments. What kind of societal developments have been most crucial in framing the arena of change for forestry? What professional ideological core has been at odds with these external catalysts? How did the social change affect the policy landscape in terms of actors' constellations and power? These and other questions will be addressed, illustrated by examples from so-called countries in transition. Rather pretending value-neutral objectivity, the author will not be shy off providing an evaluative touch, sharing his own views on (mis)achievements in forest governance.

Tropical forest and likely futures: an analysis of different pathways to reach sustainable economic growth in Indonesia

Esther Boere¹, Aline Mosnier¹, Andree Ekinata², Ping Yowargana¹, Adrian Dwiputra², Betha Lusiana², Fulvio Di Fulvio¹, Pekka Lauri¹, Dmitry Schepaschenko¹, Juraj Balkovic¹, Hugo Valin¹, Florian Kraxner¹

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²ICRAF, Bogor, Indonesia (boere@iiasa.ac.at; mosnier@iiasa.ac.at; a.ekinata@cgiar.org; yowargana@iiasa.ac.at; a.dwiputra@cgiar.org; b.lusiana@cgiar.org; difulvi@iiasa.ac.at; lauri@iiasa.ac.at; schepd@iiasa.ac.at; balkovic@iiasa.ac.at; valin@iiasa.ac.at; kraxner@iiasa.ac.at)

The role of competing land uses in the decline of Indonesia's natural forest cover has been extensively discussed. Commitments to reduce GHG emissions by 26% by 2020, together with a moratorium on clearing of primary forests and peatlands helped strengthen the countries' environmental goals. Simultaneously, Indonesia experiences significant economic growth based on natural resources and growing demand for some of its key products. Future impacts of these economic pressures on forest cover and the environment remain largely unknown. This study presents a spatially-explicit assessment of Indonesia's agriculture and forestry-sector trajectories, and how various policies can influence them, until 2050. GLOBIOM-Indonesia, a recursive-dynamic economic model tailored to Indonesia, is used to assess the impact of agricultural intensification, natural forest and peatland conservation, restoration of degraded forests and rewetting of peatlands as distinctive future scenarios. Our results show that, under full enforcement, policy interventions aimed at conservation and restoration can save 33 to 36% of total forest cover losses and 36% of annual GHG emissions from the AFOLU sector by 2050. If combined with intensified agricultural management practices, this leads to an increase of 30% in area and 55% in production of rice and corn, but a decrease of 46% in area and 14% in production of the more forest-competing oil palm. Furthermore, results show that intensifying agricultural practices without promoting forest conservation or restoration leads to a slight increase in deforestation due to the increased competitiveness of Indonesia compared to other world regions, highlighting the need for inclusive policy-making.

A9f: GOVERNING FARM-FOREST INTERFACES: LESSONS FROM PRACTICE AND METHODOLOGICAL ADVANCES TO IMPROVE POLICY

Effective inclusion of family farmers in the forest sector of Peru requires a multi-sectoral approach

Valentina Robiglio¹

¹World Agroforestry Centre, Lima, Peru (v.robiglio@cgiar.org)

This paper seeks to identify the key ingredients of the transition towards agroforestry and sustainable land management (including small-scale forestry) by farmers living at the tropical forest-agriculture interface. It takes the case of Agroforestry Concessions (AC) in Peru, a promising legal mechanism in the last national Forest Law, that seeks to slow down deforestation in public forest land by formalising land and tree rights of encroaching smallholders, enabling their inclusion in the forest sector. The concession consists of a 40 years contract that commits the farmers to avoid deforestation and manage land sustainably. First, we map the multiple sectorial policies and institutional arrangements that regulate smallholders' land trees and production systems at the forest margin. Then we assess the coherence of their articulation in light of the challenges to comply with AC requirements and to manage or market forest products. We do so by analyzing data from a study of livelihoods and land and trees resources management by 120 potential beneficiaries of the Agroforestry Concession in 8 communities at the forest margin, complemented by focus group work on local governance and land cover and use dynamics, and on local actors' perceptions of risks and opportunities related to AC. We conclude that AC successful implementation depends on household level factors (such as farm size and composition), on the performance of the agricultural component of the farm, in particular on productivity, and ultimately on a set of complementary incentives, regulations and institutional arrangements from different sectors, besides, of course, the forestry one.

Jurisdictional approach of farm-forest interfaces in Paragominas, PA: a municipal strategy to guarantee agricultural sustainable intensification and forest conservation in Amazonian landscapes

René Pocard-Chapuis^{1,2}, Marie-Gabrielle Piketty^{1,3}, Jaqueline Peçanha⁴, Isabel Drigo⁵, Mario Oliveira Gomes², Pablo Pacheco⁶

¹CIRAD, Montpellier, France; ²Embrapa Oriental, Paragominas, Brasil; ³Pontifícia Universidad Javeriana, Bogota, Colombia; ⁴Paragominas Municipal Government, Paragominas, Brasil; ⁵Instituto de Manejo e Certificação Florestal e Agrícola, Piracicaba, Brasil; ⁶WWF, Washington, USA (renepocard@gmail.com; marie-gabrielle.piketty@cirad.fr; jaquelineadvambiental@gmail.com; isabel.drigo@gmail.com; mario.gomes@embrapa.br; pablo.pacheco@wwf.org)

In the Brazilian Amazon, since the last ten years, federal policies and value chains private commitments have been successful in reducing deforestation. However, the Amazonian landscapes are facing remaining challenges at the farm-forest interfaces such as halting forest degradation, restoring degraded lands, intensify and diversify land uses. Innovative local governance mechanisms are needed. This contribution will present a jurisdictional initiative in the Municipality of Paragominas (19342 km²), the first green municipality of the Brazilian Amazon. A geographic information system (GIS) has been developed, combining several data such as soils texture, slope, hydrographic and transport networks, land uses, forest cover including several level of degradation. It allowed to identify, for the whole municipality, land suitability for agricultural intensification and diversification, forest conservation and restoration and to support participative forward-looking scenarios. A municipal plan to reorganize land and forest uses has then been elaborated. Such plan allow to preserve or restore 9000 km² of forests and to reforest 3500 km² of land strategic for the production of ecosystems services. More 3500 km² of degraded forest could be converted into productive agricultural systems and 4200 km² of productive deforested areas could be intensified. Conversely to the classical opposition between production and conservation, this win-win strategy allows to build efficient landscapes and engage public and private actors. More, the GIS allows to monitor a large set of indicators that can be verified by third parties, such as certifying bodies, to transparently attest to the municipality's progress towards sustainability beyond the end of deforestation.

Turning words into actions: analyzing forest interventions and their effects on land use and welfare in rural settlements in Acre and Northwestern Mato Grosso, Brazil / Transformando palavras em ações: analisando intervenções florestais e seus efeitos no uso do solo e bem-estar em assentamentos rurais no Acre e noroeste do Mato Grosso, Brasil

Mayte Benicio Rizek¹, Amy E. Duchelle², Peter H. May³

¹Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brasil; ²Center For International Forestry Research (CIFOR), Bogor, Indonesia; ³Universidade Federal Rural do Rio de Janeiro, Rio de Janeiro, Brasil (mayte.cifor@gmail.com; a.duchelle@cgiar.org; peterhmay@gmail.com)

Os estados amazônicos comportam 81% da área destinada para a reforma agrária no Brasil. Se estes assentamentos rurais teriam potencial de formar bolsões de baixa concentração de terra e gestão sustentável dos recursos florestais, a realidade aponta um contexto de desigualdade, informalidade e invisibilidade, levando ao fracasso, migração e a reconcentração da terra em sistemas de agropecuária extensiva com alto impacto ambiental e baixa rentabilidade. Para reverter a trajetória de desmatamento em assentamentos rurais o Brasil tem contado com apoio financeiro internacional para a implementação de intervenções florestais, definidas por iniciativas introduzidas ou apoiadas por entidade não comunitária que busca influenciar direta ou indiretamente a maneira como comunidades gerenciam suas florestas. Parte de um estudo comparativo global do CIFOR, este estudo identifica intervenções florestais e avalia seus efeitos no uso do solo e bem-estar com dados empíricos coletados em assentamentos com delineamento antes/depois e com/sem intervenção florestal. Os resultados indicam que as intervenções do Acre melhoraram o bem-estar familiar, mas não foram capazes de conter o desmatamento. Já nos assentamentos do Mato Grosso observou-se uma redução do desmatamento, aparentemente sem afetar o bem-estar familiar. Em todos os casos o desmatamento está associado com a área de floresta, apontando um custo de oportunidade com relação ao potencial de desenvolvimento de base florestal. Ou seja, mesmo para um País tropical relativamente capaz, como é o caso brasileiro no período estudado, o desenvolvimento de base florestal enfrenta desafios para se estabelecer como o uso do solo mais atraente, especialmente no contexto dos assentamentos rurais.

Cerrado Biome: agricultural production and territorial dimension of environmental preservation areas registered in the Brazilian rural environmental registry

Gisele Freitas Vilela¹, André R. Farias¹, Fernando A. de Pádua Paim¹, Gustavo Spadotti A. Castro¹, Osvaldo Tadatomo Oshiro¹, Carlos A. de Carvalho¹

¹Embrapa Territorial, Campinas, Brasil (gisele.vilela@embrapa.br; andre.farias@embrapa.br; fernando.paim@embrapa.br; gustavo.castro@embrapa.br; osvaldo.oshiro@embrapa.br; carlos-alberto.carvalho@embrapa.br)

In this study we analyzed the territorial occupation of the Brazilian Cerrado biome considering the areas within rural properties that are dedicated to environmental preservation – such as Permanent Preservation Areas (APP), Legal Reserves (RL), and additional vegetation areas –, ADPs, and areas occupied with agriculture,

production, and the gross value of the main agricultural products (soybean, maize, cotton, coffee, sugarcane, citrus and beans). With the aim of making the physical boundary of the Cerrado biome compatible with the country's political-administrative structure, all microregions featuring at least 25% of Cerrado areas within their coverage were considered, which amounted to a total of 234.9 million hectares under 132 microregions and 1,394 municipalities. This Cerrado clipping encompasses 1,047,898 rural properties registered under SICAR (in January 2019), amounting to a total of 166 million hectares or 70.7% of the total Cerrado area. These rural properties preserve 66.9 million hectares of ADPs and 40.2% of their land, which accounts for 28.4% of the Cerrado study area. The gross value of the selected agricultural products – soybean, maize and cotton – accounts for more than 50% of the total produced in Brazil. The agricultural production in this territory, when compared against the country's total production is: soybean (55%), maize (58%) and cotton (98%). The areas planted with soybean, maize and cotton cover 28.7 million hectares. In this study we verified that the implementation of the Brazilian Forest Code is ensuring the preservation of ¼ of the Cerrado biome in this very important agribusiness region.

A multi-faceted approach to overcoming obstacles to the uptake of sustainable agricultural practices - outcomes of the low carbon agriculture project

Luis Tadeu Assad¹, Gracie Verde Selva¹

¹Instituto Brasileiro de Desenvolvimento e Sustentabilidade, Brasília, Brasil (assadmar@iabs.org.br; t-gracie@iabs.org.br)

Reducing carbon emissions from the agricultural sector is a key component of Brazil's national climate strategy. Low-carbon agricultural practices include many forest-centric activities including forest restoration and management. The implementation of low-carbon agricultural technologies by small and medium sized land holders faces many barriers including insufficient knowledge of available technologies, access to technical support and a lack of incentives for farmers to invest the necessary time and energy. The low-carbon agriculture project was implemented with the aim of promoting sustainable rural development in the Brazilian Amazon and Atlantic Forest biomes. It reached over 3000 small and medium sized private land-holders, supporting the implementation of sustainable agricultural practices such as integrated crop-livestock-forestry systems. The Project, the result of technical cooperation between the British Government, the Ministry of Agriculture and the Inter-American Development Bank and executed by IABS, utilised a three-prong approach. First the project provided access to information, through demonstration units, field days and the distribution of educational and technical materials. Second it offered rural producers a financial incentive for the implementation of one or more of four low-carbon agricultural practices promoted by the Project, prioritizing those with a forest component. Third the project provided training opportunities to local technical assistance agents that supported land-owners throughout implementation. This presentation will explore some of the results of the project in promoting sustainable rural development. It offers insights on how to combine governance interventions at national, state and local levels to achieve environmental and socio-economic development goals at the farm-forest interface.

Relationship between farmers and the forest within Machadinho D'Oeste/RO's settlement project: using fauna as a bioindicator

Angelo Mansur Mendes¹, José Roberto Miranda¹, José Paulo Franzin¹, Bruno Scarazzati¹, Fernando Antonio de Pádua Paim¹, Jaudete Daltio¹, Gisele Freitas Vilela¹

¹Embrapa Territorial, Campinas, Brasil (angelo.mansur@embrapa.br; jose-roberto.miranda@embrapa.br; jose.franzin@embrapa.br; bruno.scarazzati@embrapa.br; fernando.paim@embrapa.br; jaudete.daltio@embrapa.br; gisele.vilela@embrapa.br)

Monitoring farms in a settlement project in Amazônia for a period of 100 years is an initiative that produces a series of data on soil use and occupation dynamics by small farmers. These data enable producing sustainability indicators, which offer elements for understanding the consequences of the articulations among local strategies and public policies which aim to strengthen small farming in Amazônia. The aim of this study was to analyze the data collected in the survey carried out in 2018, 36 years after the settlement of the farmers in PA Machadinho D'Oeste-RO, using fauna as an ecological indicator. The survey was carried out in 414 lots. Their farmers were interviewed regarding their visual perception of the fauna: frequency of spotting (often; regularly; occasionally; once; and never); predation (animal attacks on crops or livestock); accidents (harmful effects on health); and consumption (fishing and hunting). The data collected enabled analyzing the distance between the forests and the lots, and also separating the forest's indirect effects through the fauna as positive (food security) or negative (accidents and predation).

Quality management of agroforestry products focusing on cultivated mountain ginseng

Tae Hoon Kim¹, Mi Sun Park¹ 

¹Seoul National University, Pyeongchang, Republic of Korea (switch-thkim@snu.ac.kr; mpark@snu.ac.kr)

Forest farming is the most common type of agroforestry in the Republic of Korea. Agroforestry products are recognized as cleaner products comparing with other agricultural products in the Korean market. Accompanied with positive market perception, demand on agroforestry products is expected to increase. This paper focused on cultivated mountain ginseng as a non-timber forest product. It aims to scrutinize the current status of producing cultivated mountain ginseng and policies for improving production of cultivated mountain ginseng in the Republic of Korea. Policy instruments for supporting production of cultivated mountain ginseng were analyzed. Policy instruments include regulatory, economic, informational, organizational and planning instruments. In particular, traceability scheme of cultivated mountain ginseng as an innovative policy instrument was introduced. This study indicates combination of multiple policy instruments for supporting cultivated mountain ginseng producers and consumers in the Republic of Korea. Base on the research results, this research suggests policy recommendation to reduce institutional barriers and facilitate agroforestry activities in the Republic of Korea.

Facilitating women's participation to improve management of the forest farm interface: participatory lessons from Northern Ghana and Southern Burkina Faso

Peter Cronkleton¹

¹CIFOR, Lima, Peru (p.cronkleton@cgiar.org)

In the Sahelian landscapes of Southern Burkina Faso and Northern Ghana, the integration of agriculture, forestry, and livestock within the natural resource management systems used by smallholder households makes it difficult to separate agricultural land use from forest and tree use. Women play integral roles in these systems, particularly in the management of trees. However, customary systems of land and tree tenure differentially constrain women's access to resources, while national policies do not acknowledge or support their roles as resource managers. In such context, multi-stakeholder dialogues could be an effective strategy for assisting policy makers to better understand these complex production systems. However ensuring that such fora include the perspective of both male and female managers is crucial and creating conditions in which women can share their resource management knowledge and experience is

central to guaranteeing the inclusion of their concerns. This paper analyzes efforts to use participatory methods in two multi-village landscapes to facilitate women's engagement, give voice to their priorities, and frame debate around topics important for their livelihoods. It builds on fieldwork conducted by CIFOR, ICRAF and Tree Aid as part of the West Africa Forest Farm Interface Project (WAFFI) funded by IFAD. The WAFFI team used participatory approaches to facilitate smallholder involvement in the definition, analysis and evaluation of management issues. As a result of these activities, women's groups catalyzed dialogue on conflict of use problems related to shea (*Vitellaria paradoxa*), unintended consequences of conservation boundaries and resource degradation due to uncontrolled bushfires.

Governing non-timber forest products in the Congo Basin farm-forest interface

Verina Ingram¹, Donald Midoko Iponga², Abdon Awono³, Christian Yobo Mikolo², Denis Sonwa³

¹Wageningen UR, Wageningen, Netherlands; ²IRET, Libreville, Gabon; ³CIFOR, Yaounde, Cameroon (verina.ingram@wur.nl; dmiponga@gmail.com; a.awono@cgiar.org; jaggermike2012@gmail.com; d.sonwa@cgiar.org)

In the Congo Basin, farms and forests are governed by separate regimes. This paper provides insights into the practices in which the transition from farm to forest (farm, agro forestry mosaics, fallows, farm forests, agro forestry mosaics, enriched forests) is governed in different cultural, economic and geographic contexts. The resulting fragmentation in governance regimes affects both access to forests, land and resources, and access to markets for products originating from these systems. The practices of both smallholders and larger landowners within this farm-forest interface are often bricolages to meet the demands of state, voluntary market and customary governance arrangements. This paper provides evidence and recommendations for how farm-forest interfaces in the Congo Basin can be governed such that multi-use practices are accommodated and result in positive sustainable, people centred outcomes.

A9g: INNOVATIVE FOREST LAWS AND ENVIRONMENTAL LEGISLATION FOR ENHANCED FOREST ECOSYSTEM SERVICES IN LOCAL COMMUNITIES

Land and forest of Amazonian indigenous peoples: Why should they have ownership rights over both?

Siu Lang Carrillo Yap¹

¹Göttingen University, Göttingen, Germany (siulang.muchik@gmail.com)

This research explores the level of recognition of the rights of Amazonian indigenous peoples to their land and forest and identifies the key aspects that must be considered for the strengthening of their rights, including a common regulation of their property rights over land and forest. The scope of the research is limited to four countries, which cover around 80% of the Amazonian region, namely Bolivia, Brazil, Ecuador and Peru. In this research, firstly, the overall conditions of the relationship between national States and indigenous peoples are discussed. Here, the status of indigenous peoples in constitutions and national laws is explored; their status influences their capacity to acquire and to manage their lands and forest resources. Secondly, the land rights of indigenous peoples are analyzed, considering two levels of control over land: property rights and indigenous territorial units. In this part, three models for recognizing the land rights of indigenous peoples are identified. Thirdly, the rights of indigenous peoples over their forest resources are examined. In this part, the types of recognized rights of indigenous peoples as holders of the titularity over the forest resources are analyzed, considering the attributions provided by these rights. Finally, the key elements that should be considered for reinforcing the land and forest rights of Amazonian indigenous peoples are reflected upon, considering land and forest rights as one unit (a right to the territory) and applying findings of natural sciences and property law theory.

Forestland in Eeyou-Istchee: exploration of a far-reaching case of indigenous co-governance in Quebec, Canada

Francois-Xavier Cyr¹, Stephen Wyatt², Martin Hebert¹

¹Université Laval, Quebec, Canada; ²Université de Moncton, Edmundston, Canada; (francois-xavier.cyr.1@ulaval.ca; stephen.wyatt@umoncton.ca; martin.hebert@ant.ulaval.ca)

Forest governance arrangements for Indigenous peoples often include legal framing through treaties and/or land rights and shared institutions or management arrangements. In Canada, the 1975 James Bay and Northern Quebec Agreement (JBNQA) marked the first of a series of "modern" treaties and first attempts at creating mechanisms and institutions that would provide the James Bay Crees with increased power and responsibility over their territory of Eeyou-Istchee. A subsequent agreement in 2002, the "Paix des Braves" led to the creation of the Cree-Quebec Forestry Board (CQFB) by which the Cree and the government of Quebec collaborate to oversee the co-governance of forest resources of Eeyou-Istchee. This presentation examines the history and functioning of the CQFB, and its efforts to balance the aspirations of the James Bay Cree in asserting their sovereignty over their traditional lands and those of the Quebec government in maintaining ultimate authority and in promoting industrial development of natural resources. In particular, we consider the governance processes that are used at different levels, as well as the monitoring instruments that are used to determine the effectiveness of forest management efforts in maintaining the Cree way of life and on promoting closer relations between Indigenous and non-Indigenous inhabitants of the land.

Analysing Zambia's community-based forest's legal framework and its potential to improve forest management and livelihoods

Felix Kalaba¹

¹School of Natural Resources, Copperbelt University, P.O Box 21692, Kitwe, Zambia (kanungwe@gmail.com)

This study examined Zambia's community forestry regime using the FAO's analytical framework for the assessment of extent and effectiveness of community based forestry (CBF) regimes and identify areas of improvement to ensure sustainable forest management for food. The methodology included policy analysis and key informant interviews which followed a combination of purposive and snowball sampling. Policy documents analysed included Zambia Forest Policy of 2014, Forest Act of 2015, Wildlife Act of 2015. This was followed by in-depth interviews with key experts which included government officials at district level responsible for Forestry, wildlife, planning and agriculture. Findings show institutionalisation of CBF in the legal framework. There is recognition of the rights of forest communities for all the analysed CBF types. Enjoyment of rights is outlined in the policy and legal framework though hindered by factors such as access to markets, lack of recognition of gender and marginalised members of communities. Access to justice in case of disputes is through formal dispute resolution processes which has challenges of human and financial resources. The legal framework however lack provisions and specific strategies addressing gender in recognition of rights. Subsidiary laws lack provisions and specific strategies for addressing historical and cultural gender disparities. The law is further silent on compensation of forest owners when rights are revoked under community forest or JFM regimes. There is need for recognition of rights and deliberate promotion and recognition of women in CBF regimes if sustainable management of forests and livelihood improvement are to be achieved.

Forest access, rights, and benefits: exploring the role of community forests as an innovative tenure regime for protecting ecosystem services in the US

Kathleen McGinley¹, Frederick Cubbage², Gregory Frey³, Meredith Hovis², Megan Lupek², Han Xue³

¹U.S. Forest Service, International Institute of Tropical Forestry, Rio Piedras, Puerto Rico; ²North Carolina State University, Dept. of Forestry and Environmental Resources, Raleigh, USA; ³U.S. Forest Service, Southern Research Station, Raleigh, USA (kmcginley@fs.fed.us; fred_cubbage@ncsu.edu; gregoryfrey@fs.fed.us; mehovis@ncsu.edu; mlupek@ncsu.edu; xue.han@usda.gov)

Forests in the United States of America (U.S.) support livelihoods, protect environmental quality, and provide social benefits. However, their modest market returns and provision of nonmarket goods and services that often go uncompensated place them at some risk of over-exploitation and loss to other land uses with greater market values. A promising renewed approach to redress the imbalances between social forest benefits and limited market returns are 'community forests' that permit forest tenure rights holders to cooperatively identify and develop forest resource benefits; achieve economies of scale; capture increased market and nonmarket returns; contribute to rural economic development; and enhance forest retention and management. Community forests in the U.S. occur on tribal forest lands, federal forest lands under stewardship contracts to community-based organizations, and lands held in trust for communities by local government or non-profit entities, among other models. However, there is limited empirical data on the status, trends, characteristics, or outcomes of these forests. Through mixed methods research, we take stock of the broadening range and extent of community forests in the U.S. to qualify and quantify their legal designations, tenure regimes, governance mechanisms, management practices, and outcomes and to evaluate the associated contexts, enabling factors, and limiting conditions. The results shed light on the state of community forestry in the U.S. and the characteristics and conditions that lead to enhanced forest retention, ecosystem services provision, environmental protection, profitability, and community well-being and resilience.

Legal aspects of providing forest ecosystem services: case of the Slovak land associations

Rastislav Sulek¹, Jan Lichy¹, Martina Kasubova¹

¹Technical University in Zvolen, Zvolen, Slovakia (sulek@tuzvo.sk; jan.lichy@tuzvo.sk; kasubova.martina@gmail.com)

The provision of forest ecosystem services is closely interlinked with the specific impacts of forest resource management that are determined by the internal business circumstances as well as by the external restrictions. While the internal conditions are determined by the economic efficiency of forest enterprises, the external restrictions are governed, except for the nature conditions, by the regulative state measures, characteristics of business environment, and principles accepted by the whole society. Land associations belong to the important legal type of the Slovak forest enterprises – they manage almost 30 % of forest land. Still, their legal regime is somehow specific in comparison with the other legal types of forest enterprises. The provision of forest ecosystem services by land associations is thus affected by a number of factors – the most important ones are specific property rights in land associations, interests of forest landowners, legal restrictions, social and environmental interests and preferences of the society. The anticipated contribution of the paper is, based on the analysis of legal factors that affect the provision of ecosystem services under specific conditions of land associations in Slovakia, to model the most important legal aspects of the optimal provision of forest ecosystem services in common forests.

Role of spatial development planning towards sustainable forest management

Līga Menģele-Stillere¹

¹State Forest Service, Riga, Latvia (ligamenstill@inbox.lv)

Interests how to use forest land vary from economic ones till social and environmental interests where people want to use forest for recreational purposes or protect forest nature values. Question is: How to balance all different interests of land use and who should do it? State through legislative procedures has to form the system of spatial development planning and local authorities have to realize this process. Spatial development planning results are foundation for further land use realization. Spatial development planning legal regulation has strong impact on balancing different interests in forest sector. Planning documents adopted as a result of spatial planning must be like agreements between representatives of several interests. Legal acts guarantees rights – access to information, public participation in decision – making and access to justice in environmental matters. These Environmental procedural rights has to be used actively by NGOs representing several interests in land (and forest as well) use and protection starting from the beginning of the spatial planning process, but not after land owner starts tree harvesting in his ownership. Ability of local governments to find the right balance of several interests in some cases is not satisfactory, that can be illustrated with some Constitutional Court cases in Latvia.

Rural environmental register in Espirito Santo, Brazil: more than 3 million hectares registered so far / Cadastro ambiental rural no Espírito Santo: mais de 3 milhões de hectares já cadastrados

Livia Almeida¹, Fabrício Zanzarini¹, Michel Simon¹

¹IDAF, Vitória, Brasil (livia.almeida@idaf.es.gov.br; fabricio.zanzarini@idaf.es.gov.br; michel.simon@idaf.es.gov.br)

O Cadastro Ambiental Rural (CAR) foi instituído por meio do novo Código Florestal Brasileiro, (Lei 12.651/2012) e o Espírito Santo foi um dos primeiros estados a regulamentá-lo, já em 2013. Após seis anos de implementação do CAR no estado, é possível afirmar que a ferramenta confere um diagnóstico detalhado das áreas rurais do estado, por meio do qual é possível obter informações sobre o uso do solo de cada propriedade rural, com o mapeamento das áreas de vegetação nativa, Áreas de Preservação Permanente (APPs) e a demarcação das áreas de reserva legal, especialmente. De acordo com estimativas do Instituto de Defesa Agropecuária e Florestal do Espírito Santo (Idaf), órgão gestor do CAR no estado, o Espírito Santo possui cerca de 133 mil propriedades rurais e os números registrados até o início de 2019 mostram que mais de 84 mil imóveis já estão inscritos, sendo mais de 64 mil já validados. Extrapolando para área, são mais de três milhões de hectares cadastrados, correspondendo a 73% da área rural do estado. A partir dos dados declarados no CAR, até o momento foram mapeados mais de 638 mil hectares de florestas preservadas, o que equivale a 20% da área cadastrada. Desse total, cerca de 360 mil hectares foram demarcados como reserva legal e outros 67 mil estão em APPs. Em paralelo, foram demarcados 78 mil hectares de reserva legal e 86 mil hectares de APPs que deverão ser recuperados para adequação ambiental dos imóveis, por meio do Programa de Regularização Ambiental (PRA).

New Brazilian Forest Code, PSE programmes and deforestation: What are the links?

Leidimari Neves do Prado¹

¹Institut National de la Recherche Agronomique, Nancy, France (leidimari.neves-do-prado@inra.fr)

Since the reformulation of Brazil's Forest Code (BFC - law 12.651/2012) in 2012 the Brazilian government made a move towards more stringent environmental conservation and announced that landowners in disconformity with this law would be punished (e.g. fines and additional barriers to obtain bank loans). This announcement had great impact on the landowners' perception of the importance to comply with the law. In parallel, the Brazilian government set up, in 2012, at the Piripau River Basin (Federal District) the Water Producer Programme (WPP): the foremost example of PES schemes in Brasil. WPP deviates largely from other predominant approaches: Contract signatories are subsidized of all implementation costs, such as restoration of Areas of Permanent Protection (APP) and Legal Reserves (RL), two important environmental obligations demanded by the BFC to all Brazilian landowners. Those landowners who do not sign the contract must regularize the property in a 20-year period starting from 2012, with at least 10% of the total area rehabilitated every two years. All these aspects are great challenges for producers because they cost not just effort but also money and time. This paper studies the links between BFC, WPP and deforestation in the Cerrado biome. Our results show that deforestation is strongly correlated with law-incentives for agricultural expansion. The reformulation of BFC with a special focus on PES programmes was an important tool to reduce deforestation and increase the restoration area and the recovery of all deforested areas will be reached long before 2032, the expected date by BFC.

A9h: NATURE'S CONTRIBUTION TO PEOPLE IN TRANSITIONING FOREST LANDSCAPES

The encroachment of ecosystem services into forest restoration discourses

Wilhelmus de Jong¹

¹Kyoto University, Kyoto, Japan (dejongwil@gmail.com)

Forest restoration refers to conscious efforts that are being made to bring back forest where it has disappeared or restore the condition of degraded forests. The last three decades or so, have seen a tremendous global commitment in target areas of forest land where forests is to be restored. The multiple global or regional forest restoration targets reflect an expanding interest and commitment in forest restoration practice, advocacy and discourses. The current surge in restoration efforts, analysis and debates can be originated somewhere in the early 1990s. Over the period of the last two to three decades the forest restoration discourse and debates have shifted. Two terms have been competing in the related academic and non-academic literature, rehabilitation and restoration. The latter term has now taken over in the global forest restoration discourse. This reflects a progressive dominance of forest restoration advocates who emphasize ecological services of restored forests, in addition to providing provisional ecosystem services to society, which are functions emphasized by a forest rehabilitation camp. The paper will analyze the changes in discourses related to forest restoration in general, and in particular how ecosystem services explicitly or implicitly have appeared in those shifting forest restoration discourses. The paper is based on research of a relevant number of academic papers, advocacy pieces as well as written materials produced by several key actors with interest and commitments related for forest restoration.

A system dynamics framework for policy impact on forest ecosystem services

So-Hee Park¹, Youn Yeo-Chang¹, Nathaniel Anderson²

¹Seoul National University, Seoul, Republic of Korea; ²United States Forest Service, Missoula, USA (dannysohui@snu.ac.kr; youn@snu.ac.kr; nathaniel.m.anderson@usda.gov)

Ecosystem services-based decision-making has advantages in that it can provide policy alternatives to have a balanced supply and distribution of ecosystem services value. To support the ecosystem services-based decision-making, research should be conducted to understand the process and structure of ecosystem services from forest ecosystem, evaluate supply and value of ecosystem services, as well as impacts of policy and management system on ecosystem services. This study aims to develop a system dynamics framework in the form of causal loop diagrams in order to determine relationship between forest ecosystem services and management system including policy. First, this study develops causal loop diagrams for forest ecosystem services considering synergies and trade-offs among various types of ecosystem services to assess supply and value of ecosystem services. How four types of forest ecosystem services (provisioning services of timber and non-timber forest products, regulation services of water storage, soil erosion prevention, and carbon absorption, supporting services of species diversity, and cultural services of recreation and scenery) are linking with forest ecosystem characteristics (e.g. as forest area, growing stock, soil characteristic and depth, forest road system, etc.) in the causal loop diagrams is explored in this study. Second, policy-ES integrated model is developed by grafting policy factors onto a causal loop diagrams of forest ecosystem services in order to determine impacts of policy and management system on ecosystem services. This framework might contribute to evaluate effectiveness of forest management on ecosystem services and develop optimization strategies for the provision of ecosystem services.

Effects of farmer income and roads on forest transition

Xiaodi Zhao^{1,2}, Lingchao Li², Lingchao Li²

¹Chinese Academy of Forestry, Beijing, China; ²Beijing Forestry University, Beijing, China (edison19890918@126.com; lowrychen@sina.com; 847317773@qq.com)

Objective To study the impact of farmers' income and roads on forest transition and provide reference for promoting the coordinated development of regional socio-economy and forest ecology. Method based on the remote sensing images and socio-economic statistics of 32 sample counties in Fujian province from 2000 to 2016, this paper studies the impact of farmer income and roads on forest transition under different resource endowments by quantile regression method, explores the influence of interaction between farmers' income and road conditions on forest cover changes and analyze the moderating effect of roads on farmers' income. Results 1) Farmer per capita income has a significant effect on the growth of forest area, and in counties with moderate forest resources endowment, per capita income has a greater effect on forest transition, while in counties with rich or relatively low forest resources endowment, per capita income has a smaller effect; 2) Road density has a significant negative impact on forest area, the higher the forest resources endowment, the greater the negative effect of road density on forest transition; 3) The concurrent of low rural road density and high farmer income are more conducive to promoting forest transition. Other things being equal, the lower the density of rural roads, the greater the comprehensive impact of farmer income on forest transition. Conclusion Income growth of farmers is an important factor to promote forest transition in Fujian, and road facilities will have a negative effect on forest transition. Under different forest resources endowment conditions, income and road shave different effects on forest resources, and road density has a negative moderating effect on income.

The power of actors behind the change of relationship between human beings and Asian elephants: a case study of Xishuangbanna

Pei Zhang¹, Jiacheng Zhao¹

¹Renmin University of China, Beijing, China (zhangpei9511@163.com; zhaojiacheng@ruc.edu.cn)

With the development of Chinese society, the relationship between the humanity and wildlife has undergone profound changes, of which the relationship between people and the Asian elephant is the epitome. This paper hopes to reveal the power of actors hidden in the transformation of the relationship. Taking Actor-centered power theory as the analysis framework, this paper analyzes three important periods of relationship between human and Asian elephant based on the case of Xishuangbanna. The first is the attack period, with the implementation of policy of developing Xishuangbanna as a turning point. The government and the immigrants opened up the land together, which squeezed the habitat of Asian elephants. The second is the Transition period, with the establishment of a Tropical Rainforest Reserve as a turning point. The government turned to nature conservation which was based on Asian elephant, while the community, as a powerful actor, continued to develop natural resources under the encouragement of the market element. The third is the defense period, with the prohibition of reclamation as a turning point. The government which gained powerful status through compulsory, incentive and informational means prevented the community continuing land reclamation and the relationship between people and Asian elephants reversed. In conclusion, the relationship between humans and Asian elephants has been deeply embedded in social networks where the power game of actors happens. From this perspective, in the critical period of China's construction of ecological civilization, this paper hopes to bring inspiration for the further studies of nature conservation.

Conservation and recovery participatory of forest in the Mixteca Geopark, Oaxaca, Mexico

J. Antonio Hernández-Aguilar¹, Elvira Durán¹

¹CIIDIR Oaxaca - Instituto Politécnico Nacional, Santa Cruz Xoxocotlán, Oaxaca, Mexico (antonio.hernandez.aguilar@gmail.com; eduran3@hotmail.com)

In contrast to deforestation, the trends of forest recovery have been still insufficiently studied, particularly when they are impulse by social involvement. Before the current century, Mexico was a high deforestation rate, one extreme case was in the indigenous Mixteca region in Oaxaca State, consider with the highest soil erosion and forest degradation in the world. Because of the impressive landscape degradation, UNESCO gave it in 2016 the recognition of "Geopark". With this study, we analyze the forest recovery in the Mixteca Geopark and the role of local people in conducting the tendencies. Field trips and satellite images classification were made to identify the status of the forest remnants and the cover recovery. In addition, five workshops were organized and semi-structured and informal interviews with leaders and inhabitants documented social processes and local actions that have helped forest recovery. It found 120% (495 ha) of pine-oak forest increase during the period 1990-2018, and a growth of 35% (317 ha) of secondary forest (pine). The recovery result of collective reforestation activities since 1995, based on local initiatives with supported for governmental programs. Besides reforestation activities, regulations to prohibited free logging and grazing for more than two decades allow the forest natural recovery. We concluded that the people from Mixteca Geopark intentionally stop and begin to reverse deforestation, though collective action and communal rules. The Geopark status started to promote social learning about the severe degradation of the territory and the importance of forests for soil protection, carbon capture and water recharge.

Local people participation in climate change related projects: its impacts to social capital and livelihoods

Roswin B. Valenzuela¹, YOUN Yeo-Chang¹, Mi Sun Park¹

¹Seoul National University, Seoul, Republic of Korea (roswinbobisvalenzuela@gmail.com; youn@snu.ac.kr; mpark@snu.ac.kr)

Climate change is a global problem caused by the cumulative actions of multi-level actors; therefore, solving the climate change problem requires collective action. Networks have been created to establish cooperation and collaboration between multi-level stakeholders, this facilitates the exchange of knowledge and strengthens the cooperation between the stakeholders. Cooperation is not only significant for the actions against climate change, but it also contributes to the local communities by increasing their social capital through their involvement in climate change mitigation projects. Through the increase of the connections and relationships of the local communities with other stakeholders, their assets also increase, which are important in accumulating more capitals and in gaining economic profits. This study focuses on the impacts of local community participation in climate change related projects to the level of social capital. Moreover, the study analyses the impacts of the changes in the level of social capital to the local communities' access to resources and services, and to the flow of information in the community; these two variables are essential in improving the livelihoods of the local communities. The improvement of the livelihood of the local communities is critical in the natural resource conservation since it can reduce the pressure to resource dependency, especially to the poor people with no other means of acquiring resources for their needs, subsistence, and livelihood. The study will be done in the Province of Quezon, Philippines. Household interviews and key informant interviews will be conducted for the data gathering.

A9i: POLICY AND PRACTICE FOR SUSTAINABLE FOREST-BASED TOURISM AND RECREATION

Forests, nature-based tourism trends and the drivers behind

Peter Fredman¹, Jan Vidar Haukeland¹, Liisa Tyrväinen², Dominik Siegrist³, Kreg Lindberg⁴

¹Norwegian University of Life Sciences, Ås, Norway; ²Natural Resources Institute Finland, Helsinki, Finland; ³Hochschule für Technik, Rapperswil, Switzerland; ⁴Oregon State University, Bend, USA (peter.fredman@nmbu.no; jan.vidar.haukeland@nmbu.no; liisa.tyrvaainen@luke.fi; dominik.siegrist@hsr.ch; kreg.lindberg@osucascades.edu)

Forests are an important resource for the delivery of tourism and recreation services in many parts of the world. Recreation in the outdoors have potential to improve quality of life and nature-based tourism to support regional development outside the urban districts. Recent trends in the tourism and recreation sectors show evidence of increased diversification and globalization, driven by social, technological, economic, environmental and political factors. To understand these dynamics better, this presentation reports findings from a Delphi-study including 70 experts in Norway, Sweden, Finland, Central Europe and Western United States. The Delphi method is a structured communication technique organized in several iterations where respondents get controlled feedback for each repetition and the researcher is looking for convergence in the distribution of opinions. The first iteration had an open-ended format asking questions about the most significant trends, associated drivers, challenges and opportunities. The following two iterations operated with closed-ended questions, measuring the significance of the trends identified. The study is part of the BIOTOUR project, a Norwegian multi-disciplinary research project with the overall hypothesis that an integrated perspective of the nature-based tourism sector will provide a basis for both innovative products and a more sustainable development. The presentation will discuss the study results in the light of policies and practices to manage tourism and recreation for a more sustainable use of forests and other natural resources for the benefits of people.

Using the extension service to increase the capacity for ecotourism development in Florida, USA

Taylor Stein¹, Shane Feyers¹, Katherine Nelson¹, Kotryna Klizentyte¹

¹University of Florida, Gainesville, USA (tstein@ufl.edu; sfeyers@ufl.edu; knelson407@ufl.edu; kklizentyte@ufl.edu)

Florida is one of the most popular tourism destinations in the USA, but as an ecotourism destination, it is relative unknown. Facing unprecedented growth in new residents and tourism arrivals, Florida has the potential to use ecotourism as an industry to promote sustainable development, while contributing to the improvement of local economies and quality of life. The Florida Extension Service, which has traditionally been associated with agricultural education, has the capacity to help Florida tourism businesses, policy makers, and land management agencies use ecotourism as a development strategy, but research is needed to understand Extension's role to aid in ecotourism development. Researchers conducted six nominal group interviews, two surveys of nature-based tourism providers, and individual interviews with tourism professionals to understand how the Extension Service can best assist in Florida's ecotourism development. Results show stakeholders believe the Extension Service must take on a leadership role, as well as, an educational role to help Florida's counties implement ecotourism. Specifically, many Florida counties are working to develop sustainable tourism enterprises, but they are not integrating nature into their tourism planning. Extension professionals have the ability to not only educate diverse stakeholders on successful nature-based tourism planning, but they also have the capacity to form innovative and valuable partnerships between stakeholders, which previously did not exist. This presentation will discuss how diverse stakeholders believe the Extension Service can help Florida counties achieve specific ecotourism outcomes and the methods to achieve those outcomes.

Creating markets for forests amenities in nature-based tourism context: case of Ruka-Kuusamo Finland

Liisa Tyrväinen¹, Erkki Mäntymaa², Artti Juutinen², Mikko Kurttila³

¹Natural Resources Institute Finland, Helsinki, Finland; ²Natural Resources Institute Finland, Oulu, Finland; ³Natural Resources Institute Finland, Joensuu, Finland (liisa.tyrvainen@luke.fi; erkki.mantymaa@luke.fi; artti.juutinen@luke.fi; mikko.kurttila@luke.fi)

Nature-based tourism is an important and growing economic sector in Europe that builds on attractive nature environments, experiences and activities. In many European countries, and in particular in the north, intensified wood production with shortened rotation cycles and large size of management units negatively affect the scenic and environmental qualities of forests and decrease locally their suitability for tourism. Therefore, new policy instruments, such as Payments of Ecosystem Services (PES), are needed to secure and enhance the quality of forest landscapes. These instruments could engage private forest owners and nature-based tourism companies (NBTs) to cooperate in enhancing production of forest amenities. This presentation sums up research results and experiences regarding development of landscape and recreation value trading model in Ruka-Kuusamo region, Finland, where both commercial forestry and nature-based tourism are important. Research results show that tourists' are willing to contributing to funding of landscape and biodiversity protection during their stay. Moreover, landowners are relatively willing to participate in suggested payment scheme if reasonable compensation is paid and, have increased interest if both landscape and biodiversity will be protected. In contrast, local tourism entrepreneurs' are less interested in funding production of forest amenities, although they see forest landscapes important for their business. Therefore, awareness raising, improved communication of benefits of environmental investments are needed. The key actors include forest owners, authorities and managers as well as nature-based tourism companies, planners and managers. The presentation discusses also ongoing collaborative deliberation, co-design and communication processes involving multiple stakeholders striving for implementation of the mechanism.

Igniting the Science of Outdoor Recreation (ISOR): introducing a research strategy developed through a National assessment and multi-stakeholder process

Anna Miller¹ , Steven Selin², Lee Cerveny¹, Monika Derrien¹

¹USDA Forest Service, Seattle, USA; ²West Virginia University, Morgantown, USA (annamiller@fs.fed.us; sselin@wvu.edu; lcerveny@fs.fed.us; mderrien@fs.fed.us)

Enhancing sustainable recreation opportunities has emerged as a priority for protected area and public land managers globally. In many regions, management and research capacity to support recreation decision-making has diminished over the past two decades, while visitation to public lands has increased. Updated conceptual frameworks and management tools are needed to guide agency decision-makers. This presentation reports on outcomes of the interagency "Igniting the Science of Outdoor Recreation" (ISOR) collaborative in the United States. The mission of ISOR is to generate new energy and focus, resulting in outdoor recreation research that addresses pressing land management challenges. This effort has produced a Research Strategy, which synthesizes management challenges and identifies areas of research to address them. The Research Strategy was developed over 18 months and involved dozens of outdoor recreation professionals, including resource managers, researchers, and practitioners from multiple agencies. A series of events including two workshops and an international needs assessment were conducted, resulting in ideas that were synthesized by interdisciplinary writing teams to produce the final document. This presentation will introduce the final Research Strategy document. The document covers nine Research Focus Areas (RFAs) including: Integrative Outdoor Recreation Planning, Transforming Organizational Culture, Outdoor Recreation Drivers, Visitor Monitoring, Health Benefits, Fostering Nature Connections, Enhancing Heritage and Shared Stewardship, Sustainable Tourism, and Ecological Interactions. Cross-cutting themes synthesized from the RFAs include systems thinking, integration, and resilience. We will present strategies identified to implement the Research Strategy and implications of this document for the international management of public lands.

Local community's perceptions of sport fishing in the Amazon

Yasmin Cristina Hess¹, Teresa Cristina Magro Lindenkamp¹, Carlos Gabriel Koury²

¹Universidade de São Paulo, Piracicaba, Brasil; ²IDESAM-Instituto de Conservação e Desenvolvimento Sustentável da Amazônia, Manaus, Brasil (yasmin.hess@usp.br; teresa.magro@usp.br; carlosgabriel@idesam.org.br)

Tourism in the Uatumã Sustainable Development Reserve (RDS) is an activity with potential for social inclusion, income generation, community empowerment and natural resource preservation. According to the Management Plan, 30% of the residents consider that tourism causes damages and complain about the difficulty of catching fish after tourism and sport fishing activities. In this context, we developed a protocol to monitor the impact of the sport fishing and its relationship with the traditional community in the Uatumã RDS. We work with the perceptions of community members regarding a series of indicators identified through interviews. Regarding boat traffic, boat speeding and dead fish the opinion of the interviewed was less negative when they had a relation with sport fishing. Residents with a direct relation to sport fishing considered these indicators less impacting than those who do not work with sport fishing. Surprisingly, residents with no relation with tourism don't criticize the presence of oil in the water. Most likely because they don't perceive the pollution. Among the parameters evaluated, the change in watercolor was the most negatively assessed indicator by the residents. In general, the indicator evaluation shows that sport

fishing has little effect on the inhabitants of the Reserve. The RDSU has the potential to carry out sport fishing activities and bring benefits to the community, but we emphasize that this research shows only the perception of the residents. More study is necessary related to the impacts of sweet water life.

Determination of carrying capacity for Quezon protected landscape's ecotourism attractions

Gerald Eduarte¹, Rogelio II Andrada¹

¹University of the Philippines Los Banos, Los Banos, Philippines (gteduarte@up.edu.ph; rtandrada@up.edu.ph)

Protected areas are becoming extremely important ecotourism destinations. These areas are at risk from uninformed and uncontrolled visitors which can cause pollution (air, noise, water, etc.) and alteration of the natural ecosystem processes. An effective ecotourism planning and management approach should consider and define an optimum threshold level for the use of ecotourism attractions while maintaining a sound biophysical and social environment. Although carrying capacity is important in regulating visitor influx, the application and practice of this concept is not being observed in Malabayabas forest, Pinagbanderahan trail and peak, which are ecotourism attractions of Quezon protected landscape in Atimonan, Quezon Province. This study focuses on the carrying capacity standards of these ecotourism attractions with considerations of site-specific factors. The physical, biological/ecological, social and economic conditions of the site were assessed. Data concerning demographics and visitation characteristics were collected through a survey, administered in August to December 2015. The results demonstrated that the actual number of visitors in these ecotourism attractions is currently lower than the calculated carrying capacity. In reality, there is still a risk for congestion and overcrowding particularly during high visitation. Therefore, a responsive visitor management program should be developed.

Nature-based tourism governance in addressing paradigm shifting challenges in managing protected areas of Bangladesh

Md. Wasiul Islam¹ ; Md Nazmus Sadath¹

¹Forestry and Wood Technology Discipline, Khulna University, Khulna, Bangladesh (wasiulislam7@yahoo.com; mnsadath@yahoo.com)

Currently, most of the protected areas of Bangladesh are undergoing a transition period between traditional management approach to collaborative management (co-management) approach to ensure a better management system basically through shared governance system. However, such paradigm shifting in protected area management approach is not that smooth as anticipated earlier. Various types of socio-economic, environmental and institutional challenges are impeding this paradigm shifting. This qualitative study has explored how nature-based tourism governance system under co-management approach can influence these challenges. Nature-based tourism has been implementing in these protected areas as one of the eco-friendly enterprises and alternative income generating opportunities under this bottom-up approach. Such tourism governance system is facilitating multi-stakeholder participation, transparency, accountability, social learning, decentralization of power and local empowerment, and following rules of laws in these protected areas which ultimately contributes to reduce above-mentioned various challenges and motivating local stakeholders to support and promote co-management approach as an alternative protected area management approach. Nature-based tourism is treated as the sole revenue generating enterprise in these protected areas which is not only generating revenues for different stakeholders but also facilitating significantly to improve environmental awareness and education which ultimately promoting protected area management and conservation. Additionally, it is accelerating to address various issues of traditional management approach particularly through improving collaboration among various stakeholders, decision-making process, resource leveraging, institutional arrangement, lesson and learning opportunity, and so on. Adaptive co-management is an advanced, dynamic, and innovative governance approach can further improve the overall governance system of these protected areas.

Challenges and potentials of ecotourism practices: a case study of Sinharaja rainforest in Sri Lanka

Manjula Karunaratne¹ ; Indi Akurugoda¹

¹University of Ruhuna, Matara, Sri Lanka (mlankanath@gmail.com; ndiakuru@gmail.com)

Tourism is one of the major income sources of Sri Lanka. The government, therefore, has given the top priority to tourism sector development. However, government approaches are not effective and efficient to promote some of the newer, significant and diverse tourism concepts such as ecotourism and forest-based tourism. When these tourism concepts being applied in forest peripheries, several mismatches and malpractices occur. This study mainly focuses on why the concept of ecotourism does not contribute towards benefitting development and conservation initiatives. The study identifies challenges and potentials of ecotourism practices in the Sinharaja rainforest in Sri Lanka. The Sinharaja rainforest is a UNESCO world heritage site which is famous among local and foreign tourists throughout the year. This research used the semi-structured interview method to collect primary data from villagers live in the Sinharaja forest periphery, the forest officials and local and foreign tourists who visit Sinharaja rainforest. Secondary data were collected using books, journals, reports and websites. According to research findings, although the authorities have identified and introduced certain tourism practices in Sinharaja under the name of ecotourism, such practices do not embody at least the basics of such tourism concept. The authorities do not have the knowledge to identify or promote ecotourism and therefore, their activities have led to certain discouragements of tourism promotion. Making communities and officials aware of ecotourism practices in Sinharaja has a potential to benefit people in the area and contribute in sustainable forest conservation and management.

Birds and shutterbugs: how nature photography is driving local conservation efforts in the Eastern Himalaya

Deepa Basnet¹ ; Yang Jianmei², Yi Shaoliang¹

¹International Centre for Integrated Mountain Development (ICIMOD), Kathmandu, Nepal; ²Southwest Forestry University, Kunming, China (deepa.basnet@icimod.org; yangjm21@qq.com; yi.shaoliang@icimod.org)

The Eastern Himalaya encompasses several Important Bird Areas (IBA), with high species diversity and endemism. Avifaunal diversity is not only ecologically important but also provides cultural and recreational services. Due to rich bird diversity, the area has gained popularity among birdwatchers/ photographers, researchers, and nature lovers. The villagers of Hanlong, southeast of Gaoligongshan National Nature Reserve (GNNR) are engaged in bird photography tourism by developing hides, establishing feeding and watering spots, and providing infrastructure to cater to the needs of photographers who seek convenient and less strenuous ways to photograph birds. As tourist numbers increased, the number of ponds grew from 6 in 2013 to over 100 in 2018. Using a mixed-methodology [(eg: household interviews (50), focused group discussions (3), web survey of visitors (90), and expert opinions of ornithologists and conservation experts (6)], assessment of this newly-adopted bird photography tourism was carried out. It also included a review of documents from local government and protected area management departments. References to published and un-published documents from various sources including journals, institutions, travel magazines, national park offices, planning documents etc. were collected and analyzed based on the structured literature review of more than 60 publications in 2017 & 2018 to understand the historical and policy contexts of the study area. The publications were collected using search engine Google Scholar. Bird photography tourism is a major source of income for Hanlong engaging about 86% of local people; 50% percent of households earned about 2,900 USD,

16% earned 2,900-5,800 USD, and 10% earned 5,800-8,700 USD from homestays, ponds and hides, transportation services, and as guides. Birdphotography tourism has benefited women by improving their knowledge of birds, enhancing their visitor management and hospitality skills, and exposure to new viewpoints gained from interactions with tourists. The growth of tourism has encouraged biodiversity conservation. Local dependence on forest resources has decreased exponentially and local perceptions of forest use and ecosystem services has changed. In terms of perceived benefits, 100% of respondents valued the regulating services, 21% provisioning services, and 88% cultural services; 64% of visitors to Hanlong are attracted through online and social media marketing, and referrals on social media. In the case of Hanlong it has led to spontaneous protective actions and change in local perceptions of ecosystem services. It is also an effective way to enhance public awareness and knowledge of biodiversity.

A9j: POLITICS OF INTERNATIONAL FOREST REGIMES

Governing forests as global commons for achieving sustainable development goals: a review of policy design and effectiveness of the international forest regime complex

Metodi Sotirov¹, Benno Pokorny¹, Daniela Kleinschmit¹, Peter Kanowski²

¹University of Freiburg, Freiburg, Germany; ²Australian National University, Canberra, Australia

(metodi.sotirov@ifp.uni-freiburg.de; benno.pokorny@waldbau.uni-freiburg.de; daniela.kleinschmit@ifp.uni-freiburg.de; peter.kanowski@anu.edu.au)

This paper reviews the International Forest Governance (IFG) and analyses their impacts on tackling deforestation, forest degradation, biodiversity loss, climate change while achieving sustainable forest management. Based on international relations and the “governance triangle” literatures, six basic types are derived that the IFG elements are clustered into: (1) multilateral intergovernmental treaties (ITAA, UNFCCC, CBD, failed forest convention), (2) non-legally binding multilateral agreements (IAF), (3) transnational hybrid governance regimes (FLEGT/timber legality regime), (4) public-private-partnerships (e.g., REDD+ initiatives), (5) non-state market driven governance (FSC/PEFC), and (6) private sector partnerships (deforestation free initiatives). In addition, forest adverse governance arrangements outside the forest sector (e.g., agriculture, bioenergy, mining) are assessed. All processes are reviewed and compared in terms of their governance approaches. This refers to analysis of the involved state and non-state actors including their positions, mind-sets and coalitions, as well as their specific policy aims, tools, management concepts, monitoring and control mechanisms, and main pathways of influence. Thereby, important challenges in the design and implementation as well as in the coordination, integration and coherence of all these governance elements are identified. Last, but not least, the paper synthesizes (i.) the analysis of policies, governance processes and other actions affecting the drivers and global contributions of forests with an (ii.) the assessment of the existing, probable and needed functions of forests as global commons in order to (iii.) offer a critical reflection about the need and possibilities for transformative changes to secure the global commons function and sustainable development of forests.

Comparing forest policies of regional regimes: the cases of ACTO and Mercosur

Sarah Lilian Burns¹, Lukas Giessen²

¹LISEA - FCyF - UNLP, La Plata, Argentina; ²European Forest Institute, Bonn, Germany (salibu@agro.unlp.edu.ar; lukas.giessen@efi.int)

Forests as an issue in world politics are governed by global and regional regimes. Political analyses have mainly focused on international forest governance by global forest-related regimes, e.g. on sustainable forest management. In addition to these global forest-related regimes a number of studies acknowledge the relevance of regional forest-related regimes in the form of “regional organisations, institutions, instruments, processes, initiatives and networks”. So far such studies, however, do not provide for detailed empirical analyses. According to previous studies regional forest regimes differ in their institutional design regarding the way in which they address forests as issues, ranging from forest-focused regimes with forests as the main issue to forest-relevant regimes, which do not address forests formally and explicitly, but have empirical relevance for forests on the ground. The potential of regional forest regimes and their policies with weak or no formal link to forests, but with a potentially immense influence on forests has only rarely been analyzed. By applying an interest-based, actor-centered, and bureaucracy-oriented approach our study aimed to analyze two regional regimes from South America, the Amazon Cooperation Treaty Organization and the Mercosur with differences in the focus on forests as issue, acknowledging the key role state bureaucracies play in the design of international regimes and their policies. Qualitative content analysis of key policy documents was used on regime design and on the individual forest policies developed within both selected regimes. Our results show that despite a weak forest focus, forest-relevant regimes, like Mercosur, can develop strong forest policies.

Comparing forest policies of regional regimes: formality, sectors, and hegemony as drivers?

Pradip Kumar Sarker^{1,2}, Lukas Giessen¹

¹European Forest Institute, Bonn, Germany; ²Goettingen University, Goettingen, Germany (protikswa@gmail.com; lukas.giessen@efi.int)

In the absence of a comprehensive forest regime at the global level, a number of forest-focused but also forest-relevant initiatives, processes, and institutions have proliferated at regional scales around the globe and by different sectors. Over time, a number of such regional regimes developed policies for addressing forests in multiple ways. This paper aims at comparing the forest policies of selected regional regimes, trying to identify key factors determining whether these policies are strong or weak. We use a fuzzy set Qualitative Comparative Analysis (QCA) methodology as well as deep empirical insights into a number of regional regimes for this comparison. The results provide indications on whether sectoral, forest-focused regimes produce weaker forest policies than general regimes on e.g. economic integration. Likewise, the influence of the degree of regime formality (i.e. informal vs. formal treaty/convention regimes) on regime policies will be presented. Lastly, the influence of hegemonic regional powers on the regimes' forest policies will be revealed. The study concludes with indications of factors and combinations thereof, which lead to rather strong or weak forest policies of a wide array of regional regimes.

Comparing the effects of international regimes in unitary and federal systems: insights from plantation forest development in Argentina and Uruguay

Julian Daniel Mijailoff^{1,2}, Sarah Lilian Burns², Lukas Giessen³

¹CONICET, La Plata, Argentina; ²LISEA, Facultad de Ciencias Agrarias y Forestales, Universidad Nacional de La Plata, La Plata, Argentina; ³European Forest Institute, Göttingen, Germany (julymihail@hotmail.com; sarahlilburns@gmail.com; lukas.giessen@efi.int)

Plantation forests are rapidly expanding, concentrating mainly in the southern hemisphere where they are becoming one of the main land use changes. In South America, this expansion has been promoted by international actors, with the aim of creating a pulp production cluster. Previous studies have described the

influence of the international forest regime (IFR) in the definition of national policies that promote plantation forests. However, recent studies suggest that it is the domestic setting with their competing actors, which determines the influence the IFR at the domestic level. It is then expected that the way the IFR influences the domestic level will vary between federal and unitary countries. Hence, the aim of our study was to analyse how the influence of the IFR differs in federal and unitary systems. In order to do so, the cases of Argentina (federal country) and Uruguay (unitary country) were selected as two neighbouring countries from the global south with similar ecological conditions for the establishment of plantation forests. Process tracing of the development of the plantation forest sector in both countries was carried out using extensive data from expert interviews and document analysis. The results shed light on why the unitary system was able to fruitfully utilize the IFR in support of plantation forestry, whereas the federal system displayed severe constraints in this regard. The paper concludes that despite cross-sectoral competition among different land uses, the domestic multi-level setting is a decisive factor in enabling or constraining effects of the IFR in national contexts.

The two faces of international forest governance: customising international regimes through domestic politics

Lukas Giessen¹

¹European Forest Institute (EFI), Bonn, Germany (lukas.giessen@efi.int)

A large number of international, i.e. global, regional and bi-lateral governance regimes and initiatives tackle forests at international levels. On the one hand, they strive for making a meaningful addition to the existing set of international governance arrangements. On the other, they aim to achieve political and biophysical impacts in national settings. For the latter, international forest governance regimes and initiatives crucially depend on domestic partners, who in turn utilize and customize international processes according to their interests. This customization of international governance initiatives in multiple domestic contexts lends those initiatives two faces - an international as well as a domestic one. Using theories and methods from public policy and international relations, and based on multiple empirical insights from around the globe, this paper illustrates how international forest governance initiatives and regimes are being customized by powerful actors in domestic settings. Cases include bi-lateral forest development policy in Bangladesh, forest-related World Bank interventions in Argentina, EU Biodiversity policy in Poland, as well as forest-related palm oil politics in Indonesia. The paper concludes with methodological and empirical questions and directions for future research into the effects of internationalization and international governance concerning forests.

International forest policy: an example for output convergence?

Helga Püzl¹  Catherine Ohler¹

¹University of Natural Resources and Life Sciences, Vienna (BOKU), Vienna, Austria (helga.puezl@boku.ac.at; catherineloehler@gmail.com)

Presently, international forest policy is occurring within an intricate governance arrangement viewed by as complex, including many actors and forums as well as agreements conventions, and policy documents. One major critique is that it is ineffective, lacking the ability to adequately solve the global forest-relevant problems of today. Institutional fragmentation and fragmentation of objectives are most often understood the cause of ineffectiveness. Since those have already been widely explored, the paper is focused on the fragmentation of addressed issue areas and regime outputs. Furthermore, the study also aims to determine in what subject or issue areas the fragmentation and overlaps can be found. This is to determine if it is highly fragmented or it does in fact exhibit levels of coherence and synthesis. The goal is to explore how the regime is fragmented through the use of content analysis using MAXQDA. The results reveal that the regime contains instances of both overlap and fragmentation. Overall, there is substantial overlap when considering the many different topics addressed. Additionally, while there may be institutional fragmentation and fragmentation of objectives there was considerably less fragmentation of outputs. Despite the existence of many overlapping forest-relevant subject areas, there is still substantial room for strengthening existing synergies and fostering new relationships from these overlaps through the use of various coordination efforts. Consequently, the ultimate goal of improving the effectiveness of the IFRC can be reached through the use of coordination mechanism that promote the enhancement of synergies amongst regime elements.

The future of global forest governance: a transdisciplinary Delphi study

Begemann Anna¹, Lukas Giessen¹, Georg Winkel¹

¹European Forest Institute, Bonn, Germany (anna.begemann@efi.int; lukas.giessen@efi.int; georg.winkel@efi.int)

Since the early 1990ies, a large number of state- as well as private sector-driven global forest governance initiatives emerged, many of which achieved only modest implementation impacts. This way many lessons could be learnt. However, the trends of deforestation and forest degradation in the tropics could not be reversed. Hence, being somewhat at the crossroads, taking stock of the lessons learned as well as looking into the anticipated future pathways and options of global forest governance is an important enterprise. Against this background, this study aims to 1) assess major challenges and lessons learnt for Global forest governance initiatives and to 2) identify possible pathways for the future of global forest governance. In order to achieve this, the European Forest Institute's Bonn office carried out a Delphi assessment based on a high-level panel of 38 experts from international governmental and non-governmental organizations, public administrations, and academia. The Delphi method consisted of three consecutive steps: 1. expert interviews among panellists, 2. an online survey, 3. a joint workshop, whereby the results were reflected back and validated by the expert panel. The paper will showcase selected results of the study including the experts' perceptions on important challenges in and effects of global forest governance, the most and least promising initiatives, the most and least important actors and possible future pathways of Global forest governance, including salient but unexplored research topics. In addition, it will highlight options for action for the future of Global forest governance.

Are international forest regimes being formed on social media? A review and a case study

Ida Wallin¹

¹University of Freiburg, Freiburg, Germany (ida.wallin@ifp.uni-freiburg.de)

International forest regimes involve the reconciliation of dissimilar values, beliefs and ideas held by the various stakeholder groups that participate in the decision-making process. Regimes are thus influenced by the different policy ideas, narratives and frames held by the stakeholders. Today forest-related policy ideas, narratives and frames are frequently occurring and debated on social media platforms. Here, individuals and organizations alike shape and reshape their own and others' ideas concerning the future of forests. The potential of social media content to influence the development of international forest regimes is yet to be explored and researchers need to take a closer look into these activities. Social media is arguably the most dynamic, largest and richest source of information about human behavior. Activities on social media platforms contribute to the co-production of knowledge, norms and public opinions for all aspects of society and forests are no exception. Actors, both individuals and organizations, battle for control over ideas by framing and connecting statements to their preferred

narratives. For example, each tweet is a microblog and a story-line, carrying meaning directed to decision-makers. This presentation reviews current knowledge about international forest-related debates on social media platforms and discuss the potential for improving our understanding of international forest governance development through studying social media. It covers a literature review and a case study of Twitter debates concerning forest-related issues in Europe and the EU.

Coalitions, collaborations and conspiracies: dynamics of REDD+ and Global forest politics

Maria Brockhaus^{1,2}, Grace Wong³, Cecilia Luttrell⁴, Moira Moelinono⁴, Thu Thuy Pham⁵

¹University of Helsinki, Helsinki, Finland; ²Helsus, Helsinki, Finland; ³Stockholm Resilience Centre, University of Stockholm, Stockholm, Sweden; ⁴CIFOR, Bogor, Indonesia; ⁵CIFOR, Hanoi, Vietnam (maria.brockhaus@helsinki.fi; grace.wong@su.se; cecilia.luttrell@gmail.com; m.moelinono@cgiar.org; t.pham@cgiar.org)

In 2005, RED(D+) emerged as a climate mitigation strategy to reduce emissions from deforestation and forest degradation in the tropics under the UNFCCC. Despite a number of contestations, a wide range of diverse actors were able to unite under the canopy of REDD+ objectives of halting deforestation while providing for development and delivering other co-benefits. The contestations remain however and include fundamental questioning of the instruments and measures to realise these objectives, such as the concept of a forest carbon market and offsetting, which raises global climate justice concerns. Within REDD+ target countries, indigenous rights organisations put forward equity concerns of REDD+ being used to justify a recentralisation of forest resources rather than devolution of rights and tenure for local forest stewards. Effectiveness and cost-efficiency of a REDD+ mechanism was also questioned by researchers, civil society, business and state actors with regards to leakage and permanence, and the untackled political economy of deforestation. Voices within the long-standing international forest regimes criticised REDD+ for taking away financial resources and global attention from established approaches to the governance (and management) of forests and forest land in the global South. Building on a global comparative dataset of national REDD+ policy networks, and participatory observations and interview material from UNFF meetings, UNFCCC COPs, SBSTAs, IUFRO conferences and other international meetings since 2007, we explore the coalitions of adversaries and advocates of REDD+, and discuss how politics and the underlying beliefs, interests, and discourses affect objectives to reduce emissions from deforestation and forest degradation.

The private in the public of international forest regimes

Daniela Kleinschmit¹

¹University of Freiburg, Freiburg, Germany (daniela.kleinschmit@ifp.uni-freiburg.de)

The role of private actors in international regimes has been investigated for a long time resulting in different conclusions, ranging from “hollowing out the state” to “governance in the shadow of hierarchy” depending on the perspective taken and the process analysed. A comprehensive analysis about the role of private actors is missing so far and the specific situation of international relations in the area of forest policy with its long-term relationship between traditional actors is hardly acknowledged. This presentation starts out from the understanding of public and private in the way it is regarded by western modernity, demarcating the “public” domain of state power from the private domain of market and civil society. Concentrating on at the first glance intergovernmental processes within the international forest regime this presentation aims to unlock the role of private actors in negotiations and standard setting. Building on the theory of network governance and the concept of legitimacy three main research questions are addressed: (i) how far are private actors formally and informally involved in forest centred and related intergovernmental processes, (ii) whether private actors have influenced the process and (iii) the involvement is perceived as legitimating the process. Theoretically, the presentation builds on a network governance perspective adding the concept of legitimacy. Findings resulting from a comprehensive analysis of international governance literature and additional analysis of policy documents will close the gap of so far only isolated and scattered results of private actors involvement in international forest regimes.

A9k: STATUS AND CURRENT DEVELOPMENTS IN SOUTH-SOUTH COOPERATION IN FORESTRY

Status and current developments in South-South cooperation (SSC) in forestry

Stephan A. Pietsch^{1,2}

¹IIASA, Laxenburg, Austria; ²BOKU, Vienna, Austria (pietsch@iiasa.ac.at)

In 1978 the UN-Conference on Technical Cooperation among Developing Countries in Buenos Aires acknowledged South-South Cooperation (SSC) as significant tool of development and poverty reduction. The similarity in problems and challenges logically suggests the exchange and transfer of successful solutions. Since the First South Summit, held in Havana in 2000, the evolution and agenda of South-South cooperation (SSC) made progress at technical, scientific, institutional and policy levels and delivers a significant contribution to sustainable development. This presentation will give an overview of past achievements and current developments of SSC activities within the forestry sector.

Options for inner-African South-South cooperation

Coert J Geldenhuys¹

¹Plant & Soil Sciences, University of Pretoria, Pretoria, South Africa (cgelden@mweb.co.za)

Africa has vast tropical moist forests and seasonally dry, deciduous woodlands. These resources of timber, non-timber and non-wood forest products are used globally, mostly for economic development elsewhere. Forest policies seem to be imposed onto governments across the continent, mostly from elsewhere, via FAO, seemingly without or very little consideration for the ecology of the different systems, nor for the needs of the rural societies living within these resource areas. Conflicts exist between policies for forestry, agriculture, conservation and rural development towards sustainable development. Some regulations are enforced with reference to local and regional timber concessionaires, but ignored when multinational groups or companies export large timber volumes, often of trees of small sizes. There is no care for proper silvicultural management of the remaining resources. Some ideas will be presented with examples from the different management conflicts.

Forestry training, education and research in the Congo basin

Damase P. Khasa¹, Claude Kachaka^{2,3}, Stephan A. Pietsch³

¹Université Laval, Quebec, Canada; ²RIFFEAC, Yaounde, Cameroon; ³University of Kinshasa, Kinshasa, Democratic Republic of the Congo, ³IIASA, Vienna, Austria (damase.khasa@sbf.ulaval.ca; kachaka_sudi@yahoo.com; pietsch@iiasa.ac.at)

The Congo basin is the world's second largest tropical forest after the Amazon basin. This region is undergoing rapid socioeconomic development coincident with problems such as rapid population growth, poverty and hunger, and accelerating rates of natural resource exploitation, often involving powerful foreign interests, political and social tensions, and weak governance of institutions. The success of economic development and green growth efforts often hinges on the ability to strengthen human and institutional capacity, e.g., by promoting education, training, research and building institutional capacity. In this paper, we aim to present the work undertaken since the early 1970s by the Faculty of Forestry, Geography and Geomatics of Université Laval (the oldest French-language university in North America) and its partners, more specifically the Network of Environmental and Forest Training Institutions in Central Africa (RIFFEAC), in capacity building to promote the conservation and sustainable management of tropical forests in Congo Basin's natural resources, in accordance with the Revised Convergence Plan of the Central African Forest Commission (COMIFAC) (2015-2025). Ex-post-analysis of different training projects was conducted for looking at their strengths, weaknesses, opportunities, and challenges (SWOC). The analysis took into account different aspects including the funding in higher education and research, the development of curricula, the training of highly qualified personnel both at university and technical levels, and job opportunities.

Lessons learned from the EU FLEGT process to spur the Chinese “Global Green Supply Chain” (GGSC) initiative offering opportunities for China-Africa cooperation

Ralph Ridder¹

¹Consultant for the GIZ Forest Policy Facility in Beijing, China., Geneva, Switzerland (ralph.ridder@bluewin.ch)

Assessing the results of the ongoing FLEGT process can provide valuable input to the newly created GGSC initiative by Chinese wood importing/wood processing industry. China-Africa south-south cooperation strengthening GGSC in reaching its targets of sustainable wood production and sustainable supply can contribute to improving forest governance in African wood exporting countries as well as helping EU wood product imports to comply with EUTR.

A91: SUSTAINABLE DEVELOPMENT GOALS: THEIR IMPACTS ON FORESTS AND PEOPLE

Sustainable Development Goal #1 and forests: implications of expanding social protection, securing tenure, and building resilience to environmental shocks

Kathleen Lawlor¹, Stibniati Atmadja², Liwei Lin³, Karnjana Songwathana⁴, Erin Sills³

¹University of North Carolina at Asheville, Asheville, USA; ²CIFOR, Addis Ababa, Ethiopia; ³NC State University, Raleigh, USA; ⁴Bangkok University, Bangkok, Thailand (klawlor@unca.edu; s.atmadja@cgiar.org; livia1020@gmail.com; karnjana.s@bu.ac.th; sills@ncsu.edu)

Sustainable Development Goal (SDG) #1 seeks to “end poverty in all its forms everywhere.” The effects on forests will depend on how poverty alleviation is approached. SDG#1 calls for reducing poverty specifically by ensuring that the poor are covered by social protection systems; by securing the poor's rights to economic resources, access to basic services, and property ownership; and by building their resilience to economic, social and environmental shocks. The empirical literature shows that social protection in the form of cash transfers and more secure property rights – especially for community land - can be conducive to forest conservation, given the right context and conditionalities. As demonstrated by programs for reforestation of hillsides in China and mangroves in many other countries, policies designed to reduce vulnerability can promote ecosystem-based adaptation, including expansion of forest cover. This is consistent with the scientific evidence that forests are both a mainstay of rural livelihoods and a buffer and source of natural insurance. However, there is relatively little evidence that this scientific knowledge is actually shaping poverty alleviation and national development strategies. To the extent that those strategies continue to be based on infrastructure and agricultural development, they are likely to remain in conflict with the conservation and sustainable management of forests.

Achieving Sustainable Development Goals on food security and nutrition: the impacts on forests and livelihoods

Terence Sunderland^{1,2}

¹University of British Columbia, Vancouver, Canada; ²Centre for International Forestry Research, Bogor, Indonesia (terry.sunderland@ubc.ca)

As the human population continues to grow, so does pressure to increase food production. Agriculture now dominates the Global landscape and more food is being produced than ever before. Yet, our population is characterized by alarming rates of obesity and malnourishment. Concomitantly, much of the agricultural expansion related to achieving Global food security is at the expense of forest ecosystems, critical for biodiversity and the provision of ecosystem services. SDG 2: Zero Hunger seeks to “End hunger, achieve food security and nutrition and promote sustainable agriculture”. In this chapter we explore the potential impacts of achieving SDG 2 on forests and forest dependent people. We focus on five of the targets (2.1-2.5) under SDG 2 which are closely entwined with forests and forest related livelihoods. We discuss how the current food system polarises food production and forest conservation, when in fact, they should, and can be harmonised. Paying special attention to the role of maintaining genetic diversity (Target 2.5) and investing in small-scale food producers (Target 2.3) in sustainable food systems (Target 2.4) to reduce hunger and malnutrition (Targets 2.1 and 2.2). We close with observations on the potential tradeoffs and synergies between SDG 2 and the other SDGs, emphasizing the need for integrated land use management.

Impacts of addressing Sustainable Development Goal 3 health and Wellbeing on forests and forest people

Rosemary McFarlane¹, John Barry², Guéladio Cissé³, Maya Gislason⁴, Marta Gruca⁵, Kerryn Higgs⁶, Pierre Horwitz⁷, Giang Huu Nguyen⁷, Jane O'Sullivan⁸, Subashis Sahu⁹, Colin Butler¹⁰

The achievement of the third Sustainable Development Goal (SDG3), Health and Wellbeing for All, depends on many other SDGs but there are also potential conflicts and trade-offs. We have examined SDG3 targets and identified the contexts in which positive outcomes for both forests and people can be met. We stress the importance of forests to global health and wellbeing as well as for Indigenous and local populations. In contrast, short-term economic and human health gains from further forest conversion (e.g. deforestation for food production) will create direct and indirect health risks for humans, as well as for other biota. Controlling indiscriminate burning and clearing of forests can reduce significant harm to health and wellbeing, via improved quality of water, soil, air (a transnational issue), by reducing exposure to some infectious diseases, through preservation of traditional (and future) medicines, and by supporting other forest resources and services, including climate regulation. Many infectious diseases are associated with forest disturbance and intrusions and some may be prevented or modified through forest management. Universal access to sexual and reproductive health-care services, including for family planning, is a critical SDG3 target to decrease demographic pressures on forests at local, regional and global scales, and to enhance wellbeing. Greater exposure to green space, including the 'urban forest', is likely to have many benefits for mental, social and physical health for the increasingly urban global population. More broadly, forests play important roles in enriching cultural and religious wellbeing.

“The golden thread”: Sustainable Development Goal 4 education for all, and forests

Peter Kanowski¹, Dollie Yao¹, Stephen Wyatt²

¹Australian National University, Canberra, Australia; ²Université de Moncton, Moncton, Canada (peter.kanowski@anu.edu.au; dollie.yao@anu.edu.au; stephen.wyatt@umoncton.ca)

Education has been characterised as “the golden thread that runs through all 17 Sustainable Development Goals (SDGs)”. This paper explores the relationships between SDG4, “Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all”, and forests and their benefits and services. SDG4 focuses on broadening the depth and breadth of education; it expands the scope of ‘education’ beyond the traditional focus of formal schooling environment and years, to a lifelong process spanning a range of non-formal and informal settings; and emphasises quality of access to education, particularly for girls and women and marginalised groups. We draw on literature exploring “pro-environment” behaviour to consider how progress towards SDG4 might impact on forests, forest ecosystem services, and forest-related livelihoods. We introduce the concept of “pro-forest” behaviour to describe those elements of pro-environment behaviour related to forests. We suggest that encouraging and enabling pro-forest behaviour is the basis of the relationship between SDG4 and forests. Inclusive education that builds and reinforces understanding and knowledge of forests, and that helps individuals and communities feel or stay connected to forests, will foster and sustain pro-forest behaviours. Progress towards SDG4 will benefit forests if education; Informs, encourages and enables ‘pro-forest’ behaviour; Respects, nurtures and enables Indigenous and traditional knowledge; Promotes forest-related Education for Sustainability and Environment in each of formal, non-formal and informal settings; Strengthens forest-related professional and technical and vocational education and training, and capacity development; Capitalises on the power of both established and new media.

Taking SDG 5 seriously

Seema Arora-Jonsson¹, Shruti Agarwal², Carol J. Pierce Colfer^{3,4}, Stephanie Keene⁵, Priya Kurian⁶, Anne Larson³

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²Center for Science and Environment, New Delhi, India; ³CIFOR, Bogor, Indonesia; ⁴Cornell University Ithaca USA; ⁵Rights and Resources Initiative, Washington, USA; ⁶University of Waikato, Hamilton, New Zealand (seema.arora.jonsson@slu.se; shruti_agarwal@cseindia.org; cjpcolfer@gmail.com; skeene@rightsandresources.org; priya.kurian@waikato.ac.nz; a.larson@cgiar.org)

Taking SDG 5 seriously brings to the fore issues usually taken for granted in forest debates – people, their relationships to one another and to the forests, which together determine forest outcomes. We first analyze the forest context for SDG 5; second, we consider the impacts of taking SDG 5 and its targets seriously on forests and people’s livelihoods. Overall, little progress has been made in implementing these targets within the forestry sector. We will need a fundamental change in approaches to forests and the environment---one that incorporates systemic and contextual factors as well as the people’s relations outside of forestry (e.g., Health, violence, unpaid care work, both in and outside the forest). Closer attention to SDG 5 can highlight the invisible labor and relations so crucial to good forest management and help to develop democratic and sustainable strategies so key to sustainable forest relations and of benefit to forest peoples. Politically we need to transform unequal relationships, to challenge privilege based on sex, class, ethnicity or caste and to destabilize inequitable micro and macro-economic structures (based on notions of private property, commodification, etc.). Iufro has an important role to play in this context in questioning its own business as usual and also in undertaking gender research and analysis of forestry policies and programs to better understand gender dynamics. The welfare and dignity that achieving SDG 5 would bring to forest peoples and livelihoods is essential to ensuring better managed and sustainable forests.

Decent work and economic growth: potential impacts of SDG 8 on forests and forest-dependent livelihoods

Dietmar Stoian¹, Iliana Monterroso², Dean Current³

¹World Agroforestry Centre (ICRAF), Montpellier, France; ²CIFOR, Guatemala City, Guatemala; ³University of Minnesota, St. Paul, USA (d.stoian@cgiar.org; i.monterroso@cgiar.org; curre002@umn.edu)

This paper assesses the potential impact of Sustainable Development Goal (SDG) 8 on forests and forest-dependent people. The concepts of decent work and economic growth are put in the context of predominant development theories and paradigms (modernization, economic growth, basic needs, sustainable development) which shape the agendas of governments, private sector, civil society, and investors. These stakeholders pursue different goals and interests, with uneven prioritization of SDG 8 targets and mixed impacts on forests and livelihoods. Significant trade-offs are expected for countries where growth strategies and policies focus on sectors competing with forestry for space and resources, such as agriculture, energy, and mining. In these cases, the decoupling of economic growth from environmental degradation will be a major challenge. At global level, trade-offs are anticipated as the combined effects of such policies and strategies contribute to climate change. A potential for synergies between SDG 8 and forests exists where growth is explicitly sought for in the forest sector, focusing on tree plantations, timber and NTFPs from natural forests, eco-tourism, and environmental service payments. Advancing decent work in the forest sector requires addressing issues related to gender, ethnicity, mobility associated with forest-based operations, and labor safety. Improvements in the enabling environment can help minimize trade-offs and maximize synergies by reconciling government policies and private sustainability standards (e.g. zero deforestation, sustainable palm oil and cocoa), formalizing community stewardship of tropical forests, addressing informality prevalent in forest product value chains, and providing incentives for youth to become involved in forest-based economic activities.

Anticipating the potential impacts of Sustainable Development Goal 9 on forests and forest-based livelihoods

Maria Fernanda Tomaselli¹, Joleen Timko¹, Robert Kozak¹

¹University of British Columbia, Vancouver, Canada (fernanda.tomaselli@ubc.ca; joleen.timko@ubc.ca; rob.kozak@ubc.ca)

Sustainable Development Goal (SDG) 9 is centered on three main pillars – industry, infrastructure and innovation. With eight targets and twelve indicators, SDG 9 will have multiple impacts on forests, forest-based livelihoods and forest-based economies. This presentation highlights some of the potential implications of SDG 9, as currently written, on forests and forest-dependent people. Drawing on a comprehensive literature review, we will elucidate possible interactions, synergies, and trade-offs that could be at play as SDG 9 is implemented. For example, major trade-offs will exist between SDG 9 and SDG 15, especially if economic expansion and increasing planetary impacts remain coupled. More specifically, target 9.1 and its corresponding indicators (road, infrastructure and transportation expansion) risk irreversible and widespread forest degradation and deforestation; thus, the short and long-term environmental and social costs of this goal need to be better assessed. The impacts on forests and livelihoods of other targets (e.g. small-scale industry expansion [Target 9.3]; access to information and communications technology [Target 9.c]) will largely depend on how they are implemented. We conclude our presentation with a call for reforming SDG 9 to promote and support alternative socioeconomic models that are not based on indefinite economic growth, nor reliant on the ongoing expansion of infrastructure, and in which, the maintenance of ecosystem services and forests would be seen as essential building blocks of a green and sustainable economy.

Impacts of the urban Sustainable Development Goal 11 on forests and people

Tahia Devisscher¹, Cecil Konijnendijk¹, Lorien Nesbitt¹, Jennifer Lenhart², Fabio Salbitano³, Zhaohua Cindy Cheng¹, Shuaib Lwasa⁴, Matilda van den Bosch¹

¹University of British Columbia, Vancouver, Canada; ²Worldwide Fund for Nature, Santiago, Chile; ³Università di Firenze, Florence, Italy; ⁴Makerere University, Kampala, Uganda (tahia.devisscher@ubc.ca; cecil.konijnendijk@ubc.ca; lorien.nesbitt@ubc.ca; jennifer.lenhart@wwf.se; fabio.salbitano@unifi.it; zhaohua.cheng@ubc.ca; lwasa_s@caes.mak.ac.ug; matilda.vandenbosch@ubc.ca)

Addressing this century's urban challenges greatly depends on how cities prioritise resources and urban planning strategies over the next decade. In 2015, a global effort to address urban challenges was endorsed by 193 countries as part of the United Nations 2030 Agenda for Sustainable Development and its Sustainable Development Goal 11 (SDG11) to “make cities and human settlements inclusive, safe, resilient and sustainable”. By endorsing a stand-alone goal on cities, the international community recognized urbanisation as a transformative force for innovation and sustainable development. We provide an analysis of SDG11 implementation taking into consideration global monitoring of SDG11 impacts, and different local priorities linked to distinct urbanisation patterns. We focus particularly on the effects on forests and forest-based livelihoods, and propose a framework to assess synergies and trade-offs between SDG11 and other SDGs accounting for diverse city types. As part of global SDG11 implementation, we found that countries tend to prioritise access to adequate housing and sustainable transport with interlinkages to health, education, and employment. Few countries enforce policies to ensure safe, green and accessible public places and the protection of cultural and natural heritage in and around cities, despite the manifold benefits urban forests can bring. Little attention is given to building strategic social and environmental links between urban and rural areas. A more integrated approach to urban-rural territorial planning could have a positive impact on forests and forest-based livelihoods by diversifying and improving access to ecosystem services and socio-economic benefits generated by forests.

Are peace and justice good for forests? An analysis of SDG 16 and its implications for forests and people

Constance McDermott¹, Seema Arora-Jonsson², Rebecca Asare³, Wil de Jong⁴, Mark Hirons¹, Kaysara Khatun¹, Mary Menton⁵, Fiona Numan⁶, Mahesh Poudyal⁷, Abidah Setyowati⁸, Emmanuel Acheampong⁹

This chapter assesses the implications of implementing UN SDG 16 - “Peace, Justice and Strong Institutions”, for both forests and people. Despite the widespread appeal of “peace” and “justice” as international goals, the intense debates preceding agreement on SDG 16 highlight the power dynamics underlying its interpretation and implementation. Our analysis focuses in particular on three thematic areas: 1) peace and the reduction of armed conflict, 2) the rule of law, accountability and transparency, and access to justice and 3) inclusiveness and participation. Regarding peace and conflict, existing literature reveals highly variable outcomes: conflict may either curtail agricultural expansion into forest frontiers and/or drive illicit crop production, and foster migration in or out of forested areas; while peace is often accompanied by state-supported mining and expansion of commercial crops. More generally, national laws governing forests and land use in many countries favor political elite, large-scale industry actors and international trade. Hence if SDG implementation emphasizes strengthening state institutions, the rule of law and transparency linked with international trade, it is likely to reinforce existing inequalities, unless it is counter-balanced with legal reforms that strengthen local rights to land and resources. While there has been much recent progress in expanding forest areas under “community-based” or “participatory” forest management, in many cases this has been tightly controlled by the state, contributing to local administrative burdens without significantly redistributing power and benefits. In sum, the impacts of implementing SDG 16 on forests and people depend on socio-political priorities and power dynamics.

SDG17 and sustainable forest management: strengthening the means of implementation and revitalising the global partnership for sustainable development

David Humphreys¹, Benjamin Singer², Kathleen McGinley³, Roy Smith⁴, Jessica Budds⁵, Monica Gabay⁶, Shonil Bhagwat¹, Wil de Jong⁷, Newing Helen⁸, Charlotte Cross⁹, Poshendra Satyal⁵

This paper examines how actions in support of SDG17 can promote sustainable forest management. Statistical evidence is provided to show that funding for forests from both ODA and other sources is trending upwards since 2000, providing reason for cautious optimism. While finance for REDD+ is in decline, private sector

investment remains important. The idea of impact investment, which aims to solve pressing environmental and social problems, may make a significant contribution to the sustainability agenda. The paper argues that the policy of zero net deforestation (ZND) is leading to the creation of some important partnerships, some of which include the financial sector, that aim to ensure deforestation-free commodity supply chains of key agricultural commodities. However, tensions remain between some SDGs and not all sustainable development finance promotes the conservation of forests. The target of increasing funding for agricultural production to contribute to SDG2 (zero hunger) often incentivises the conversion of forests to agricultural land and livestock. In several countries international forest-related ODA is dwarfed by domestic subsidies to agricultural production. This provides a structural incentive for the conversion of forests to agricultural land, in particular of the four forest risk commodities. Realising forest-related sustainable development thus depends on policy coherence between the forests sector and forest-related SDGs, and the complex conflicts and synergies between them. However, partnerships for sustainable development exist within a neoliberal global economic order in which there are net financial flows from the global South to the global North that often negate financial flows for sustainable development.

Health, gender, equity, and justice: potential synergies among SDGs

Carol J. Pierce Colfer^{1,2}, Rosemary A. McFarlane³, Richard Dudley⁴, Seema Arora-Jonsson⁵, Bimbika Sijapati Basnett¹, Constance McDermott⁶

¹CIFOR, Bogor, Indonesia; ²Cornell University Ithaca USA; ³University of Canberra, Canberra, Australia; ⁴Indonesia; ⁵Swedish University of Agricultural Sciences, Umeå, Sweden; ⁶University of Oxford, Oxford, United Kingdom (cjpcolfer@gmail.com; romcfarlane@gmail.com; rgdudley@gmail.com; seema.arora.jonsson@slu.se; bimbika@gmail.com; constance.mcdermott@ouce.ox.ac.uk)

Building on several chapters of the IUFRO WFSE project's newly published book, Sustainable Development Goals: Their Impacts on Forests and People, this presentation focuses on the following people-oriented SDGs, SDG 3 (health), SDG 5 (gender), SDG 10 (equity), and SDG 16 (justice). The book considers the potential and likely impacts of the implementation of each of the SDGs on forests and people. The findings from across the globe show an evident lack of attention to these people-oriented SDGs, which if implemented with care, represent a combination that has the potential to work in a transformative manner for both people and for forests. The presentation examines some of the potential synergies among these SDGs and identifies some of the shortcomings in current implementation efforts. Particular attention is devoted to 1) the potential to stimulate and support constructive efforts of the female half of the global population (including traditional knowledge, creativity, energy, and motivation); 2) how to activate currently marginalized groups (certain ethnic groups, lower castes, those financially strapped, LGBTQ individuals, etc.); 3) the synergies between progress in establishing greater global justice (between the 'rich' and the 'poor' and among groups within each broad category) with clear impacts on and roles for marginalized groups; and 4) the positive contributions to forests and peoples of improved health for forest populations.

A9m: POLITICAL ECOLOGY AND INTEGRATED LANDSCAPE APPROACHES: COMPLEMENTARITY OR UNHAPPY MARRIAGE?

Political ecology and integrated landscape approaches: complementarity or unhappy marriage?

Mirjam Ros-Tonen^{1,2}, Bas Arts^{3,4}, Terry Sunderland⁵

¹University of Amsterdam, Amsterdam, Netherlands; ²PBL Netherlands Environmental Assessment Agency, The Hague, Netherlands; ³Wageningen University, Wageningen, Netherlands; ⁴Centre for International Forestry Research, Bogor, Indonesia; ⁵University of British Columbia, Vancouver, BC, Canada (m.a.f.ros-tonen@uva.nl; bas.arts@wur.nl; terry.sunderland@ubc.ca)

Forests play a rapidly changing role in the livelihoods of rural people as they find themselves increasingly embedded in multifunctional landscapes, where trade-offs exist between competing land uses. Integrated landscape approaches (ILAs) are gaining ground to negotiate such trade-offs. Although power imbalances are increasingly acknowledged as a challenge to achieving negotiated outcomes in ILAs, the politics of negotiated landscape governance still remain underexposed in the literature. Based on a review of literature, this paper aims to explore whether and how synergy can be created between two seemingly contradictory approaches towards global challenges affecting landscapes, such as deforestation, biodiversity loss, climate change and food security. Whereas ILAs are based on a rather naïve assumption that landscape actors are on the same page in their determination to address these challenges, critical approaches such as political ecology take power imbalances and unequal access to natural resources as a starting point to analyze landscape dynamics. In this paper, we argue that both approaches are needed for integrated and inclusive landscape governance. Political ecology and critical studies more broadly provide insights into the politics and framing of human-nature interactions as well as the diverging interests, power imbalances and inequalities in resource access and decision-making at landscape level. We explore how these insights can be made functional to the operationalization of ILAs, thus contributing to both theory building and the operationalization of integrated landscape governance.

Implementing landscape conservation from above: donor funding, conservation politics and local struggles over land in Mchemba village, Tanzania

Numan Amanzi¹

¹Tanzania Forestry Research Institute, Morogoro, United Republic of Tanzania (numansaidi@gmail.com)

Current conservation emphasizes territorial expansion beyond traditional protected areas to safeguard boundless spaces for wildlife and bring more forests under the reserved estate. Territorial expansion in Tanzania is pursued through Wildlife Management Area (WMA), and through community-based forest management. These two approaches are pursued by different institutions who compete over authority to claim and set aside village land as a WMA or as a village land forest reserve. This competition is shaped by changing priorities of international donor financing for conservation and shifting institutional landscapes and political priorities in the Tanzanian government. In this paper we trace the struggles of a village in navigating this complex and changing legal and institutional landscape to maintain authority over village land. The village is facing pressures from different conservation actors to set aside parts of it for forest or wildlife management. The struggles we document are indicative of a complex politics of conservation and the significant challenges this presents to rural communities that happen to be situated in areas targeted in the name of environmental conservation. While policy makers and conservation practitioners are envisioning a world of large-scale area-based interventions to achieve globally tracked targets, the reality of doing this work on the ground defies the notion of community-based, consensus-oriented, participatory, and apolitical spaces where global ideas can be simply and smoothly implemented locally.

Exceptional bureaucratic rivalry and policy competitions in mangrove forests: explanations from the Sundarbans, Bangladesh

Faisal Abedin Khan¹, Lukas Giessen²

¹Georg August University of Göttingen, Göttingen, Germany; ²European Forest Institute, Bonn, Germany (fkhan@uni-goettingen.de; lukas.giessen@efi.int)

Bearing diversified natural resources, the Sundarbans Mangrove Forests (SMF) considered a thrust area of ecological as well as economic importance of which a number of public bureaucracies of Bangladesh are given due attention for managing its resources. The aim of this study is to analyse the high degrees of competing policy conflicts of different bureaucracies prevailed for Sundarbans management practised on both formal and informal approach. Empirically, all policies and practices pursued by multiple administrations in Sundarbans are scrutinised. As an empirical method, the content analyses of various acts, rules, policy documents, missions, mandates and development initiatives of relevant ministries and public agencies were carried out and to distinguish the activities linked with informal interest present practices were critically analysed. The study observes that being the officially responsible administration for the Sundarbans, Bangladesh Forest Department possess 'control and command' approach towards managing SMF. The position of Forest Department is empowered by the existing laws and rules though observed approach has been threatened due to multi-bureaucracies' involvement in different sectors of Sundarbans for due reasons. Other bureaucracies became influential with their institutional capacities in respective sectors resulting exceptional high degree of bureaucratic competition among relevant bureaucracies. Forest bureaucracy is currently facing challenges of technical capacities, financial resources and institutional arrangements addressing effective management of Sundarbans. Administrative structures for complex landscapes, such as mangrove forests, pose real challenge to common bureaucratic structures which recommends in this study to establish an Integrated Mangrove Authority for the Sundarbans.

Participatory spatial scenario building in a mixed cocoa-oil palm area in the Eastern Region of Ghana as a way towards inclusive governance of mosaic landscapes

Kwabena Asubonteng^{1,2}, Mirjam Ros-Tonen¹, Isa Baud¹, Karin Pfeffer³

¹University of Amsterdam, Amsterdam, Netherlands; ²United Nations University Institute for Natural Resources in Africa, Accra, Ghana; ³University of Twente, Enschede, Netherlands (k.o.asubonteng@uva.nl; m.a.f.ros-tonen@uva.nl; i.s.a.baud@uva.nl; k.pfeffer@utwente.nl)

Compositionally complex and multifunctional landscapes provide multiple ecosystem services relevant for rural livelihoods. Due to a growing population, climate change and the expansion of agricultural commodities, the future of mosaic landscapes is of scientific and societal concern. In the debate on mosaic landscapes, remarkably few scholars consider the views of farmers and other landscape dwellers. Political ecology makes local people's landscape knowledge and aspirations transparent, thus contributing to inclusive landscape governance. Employing participatory spatial scenario development with actors in a mixed cocoa-oil palm area in Ghana's Eastern Region, this study generates insights into farmers' perceived changes, desired future landscapes and the actions considered necessary to achieve them. Results show that landscape actors are aware of the state of the landscape and changes that have occurred, with the participatory scenario maps coming close to actual landscape composition and spatial configuration. Contrary to assumptions underlying many studies in the sparing-sharing debate, farmers' desired landscape is largely similar to the current situation, characterized by increasing homogenization due to expanding areas of commodity crops, as oil palm and cocoa represent the major source of stable income. Farmers however acknowledge drawbacks such as decreasing food-crop land, reduced availability of provisioning ecosystem services such as non-timber forest products, and declining presence of shade trees, and consider forest conservation and tree planting important. These findings challenge the prevailing assumption that small-scale farmers in the tropics prefer mosaic landscapes, implying that inclusive landscape governance should be based on a critical analysis of farmers' knowledge and views.

Spatial analysis to support rural development in settlements in Maranhão, Brazil / Análise espacial como subsídio ao desenvolvimento rural em assentamentos do Maranhão

Vera Maria Gouveia¹, Hulda Rocha e Silva², Anida Claudia Dominici Soares², Tatiana Ribeiro de Santana²

¹Embrapa Cocais, São Luís, Brasil; ²Incrá, São Luís, Brasil (vera.gouveia@embrapa.br; hulda.silva@sls.incrá.gov.br; anida.soares@sls.incrá.gov.br; tatiana.santana@sls.incrá.gov.br)

A maioria dos municípios no Maranhão possui base econômica nas atividades extrativistas, agropecuárias e em serviços essenciais, e envolve comunidades tradicionais e o agronegócio. O babaçu representa um expressivo recurso do extrativismo vegetal e a atividade é essencial para as quebradeiras de coco, populações rurais e indústria. Porém, a posse da terra, em geral, não é dos extrativistas cujo acesso é realizado por meio de parcerias com os latifundiários tanto na produção agrícola como na forma de comercialização das amêndoas. Apesar de sua grande área territorial o Maranhão detém uns dos mais baixos números de proprietários rurais revelando grande concentração de terra, porém, também é o 2º estado brasileiro com mais assentamentos. O presente estudo teve por objetivo realizar a Análise Hot Spot do extrativismo babaçu e das atividades agropecuárias no Maranhão e identificar a localização de assentamentos nas modalidades Projeto de Assentamento – PA, Projeto Agroextrativista – PAE e Projeto de Desenvolvimento Sustentável – PDS. Utilizou-se a ferramenta "Hotspot Analysis" disponível no software Arc GIS, pela criação de um banco de dados geográfico com a base cartográfica digital Malha Municipal Digital do Zoneamento do Estado do Maranhão, dados do Sistema IBGE/SIDRA e dados cartográficos e informações de assentamentos do Incra. Os mapas produzidos com os hot spots e com os assentamentos constitui uma abordagem espacial para identificar cenários de conflito e uma ferramenta para subsidiar políticas públicas em nível da paisagem para a proposição de projetos de desenvolvimento rural visando a manutenção de florestas e serviços ambientais.

Characterizing the space-time patterns of deforestation and land use intensification within the cattle supply sheds from meatpackers with zero-deforestation commitments in the Brazilian Amazon

Amintas Brandao Junior¹, Lisa Rausch¹, Holly Gibbs¹, Jacob Munger¹, Matthew Christie¹

¹University of Wisconsin-Madison, Madison, USA (abrandao@wisc.edu; lrausch@wisc.edu; hkgibbs@wisc.edu; munger@wisc.edu; mjchristie@wisc.edu)

Supply chain agreements launched by governmental agencies and NGOs have been pushing meatpacking companies to reduce deforestation associated with cattle raised in the Brazilian Amazon. One current challenge is the lack of precise information on the cattle supply sheds and the patterns of land use associated with the agreements. In this study, we combined cattle movement data, properties boundaries, and roads network, to identify the cattle supply sheds of direct and indirect suppliers from meatpackers located in the states of Mato Grosso, Pará, and Rondônia for the period 2013 to 2017. Next, we documented the space-time patterns of deforestation and land intensification within each supply shed, from slaughterhouses that sign and did not sign the agreements. Our results have shown that most of the cattle transactions from the plants that signed the agreements, were from ranchers near to the plants and with little recent deforestation. However, cattle farms with deforestation can travel farther to reach plants that do not monitor their suppliers or send cattle to farms without deforestation for non-slaughtering purposes, which could be an indication of laundering. Finally, we found that land was more intensified within the supply sheds from plants that

signed the agreements. We demonstrate the importance of the cattle agreements by highlighting the extent to which non-compliant producers can go to avoid conforming to deforestation-free production, given the opportunity.

A9o: FORESTRY IN TRANSITION? FOREST POLICIES IN CHANGING SOCIETIES. PART 2: GLOBAL EXAMPLES

Implementing forest devolution in a rapidly changing society: a case from China

Yiwen Zhang¹, Shashi Kant¹, Hexing Long², Jinlong Liu³

¹Faculty of Forestry, University of Toronto, Toronto, Canada; ²School of Economics, Minzu University of China, Beijing, China; ³School of Agricultural Economics and Rural Development, Renmin University of China, Beijing, China (yww.zhang@mail.utoronto.ca; shashi.kant@utoronto.ca; longhx1986@163.com; liujinlong_jl@hotmail.com)

Researchers often emphasize the significance of devolving sufficient forest rights to farmers; however, the question remains whether farmers living in a rapidly changing society can successfully manage forests even if they obtain sufficient rights. This case study focuses on a community that conducted two forest devolution reforms in different periods. These two forest devolution reforms, despite their similar contents and goals, caused totally different outcomes. Based on the process tracing method, we explore why these two devolution reforms have different efficacy by unraveling the interactions between forest devolution and the dramatic socio-economic changes of the community. We find that although the second forest devolution reform tried to duplicate the success of the first one, it neglected the socio-economic changes including income increase, outmigration, livelihood diversification, market changes and the decreasing importance of forests, thereby failing to stimulate farmers' enthusiasm about managing forests and exposing farmers to high market risks instead. Therefore, although farmers obtained substantial forest rights in the second reform, they failed to successfully self-organize to manage forests. We argue that before implementing forest devolution we need to determine whether the local socio-economic context facilitates the self-organization of managing forests and a dynamic perspective is needed to make policies compatible with rapid socio-economic changes.

Towards better information on the costs and benefits of forest and landscape restoration projects in the Sahel Region

Daowei Zhang¹

¹FAO, Rome, Italy (daowei.zhang@fao.org)

Some 160 million hectares of degraded lands need to be restored in the Sahel region, but only few attempts have been made to assess the costs and benefits of these restoration efforts. FAO has teamed up with other institutions to fill this gap by establishing a methodological framework for cost-benefit analysis and by conducting a pilot study of restoration projects in the region. Preliminary results show that the cost of restoration activities starts at about USD 300 per hectare and rises along with more sophisticated interventions and on more difficult sites. Furthermore, the tangible benefits for local residents are rather limited, but adding the benefits of other ecosystem services would make these projects have a much higher benefit-cost ratio. The results of this study would be available in the summer of 2019 and be ready to be presented at IUFRO 2019.

Re-examining of Japanese yield regulation system by recent forest growth information

Keisuke Toyama¹

¹The University of Tokyo Chiba Forest, Kamogawa, Japan (toyama@uf.a.u-tokyo.ac.jp)

In Japan, woodland owners or their agents can formulate a five-year plan named "Collective Forest Management Plan" (CFMP) and submit it to the local government, which allows them to obtain subsidies for silvicultural operations. However, each CFMP must fulfill some numerical constraints, one of which is the allowable cutting volume restriction defined by a formula similar to the Austrian formula. Although this public rule can theoretically constrain the unregulated intensive clearcutting, it seems to disturb CFMP submission in actuality and lead to the low rate of CFMP-covering area. This allowable cutting volume is calculated from the stand age and site index of each stand recorded in the public forest registries which cover the whole Japanese private forests. However, recent forest data from such as LiDAR and NFI have revealed the inaccuracy of the existing stand volume estimation model. For the sustainability of forestry and forest resource, effective yield regulation for Japanese public system is examined, considering the shift of the allowable cutting volume of Japanese CFMP system followed by additional precise forest information.

When shall forests become beautiful in Kenya! The dilemma of reconciling stakeholder interests and values

Musingo Tito E. Mbuvi¹, Paul O. Ongugo¹, Eric T. Nahama², Leila Ndalilo¹

¹Kenya Forestry Research Institute, Nairobi, Kenya; ²Kenya Forest Service, Nairobi, Kenya (mtembuvi@gmail.com; apulongugo@live.com; e_nahama@yahoo.com; leyililo@yahoo.com)

Forests in Kenya are sources of timber, firewood, grazing; and are niches for conserving biodiversity. The last three decades have witnessed a transition of forest governance from community to joint management under different governance regimes. A review of forest management documents, Discussion with Focus Groups and Key Informant revealed that: this transformation has not changed the way communities perceive forests "as a resource to support their survival". It showed that: high poverty levels are prevalent in forest adjacent communities' forests contribute to rural and urban household energy and livelihoods needs with urban forests providing both aesthetic and basic needs to the communities differentially across the well-being status. The well-off communities perceive forests as beautiful and should be preserved for aesthetic value. The provision of alternative products and services have not replaced the needs or changed less-off members value system. This poses a dilemma to the stakeholders as increasingly the country is getting urbanized and the poor are not reducing proportionately. Experts opine that by 2030 over 90% of the forests in the country will be under joint management. The country will witness forests neighbouring large urban centre being managed through co-existence with stakeholders contributing on their own volition to ensure provision of environmental services. We are moving to a time when urbanized communities will be using the slogan, "The forests are very beautiful, let us go to the forest to enjoy and relax". This move calls for a schematic engagement with stakeholders and policy makers' to support the transformation.

Key factors in the enabling environment for smallholder tree growing

Anne Arvola¹, Maria Brockhaus¹, Maarit Kallio^{2,3}, Thu Thuy Pham⁴

¹University of Helsinki, Helsinki, Finland; ²University of Helsinki, Viikki Tropical Resources Institute (VITRI), Helsinki, Finland; ³University of Helsinki, Helsinki Institute of Sustainability Science, Helsinki, Finland; ⁴CIFOR, Hanoi, Vietnam (anne.arvola@helsinki.fi; maria.brockhaus@helsinki.fi; maarit.kallio@helsinki.fi; t.pham@cgiar.org)

Attempts to encourage smallholder tree growing with policies and incentives have had variable outcomes and earlier research and theories have identified various important factors in the enabling environment and in promotional policies. Success of policies and incentives depends on the socioeconomic context where they are applied, the overall political and market environment, the perseverance of policies, and relevancy of incentives to target the actual hindrances for tree growing. A systematic analysis was carried out to complement previous qualitative research, and to clarify which factor combinations produce increased smallholder tree growing in developing country contexts. We applied two-step Qualitative Comparative Analysis (QCA) to identify necessary and sufficient factors in the enabling environment over time between 1990-2015 in Indonesian Java, Kalimantan & Sumatra, Lao PDR, Tanzania, Uganda and Vietnam. Material was collected through field research (smallholder and key informant interviews) in Tanzania and Lao PDR, and literature review. Strong tenure rights and demand were always necessary and sometimes even sufficient alone to trigger commercial tree growing. Well-functioning wood markets or strong knowledge base combined with direct incentives played their role as sufficient conditions in many cases and increased the pace of tree growing area expansion. Indirect incentives were insignificant in our case countries as an enabling factor. A key message to policy-makers is that governments are in a central role firstly, in ensuring tenure rights, and secondly as knowledge-service and incentive providers as they may be needed to set up sufficient enabling environment for smallholder tree growing to take-off.

Socioeconomic predictors of willingness to participate in forest support programs in the miombo areas of Zambia

Moses Kazungu^{1,2}, Eliza Zhunusova¹, Gillian Kabwe³, Davison Gumbo⁴, Sven Günter^{1,2}

¹Thünen Institute of International Forestry and Forestry Economics, Hamburg, Germany; ²Technical University of Munich, Germany, TUM School of Life Sciences Weihenstephan, Department of Ecology and Ecosystem Sciences, Chair of Silviculture, Munich, Germany; ³School of Natural Resources, Copperbelt University, Kitwe, Zambia; ⁴Center for International Forestry Research, Lusaka, Zambia (moses.kazungu@thuenen.de; eliza.zhunusova@thuenen.de; gkabwe@yahoo.co.uk; d.gumbo@cgiar.org; sven.guenter@thuenen.de)

Background: Zambia has a large population of its people living in rural areas and depending on forests for livelihoods. Despite high deforestation of about 250 000 to 300 000 ha/year, Zambia has about 66% of its land covered by the forests of which 45% is Miombo woodlands. Forest management in Zambia aims to strengthen participation in the utilisation of forest resources. Most forest programs, however, are often designed without taking into account the features of households that could influence participation. Ultimately this has resulted in a lack of understanding of the socioeconomic behaviours that determine households' willingness to participate in forest programs. Methods: We present preliminary findings from a cross-sectional study using data from 412 households interviewed in the Miombo areas. We introduced an instrumental variable approach to address endogeneity between latent participation and willingness to participate, and parameters estimated using two-stage least square. Predictors of willingness to participate were identified using a binary logistic regression with backward stepwise regression. Results: The factors that were significantly associated with willingness to participate in forest programs were: head of household educational level (OR = 3.31) and access to credit (OR = 2.17). The following negatively affected households' willingness to participate: access to roads (OR = 0.64), loss of forest cover (OR = 0.19), increasing age (OR = 0.98), ethnic grouping (OR = 0.61), and self-employment (OR = 1.00). Discussion: Findings are in agreement with most studies; higher educational levels, and access to credit, significantly influences willingness to participate in forest programs. Interventions such as REDD+ should target increasing community-wide access to education and credit facilities.

A9p: POLICIES FOR PUBLIC FORESTS

Araucaria angustifolia (Bertol.) Kuntze conservation and health: legal and ecosystemic bases

Alvaro Boson de Castro Faria¹

¹Brazilian University of Technology, Dois Vizinhos, Brasil (alvarob@utfpr.edu.br)

Forest health and protection have not yet been considered in the environmental assessment procedures and in the conservation policies of the Atlantic Forest. The book "Araucarias Conservation and Health: legal and ecosystemic foundations" (Conservação e Saúde das Araucárias: fundamentos legais e ecossistêmicos), presents the Brazilian legislation applied to the subject, arguing the possibility of managing with exceptional criteria, this threatened species. It proposes a classification-based system on mature trees and ways to monitor their wellness. The Decline Syndrome process is described, with a simple protocol for the diagnosis of trees at an advanced stage of development. The term Phytosanitary Management is conceptualized, justifying it for the exploitation of the Legal Reserves of the Atlantic Forest in private lands, under the Clean Development Mechanism scheme. This book integrates Environmental Legislation and Ethics, together with Forest Protection, proposing to be a reference for researchers from several areas of knowledge, as well as for people who defend the conservation of Brazilian pine. The work establishes a protocol for the diagnosis of trees, necessary for conservation within the framework of the National Plan of Action, mandatory by law due to the Convention on Biological Diversity (CBD). Universities, teachers, environmental analysts, public managers and others who believe in the term Conservation in situ with the sustainable use of specially protected forests, would be interested in this reading.

Forest concession and territorial planning: governance and conflict resolution in the Eastern Amazon

Jime Rodrigues Ribeiro¹, Iranilda Silva Moraes¹, Claudia Azevedo-Ramos¹

¹Núcleo de Altos Estudos Amazônicos, Universidade Federal do Pará, Belém, Brasil (engenheirajime@gmail.com; ira_geo4@yahoo.com.br; claudia.azevedoramos@gmail.com)

Forest concession is a public forest governance policy predominant in tropical countries. In the Brazilian Amazon, this instrument was applied since 2008 under the main premise of increasing governance in remote areas being an alternative for the development of a forest-based economy and curbing illegal deforestation. Since 2011, the concessions of the Glebas Mamuru-Arapiuns in Pará state have been implemented as a forest governance tool to promote territorial planning in a former undesignated public forestland with a history of local conflicts. This study aimed to understand how these state forest concessions may have contributed to spatial planning and a more effective governance of these areas before the beginning of forest operations. Secondary data and legal framework that focused on the discussions of the first concessions under state management were used to review the historical process. After 12 months of discussions involving 37

groups with different positions, the state strategy using a participatory process has resulted in advances on the governance of 1-million hectares of state public forests through land titling, destination for community use, creation of conservation units and forest concession, decreasing local conflicts. However, indigenous territories are still under dispute. Overall, the participatory process may be considered a successful case study of territorial planning and conflict resolution having forest concession as a starting point.

Forms of regularizing legal reserves: the preference of rural producers / Formas de regularização do déficit de reserva legal: a preferência declarada dos produtores rurais

Rayane Pacheco¹, Raoni Rajão²

¹Universidade Federal de Minas Gerais, Belo Horizonte, Brasil; ²Universidade Federal de Minas Gerais, Laboratório de Gestão de Serviços Ambientais, Belo Horizonte, Brasil (enayar.costa@hotmail.com; rajão@ufmg.br)

O Código Florestal (Lei 12.651/2012), que regulamenta a proteção da vegetação nativa, estabelece alternativas de regularização do déficit de Reserva Legal (RL) aos proprietários ou possuidores de imóveis rurais, sendo: recomposição, regeneração natural e/ou compensação da RL. Apesar das opções existentes, a efetiva regularização é uma realidade distante e pouco se sabe sobre as prováveis escolhas dos produtores rurais. Este estudo analisou qual alternativa de regularização os produtores que reconhecem possuir déficit de RL nos estados do Pará e Mato Grosso (n = 21.523) pretendem adotar. Utilizou-se de estatística descritiva e modelo logístico multinomial ajustado no R a partir do questionário preenchido junto com o envio do CAR (2017). Os resultados revelam que cerca de 46% dos produtores declararam que pretendem compensar a RL, 38% almejam permitir a regeneração natural e 16% recompor a RL. Existe maior possibilidade de a compensação ser adotada pelos agricultores, especialmente os mais jovens, os que possuem grandes imóveis (> 15 MF) e título de propriedade, ao passo que a recuperação tem maior probabilidade de ser realizada pelos pecuaristas mais velhos, os que possuem pequenos e médios imóveis e documento de posse. Conclui-se que, para os dados analisados, a compensação se mostrou a alternativa com maior demanda provável. Isso pode estar ligado à resistência dos produtores em recuperar a área consolidada, ao custo de oportunidade e ao risco de investimentos em uma restauração que pode não funcionar. Logo, as descobertas aqui apresentadas são pontos de partida nas explorações sobre os mecanismos de regularização de RL.

Assessing the impacts of visitation in Desengano State Park, Rio de Janeiro, Brazil / Avaliação dos impactos da visitação no Parque Estadual do Desengano, Rio de Janeiro

Thamires de Souza Carvalho¹, Marcello Pinto de Almeida¹, Gumercindo Souza Lima¹, Angeline Martini¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (dsc.thamires@gmail.com; marcello.efl@gmail.com; gumercindo.ufv@gmail.com; martini.angeline@gmail.com)

O uso público nas áreas naturais protegidas, quando bem manejado, traz inúmeros benefícios, como a proteção e a conservação da natureza advindos da conscientização ambiental. Dessa maneira, é de extrema importância conhecer os impactos que a visitação pode causar e, assim, evitá-los, controlá-los ou minimizá-los, permitindo a atividade turística sustentável sob o ponto de vista ambiental e econômico. Considerando a importância estratégica do Parque Estadual do Desengano na conservação dos ambientes regionais e no desenvolvimento do ecoturismo, cada vez mais estimulado na região, o presente trabalho buscou avaliar seu potencial de uso público por meio de uma análise de intensidade dos impactos da visitação, utilizando-se para tal a metodologia do Checklist. Tal metodologia propõe identificar e enumerar os impactos a partir de uma avaliação ambiental preliminar dos meios físico, biótico e socioeconômico, realizada por especialistas. Dentre os impactos ambientais observados na Trilha da Pedra do Desengano, uma das trilhas mais visitadas de todo o parque, estão: atalhos e bifurcações, vegetação de borda danificada e depredação do ecossistema. Os resultados obtidos permitem inferir que o impacto referente à depredação do ecossistema caracterizou-se principalmente pela coleta ilegal de material biológico e mineral. Os impactos relacionados aos atalhos e bifurcações e à vegetação de borda danificada foram observados com maior frequência no terço final da trilha, que coincide, majoritariamente, com os trechos mais íngremes. Visando mitigar esses impactos sugere-se que o investimento em sinalização de trilhas e em educação ambiental seja ampliado.

Seeds for implementing the Brazilian forest code and Paris agreement: an example of collaboration between the Ashaninka indigenous people and public institutions in Southwestern Amazonia

Andrea Alechandre¹, Marilene Bento¹, Brenda Melo¹, Cleverson Carvalho², Lucia Hall³, Elaine Lopes⁴, Foster Brown⁴, Eliane Yawanawa⁵, Francisco Piyako⁶

¹Universidade Federal do Acre, Rio Branco, Brasil; ²Universidade Federal do Acre, Programa de Pós-Graduação de Ciências Florestais, Rio Branco, Brasil; ³Cooperativa de Trabalho do Acre, Rio Branco, Brasil; ⁴Woods Hole Research Center, Universidade Federal do Acre, Rio Branco, Brasil;

⁵Associação Ashaninka do Rio Amônia-Apiwtxa, Rio Branco, Brasil; ⁶Associação Ashaninka do Rio Amônia-Apiwtxa, Marechal Thaumaturgo, Brasil

(andreaalechandre@gmail.com; marilenebz@yahoo.com.br; brendameloeng@gmail.com; cleversoncarvalho92@gmail.com; luciahall02@gmail.com; lopes.elaine7@gmail.com; fbrown@uol.com.br; sanayawa41@hotmail.com; francisco.piyako@hotmail.com)

Brazil committed in the Paris Agreement to recover and restore 12 million hectares by 2030. This, along with Brazil's Forest Code requirements, has created an enormous demand for certified tree seeds. The Ashaninka people of the Indigenous Territory Kampa of the Amônia River in Acre State, have their economy based on extraction of non-timber forest products, hunting and handicrafts production. In order to increase the supply of sustainable products, the process of legalization of the sale of native forest seeds was started in 2015 with technical support from the Zoobotanical Park of the Federal University of Acre-UFAC and financial contribution of the Amazon Fund / BNDES and of Sema-BID / AC. The indigenous institutions, such as the Apiwtxa Association and Ayôpare Cooperative, are responsible for managing and marketing the seeds. There are currently three Seed Collection Areas covering 550 hectares, with 840 seedlings distributed in 29 species. The period of greatest seed production runs from June to September, the period of lower rainfall in the region. The fruits / seeds collected in the indigenous area will be transported to the Seed Distribution Center, located at the headquarters of the municipality of Marechal Thaumaturgo, where they will be made available for commercialization. Certification will be done by the Acre-Lasfac / UFAC Seed Analysis Laboratory, which will carry out the analyzes and determine the quality of the commercialized seeds, thus meeting both the demand of reforestation companies and farmers who need to comply with minimum forest cover regulations.

Integrated activities to promote environmental regularization policy with social and productive improvements for family farmers in the Amazon Biome / Ações integradas para promover a política de regularização ambiental com a melhoria sócio produtiva de agricultores familiares no bioma Amazônia

Michelliny Bentes¹, Joanne Regis da Costa², Ladislau Skorupa³, Aldecy José Moraes¹, Everaldo Almeida¹, Vera Maria Gouveia⁴

¹Embrapa Amazônia Oriental, Belém, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil; ³Embrapa Territorial, Campinas, Brasil; ⁴Embrapa Cocais,

São Luís, Brasil (michelliny.bentes@embrapa.br; joanne.regis@embrapa.br; ladislau.skorupa@embrapa.br; aldecy.moraes@embrapa.br; everaldo.almeida@embrapa.br; vera.gouveia@embrapa.br)

O Código Florestal Brasileiro (CFB), ou novo Código Florestal, renovou em anos recentes algumas obrigações aos proprietários rurais, quanto à recomposição das Áreas de Reserva Legal, considerando os limites de exploração econômica dentro da propriedade, dando reforço também à importância da manutenção de Áreas de Preservação Permanente, enquanto espaços vitais de proteção biológica dos seres e organismos vivos, e dos recursos hídricos. No que se refere ao segmento produtivo familiar na Amazônia, o entendimento de aplicação dessas normativas, com alto grau de formalidade, têm promovido mais irregularidade e desmotivação, que seu próprio cumprimento. Como desafio e proposta de intervenção dessa realidade, o Projeto Inovaflora, que integra o Projeto Integrado da Amazônia (Fundo Amazônia), estabeleceu a articulação territorial com agricultores familiares, suas representações, e parceiros institucionais atuantes nos segmentos produtivo e ambiental no bioma Amazônia, e a integração de ferramentas e métodos de monitoramento e de avaliação da adoção e dos impactos, para promover a validação e o incentivo de alternativas produtivas associando florestas e culturas agroalimentares, em favorecimento ao fortalecimento de cadeias produtivas locais e aumento da participação nos programas estaduais de regularização ambiental nos territórios afetados pelo desmatamento. Estão sendo realizadas ações periódicas nos territórios, com processos de mediação e intercâmbio de informações e conhecimentos, para a conexão com experiências e saberes da agricultura familiar, e o conhecimento gerado pela pesquisa no campo da recomposição e restauração florestal, visando ampliar a inclusão socioambiental e econômica de agricultores familiares e reduzir a pressão sobre a floresta primária no bioma.

Pilot forest hub Paraíba valley (SP): incentive to multifunctional native species plantations for timber and non-timber products, and ecosystem services

Helena Carrascosa von Glehn¹, Maria José Brito Zakia² ; Silvana Nobre³ 

¹Secretaria de Infraestrutura e Meio Ambiente do Estado de São Paulo, São Paulo, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Programa Silviculture of Native Species, Piracicaba, Brasil; ³Universidad Politécnica de Madrid, ETSI de Montes, Forestal y del Medio Natural, Madrid, Spain
(hcarrascosa@sp.gov.br; zeze.zakia@uol.com.br; silvana.rnobre@gmail.com)

The Brazilian Forest Law designates 20% of all rural properties in São Paulo to be considered legal reserve (LR), which means the area, besides economic use, should provide ecosystem services such as soil conservation, water spring protection, and biodiversity preservation. Most of the properties in São Paulo do not have enough vegetation to fulfill this regulation. The LR might be subject to sustainable management; however, reforestation with native species is not conventional in Brazil due to the lack of silvicultural information and market uncertainties. The Secretariat for the Environment of the State of São Paulo (SMA-SP) led the working toward the large-scale forest plantations that fulfill ecological and economic purposes, which is crucial for the adhesion of farmers. We identified the native species to make it feasible. Furthermore, the need for structuring the chains (wood and non-timber products) became evident, guiding to a regional hub including forest production, industrial processing, and marketing. The Paraíba Valley was chosen due to its biophysical characteristics, good infrastructure, proximity to mattering markets and sources of water supply, and the underutilized degraded agricultural areas. Economic evaluations using the usual indicators revealed promising results; accordingly, the investment thesis is under development. The governance structure is being built supported by highly qualified professionals, and the active participation of local organizations, reinforcing the expectations of success. The objective of this paper is to present the status of the project, lessons learned during the process, and which actions are being taken to ensure the success of the program.

National register of public forests: 10 years of experience in Brazil

Gustavo Oliveira¹, Leandro Biondo¹, Janaina Rocha¹, Bernardo Trovão¹, Rejane Mendes¹

¹Serviço Florestal Brasília, Brasília, Brasil (gustavo.oliveira@florestal.gov.br; leandro.biondo@florestal.gov.br; janaina.rocha@florestal.gov.br; bernardo.trovao@florestal.gov.br; rejane.mendes@florestal.gov.br)

The National Register of Public Forests - CNFP is a Brazilian forestry management planning instrument. By collecting geo-referenced data on Brazilian public forests, it contributes to the strategic view of the conservation and sustainable use of forest and environmental assets, as well as the unification of destination information and the protection of these forests. This paper describes the ten years of implementation and reports the evolution of the registration and identification of these public forests. For the execution of the Union's Public Forests Map, we worked with: Survey of federal public land information (National Indian Foundation / FUNAI, Chico Mendes Conservation Institute / ICMBio and Ministry of Environment / MMA, National Institute of Colonization and Agrarian Reform / INCRA and Ministry of Defense / MD); Survey of existing forest cover in March 2006 (Public Forest Management Law, No; 11.284 / 2006); and, Crossing the qualitative information of these public forests through satellite images. Initially, in 2007, there were 193 million hectares registered and, in the 2017 update, there are already 311.6 million hectares registered (equivalent to 36.6% of the national territory). Of the total number of registered areas, 21% are Non-Targeted Public Forests (29 million federal hectares and 47 million state hectares), the remainder being divided among the categories of Community Use (50%), Biodiversity Protection (35%), Military use (1%), among others (including 1.5 million hectares allocated to the 26 sustainable forest management units under concession under both the federal 17 (1.02 million hectares) and the 9 state ones (477 thousand hectares).

A9q: FOREST POLICY AND GOVERNANCE

Brazilian forest code and forest connectivity among rural properties in the Amazon

Pedro Luis Trejo Moreno^{1,2} ; Claudia Azevedo-Ramos¹

¹Universidade Federal do Pará, Belém, Brasil; ²Universidad de Los Andes Mérida Venezuela, Republic of Bolivarian (trejopedro21@gmail.com; claudia.azevedoramos@gmail.com)

Tropical countries have developed different legal frameworks for the protection of their forests. In Brazil, the Legal Reserve - LR (a forested area within rural properties) and the Permanent Protection Areas - PPA (a riparian protection zone) were established by the Brazilian Forest Code (BFC) to ensure the conservation of natural resources. The National System of Rural Environmental Cadaster (SICAR) organizes the compulsory georeferenced registration of LR and PPA of private properties as the first step for the environmental regularization. In theory, LR and PPA may also work as important ecological corridors among forest patches depending on their spatial location. A connectivity analysis of forest fragments among properties may help to understand whether the environmental goals of BFC are being achieved. We tested this assumption using the agrarian municipality of Tomé-Açu (5.150 km² and 1994 properties) in the Amazon as a case study. Small properties (66.3%) dominate the landscape in number while big properties occupy 76.6% of the area. We calculated the Integral Index of Connectivity (IIC) using deforestation and SICAR data with the software Conefor 2.6. The IIC ranges from 0 to 1 (the best scenario). The results showed an IIC of 0.150, which means a high forest fragmentation, complicated by 11.1% of overlaps among LR. The assurance of environmental benefits from the BFC may depend on a better spatial design and restoration of LR and PPA. In this sense, the environmental public agencies may have an important role in the Environmental Regularization Program and its monitoring.

Compensation for affecting the biotic environment, developing environmental easements as an economic instrument to restore forest cover / *Compensaciones por afectación al medio biótico desarrollando servidumbres ambientales como instrumento económico de gestión para recuperar cubiertas forestales*

Jaime Alberto Moreno Gutiérrez¹

¹Universidad Distrital Francisco José de Caldas, Bogotá D.C., Colombia (jamemoreno@gmail.com)

Instrumentos como el de los Pagos por Servicios Ambientales - PSA, se convierten en instrumentos perversos para la conservación de ecosistemas forestales de no mediar un pago, en tanto que las estrategias corrientes de compra de predios para la conservación ecosistemas estratégicos existentes en ellas desencadenan desplazamiento poblacional, el presente estudio plantea desde lo teórico conceptual y la viabilidad operativa en Colombia como alternativa de alta eficacia, un mecanismo de pagos por SERVIDUMBRES AMBIENTALES, como estrategia alternativa para la implementación de compensaciones por afectación al medio biótico, derivadas del uso y aprovechamiento forestal; se plantea la conceptualización alterna a las servidumbres ecológicas para recuperación de servicios ecosistémicos en áreas donde se han perdido, esto desde el enfoque del costo de oportunidad, a partir del excedente del productor, calculado a partir del diferencial entre valor de explotación productiva de áreas con importancia ecosistémica en coberturas forestales susceptibles de ser recuperadas, restauradas o conservadas, y los costos que se enfrentan para generar dicha producción, financiándose con obligaciones de compensación emanadas de permisos.

Communication as a tool of forest policy to harmonise the needs of society and the forestry sector

Marcel Riedl¹, Vilém Jarský¹, Roman Dudík¹, Jaroslav Šálka², Jiří Oliva¹, Petra Palátová¹

¹CULS, Prague, Czech Republic; ²TUZVO, Zvolen, Slovakia (riedl@fld.czu.cz; jarsky@fld.czu.cz; dudik@fld.czu.cz; salka@tuzvo.sk; oliva@fld.czu.cz; palatovap@fld.czu.cz)

Global changes taking place both in nature and in society create new challenges for the forest policy. The basic prerequisite for their solution is effective communication both within the forestry sector and with the public. The presentation deals with the analytical process of creating an effective communication strategy as a tool for the long-term harmonisation of the needs of society and forestry using procedures based on detailed research on public lifestyle and media behaviour. Within the forestry sector, the effectiveness of the strategy based on a one-stage and two-stage communication model communicating scientific knowledge and expertise to small forest owners and the impact of this strategy on the cognitive, affective and conative attitudes of small forest owners and the possibilities of their greater activation are analysed. The presentation is complemented by a number of actual results from market research as well as demonstrating the implementation of a specific communication campaign including its media evaluation.

Deciding the future of forest ownership: opportunities and challenges of forest services and forest governance

Gun Lidestav¹, Elias Andersson¹, Anne Matilainen², Merja Lähdesmäki²

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²Ruralia Institute, Helsinki University, Seinäjoki, Finland (gun.lidestav@slu.se; elias.andersson@slu.se; anne.matilainen@helsinki.fi; merja.lahdesmaki@helsinki.fi)

Over the last decade, the increasing heterogeneity of private non-industrial forest ownership has been studied and discussed in research. Although the acknowledgment of diversity in characteristics and objectives of forest owners, the outcome in terms of diversity in forest management practice is seldom observed. Further, research on forest-related service market is very limited, but a traditional production-oriented logic seems to dominate. In the emerging circular bio-economy discourse, the role of forest owners in the value chain is often overlooked. Drawing upon a review study of Finnish and Swedish literature, this paper explores the conceptualization of non-industrial forest ownership and their decision-making, and the potential implications for policies and service provision. The results illustrate that the forest owner related factors impact on decision making at strategic, tactic and operational decision making levels, while resource and operational environment related impact mostly on certain types of tactical and operational decisions. The dominant traditional production-oriented logic and related categorization/segmentation results in limitations in the conceptions of subjectivity and agency in forest ownership. This limited understanding of the various subject positions contribute to the exclusion of individuals and the closing of space and actions. Further, it suggest restrictions in the effectiveness and legitimacy of forest governance. The implications of this will be discussed both from the perspective of research, the development of support and service to endorse the heterogeneity and specific forms of agency within forest ownership.

Multi-level and multi-stakeholder governance of non-timber forest products? Cases from Ukraine and the Russian Federation

Nataliya Stryamets¹, Marine Elbakidze²

¹Ca'Foscari University of Venice, Venice, Italy; ²Swedish University of Agricultural Science, Skinnskatteberg, Sweden (natastr@gmail.com; marine.elbakidze@slu.se)

Governance for non-timber forest products (NTFPs) is about rules, decision-making processes and institutional arrangements that govern production systems from access to the resources, its use and to markets. Compared to other forest products, there are only few studies on governance of NTFPs in European post-socialistic countries transitioning from planned to market economy. The aim of this study is to compare institutional and governance arrangements related to NTFPs using case studies in the Russian Federation and Ukraine. Both countries have a legacy of top-down forest government, state owned forests, and a rural population with a long history dependent on plant and animal-based NTFPs. To understand institutional frameworks and governance arrangements that deal with different aspects of NTFPs production systems we analysed legal documents dealing with NTFPs in each country and conducted 48 expert interviews with representatives of stakeholders from public, private and civil sectors that were involved in governance of NTFPs. Governance systems of plant- and animal-based NTFPs in both countries were complex, including institutions at multiple levels. In Russia and Ukraine national level institutions and public organisations at multiple levels are supposed to ensure the sustainable use of NTFPs by defining and controlling their extraction. Global institutions influenced NTFPs governance only in the Russian case study, where forest certification facilitated stakeholders from civil sector to develop instruments that are used by local communities to protect their customary rights to secure access to NTFPs. Decentralization, stakeholder involvement and dialog are instruments to encourage multi-stakeholder multi-level governance of plant- and animal-based NTFPs.

Testing the effects of legislation on deforestation rates in conservation units within the Legal Amazon

Felipe Cozim Melges¹, Hugo de Boer², Maria J. Santos³

¹German Centre for Integrative Biodiversity Research (iDiv) Halle-Jena-Leipzig, Leipzig, Germany; ²Copernicus Institute of Sustainable Development, Utrecht, Netherlands; ³University Research Priority Program in Global Change and Biodiversity and Department of Geography, Zurich, Switzerland (fc³⁷ruqa@studserv.uni-leipzig.de; h.j.deboer@uu.nl; maria.dossantos@geo.uzh.ch)

Deforestation and destruction of natural ecosystems represent a serious threat to biodiversity and environmentally provided services. The Legal Amazon territory in Brazil is such a case, containing the largest continuous tropical forest on earth, which accounts for a large fraction of the global carbon budget, water cycle and biodiversity. The Amazon deforestation is a multi layered, complex issue involving multiple actors. Establishment of conservation units, implementation of focused legislation and adoption of deforestation programmes are considered important tools in conserving forests and biodiversity. Specifically, Federal Laws 9.985/00; 11.284/06 and 12.651/12 are designed to prevent further deforestation and harmonize economic development. Here we evaluate whether Federal Law 11.284/06 and 12.651/12, and the 2008 deforestation programmes decreased deforestation rates within conservation units in the Legal Amazon. We analyzed legislation on annual basis and found no significant change; however, we did find a significant change in deforestation rates after the compilation of operations and programs of 2008. Further, when we analyzed deforestation over a reasonable period for the effect of legislation, we found significant changes for Federal Law 11.284/06 resulting in a decrease in mean deforestation rates of 0.73 and 0.02 in absolute (km²) and relative terms (%) respectively. Federal Law 12.651/12 showed no significant change, despite increase in mean absolute deforestation (+0.11 km²) and decrease in mean relative deforestation (-0.04%). These results imply that both focused legislation and deforestation programmes contribute to reduce deforestation, conserve forest and biodiversity. However, the effects of the implementation of new legislation are not immediately clear.

The complexity of managing native forests through participation by local actors / La complejidad de la gestión del bosque natural por la participial de actores locales

Jaime Alberto Moreno Gutiérrez^{1,2}

¹Universidad Distrital Francisco José de Caldas, Bogotá, D.C., Colombia; ²Multiversidad Mundo Real Edgar Morin Mexico D.C. Mexico (jamemoreno@gmail.com)

La evolución y desarrollo de la humanidad históricamente ha estado signada por su relacionamiento con el bosque, inicialmente como proveedor de frutos y leña, que se convirtió en un determinante para intervenir el medio, hasta sostener relaciones complejas como soporte y regulación de la vida misma de la humanidad a través de los servicios ecosistémicos que provee. Esta investigación permite identificar la evolución conceptual que el hombre ha tenido del bosque, desde consideraciones netamente extractivistas por explotación hasta su tratamiento holístico por múltiples servicios ecosistémicos propios de su dinámica, bases para la consecución del desarrollo sostenible tanto de las comunidades que tiene un contacto directo con él, como de la sociedad que requiere de muchos de sus servicios para satisfacer necesidades básicas. La percepción conceptual ha evolucionado de objeto de explotación, considerado como recurso, a requerimientos de gestión multinivel para alcanzar un manejo hacia la provisión de medios para la consecución del bienestar, para su perpetuación como recurso natural renovable; así se hace necesario evolucionar de una consideración de simple factor de producción, cerniéndose entre el libre acceso y derechos de propiedad, hacia la definición de un conjunto de condicionantes o principios de arreglo institucional de relacionamiento, que se definen resultado de la presente investigación, en pro de prospectar la gestión del bosque como recurso de uso común en el siglo XXI, para hacer una efectiva gobernanza forestal.

A9r: FOREST OWNERSHIP AND FOREST VALUES

Estimation of the asset value of lands reserved for environmental preservation in Brazil

Rogério Resende Martins Ferreira¹, Daniela Tatiane de Souza¹, Gustavo Spadotti Amaral Castro¹, Evaristo Eduardo de Miranda¹

¹Embrapa Territorial, Campinas, Brasil (rogerio.ferreira@embrapa.br; daniela.souza@embrapa.br; gustavo.castro@embrapa.br; evaristo.miranda@embrapa.br)

The territorial and economic dimension of the areas devoted by farms to preserve native vegetation was not known in Brazil until the Forestry Code was promulgated (Law 12.651/2012). By law, rural properties should maintain areas with native vegetation cover in various categories (Legal Reserve, Permanent Preservation Areas, Surplus Vegetation, etc.). Created by the Forestry Code, the Rural Environmental Registry (CAR) is a mandatory electronic registry for all rural producers that became a relevant tool for agricultural and socio-environmental planning. The aim of this study was to quantify the property asset value of each hectare of legal reserve and permanent preservation areas in Brazil should they be sold for current market prices. Based on the price of land published by FNP Consultoria & Negócio for the year 2017, it is possible to assess by activity group (grain, rice, semi-arid shrubland, coffee, sugar cane, savannah, Amazon rainforest, transition forest, planted forests, fruit farming, Atlantic rainforest, horticulture, pasture, miscellaneous production) the average and full values of municipal land. With data from the CAR regarding the territorial area of the 218 million hectares of areas devoted to preserving native vegetation in Brazilian rural properties, produced by Embrapa Territorial, reserved areas were calculated by municipality, micro-region, and state. The results were then multiplied by the respective full land values (FNP, 2017). The national total shows that Brazilian farmers and cattle ranchers own land assets reserved for the benefit of the environment in excess of 3.1 trillion reais.

Costs of opportunity and potential for the generation of jobs, taxes, and food in mandatory environmental reserves of Brazilian rural properties

Daniela Tatiane de Souza¹, Rogério Resende Martins Ferreira¹, Gustavo Spadotti Amaral Castro¹, Evaristo Eduardo de Miranda¹

¹Embrapa Territorial, Campinas, Brasil (daniela.souza@embrapa.br; rogerio.ferreira@embrapa.br; gustavo.castro@embrapa.br; evaristo.miranda@embrapa.br)

The assessment of costs of opportunity is one way to estimate the wealth that was renounced with the legal obligation to keep areas with productive potential as environmental reserves in Brazil. Knowing the costs of opportunity is relevant in order to estimate the economic value of ecosystem services, providing environmental information to agents, aiming to underline the role of farmers in the preservation of nature and its impact in society, in socioeconomic terms as well as in terms of food production. The goal was to calculate the costs of opportunity, generation of jobs, taxes, and food in mandatory environmental reserve areas in Brazil. To calculate the cost of opportunity, we considered the main crop in the municipality under assessment, as well as corn, which has a more widespread territorial distribution. For the number of jobs to be generated, we used the average direct jobs in the corn sector. Tax generation was calculated

based on Funrural (Law 13,606/2018). Information about environmental reserves was extracted from the Rural Environmental Registry (2018) and organized by staff from Embrapa Territorial. Taking into consideration the main crop in each municipality, the 97.9 million hectares of mandatory environmental reserves in Brazil have a cost of opportunity of 309.8 billion reais. Taking into consideration corn for all municipalities, the value is 246.5 billion reais. Annually, more than 419.8 million tons of corn could be produced, an amount that could feed approximately 1.68 billion people, generate 4.9 million direct jobs, and collect 4.6 billion reais in taxes (Funrural).

Forgotten forests in the Brazilian Amazon: policy and territorial planning

Claudia Azevedo-Ramos¹, Paulo Moutinho²

¹Núcleo de Altos Estudos Amazônicos, Universidade Federal do Pará, Belém, Brasil; ²Instituto de Pesquisa Ambiental da Amazônia, Brasília, Brasil (claudia.azevedoramos@gmail.com; moutinho@ipam.org.br)

The Brazilian Amazon had ca. 65.4 million hectares of undesignated public forestlands in 017. This massive block of forests is not under some category of use or effective supervision by a designated public agency, increasing the risk of continued land grabbing and predatory use. We estimated that ca. 25% of Amazon annual deforestation occurred in these forestlands between 2015-2018, responding for 200 million tons of CO₂ emissions. Under the current scenario of deforestation growth in the region, the immediate allocation of undesignated forestlands to production, conservation or social use by the government would reduce the availability of unsupervised public land, increase forest protection and, therefore, decrease deforestation and carbon emissions. The careful designation planning and landscape design may contribute to form a mosaic of different categories of forest protection that may optimize the maintaining of ecosystem services in large extensions of forests, mitigating the effect of climate changing and its consequences. Doing so, Brazil will also increase governance of its large share of the Amazon forest.

Assessing indigenous people's perception and preference for ecosystem services: case study of Omo Biosphere Reserve, Nigeria

Opeyemi Adeyemi^{1,4}, Paxie Chirwa², Folaranmi Dapo Babalola^{2,5}, Pasicha Chaikaew³

¹Federal University of Technology, Akure, Nigeria; ²University of Pretoria, Pretoria, South Africa; ³Chulalongkorn University, Bangkok, Thailand;

⁴University of Pretoria Pretoria South Africa; ⁵University of Ilorin, Ilorin, Nigeria (adeyemiadetunji@up.ac.za; paxie.chirwa@up.ac.za; folababs2000@gmail.com; pasicha.c@chula.ac.th)

Biosphere reserves are designated to harmonize the relationships between humans and their environment in order to mitigate biodiversity loss which underpins ecosystem services and environmental sustainability. However, previous studies have shown an increasing decline in the availability of ecosystem services over the past few decades due to unsustainable use and management of forest resources. Though an urgent intervention program is needed for sustainable ecosystem services provision for the local communities, the translation of indigenous people's perception of ecosystem services into actionable strategies is still lacking. This study aims to understand local people's perception of ecosystem services that are of priority for their basic needs. Such understanding will help in focusing intervention programs to conserve the ecosystem services while conserving forest resources. To achieve this, empirical data will be collected using a face-to-face questionnaire survey. The questionnaire will be designed to collect information relating to socioeconomic, demographic, identification of ecosystem services, perception about ecosystem services in terms of importance and preferences, accessibility to ecosystem services, and willingness to conserve ecosystem services. Frequencies and multinomial logistic regression will be used to determine which ecosystem services are perceived as important and likely to be utilized in Omo Biosphere Reserve and other similar landscape. This study will help to understand direct users' preferences which will facilitate policy-makers to respond to stakeholders' priorities and better orient management of forest resources. Such orientation can help to improve indigenous peoples' livelihood while contributing to the Global Sustainable Development Goals

How to choose a suitable family forest cooperative organization for local small-scale private forestry in China: a successful experience from Yongan county

Hesheng Xie¹, Youjun He¹, Dengju Wang¹

¹Research Institute of Forestry Policy and Information, Chinese Academy of Forestry, Beijing, China (791555389@qq.com; hyjun163@163.com; wdengju@163.com)

Since the Chinese Collective Forest Tenure Reform (CCFTR), three typical Family Forest Cooperative Organizations (FFCOs) in the form of Forestry Professional Cooperatives (FPC), Family Stock-Cooperative Forest Farm (FSCFF) and Forestry Association (FA) have been successfully established and operated at most of local villages. Based on the sample data of 143 FFCOs and the villages where they locate in in Yongan, a successful demonstration county of CCFTR, we make a model by Multiple Logistic Regression and Stepwise Regression through using R software. Results show that the model with the smallest Akaike Inf. Crit. (AIC) of 67.06 is selected, and influencing factors such as local race category, forest resource category, law condition, land scale served by FFCOs, number of the Party member, distance to town or market, proportion of migrant worker and forest land scale managed by family are significant at 1% probability level. It is concluded that, compared with FA, FPC and FSCFF, especially FPC with good policy conditions, are chose with big probability by local, and more suitable for local SHE race villages, or local with timber or bamboo forest, or smaller land scale served by FFCOs, or smaller forest land scale managed by family, or more Party members, or long distance to town, or more proportion of migrant workers. Finally, we suggest that the successful experience of demonstration county should be actively summarize, and appropriate FFCOs should be selected and popularized for other small-scale family forestry according to local actual conditions such as forest resource conditions, village social conditions, and policy environment.

Economic optimization of landscape restoration in Latin America

Rene Zamora Cristales¹

¹World Resources Institute, Washington DC, USA; ¹Oregon State University Corvallis, Oregon USA (rene.zamora@wri.org)

Landscape Restoration in Latin America is becoming an increasable feasible strategy to mitigate and adapt to climate change effects. Restoration includes interventions such as reforestation, agroforestry, and silvopastures. Many governments in the region have committed to restoring about 50 million hectares to the Bonn Challenge, Initiative 20x20 and the New York Declaration on Forest. However, challenges remain about where, when, and how to implement restoration activities in the landscape. In this study, we developed a multi-objective multi-criteria spatial optimization model to identify, rank and prioritize different restoration opportunities based on their contribution to multiple objectives. The model optimizes spatial resource allocation to priority areas to restore forest connectivity, improve carbon stocks and protect water resources. We have applied the model in two countries, Guatemala and Colombia to estimate the

most cost-effective restoration strategies that can be implemented in the landscape to achieve the objectives of mitigation and adaptation to climate change. In Guatemala, the analysis focused on how and where to allocate forest incentives (direct payments to landowners) to restore degraded land. In Colombia, the analysis focused on identifying areas to improve connectivity through productive restoration strategies between two nature reserves. In both countries, the model provides decision support to identify where and how to restore key areas in the landscape. We applied a combination of Mixed-integer programming, simulated annealing heuristics, and spatial analysis to develop the model as a toolbox in ArcGIS. Results from the model are being used by governments to implement better strategic planning of landscape restoration.

Spatial distribution of forest ownership as a result of the restitution process

Jan Wild¹, Vilém Jarský¹

¹Czech University of Life Sciences Prague, Prague, Czech Republic (wild@fzp.czu.cz; jarsky@fld.czu.cz)

Forest ownership structure in post communistic countries, including the Czech Republic, strongly changed after the end of communistic era. Restitution of nationalized forestland to the former private owners and further demographic and legal processes affect mainly the size of forestland parcels and the distance between the forestland and place of residence of its owner. The size and especially the distances may strongly influence in which way the forest is managed. Within the project NAZV QK1820041 we have analyzed distances of more than 1.4 million of forest parcels and place of residence of their ca 300,000 individual private owners (18 % of the forestland in the country). Anonymized data were provided by Czech Office for Surveying, Mapping and Cadaster and analyzed using ArcGIS 10.5 and R statistical software. Here we present the basic explorative analyses of spatial relationship between forest parcels and their private owners. We found that shorter distances prevail. Local owners possess ca 74 % of total forest land owned by private owners. Average distance from owner residence to his/her forest is 23.8 km (5th percentile = 0,4 km; 95th percentile = 119 km; sd = 48.2 km). Most of owners (81 %) also live outside larger cities (> 40,000 inhabitant) and possess almost 80% of forest land owned by private owners. Spatial data also allow us visualize distribution of ownership structure and thus further support the understanding of this phenomena. The real ownership structure and its spatial distribution is essential for proper targeting of forest policy.

Calculating environmental damage to deforested rain forests in the Amazon region of Pará / Valoração dos danos ambientais em Florestas Ombrófilas desmatadas na Amazônia paraense

Cyro José Matavelli^{1,2}

¹Polícia Federal, Setor Técnico-Científico, Florianópolis, Brasil; ²Universidade Federal de Santa Catarina, Florianópolis, Brasil (cjmatave@yahoo.com.br)

Nas últimas décadas, em razão da intensificação da expansão agropecuária, o desmatamento avança na região Amazônica. No Estado do Pará, a especulação e grilagem de terras, a criação de assentamentos rurais e a pavimentação de rodovias, contribuem para uma migração espontânea e desordenada, em busca de novos recursos naturais. Nesse contexto, a ocorrência de crimes ambientais é frequente e a sua materialização pode ser determinada através de perícias ambientais. No entanto, não basta somente materializar o dano, também se deve valorá-lo através de metodologias que cumpram algumas exigências, tais como praticidade, rápida execução, baixo custo e plausibilidade da aceitação na esfera judicial. O presente estudo tem por objetivos estimar o volume de madeira comercial explorado em florestas no Estado do Pará, por meio de dados de inventários florestais e de sensoriamento remoto, a fim de utilizá-lo como principal componente do valor de uso direto. A área de estudo situa-se em uma faixa de 50 km de cada lado ao longo do trecho paraense da BR-163, perfazendo 6,2 milhões de hectares, grande parte inserida em Unidades de Conservação, Terras Indígenas e Áreas Militares. A área desmatada através de corte raso até o ano de 2015 foi estimada em 1,2 milhões de hectares. O VUD, baseado nos componentes valor da madeira comercial e custos da recuperação, em 481 mil hectares, perfaz um total de 9 bilhões de reais. Espera-se uma maior eficiência na elaboração de Laudos na Amazônia, com o dano materializado e valorado, auxiliando na persecução penal e civil.

A9s: SOCIAL ISSUES IN FORESTRY

How the “tourism-based country promotion policy” effects Japanese nature-based tourism

Nobuhiko Tanaka¹

¹Tokai University, Tokyo, Japan (tanaka_nobuhiko@tokai-u.jp)

To change from a less-developed country in terms of its “Tourism industry,” particularly inbound tourism and regional revitalization aspects, Japan has commenced with the “Tourism-based Country Promotion Policy” as of the beginning of 21st century. For instance, the Japanese government started the “Visit Japan Campaign” in 2003, enacted the “Tourism-based Country Promotion Basic Act” in 2007, founded Japan Tourism Agency in 2008, and established “Our Vision to Support the Future of Japan Through Tourism” in 2016. According to this vision, Japanese nature-based tourism policies have also been dramatically changed during this decade. This vision uses the following three viewpoints: 1. Tourist resource issues, 2. Tourism industry issues, 3. Tourist convenience issues. The first one is closely related to forest nature-based tourism. And this vision also advocated the 10 significant reforms necessary to make Japan a “Tourism Advanced Country.” “The reform of national parks” and “the reform of landscape” are included among these 10 reforms for Japanese tourism promotion. To undertake these reforms effectively, the Japanese Ministry of the Environment started the “Project to Fully Enjoy National Parks.” The Japanese Forestry Agency also started policies for forest recreation and tourism in the National Forest. This study summarizes the recent political situation vis-à-vis Tourism policy making, and discuss the ideal state of Japanese nature-based tourism policy in the near future.

Synchronizing the sustainable development goals into forestry, a case study of Austria

Reneema Hazarika^{1,2}, Robert Jandl²

¹Institute of Geography, University of Hamburg, Hamburg, Germany; ²Austrian Research Centre for Forests, Vienna, Austria (reneema.hazarika@studium.uni-hamburg.de; robert.jandl@bfw.gv.at)

Since its inception, there has been much conceptual progress on the linkages of the Sustainable Development Goals (SDGs) and their targets in a comprehensive way. While this conceptualization is an essential first step, action must now move towards translating such concepts into concrete results. One such important inter-linkage is between forestry and the Goal-15 (life on land). Global change factors such as climate change are likely to challenge the ambitions of development laid down in these goals. Such challenges are predicted to be intense in countries with mountain forests such as Austria where effects of climate

change have already started to manifest. Therefore evaluating the forestry sector within Europe with the sustainable management of Austrian forests in focus can be interesting. We reviewed the linkages and tradeoffs between the SDGs and the principles of sustainability in the Austrian forestry sector. In addition, we compiled the perceptions of Austrian opinion leaders on such linkages and tradeoffs. We found strong linkages between SDG-15 and Austrian forestry sector. The opinion leaders perceive the SDGs as well-placed but broad and at times lacking clarity. The 15-year tenure of the SDGs was perceived to be inadequate to match the temporal scale of forest's development which spans across decades. Apparently, the success of the SDGs will depend upon coordination, governance and most importantly awareness among all stakeholders. Therefore in addition to "leaving no one behind" the development goals must evidently provide incentives for benefitting everybody.

Forest law and environmental legislation for enhanced ecosystem services in Serbia

Nataša Tomić-Petrović¹, Mirjana Stevanov²

¹University of Belgrade, Belgrade, Serbia; ²University of Novi Sad, Institute of lowland forestry and environment, Novi Sad, Serbia (atlantic@orion.rs; mzavodj@gwdg.de)

Key challenges of European integrations are in environmental protection. In Serbia since 2007 the Ombudsman has received almost 500 complaints regarding the violation of rights in the field of environment. It shows that citizens do not recognize these problems enough, but that they are also afraid to report them. In our capital Belgrade the first Ministerial Conference "Innovative decisions against pollution in the South and South-East Europe" was held in December 2018. There were representatives from 20 countries of the Southern and South-Eastern Europe and the final document called "Common regional vision of the innovative solutions for decrease of pollution in the South and South-East Europe" was adopted. Serbia is forested 27%, what is very good, but we have a problem in Vojvodina, where only 6-7% of the territory is covered with forests. Unfortunately problems with soil erosion and flood are causing huge damage to all areas of life in Serbia. It is necessary to harmonize our positive regulations in Serbia with regulations in the European Union referring to the cutting of forests, but also the control of import and export of wood and wood products. In Serbia, the current issue is trade of illegally-cut trees for fuel. After the amendments to the Law on Forests ("Official Gazette of the Republic of Serbia", no; 89/15) except market inspectors, now foresters, i.e. forestry inspectors and technicians, are allowed to intervene if they find out that someone traded illegally with felled wood, even if they were from his private forests.

Accountability issues in centrally-led forest governance: addressing climate and development challenges through enabling local communities in Sri Lanka

Indi Akurugoda¹ ; Manjula Karunaratne¹

¹University of Ruhuna, Matara, Sri Lanka (indiakuru@gmail.com; mlankanath@gmail.com)

As a developing country where government policies have the top priority on large scale infrastructure development projects using deforested lands, Sri Lanka faces extreme impacts of climate change. The export-oriented plantation economy introduced by the British colonial rulers contributed to forest land clearance prior to independence in 1948. After independence, new major development projects have added further strains on deforestation. The 2019 Long-Term Climate Risk Index has listed Sri Lanka as the second most affected country by extreme weather events. According to the UN-REDD programme in 2017, Sri Lanka's forests, which currently cover 29.7 percent of the total land area can make a significant contribution to both adaptation and mitigation of climate change impacts. Sri Lanka's forest governance is centrally-led. Although there are a number of central government authorities such as the Ministry of Wildlife, Forest Department, Department of Wildlife Conservation and the Central Environmental Authority, which are accountable for forest governance and wildlife conservation, there are several policy fragmentations and accountability clashes. Based on Sinharaja and Kanneliya rainforests, this research explores why the centrally-led forest governance is less accountable for addressing climate and development challenges, and how to enable local communities to address such challenges. Using the data gathered by interviewing forest and wildlife officials, this research identifies the gaps in centrally-led forest governance. The paper observes the potential of enabling local communities in protecting forests from degradation and deforestation and facing climate and development challenges.

Transformative change to a sustainable use of firewood in southern Chile, a wicked problem

Gustavo Torres¹

¹Programa de Doctorado de Ciencias Sociales en Estudios Territoriales, Universidad de Los Lagos, Osorno, Chile (gustavo.torres@ulagos.cl)

In southern Chile there are socio-metabolic needs to use energy for heating in the residential sector during several months of the year. This demand has historically been met with firewood or dendroenergy, with the current consumption of 450,000 m³ /year in the Province of Osorno, which is obtained mainly from the native forest, where rural producers face problems of poverty and depletion of forests. Firewood is traded in a mostly informal market, where there is no regulation of its quality. Due to this and an inappropriate combustion, there are episodes of high air pollution and health problems in the population. Recently the Government is facing the situation through policy measures restricting the use of wet firewood, however it has not been possible to meet the proposed goals. Thus, the sustainability of the use of firewood is a wicked problem and to address it, the present study proposes a systemic and interdisciplinary approach defining it as a Socio-Ecological System (SES). As an initial result, a proposal for a general analytical framework for the SES of firewood will be shown. Using it, the available information is synthesized to determine the key interactions between the natural system and the social system, emphasizing the main socio-ecological traps that must be addressed to visualize the possibilities for a transformative change towards a sustainable use of firewood in the Province of Osorno. The present study is part of the author's doctoral thesis. The contributions of the Projects FIC BIP 30233422-0 and FONDECYT 1181282 are gratefully acknowledged.

Actionable knowledge for wicked problems: co-production in the USDA Forest Service Rocky Mountain Research Station

Daniel Williams¹, Evora Glenn^{2,3}, Carina Wyborn², Laurie Yung²

¹USDA Forest Service Rocky Mountain Research Station, Fort Collins, USA; ²University of Montana, Missoula, USA; ³Luc Hoffmann Institute, Gland, Switzerland (drwilliams@fs.fed.us; evora.glenn@umontana.edu; cwyborn@wwfint.org; laurie.yung@umontana.edu)

The mission of the Rocky Mountain Research Station (RMRS) is to support public and private landowners with best available science to inform land management decisions. Those decisions, however, have become increasingly wicked, complex, and interdisciplinary. To address growing demands for actionable science RMRS is engaging land managers, local communities, and other stakeholders in the co-production of science and science products. Knowledge co-production emphasizes collaboration between researchers and stakeholders to jointly define challenges, identify knowledge gaps, and determine actions to address them. These approaches focus on creating durable, iterative collaborative processes that facilitate co-developing and learning

together. Co-production seeks to build reciprocal connections between knowledge (scientific, local, experiential, traditional etc.) and decision-making (in policy and practice) to achieve outcomes that are collectively agreed on by those engaged in the process. This presentation describes recent projects involving RMRS in science-management collaborations that incorporate principles of co-production, and examines the ways that RMRS institutional structures and cultures impact the process and outcomes of co-production in these projects. The projects studied include seven research projects covering a variety of landscapes and management problems. In each case, researchers work with managers and other stakeholders to collaboratively describe the multiple dimensions of resource challenges and identify solutions that can address these many dimensions effectively. We will highlight lessons learned from these projects, particularly with respect to the strategies that can be employed by science and management agencies to support co-production processes to realize their aspirations for change.

Integrated management of trophic interactions: moose, red deer and sustainable forest management in Sweden, Belarus and Republic of Moldova

Vitalie Gulca¹, Per Angelstam², Robert Deal³

¹State Agricultural University of Moldova, Department of Forestry and Public Gardens, Chisinau, Republic of Moldova; ²Swedish University of Agricultural Sciences, School for Forest Management, Skinnskatteberg, Sweden; ³USDA Forest Service, Pacific Northwest Research Station, Portland, USA (vitalie.gulca@gmail.com; per.angelstam@slu.se; rdeal@fs.fed.us)

Sustainable forest management includes the integration of biophysical, economic and social considerations and the management of many important ecosystem services for forest landowners. Damages to tree regeneration caused by browsing large herbivores depend on their density and the amount of food available under different forest landscape management systems. Within the hemiboreal and temperate ecoregions different countries provide different social-ecological and governance contexts and thus opportunity for comparative studies regarding the trade-offs among different variables. Currently, wildlife law is being reformed in Sweden, Belarus and Republic of Moldova. In Sweden moose browsing hampers regeneration of Scots pine for wood production and deciduous tree species for biodiversity conservation. Complex governance makes regulation difficult. In Belarus moose hunting is a significant ecosystem service delivered by forests, which can be steered top-down by development and change of hunting and forests. Decision to increase the number of red deer populations for hunting revenue in Republic of Moldova may compromise another strategic national task, to increase forest area. First, based on interviews we assessed stakeholders' perceived ecosystem services linked to moose, red deer and forests. Second, we assessed the carrying capacity for moose and red deer in case study landscapes in these three countries. The big difference in moose and red deer density and harvest between the countries was linked to different carrying capacities. Finally, we propose innovative wildlife law focused on integration of the interactions between wild herbivore populations, sustainable forest management and local communities.

Hiking as a certified ecosystem service tool to promote healthy life style (HLS) and to increase forestland value

Vitalie Gulca¹, Marion Karmann², Robert Deal³, Lu Wenming⁴

¹State Agricultural University of Moldova, Chisinau, Republic of Moldova; ²FSC International, FSC Global Development GmbH, Bonn, Germany; ³USDA Forest Service, Pacific Northwest Research Station, Portland, USA; ⁴Chinese Academy of Forestry, Beijing, China (vitalie.gulca@gmail.com; m.karmann@fsc.org; rdeal@fs.fed.us; luwenmingcaf@126.com)

The most unique and effective recovery, scientists say today is healing in the forest. The scientific report of Japanese scientists in 2011 officially confirmed that "forest baths" are not just fun. Having visited once in a forest "clinic", a person develops resistance to all diseases, relieves stress and overcomes chronic fatigue, lowers blood pressure, sugar in the blood and depression, increases concentration and memory, increases self-esteem, develops an independent view of the world, in which its modern civilization drives. Similar results were demonstrated by the latest research conducted in Sweden, England, Canada, the USA. They were attended by 8,500 people and as a result the scientists came to the conclusion: the connection of man with nature gives him a sense of happiness. The goal of the paper in that context is to develop a hiking as a labelled product of emerging markets for ecosystem services (ES) for assessing and communicating the environmental and social performance of forest operations and HLS. Article has an objective to develop a policy for family hiking routes. We hypothesize that hiking present new opportunities for forest landowners and managers, with increasing international recognition of the importance of ES markets and national values. To realize our paper, we have analyzed the health as a system, confronted health and forest legislations, studied the hiking as a process in organizing periodically hiking tours in Republic of Moldova.

A9t: FOREST POLICY AND ECONOMICS - III

A prospectus of leading and lagging indicators for forest restoration in the Philippines

Liz Ota¹, John Herbohn¹, Nestor Gregorio¹, Arturo Pasa², Dennis Peque², Jennifer Firm³

¹University of the Sunshine Coast, Sippy Downs, Australia; ²Visayas State University, Baybay, Leyte, Philippines; ³Queensland University of Technology, Brisbane, Australia (lizmsota@gmail.com; jherbohn@usc.edu.au; ngregori@usc.edu.au; arturo.pasa@vsu.edu.ph; dpeque@vsu.edu.ph; jennifer.firm@qut.edu.au)

We aim at proposing a prospectus of leading and lagging indicators for forest restoration in the Philippines. While leading indicators point to the likelihood of an outcome, lagging indicators represent realised outcomes of a process. Current forest restoration approaches are focused on much more than just reintroducing trees to the landscape. They acknowledge that a landscape comprises multiple stakeholders who pursue different objectives in a multi-governance structure, and are aimed at providing environmental benefits while improving human well-being. Therefore simple measures of effort (e.g. number of seedlings or area planted) or of short-term outcomes (e.g. tree growth and survival rates) are not enough to assess forest restoration, and several lagging indicators are needed across time and scales. However, forest restoration is a long-term process and some impacts can only be observed years or even decades after its commencement. Leading indicators that suggest our current actions will likely result in the desired outcomes can assist to guide interventions.

Harmonizing trans-boundary wildlife management to improve ecological connectivity of chamois and Alpine ibex

Aleš Poljanec¹, Andrej Arih², Stefano Santi³, Chris Walzer⁴

¹Slovenia Forest Service, Ljubljana, Slovenia; ²Triglav National Park, Bled, Slovenia; ³Prealpi Giulie Nature Park, Resia, Italy; ⁴University of Veterinary Medicine Vienna; Research Institute of Wildlife Ecology, Vienna, Austria (ales.poljanec@zgs.si; andrej.arih@tnp.gov.si; stefano.santi@parcoprealpigiulie.it; chris.walzer@vetmeduni.ac.at)

The behaviour and habitat use of animals can be strongly affected by hunting methods and wildlife management strategies. Lack of consistency in wildlife management between regions can cause problems for population connectivity for some species, particularly for those with large home ranges. Thus, to facilitate the goals of ecological connectivity, ALPBIONET2030 aims to improve wildlife management of chamois (*Rupicapra rupicapra*) and Alpine ibex (*Capra ibex*) in cross-border area of the Julian Alps (289.660 ha). A participatory process, consisted of several expert meetings and workshops was used to discuss possibilities for reconciling land use conflicts and to set up the long-term vision for conservation, protection and sustainable management of both species and their habitats. The process targeted stakeholders from the Alpine regions, including representatives from wildlife management, hunting, park management, forest management, and other interested area residents. The results of the participatory process and applicability of approaches and methods for improving ecological connectivity of wildlife species in cross-border areas will be presented and further discussed. The research is financed by the ALPBIONET2030 project and co-financed by the European Union as part of the Alpine Space Program.

Towards a theory of change to enable forest people to build prosperity while delivering Global benefits for adaptation, mitigation, biodiversity, ecosystem services and cultural heritage

Andrew Taber¹, Jose DiazDiaz¹, Marta Gruca¹, Safia Aggarwal¹, Jeremie Mbairamadji¹

¹UN Food and Agriculture Organization, Rome, Italy (andrew.taber@fao.org; jose.diazdiaz@fao.org; marta.gruca@fao.org; safia.aggarwal@fao.org; jeremie.mbairamadji@fao.org)

Forest communities, often indigenous peoples, face high levels of poverty and social, economic and political marginalization in many parts of the world. Yet they inhabit biologically diverse landscapes that provide a wide range of ecosystems services at greater scales, including for bolstering resilience in response to climate change. They also harbor rich cultural heritage and traditional knowledge; and produce a variety of wood and non-wood forest products, as well as services such as ecotourism that contribute to local, national and international economies. Research has documented their contributions. However, full recognition is lacking of the existing and potential role of forest communities, under the right conditions, for securing a wide range of environmental goods and services of vital importance to forests and global sustainability while improving their lives and livelihoods. In this poster, we review impediments for forest peoples to realize their potential, and present a theory of change based on the implementation of a holistic and integrated policy and practice framework. This includes strengthening recognition of rights, particularly for forest lands and resources, culturally and gender sensitive economic empowerment and education, and mechanisms to incentivize and sustain their contributions to global environmental goods and services.

Addressing policy-makers in stakeholder communication: LIFE GENMON project case study

Tjaša Baloh¹, Boris Rantasa², Katja Sonnenschein¹, Veronika Vodlan³, Marjana Westergren¹, Fotios Kiourtsis⁴, Xrysi Sarvani⁴, Ermioni Malliarou⁵, Mark Walter⁶, Nikitas Fragiskakis⁴, Andrej Breznikar², Hojka Kraigher¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Slovenia Forest Service, Ljubljana, Slovenia; ³Center for Information service, co-operation and development of NGOs, Ljubljana, Slovenia; ⁴The Decentralized Administration of Macedonia – Thrace, Thessaloniki, Greece; ⁵Aristotle University of Thessaloniki, Thessaloniki, Greece; ⁶Bavarian Office for Forest Seeding and Planting, Teisendorf, Germany (tjasa.baloh@gozdis.si; boris.rantasa@zgs.si; katja.sonnenschein@gozdis.si; veronika.vodlan@civos.si)

One of the LIFE GENMON project aims is to raise awareness of the importance of genetic diversity of forests for their survival and the importance of implementation of policies that promote such diversity. The obstacles to achieve policy implementation is often unclear communication due to technical language, lack of understanding of the policy-making process and consequently, unrealistic expectations on the side of scientists and a lack of knowledge and understanding of the problem on the side of policy makers. The other obstacle is difficulty to reach all interest groups in policy-making arena. To address the problem of the gap in knowledge between scientists and policy makers, the case study delves into the forms of communication that would successfully warn policy makers and other stakeholders about problems and guide them toward solutions in an innovative way. Moreover, it tries to recognize the moments of opportunity and possibilities to effectively act on them. To address the problem of stakeholders' participation in decision-making processes, the case study focuses on observing activities carried out within the LIFE GENMON project to reach policy-makers and analyses results in terms of their expected and achieved impact. The study provides recommendations in response to specific problems identified. The presentation contributes to the aims and means of the project LIFE GENMON (LIFE13 ENV/SI/000148) for European forest genetic monitoring system, co-financed by the Ministry for the environment and spatial planning RS, and in Slovenia by the Ministry for agriculture, forestry and food and the Slovenian Forestry Institute.

Community forest management and ecosystem conservation in the Vicos Recuayhuanca microbasin, Ancash, Peru

Aurea Erica Castro Aponte^{1,2}

¹Pontificia Universidad Católica del Perú, Lima, Peru; ²Forest Stewardship Council (FSC), Lima, Peru (ericaforestales@gmail.com)

During the last years communities around the world are playing a more central role in the management of local forest and ecosystem conservation. In the Andes communities have a long tradition in managing the forest based on a particular worldview. This research contributes to the understanding of the management and conservation strategies of local forest by the community of Vicos. The research aimed to shed light on the engineering and social practices, and on the strategies of organizational management at community level. The methodology applied is qualitative. Peasants, public agency officers and local NGOs representatives were interviewed. The research concludes that social practices such as solidarity, reciprocity, collectiveness and equity are key to manage the forest sustainably by the Vicos community and the those practices condition the organizational structure, power relationship and collaboration schemes in the community. The research identifies that the efforts of the Vicos community are not backed by the Peruvian state agencies and most of local NGOs, as a result the community social practices are being eroded and conflicts enhanced. Finally, the research suggests a model of sustainable forest management at community level worldwide based on the Vicos community case and the monitoring of organizational and cultural aspects beside of ecological ones for a sustainable community forest management.

Understanding expert disagreements and finding common ground: the case of forest policy research and advocacy in India

Vanya Bisht¹

¹School for the Future of Innovation in Society, Arizona State University, Tempe, USA (vbisht2@asu.edu)

A crucial forest policy problem in many developing countries is the challenge of effectively managing forest resources to meet the competing social, ecological and economic goals of the countries. On one hand there is a need to safeguard the rights of traditional forest dwelling communities to access and manage their

resources, and on the other hand the need to utilize those resources for meeting industrial demands for the national economy, while maintaining ecological and climatic stability. Solutions or policy recommendations to the above problem coming from experts or policy advisers in different academic disciplines tend to diverge or disagree with one another over critical issues. This often results in a stalemate and impedes major policy decisions. This research investigates the multiplicity of policy recommendations offered by researchers, thinkers and practitioners in the context of forest governance in India. Academic and non-academic writings (in the form of journal publications, and articles in newspaper and magazines) giving recommendations on forest policies have been analysed to understand how the framing of the problem and approaches to solutions vary across academic and professional silos. This study explores the possibilities of places where commonalities can be found among the policy approaches suggested by different groups. The results are useful in facilitating interdisciplinary collaborations in policy research, overcoming policy stalemates and solving complex forest policy problems in India as well as other countries.

Flora, population structure and conservation management plan of natural monument coastal tree *Koelreuteria paniculata* community in South Korea

YoungHan You¹, Kyu-Tae Cho^{1,2}, SeungYeon Lee¹, EungPill Lee¹, YongSik Hong¹, Euijoo Kim¹

¹Kongju National University, Kongju, Republic of Korea; ²Kongju National University, Kongju, Republic of Korea (youeco21@kongju.ac.kr; rbxo38@kongju.ac.kr; ecollee21@kongju.ac.kr; lyp2279@kongju.ac.kr; hongfin@kongju.ac.kr; euijoo@kongju.ac.kr)

This study was conducted to investigate the external factors and problems that inhibit the sustainability of Natural Monument Coastal Tree *Koelreuteria paniculata* Communities in two local area (the natural monument No; 138 and No; 428) and to establish an effective conservation management plan for these forests. The field investigation surveyed the flora, tree counting, growth status, succession status, surrounding facilities and management status in three times (Spring, Summer, Autumn) in 2016. A total of 133 taxa (60 families, 109 genera, 115 species, 11 varieties, 4 forms, 3 subspecies) appeared in the tree communities of Taean County. A total of 253 trees were 2-8 m high with growth performance. There were seedling and sapling plants due to seed germination evenly throughout the growing area, but they were decreasing due to weed cutting activity. A total of 86 taxa (46 families, 76 genera, 76 species, 10 varieties) appeared in the tree communities of Wando Island. A total of 600 trees were 2-17 m high with growth performance. There were many seedling and sapling plants due to seed germination in edge and open area of the forest. In order to conserve these plant communities, management measures should be prepared such as strengthening regular management in protected areas, improving methods of removing weeds in lower layer, regular monitoring for population dynamics, and strengthening local residents' participation in preventing artificial damage.

Costs of threatened species conservation: evidence from Australia

Ram Pandit¹, Asha Gunawardena¹, Stephen Garnett², David Pannell¹, James Brasill-Boast³, Kerstin Zander²

¹University of Western Australia, Perth, Australia; ²Charles Darwin University, Darwin, Australia; ³Office of Environment & Heritage, New South Wales, Sydney, Australia (ram.pandit@uwa.edu.au; asha.gunawardena@uwa.edu.au; stephen.garnett@cdu.edu.au; david.pannell@uwa.edu.au; james.brazillboast@environment.nsw.gov.au; kerstin.zander@cdu.edu.au)

Species conservation decisions are inherently complex, require careful analysis of different types of information and are also made with resource constraints. Both globally and locally, there are more species to conserve with limited budget. Incorporating economics into conservation planning right from the beginning of developing recovery plans to implementing and evaluating their success is vital. This study aims to examine conservation of threatened species planning in Australia using recovery actions level costs data from a large- scale systematic database of New South Wales. It also explores the determinants of actual expenditure of recovery actions and reporting gaps in current practice to improve systematic conservation planning of threatened species in Australia.

THEME B: FORESTS AND CLIMATE CHANGE

B1a: INITIATIVES FOR RESTORATION AND MONITORING OF DEGRADED AREAS IN LATIN AMERICA

Monitoring and transparency of restoration in Latin America: a landscape sustainability index

Rene Zamora Cristales^{1,2}

¹World Resources Institute, Washington DC, USA; ²Oregon State University Corvallis, Oregon, USA (rene.zamora@wri.org)

Monitoring the impacts of restoration activities in the landscape as a system is particularly difficult and it poses some challenges to identifying strategic areas within the landscape that can signal an effect in the overall sustainability. In this study, we developed a cost-effective Landscape Sustainability Index (LSI) to measure the sustainability of the landscape due to restoration against baseline conditions. The LSI is intended to demonstrate correlation (positive or negative) between the restoration activities that are being implemented and the impacts stated in the national restoration plans of countries in Latin America. The LSI is composed of cost-effective social, environmental and economic qualitative and quantitative indicators and uses information available in most of the countries. For social aspects, we developed a governance indicator to measure the level of coordination and organization of the communities living in a landscape. For environmental aspects, we develop indicators for carbon, water quality, water quantity, and soil carbon. To assess the economics, an indicator of employment generated by restoration activities was introduced. The index was implemented in a pilot landscape in El Salvador, Apaneca/ El Imposible /Barra de Santiago where restoration activities have been carried out since 2012. Results show that the sustainability of this landscape has increased since 2011. THE LSI estimated a positive correlation between restoration interventions and carbon stocks, water quality, and connectivity since 2011. The index is the first of its kind to provide a holistic method to monitor impacts of restoration in Landscapes in Latin America.

Initiative 20 x 20: The rise of a movement to support landscape restoration in Latin America

Rene Zamora Cristales¹

¹World Resources Institute, Washington DC, USA (rene.zamora@wri.org)

Initiative 20x20 is a country-led effort to bring under restoration 20 million hectares of degraded land by 2020. This country-led platform is the largest regional movement supporting the Bonn Challenge effort of restoring 150 million hectares worldwide. Currently, 17 countries have pledged more than 50 million

hectares to restore. In addition to that private sector partners have earmarked 2 billion USD to invest in productive restoration across the region. Also, technical assistance is provided to the countries, through more than 30 technical partners that are helping the countries with capacity development and research to achieve their restoration targets. Countries are developing on plans and strategies to support restoration ambitions with special priority on rehabilitating the functionality of the land to improve livelihoods, biodiversity and provide sustainable financial resources to landowners. Private partners, financial institutions and technical partners are working together to unlock private investments in lands restoration using different mechanisms. These mechanisms include the deployment of a partial risk mitigation guarantee, the structuring of an investment readiness fund to prepare potential restoration projects to be investment ready and the use of highly valuable forest species (from commercial and biodiversity point of view) as collateral to allow landowners to access to credits. The landscape restoration activities under the initiative aim to restore degraded land functionality to increase social wellbeing while improving environmental conditions and generating financial and economic benefits. Strategies may include but not limited to agroforestry, tree plantations, silvopasture systems or silvicultural management of degraded and secondary forests.

The alliance for restoration in the Amazon and the importance of scaling up forest landscape restoration as a nature based solution for societal challenges

Miguel Moraes¹, Catarina Jakovac², Danielle Celentano³, Marcos Tito⁴, Marlúcia Martins⁵, Rodrigo Freire⁶, Rodrigo Junqueira⁷, Rodrigo Medeiros⁸, Sâmia Nunes⁹

¹Conservation International, Rio de Janeiro, Brasil; ²Centro de Ciências da Conservação e Sustentabilidade, Rio de Janeiro, Brasil; ³Universidade Estadual do Maranhão, São Luiz, Brasil; ⁴União Internacional para a Conservação da Natureza, Brasília, Brasil; ⁵Museu Goeldi, Belém, Brasil; ⁶The Nature Conservancy, Belém, Brasil; ⁷Instituto Socioambiental, Brasília, Brasil; ⁸Conservation International, Rio de Janeiro, Brasil; ⁹Vale Environment Technology, Belém, Brasil (mdmoraes@conservation.org; c.jakovac@iis-rio.org; danicelentano@yahoo.com.br; marcos.rugnitz@iucn.org; marlucia@museu-goeldi.br; rfreire@mc.org; rodrigojunqueira@socioambiental.org; rmedeiros@conservation.org; samiasnunes@gmail.com)

Large-scale forest landscape restoration in the Amazon is an agenda of human development, environmental sustainability and agricultural productivity. It represents a virtuous change in the paradigm of economic development in the Amazon, since it generates jobs and income, integrates different productive and social sectors, values its biological and cultural diversity, avoids deforestation and prevents against violence in land disputes. In the Amazon, the forest is synonym for water, wealth, abundance and prosperity. Defining territorial priorities and identifying areas where restoration maximizes ecological, social and economic benefits are fundamental to scale-up forest landscape restoration. Furthermore, the implementation of public policies for large-scale restoration in the Amazon depends on regulation and compliance with environmental legislation, at national and subnational level. Public and private investments in research, development, innovation and human capital are also needed. However, the capacity to articulate all sectors of society is probably one of the greatest challenges ahead of us. The Alliance for Restoration in the Amazon is working to bring key stakeholders together to promote, qualify and expand the scale of Forest Landscape Restoration in the Amazon. The Alliance is an inter-institutional and multi-sectoral articulation, established in 2017, which believes that by restoring forests in the Amazon, land use efficiency will be increased, and ecosystem services provision will be enhanced, strengthening local economies and promoting well-being. Therefore, working groups have been established to define technical priorities, promote advocacy, and raise awareness of the importance of Forest Landscape Restoration for the Amazon, Brazil and the Planet.

Restoration opportunities in Colombia: the multispecies and multiscale approach to territory management in Colombia / Oportunidades de restauración en Colombia: el enfoque multiespecies y multiescala para la gestión del territorio en Colombia

Paola Isaacs¹, Wilson Ramírez², Vivian Ochoa¹, Wilmer Marin¹, Mauricio Aguilar¹, Angelica Diaz¹, Talia Waldron¹, Julián Díaz-Timoté²

¹Instituto Humboldt, Bogotá, Colombia; ²Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (ecologa@gmail.com; wramirez@humboldt.org.co; vochoa@humboldt.org.co; wmarin@humboldt.org.co; maguilar@humboldt.org.co; adiaz@humboldt.org.co; twaldron@humboldt.org.co; jjulianidiaz@hotmail.com)

El reto de contribuir a la restauración del 15% de la superficie del mundo, requiere esfuerzo interdisciplinario a escala de paisaje. Colombia se comprometió a millón de hectáreas, con una tasa actual de 200.000 ha deforestadas en especial en zonas de posconflicto, lo cual requiere de abordajes ambiciosos. Se realizó una propuesta desde lo social, económico y biótico para definir oportunidades de restauración del paisaje. Se desarrollaron modelos de conectividad para grandes felinos, como base para definir prioridades de restauración, preservación y uso mediante modelos de servicios ecosistémicos (carbono, alimento, polinización, oferta y regulación hídrica, control de erosión y de remoción en masa) y aptitud de uso de la tierra para la gestión del riesgo a escala 1:100.000. Se analizaron modos de vida de las comunidades y evaluación económica de sus formas de producción versus reconversión productiva. De acuerdo a la zonificación multicriterio propuesta, se realizan modelos de finca, en áreas priorizadas para restaurar corredores. Se implementaron propuestas de productividad para el bienestar y la producción, y restauración en áreas erosionadas y corredores riparios, con producción adaptada para disminuir el conflicto felino actual. Se zonificaron 360.000 ha de paisajes funcionales con enfoque socioecológico que puede ser monitoreada al corto y largo plazo y que permite incrementar la productividad del campesino para detener las tasas de deforestación y optimizar el uso de la tierra dentro de áreas que son corredores importantes para la fauna.

An approach to restore functionality and productive capacity of degraded native forests in South-Central Chile

Gerardo Vergara-Asenjo¹, Bastienne Schlegel¹, Christian Little¹

¹Instituto Forestal, Valdivia, Chile (gevergara@gmail.com; bschlegel@infor.cl; clittle@infor.cl)

Forest degradation has been identified as one of the most significant anthropic forces affecting forests in Chile and constitutes one of the most important challenges in achieving sustainable management in native forests. Nevertheless, clarity and consensus on the meaning of degradation has been a constraint for the development of management plans and restoration practices in the country. This presentation explores the results of a research program at the Instituto Forestal (INFOR) that works on restoration of degraded native forests. Here we focus in three main topics: A conceptual approach to forest degradation. Using an operational approach, we present the theoretical aspects of forest degradation based on elements of forest dynamics, resilience and the national regulatory framework. Here we distinguish between process and state of forest degradation, which are linked to anthropic actions affecting key ecological processes and induce an arrested succession. The approach was discussed with local stakeholders (wood local associations, NGOs, research centers) which enriched the proposal. Exploring indicators and thresholds. To identify the indicators and thresholds of forest degradation, the gradients of past anthropic interventions in the Los Rios Region in southern Chile were explored. The results provide key information to identify arrested succession, as well as to categorize other anthropic impacts on forests. Implications for decision making. We discuss the implications of applying this approach on native forests in the country. Aspects such as national laws, management plans and the costs of restoring the functionality and productivity of native forests in the medium and long-term are considered in the analysis.

Standard for planning and executing restoration processes with a forestry landscape approach

Elizabeth Bustos¹, Roger Villalobos¹, Fernando Carrera¹, Diego Delgado¹

¹CATIE, Turrialba, Costa Rica (elizabeth.bustos@catie.ac.cr; rvillalo@catie.ac.cr; fcarrera@catie.ac.cr; ddelgado@catie.ac.cr)

Although the restoration of landscapes is a concept used more and more frequently in the literature and is mentioned in international discussions and commitments, there are still many doubts about how to organize and execute forest landscape restoration processes. Model forests are cross-sectoral social platforms of governance for large forest landscapes, in which there are diverse agricultural, forestry, urban or industrial land uses; various forms of tenure, social groups, interests and values. The partners of the Ibero-American Model Forest Network have been promoting, or wish to promote, restoration processes with a landscape approach in their areas of influence. That is why, from the analysis of processes and the discussion with managers of 4 Model forests, in Peru, Colombia and Costa Rica, a standard was developed to guide the development of productive restoration of forest landscapes. This standard consists of five principles. The first one refers to the ordering of the restoration actions themselves, the second to the political and institutional conditions that are required, the third to the conditions of local governance, the fourth to the availability of financial resources and market conditions, the fifth to the structures required for the process to be adaptive, including ongoing monitoring and evaluation. These principles are divided into 19 criteria and 51 possible indicators, which must be adapted to each particular situation.

Effect of the application of sewage sludge on the foliar contents of B, Cu, Fe, Mn and Zn in native species of the Atlantic Forest

Pedro Henrique Proença Nalessio¹, Rafael Barroca Silva¹, Marianne Fidalgo de Faria¹, Livia Mara Lima Goulart², Iraê Amaral Guerrini¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil; ²IFRR, Novo Paraíso, Brasil (pedronalessio@hotmail.com; rafael.barroca@outlook.com; marianneffaria@hotmail.com; liviamlgoulart@yahoo.com.br; irae.guerrini@unesp.br)

Sewage sludge is a source rich in organic matter and nutrients, being an alternative for the recovery of degraded areas. The objective of this study was to evaluate the effect of sewage sludge on the micronutrient foliar content of native Atlantic Forest species after 10 years of application of the residue. The experiment was set up in 2005 on the farm Entre-Rios, in the region of Itatinga-SP, Brazil. The experimental area was divided into 32 plots where 9 native species were planted. The experimental design was randomized blocks with four replications, considering the five increasing doses of sludge (2.5; 5; 10; 15 and 20 t ha⁻¹) with supplementation of K; mineral fertilization; dose of K used as supplementation and control, totaling 8 treatments. In 2015, leaves of three species (aroeira-pimenteira, canafístula and copafba) were harvested, for subsequent evaluation of the micronutrient content. The data were submitted to analysis of variance and the means were compared by the Tukey test at 5%. It was observed a significant effect of the sewage sludge on the foliar contents of B, Fe, Mn and Zn for aroeira-pimenteira, Cu, Fe and Zn for canafístula and Fe and Zn for copafba. The highest mean values of leaf contents for micronutrients were found in the highest doses of sludge and in mineral fertilization. In general, the doses of sewage sludge provided higher leaf contents of B, Cu, Fe, Mn and Zn for the species studied in relation to mineral fertilization.

Priority areas for forest restoration after Geographic Information Systems in Paraguay's San Rafael National Park Reserve / Áreas prioritarias para restauración forestal desde los Sistemas de Información Geográfica en la Reserva para Parque Nacional San Rafael, Paraguay

Fabiana Miranda¹, Stella Mary Amarilla¹, Janet Villalba¹, Lourdes González¹

¹Universidad Nacional de Asunción, San Lorenzo, Paraguay (fabianamgaray@gmail.com; stella.amarilla@agr.una.py; janetvv@gmail.com; lourdesgspy@gmail.com)

Debido a la necesidad de estudios referidos al tema de la degradación y restauración de ecosistemas en Paraguay; se ha considerado importante evaluar áreas prioritarias para la restauración forestal en la Reserva para Parque San Rafael (RPSR) reconocida tanto por su importancia para la conservación, como por sus procesos de degradación históricos, siendo este tema el objetivo general de la investigación. La RPSR ubicada entre los departamentos de Itapúa y Caazapá es considerada un remanente boscoso representativo de la ecorregión Bosque Atlántico del Alto Paraná. La metodología se basó en la priorización espacial de criterios relacionados a la restauración de bosques a través de Sistemas de Información Geográfica. Se utilizaron imágenes satelitales Sentinel 2-A, cartografías temáticas y herramientas ArcGis 10.3 y QGIS 2.18. Se aplicó una evaluación multicriterio, con la cual se combinaron 14 capas de información para obtener el mapa final de áreas prioritarias para acciones de restauración forestal. Los resultados indican que la categoría máxima prioridad de restauración representa el 7,03% y la categoría alta prioridad el 17,86%, ambas ubicadas en la zona Oeste del área protegida. Esta investigación buscó facilitar información para futuros proyectos de restauración forestal y otras acciones de manejo y conservación, oportunamente enmarcados en la declaración de la Década de las Naciones Unidas para la restauración de los ecosistemas (2021-2030).

Structural heterogeneity and tree species mixing as basis of climate smart forest management

Hans Pretzsch¹

¹Chair for Forest Growth and Yield Science, Center of Life and Food Sciences Weihenstephan, Technical University of Munich, Freising, Germany (hans.pretzsch@lrz.tum.de)

Firstly, this talk will give an overview of the species' interactions and growth reactions in mixed-species stands under chronic and acute drought. In the second part, the species-specific mixing reactions on drought are traced from the stand to the species, tree and organ level. A focus will be on drought stress effects on the growth, partitioning between the trees of different species and sizes in a stand. Thirdly, the mixing reactions on drought are analyzed in dependence on site conditions and stand structure. Fourth, we show how the results can be applied to design drought tolerant mixed-species stands. Fifth, the next steps for research and implementation will be discussed: Mixed-species experiments along environmental gradients, experiments with water retention for a better understanding of species stress behaviour in intra- and inter-specific environments, process-based models for scenario analyses, and guidelines for the design of drought tolerant forest stands. The results are based on the EU funded projects REFORM (Mixed species forest management. Lowering risk, increasing resilience # 2816ERA02S) and COST CLIMO (Climate-Smart Forestry in Mountain Regions # CA 15226).

Applying post-forest-fire restoration techniques to erosion control: the case of CONAF, Chile / Aplicación de técnicas de restauración post-incendios forestales para el control de la erosión - experiencias de CONAF Chile

Samuel Francke¹

¹Corporación Nacional Forestal, CONAF, Santiago, Chile (samuel.francke@conaf.cl)

Uno de los principales efectos de los incendios forestales resulta en impactar en los procesos de erosión de suelos al destruir la vegetación, la hojarasca del suelo e incluso inducir a procesos de calcinación, los procesos de laterización e hidrofobia en el suelo mineral, dependiendo de su intensidad afectando la textura, estructura, materia orgánica y alteración de las relaciones hídrico-edáfico. El fuego afecta el perfil del suelo, sus propiedades físicas, químicas y biológicas, en síntesis, se destruye la función de protección y estabilidad del suelo, favoreciendo los procesos de erosión y sedimentación. Las tasas de erosión pueden variar en promedio de 10 a 30 ton/ha/año, dependiendo de factores como la topografía la erosividad, la erodabilidad y la práctica de conservación de suelo y aguas, entre otros factores. La idea del proyecto emana de la temporada 2017/2018, donde se afectaron 518.448 ha en Chile, el segundo mega incendio forestal de Chile del siglo y calificado por expertos de la UE, como de sexta generación. Se detenta como conaf diversas y valiosas experiencias de restauración hidrológica forestal de cuencas hidrográficas post incendios forestales en Chile. Se describen 20 prácticas y técnicas más comunes de rehabilitación suelos y cuencas hidrográficas post incendios forestales, se clasifican y ordenan de acuerdo a su funcionalidad a nivel de suelo y de su aplicación a nivel de la cuenca hidrográfica: regulación de flujos hídricos, de regulación de flujos hídricos de cauces, de estabilización de laderas mediante siembras (con hidro-mulch) y de retención de erosión y sedimentos.

Selected C fluxes in *Nothofagus* forests under different levels of degradation in the the Andes and Coastal Mountain Ranges of Southwestern South America

Francis Dube¹, Neal Stolpe¹, Carlos Valenzuela¹

¹University of Concepción, Concepción, Chile (fdube@udec.cl; nstolpe@udec.cl; cvalen@udec.cl)

This study was undertaken to measure certain carbon (C) fluxes in *Nothofagus* forests with different levels of degradation (degraded-DEF, partly-degraded-PDF and undisturbed-UNF forests). Litter decomposition was determined using the litterbag method. Leached soil solution was collected with tension lysimeters at 80 cm depth, and soil respiration evaluated in situ with the soda lime technique for CO₂ absorption. Soil samples were taken at 0-5, 5-20 and 20-40 cm depths. In the Andes Mountains, rates of litter decomposition were lower in UNF and higher in DEF (21.8 and 14.1% remaining residue weight after 30 months, respectively), while in the Coastal Mountains, these values were 22.6 and 13.9%, respectively. On the other hand, total soil respiration was greater in UNF than DEF (0.37 vs; 0.32 g CO₂ h⁻¹ m⁻², respectively) in the Andes, and 0.44 vs; 0.36 g CO₂ h⁻¹ m⁻², respectively, in the Coast. Regarding soil microbial respiration at 0-5 cm depth, a significant difference was only observed in the Coastal Mountains, with 2.44 and 3.71 cm³ CO₂ h⁻¹ 100 g dry soil⁻¹ in DEF and UNF, respectively. Despite not obtaining significant differences in the NO₃⁻ and NH₄⁺ contents in soil leachates, a trend of higher content was found in the undisturbed soils. The overall soil organic carbon (SOC) and N contents at 0-40 cm depth decreased significantly in the order UNF>PDF>DEF. The presence of greater plant coverage and number of species in undisturbed forests favored the productivity of the ecosystem, conserving nutrients and sequestering more carbon in the vegetation and soil.

Evaluation of two tropical wet forest restoration practices through assisted secondary succession in Costa Rica

Ana María Sierra¹, Roger Villalobos¹, Diego Delgado¹, Christian Herrera¹, Milena Gutiérrez²

¹CATIE, Turrialba, Costa Rica; ²SINAC, Liberia, Costa Rica (ana.sierra@catie.ac.cr; rvillalo@catie.ac.cr; ddelgado@catie.ac.cr; christian.herrera@catie.ac.cr; mgutierrez@acguanacaste.ac.cr)

The performance of two assisted restoration practices of humid tropical forests, aged between 18 and 22 years, was analyzed in the Rincon Cacao Biological Corridor, Costa Rica, consisting of the plantation (1999-2000) of the exotic species *Gmelina arborea*, as nurse tree, and islands of plantation of native species. The previous condition was degraded grasslands for livestock; 31 plots of 0.04 ha and 62 of 0.0025 ha were established, where the structure and species composition of each treatment was evaluated, compared to two nearby secondary forests of passive restoration of 23 and 30 years of age. Each individual was identified within the categories of 2.5 to 4.9 cm DBH and more than 5 cm DBH, ecological guilds were assigned for most species. The treatment with greater degree of development was that of *Gmelina* as a nurse species, although its diversity of species was lower than that of the reference forests, which are older. The secondary forest of more than 30 years was the one with the greatest diversity of species. There were no significant differences in the diversity indices evaluated. The most abundant ecological guild in all treatments was that of durable heliophyte species. It was found that both the melina, as a nurse species, and the cultivated islands, help accelerate the regeneration of the secondary forest in these conditions, the recovery of its structure and the presence of their original species. *Gmelina* seems to disappear as the forest matures, but this must be verified.

B1b: MANAGEMENT OPTIONS TO INCREASE THE DROUGHT-TOLERANCE OF FORESTS

Forest growth resilience to drought: tree diversity takes centre stage

Rita Sousa-Silva^{1,2}, Kris Verheyen³, Bart Muys²

¹UQAM, Montreal, Canada; ²KU Leuven, Leuven, Belgium; ³UGent, Gent, Belgium (anarita.silva@kuleuven.be; kris.verheyen@ugent.be; bart.muys@kuleuven.be)

Recent research linking forests to changes in climate – including increased temperatures and changes in rainfall patterns, with more frequent, prolonged and intense episodes of drought as a consequence – has revealed increases in tree mortality rates and die-off events in forests worldwide. The higher resistance and resilience of mixed forests has been proposed as a strategic approach for managing forests, particularly under stress conditions. Complementarity among species for resource use may lead to reduced competition and increased facilitation, resulting in higher growth rates and higher resilience to drought. In this study, we investigated how the growth and resilience to drought of *Fagus sylvatica*, *Quercus petraea*, and *Quercus robur* relate to tree diversity, across three distinct drought events, and whether declining growth was correlated with increased defoliation. We monitored over 1.900 individual trees across 90 long-term forest vitality monitoring plots between 1990 and 2016. Trees growing in mixtures were more resilient to drought compared to those growing in monocultures, and recovery after drought was also faster and more pronounced in mixtures than in monocultures. Additionally, we found a tendency towards lower resilience to drought in defoliated trees. Our results demonstrate a clear link between more frequent droughts and a reduction in forest productivity, associated with longer recovery times. Even in environments that are not normally considered water-limited, mixed-species stands presented a greater resilience to drought, which adds further evidence to the overall positive impact of diversity on forest productivity under the anticipated warmer and drier conditions.

Tree neighbourhood diversity increases community productivity and growth stability under contrasting climatic regimes

Florian Schnabel^{1,2} ; Julia Schwarz¹ ; Adrian Dănescu³ ; Andreas Fichtner⁴ ; Charles Nock⁵ ; Jürgen Bauhus⁶ ; Catherine Potvin⁶

¹Chair of Silviculture, Faculty of Environment and Natural Resources, Freiburg University, Freiburg, Germany; ²German Centre for Integrative Biodiversity Research (iDiv) Halle-Jena-Leipzig, Leipzig, Germany; ³Thünen Institute of Forest Ecosystems, Eberswalde, Germany; ⁴Institute of Ecology, Leuphana University of Lüneburg, Lüneburg, Germany; ⁵Geobotany, Faculty of Biology, University of Freiburg, Freiburg, Germany; ⁶Department of Biology, McGill University, Montreal, Canada (florian.schnabel@idiv.de; julia.schwarz@waldbau.uni-freiburg.de; adrian.danescu@thuenen.de; fichtner@leuphana.de; charles.nock@gmail.com; juergen.bauhus@waldbau.uni-freiburg.de; catherine.potvin@mcgill.ca)

There is increasing evidence that mixed-species forests can provide multiple ecosystem services at a higher level than their monospecific counterparts. Here, we provide insights into the temporal development of diversity-productivity (DPRs) and diversity-stability relationships (DSRs) in the oldest tree diversity experiment in the tropics, ‘Sardinilla’ in Panama (established in 2001). We used annually resolved inventory data of tree diameters and heights from 22 plots with a species richness gradient comprising monocultures, two-, three-, and five-species mixtures of native tree species. Combining tree neighbourhood- and community-level analyses, we tested the effects of two diversity components, species diversity and structural diversity, on productivity and stability. Over time, we found a mean overyielding (higher productivity in mixtures compared to monocultures) of about 25-30% in the two- and three-species mixtures and the highest overyielding at 50% in the five-species mixtures. Tree neighbourhood diversity enhanced community productivity but the effect of species diversity was stronger and increased over time, while the effect of structural diversity declined. The temporal stability of community productivity increased with increasing species diversity driven by two principal processes: species asynchrony and overyielding. Along with increased stability, the benefits of mixing on productivity were highest during a strong El Niño phenomenon, characterized by low precipitation. This suggests a higher resistance of the examined mixtures to droughts. These results provide new insights into mixing effects in diverse, tropical plantations and highlight the importance of analyses of temporal dynamics for our understanding of the complex relationships between diversity, productivity and stability.

The role of species asynchrony in the stability of forest productivity

Miren del Rio^{1,2}, Hans Pretzsch³, Marta Vergarechea^{1,3}

¹INIA-Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Madrid, Spain; ²Sustainable Forest Management Research Institute, Palencia, Spain; ³TUM-Technical University of Munich, Freising, Germany (delrio@inia.es; h.pretzsch@lrz.tum.de; vergarechea.marta@inia.es)

Diversifying stand composition is considered one of the management options to adapt forests to climate change, since higher species diversity is frequently linked to a greater stability of ecosystems (resistance, resilience, and temporal stability). Mixed-species stands had been found to increase the temporal stability of productivity in comparison to monospecific stands, although there are still few studies, whereas the effects of species-mixing on resistance and resilience to extreme drought events seem to vary with species composition and site conditions. One of the mechanisms identified as a possible cause of the greater stability in mixed stands is species asynchrony in responses to climate conditions, which can influence on both temporal stability and resistance and resilience to severe droughts. In this presentation we first review the main concepts of species synchrony/asynchrony and its effects on stability in mixed stands, with special emphasis on temporal stability of productivity. Then, we show some examples of intra- and inter-specific synchrony/asynchrony analysis for stands with different species compositions along environmental gradients in Europe (mixtures of two and three species), and of how inter-specific asynchrony is related to temporal stability of productivity. Finally, we discuss the results of the shown and relevance of further synchrony analysis for forest vulnerability to climate change and the implications for adapting forest management to future climate conditions. The results are based on the Sumforest ERA-net project REFORM(PCIN2017-026) and COST CLIMO (Climate-Smart Forestry in Mountain Regions # CA 15226

How does magnitude and timing of forest density reduction influence drought resilience in a Norway Spruce – Silver fir mixed forest in Central Europe?

Juan Carlos Zamora¹, Rasoul Yousefpour¹, Harald Bugmann², Peter Weisberg³, Alessandra Bottero⁴, Maxime Cailleret⁵, Marc Hanewinkel¹

Climate change scenarios forecasting increased occurrence of extreme drought events will require innovative ways of managing stand density to increase the adaptive capacity of forest ecosystems. Needed is an improved understanding of the interactions between drought and competition among forest trees for critical limiting resources, leading to quantitative, predictive models that relate stand density to drought-related tree mortality. We address this question with an adaptive approach, combining thinning experiments (field data) and historical resilience responses to natural and managed conditions (dendrochronological data) in a climate-sensitive forest gap model. The effect of the proposed strategies is tested in a gradient of site conditions of Norway spruce (*Picea abies*) - Silver fir (*Abies alba*) mixed forests in Central Europe. We hypothesize that (1) intensive reductions on large DBH-classes, in short time intervals will have bigger impacts, and (2) sites with high tree density need more intensive reductions. This methodology allows the forest manager to plan for short periods (≤ 10 years), and make the necessary changes in the strategy for a longer period (> 10 years) by monitoring forest state. Economic and ecological evaluation methods are proposed to evaluate the performance of the solutions selected for the approach. Results from this study will contribute to the risk assessment, economic evaluation and development of optimized management strategies to adapt Norway spruce and silver fir forests to extreme drought events.

Ecological and economic feasibility of adaptation strategies for Beech Forest to climate change

Dominik Sperlich¹, Marc Hanewinkel¹, Rasoul Yousefpour¹

¹Albert-Ludwigs University, Freiburg, Germany (dominik.sperlich@ife.uni-freiburg.de; marc.hanewinkel@ife.uni-freiburg.de; rasoul.yousefpour@ife.uni-freiburg.de)

Increasing drought events and decreasing precipitation trends challenge the ecological, economic and socio-economic services and functions of forests in many regions of the world. To increase the resilience of managed forest, conversion of monocultures into mixed stands are among the most prominent adaptation strategies. Potential species for the establishment of mixed forests have not only to be evaluated against their present but also future suitability with changed climate conditions. We aimed to evaluate the ecological but also economic feasibility of potential species admixtures for *Fagus sylvatica* (L.) in the Black Forest – naturally one of the most dominant tree species of central and Western Europe. We identified *Quercus* spp. for submontane and Silver fir (*Abies alba*) for

mountainous sites to potentially reduce the drought impacts on forest growth via hydraulic redistribution of soil water. We then quantified growth, productivity and economic value of a European beech stand with/without climate change scenarios and with/without species admixtures. The more profitable silver fir compensated the higher establishment costs when admixed at a stand age of 60 or earlier. Climate change reduced the total cumulative growth of beech between 15-35 % depending on the scenario with an economic loss of 15-33 % in net present value (NPV). Site-adapted admixture dampened the climate change effects on beech growth and reduced the economic losses. We stress that, beside the ecological and silvicultural feasibility of potential species mixtures, the economic implications have to be thoroughly assessed to provide a valid basis for investment decisions in forest conversion strategies.

Relative importance of climate, thinning and light use efficiency on drought vulnerability of Norway spruce and Silver fir in Central European Mixed Forests

Drought intensity and frequency are expected to increase in Central Europe, posing unprecedented challenges to forest managers, who are searching for adaptive strategies that minimize drought impacts on forests. Maintaining low stand densities and high structural diversity are advocated for moderating drought-induced tree growth reduction. However, few studies have investigated which processes most strongly influence tree drought vulnerability. We investigated the contribution of management, light use efficiency and climate on the drought response of silver fir and Norway spruce in mixed stands in Southwestern Germany. We used inventory and tree-ring data from six long-term irregular group shelterwood experiments, located along a precipitation gradient. Tree growth response to drought was expressed as indices of resistance, resilience and recovery. Silver fir was more resilient to summer drought than Norway spruce, but had a lower resistance to spring drought. Species, light use efficiency and species interactions had the strongest impact on tree growth response to drought at tree-level, while stand basal area, mean stand diameter, years since first and last intervention, and drought year were important predictors for stand-level resistance, resilience and recovery. Economically valuable species like Norway spruce might decline in the absence of adaptation measures that use thinning to obtain stand structures that can support retained trees during droughts. Our study provides quantitative information on the processes influencing the drought response of two important tree species, and provides a basis for the development of adaptive management strategies that consider not only punctual responses to drought, but also their driving processes.

Drought events and shrub encroachment reduce the functioning and resilience of water-limited ecosystems

Maria C. Caldeira¹, Raquel Lobo-do-Vale¹, Xavier Lecomte¹, Teresa S. David², Minguel N. Bugalho³, Christiane Werner⁴

¹Centro de Estudos Florestais, Instituto Superior de Agronomia, Universidade de Lisboa, Lisboa, Portugal; ²Instituto Nacional de Investigação Agrária e Veterinária I.P., Oeiras, Portugal; ³CEABN-Inbio, Instituto Superior de Agronomia, Lisboa, Portugal; ⁴Institute of Ecosystem Physiology, University Freiburg, Freiburg, Germany (mcaldeira@isa.ulisboa.pt; raquelvale@isa.ulisboa.pt; xlecomte@isa.ulisboa.pt; teresa.david@iniav.pt; migbugalho@isa.ulisboa.pt; c.werner@cep.uni-freiburg.de)

Extreme droughts and shrub encroachment are major drivers of global change that can critically affect tree and ecosystem functioning and resilience. Namely, the increase in tree mortality observed worldwide has been related to overall higher frequency and severity of droughts and locally to factors such as competition with other plant species. Shrub encroachment, i.e., the increase in density and biomass of shrubs, is increasing in many regions worldwide, including the Mediterranean region. Shrub encroachment can aggravate the effects of drought and decrease tree resistance to water stress. Nevertheless, little is known about how these drivers may interact and affect ecosystem functioning and resilience. In a 6 year (2011-2017) manipulative shrub removal experiment in a Mediterranean oak woodland, we measured sapflow and pre-dawn leaf water potential of trees and shrubs and soil water content in six plots of 25 x 25 m, where we combined shrub encroachment and shrub removal treatments. We show that the combination of native shrub encroachment (*Cistus ladanifer* L.) and drought events reduced ecosystem transpiration and the resilience of the key-stone cork-oak tree species (*Quercus suber* L.). Ecosystem transpiration was dominated by the water use of the shrub, which further increased the droughts. Tree transpiration in shrub encroached plots declined more than in plots cleared from shrubs. Our results imply that in Mediterranean-type of climate shrub encroachment by water spending species coupled with the projected recurrent extreme droughts will cause critical drought tolerance thresholds of trees to be overcome, thus increasing the probability of tree mortality.

The potential of liming to improve drought tolerance of Norway spruce (*Picea abies*)

Jürgen Bauhus¹, Joerg Kunz¹, Peter Hartmann², Lelde Jansone², Heike Puhlmann², Klaus von Wilpert², Martin Kohler¹

¹University of Freiburg, Freiburg, Germany; ²Forest Research Institute of Baden-Wuerttemberg, Freiburg, Germany (juergen.bauhus@waldbau.uni-freiburg.de; joerg.kunz@waldbau.uni-freiburg.de; peter.hartmann@forst.bwl.de; lelda.jansone@forst.bwl.de; heike.puhlmann@forst.bwl.de; klaus.von-wilpert@online.de; martin.kohler@waldbau.uni-freiburg.de)

In response to wide-spread decline in forest vitality associated with acid rain in the 1980s, liming of forest soils has been implemented in many parts of Germany. Liming may increase vitality and depth of fine-root systems and hence improve the drought tolerance of species such as *Picea abies*, which occurs mostly on acidic forest soils. However, the influence of repeated liming on drought tolerance of trees was never studied. Here we compared the resistance, recovery and resilience of radial growth in *P. abies* in relation to drought in limed and control stands and assessed how the dosage and interval between lime applications and drought years influence radial growth responses. We analyzed radial growth of 198 trees from limed and control treatments at six experimental sites in South-West Germany. Using generalized linear models we assessed the influence of drought intensity, site, and period since first liming on the drought tolerance of Norway spruce. Regardless of drought intensity, there was no general increase in drought resistance of *P. abies* in response to liming. However, recovery and resilience of radial growth after severe drought events were better in Norway spruce trees from limed treatments. This indicates a shorter stress period for trees growing on limed soil which may reduce their susceptibility to secondary, drought-related pests and pathogens. Based on the small magnitude

of the effect, liming is not recommended for the sole purpose to increase drought tolerance. Where liming is carried out to mitigate soil acidification, it does not decrease drought tolerance.

BIc: MANAGING FOR ADAPTATION: INCREASING RESISTANCE, RESILIENCE, AND TRANSFORMATIVE CAPACITY

The precautionary principle as a framework for resilience in forest planning and practices

Philip Burton¹

¹University of Northern British Columbia, Terrace, Canada (phil.burton@unbc.ca)

The “precautionary principle” has been incorporated in dozens of international environmental agreements since 1987, including Agenda 21 and the Rio Declaration stemming from the 1992 Earth Summit. The principle essentially urges that decisions regarding industrial activities and development proposals should err on the side of caution with respect to potential environmental or human impacts where scientific uncertainty exists. Many processes affecting public forestlands are subject to variability, with increasing uncertainty due to a changing climate and altered disturbance regimes. Nominally managed under a mandate of multiple use, decisions regarding timber harvesting and silviculture on public lands clearly have impacts on forest values ranging from biodiversity and carbon sequestration to hydrology and meaningful employment. Yet many forest policies and practices continue to rely on historical norms, optimistic assumptions and modelling approaches optimized for timber production. Precautionary approaches that could be applied in British Columbia, Canada, are explored, including better estimation of the likelihood of losses due to fire and insects in timber supply projections, and basing vegetation management (brushing) decisions on thresholds for crop tree survival rather than trying to achieve maximum crop tree growth. Analogous to the trade-off between high-risk stock investments and low-risk bond purchases, some profit potential needs to be foregone in exchange for greater certainty and the persistence of multiple forest values. Worst-case scenarios do not necessarily need to be followed, but precautionary decision making can do much to keep future options open and thereby promote the resilience of forests, forest workers, and forest-dependent communities.

Adapting to climate change through silvicultural opportunities to address natural disturbances

Mike Cruickshank¹, Rona Sturrock², Elisa Becker¹, Katherine Bleiker¹, Bogdanski Bryan¹, Isabel Leal¹

¹Natural Resources Canada Canadian Forest Service Canadian Wood Fibre Centre, Victoria, BC, Canada; ²Retired, Natural Resources Canada Canadian Forest Service, Victoria, BC, Canada (mike.cruickshank@canada.ca; ronasturrock250@gmail.com; elisa.becker@canada.ca; katherine.bleiker@canada.ca; bryan.bogdanski@canada.ca; isabel.leal@canada.ca)

Climate is a key driver of forest distribution, productivity, and disturbance regimes that limit growth and survival of forest species. These limits increase with the frequency and size of climate fluctuations acting on ecological functions affecting the health and productivity of forests. Adaptation strategies at the forest level are complex, and there are a limited number of options available for large areas that forests cover. Silviculture is one strategy that can alter the conditions in forests, including, but not limited to, planting adapted trees, altering tree density and age, changing species composition, and removal of inciting stress conditions mainly affecting insects and disease. Genetic variation within a population can be used to identify trees for planting that cope with heritable multiple biotic and abiotic adaptation to common stressors. Many of these are unknown. Douglas-fir half-siblings are used as an example of the frequency and size of genetic adaptations to insect, drought, and two root diseases agents. Resistance versus tolerance response mechanisms to stress are examined for trade-offs with each other and between stress agents. Also, an example of site preparation using sanitation of root disease inoculum prior to planting to increase carbon, stand productivity, and economic payback as a companion strategy to genetic adaptation. Both strategies are compatible and applied at the reforestation stage, and are discussed in terms of how they can affect trees under stress.

Increasing adaptive capacity of Urban Forests

Linda Nagel¹, Chris Looney¹, Courtney Peterson^{1,2}, Leslie Brandt^{2,3}, Maria Janowiak^{2,4}, Christopher Swanston^{2,4}, James Guldin⁵

¹Colorado State University, Fort Collins, CO, USA; ²Northern Institute of Applied Climate Science Houghton, MI, USA; ³USDA Forest Service, St. Paul, MN, USA; ⁴USDA Forest Service, Houghton, MI, USA; ⁵USDA Forest Service, Hot Springs, AR, USA (linda.nagel@colostate.edu; chris.looney@colostate.edu; courtney.peterson@colostate.edu; lbrandt@fs.fed.us; mjanowiak02@fs.fed.us; cswanston@fs.fed.us; jguldin@fs.fed.us)

With over half of the world’s population living in urban areas, forest managers must learn to implement climate-adaptive strategies in urban forests to ensure the continued provision of benefits to people living in urban communities as the climate changes. Three common adaptive silviculture options discussed in the context of climate change are: (1) resistance – maintaining relatively unchanged conditions over time; (2) resilience – allowing some change in current conditions, but encouraging an eventual return to reference conditions; and (3) transition – actively facilitating change to encourage adaptive responses. However, there is a lack of on-the-ground forest research to indicate what adaptation measures might be effective in preparing local forest ecosystems to deal with climate change, which can create challenges in translating these concepts into management decisions specific for individual forests that vary in structure, composition, function, and local management contexts. The Adaptive Silviculture for Climate Change (ASCC) project translates these adaptation concepts into on-the-ground, operational-scale research through a network of replicated sites testing ecosystem-specific climate change treatments across this gradient of adaptive approaches. The ASCC Network has established partnerships to begin applying silviculture options aimed at enhancing the adaptive capacity of urban forest ecosystems to the environmental, social, and economic implications of climate change. This includes designing adaptation and mitigation strategies that enhance carbon storage and other ecosystem services, promote urban forest health, protect high-value urban trees, and create resilience to invasive species, while incorporating a more explicit social dimension through local community education and engagement.

Why foresters do not adapt their forests to climate change while they know its impacts? The project “Adaptation measures to climate change by foresters” in France

Julie Thomas^{1,2}, Annabelle Amm³

¹Institut National de la Recherche Agronomique, Nancy, France; ²Centre National de la propriété forestière, Paris, France; ³GIP ECOFOR, Paris, France (julie.thomas@inra.fr; annabelle.amm@gip-ecofor.org)

Forests are threatened by climate change: increase of major events involve large landscape changes such as distribution range of tree species. Since the early century, several research projects about climate change forest impacts and their perception by foresters have been implemented in France. They show the need

to implement measures to adapt forests to climate change. All is knowledge necessary for forest managers. Many efforts are needed, particularly in terms of communication, to remove obstacles to the implementation of these measures without forgetting technical and financial aspects. In this context, the aim of our paper is thus to understand the reasons of the non-implementation of adaptive measures. For this purpose, we conducted surveys among forest owners and forest managers about their silvicultural practices in France and their links with climate change. Our study aims to enhance a better understanding of the perception of climate change of forest owners and forest managers, the actions implemented and their constraints to adapt their forests. It will help forest managers to be more informed about the different adaptation measures before taking decisions, and forest owners will be more supported during their adaptation process. The presentation focus on none industrial private forest owners who own 75% of French forest.

Exploring the knowledge dynamics associated with forest management for climate change in South Africa

Chidiebere Ofoegbu¹, Chinwe Ifejika-Speranza²

¹Africa Climate and Development Initiative, University of Cape Town, Cape Town, South Africa; ²University of Bern Bern Switzerland (ofoegbu.c@gmail.com; chinwe.ifejika.speranza@giub.unibe.ch)

Forests are critical for the global climate policy agenda with respect to actions for climate change adaptation and mitigation. Many people also depend on forests for their livelihoods. Although the forest industry in South Africa contributes about 2% to the national GDP, it provides direct and indirect employment to between 200,000 and 260,000 people and is a significant component of South Africa's national climate change response policy. Though information on adapting forest management practices to climate change is increasingly being generated, the adoption is very poor. Issues often mentioned in the literature with respect to this challenge include mismatch of generated knowledge with users context, poor feedback between knowledge users and producers/brokers, and poor relation ties between organizations operating in the generation and brokering of climate knowledge. This study will use the lens of the knowledge system to undertake a network analysis of the organizations working in the intersection of climate change and forest management. The aim is to understand how climate information flows among these stakeholders, and tease out the barriers and enablers of climate knowledge flow and adoption in forest management. Key informant interviews and questionnaire survey will be used to collect data. Data analysis will focus on the identification of barriers and enablers of climate knowledge flow and uptake in forest management. Insights from this study will inform future interventions aimed at improving or implementing actions for forest-based climate change interventions.

Soil and water conservation as a mechanism for adapting to climate change and impacts on the Maule River Watershed in Chile / Conservación de suelos y aguas como mecanismo de adaptación al cambio climático e impactos en la Cuenca Hidrográfica del Río Maule Chile

Samuel Francke¹, Celso Carnieletto¹, Luis Carrasco¹

¹Conaf, Santiago, Chile (samuel.francke@conaf.cl; celso.carnieletto@conaf.cl; luis.carrasco@conaf.cl)

Los impactos del cambio climático en la Cuenca Hidrográfica del Río Maule se expresan en el aumento de la temperatura promedio máxima +0,6 °C en los últimos 14 años sobre el promedio mundial (Universidad de Talca, 2017), reducción de las precipitaciones del orden 30% (periodo 1973-2013, ODEPA 2013) y una merma de caudales al 2025 del 16,3 % (DGA, 2011), como efectos hidro-meteorológicos directos. La sequía y escasez del recursos hídricos afecta la calidad de vida de los pequeños y medianos agricultores/silvicultores. Con alta probabilidad los incendios forestales 2016/ 2017, donde se afectaron del orden de 280.106 ha, constituye la evidencia empírica de un cambio climático antrópico. Se implementan y evalúan medidas adaptativas de conservación de suelos y aguas tales como subsolado con camellón y zanja de infiltración, asociadas a la forestación de plantaciones de *Pinus radiata* en 17 propiedades. En cada predio se muestrean variables dasométricas y edafométricas. Se realiza 320 parcelas de muestreo para un análisis comparativo de plantaciones con edades similares con y sin tratamientos de obras de conservación de suelos y aguas. Los resultados del estudio indican que la aplicación de medidas adaptativas al cambio climático como obras de conservación de suelos y aguas, inciden en el rendimiento hidrológico forestal a nivel de la microcuenca hidrográfica y se expresan favorablemente en la productividad del sitio forestal. De esta forma, se obtiene un manejo forestal sostenible y un manejo hidrológico forestal en plantaciones forestales en *Pinus radiata*, en función de la cuenca hidrográfica. "Los bosques en función de las cuencas".

Connecting across borders: an approach to building forest resilience across Western North America

Kristen Waring¹, Linda Nage², Christian Wehenkel³, Che Elkin⁴

¹Northern Arizona University, Flagstaff, USA; ²Colorado State University, Fort Collins, USA; ³Universidad Juárez del Estado de Durango, Durango, Mexico; ⁴University of Northern British Columbia, Prince George, Canada (kristen.waring@nau.edu; linda.nage@colostate.edu; wehenkel@ujed.mx; che.elkin@unbc.ca)

Temperate coniferous forests of western North America extend from South-Central Mexico north into boreal Canada. Some tree species span across Mexico, the United States and Canada, while other species are located primarily in one country. However, climate change may induce northward shifts in species distributions, with the extent and relative dominance of species shifting across borders. Unpredictable shifts are also likely to occur, with forest disturbances likely exacerbated by climate change. Western temperate forests are particularly vulnerable to climate-sensitive disturbances such as drought, wildfire, insects and diseases, which are often not constrained by national boundaries. Under such uncertainty, forest managers need access to emerging research along with guidance on decision-making surrounding best practices. All three countries have developed frameworks to aid managers in designing and implementing future silvicultural treatments for climate change adaptation. However, only one program in the United States (Adaptive Silviculture for Climate Change, ASCC) includes a direct pathway and assistance in developing specific prescriptions for local ecosystems within a nationwide network of sites that share experimental goals and objectives through a robust experimental design. Other frameworks provide specific management recommendations but leave the interpretation and implementation to local managers. Given the ecological, economic and social connectivity across Western North American forests, a collaborative, international network is critical to managing our collective forests now and into the future. This presentation will describe our new effort to assess and synthesize how well existing forest treatments fit these frameworks in each country, and explore expanding the ASCC network internationally.

Achieving multifunctional forest management through three-level structured silvicultural regimes: a review of case studies and pilot demonstration progress in China

Yuanchang Lu¹, Xianzhao Liu¹, Yangsheng Xie¹, Xiangdong Lei¹

¹Chinese Academy of Forestry, Beijing, China (ylu@ifrit.ac.cn; xieys@ifrit.ac.cn; xieys@ifrit.ac.cn; xieys@ifrit.ac.cn)

Multifunctional forest management (MFFM) has been the new trend in forestry development in China and the world in the 21st century. It is an innovative model which actively strengthens and develops the many forest services and provides social, economic, environmental and ecological benefits for sustainable human development. The fundamental objective of forest management is to establish and maintain the stability and resilience of the forest ecosystem to maximize its viability, productivity and service functions. In this review the concept, scientific principles, technical processes and methodology for experimental verification of the silvicultural regimes (SRs) of MFFM are described. In addition, the paper addresses a three-level structured silvicultural technical system (STS) and Chinese MFFM development system which, based on the principle of using natural and artificial forces synergistically, integrates function/condition constraints, full growth/management cycle and standardized description of measures and elements of the final target. By monitoring, comparing and analyzing data from operational and reference plots of applying this STS as a national basis for forest management were compared. These results show that the objectives of MFFM models are being achieved and the new STS with three-level SR has a positive impact on the development of multifunctional forestry in China.

Risk and governance dilemmas associated with assisted migration in the forest sector of British Columbia, Canada

Ricardo Pelai¹, Shannon Hagerman¹, Robert Kozak¹

¹University of British Columbia, Vancouver, Canada (ricardo.pelai@alumni.ubc.ca; shannon.hagerman@ubc.ca; rob.kozak@ubc.ca)

The assisted migration (AM) of trees is increasingly being proposed as a means of adapting forest management to climate change impacts. While there is a proliferation of natural science research to inform the implementation of AM, social science research in this domain remains relatively sparse. We use the case of the Canadian province of British Columbia (where AM policy is currently in development) to examine the human behavioral (e.g. perceived risks), and governance (e.g. participation in decision-making and the use of different forms of knowledge) dimensions of this emerging policy option. Based on 30 in-depth, semi-structured interviews with key government officials and forest industry professionals involved with AM, we find an overall optimistic view of AM. However, we identify three emergent dilemmas: i) narrow conceptions of the types of evidence that is required in decision-making (mostly biophysical), ii) uneven input from different stakeholder and rights holders, and iii) prevailing views that knowledge flows in a linear fashion at the science-policy interface. These findings demonstrate the contributions that social sciences (produced at multiple scales and from different worldviews) can make to decision-making for the implementation of assisted migration.

B1d: RESILIENCE OF MANAGED TROPICAL FORESTS: IT IS TIME FOR SILVICULTURE

Disturbance intensity determines recovery of multiple functions after a first logging cycle in the Brazilian Amazon

Angela Luciana de Avila¹, Ademir Roberto Ruschel², José Natalino Macedo Silva³, Lucas Mazzei², João Olegário Pereira de Carvalho³, Jürgen Bauhus⁴

¹Forest Research Institute Baden-Württemberg, Freiburg im Breisgau, Germany; ²Embrapa Amazônia Oriental, Belém, Brasil; ³Universidade Federal Rural da Amazônia, Belém, Brasil; ⁴Chair of Silviculture, Faculty of Environment and Natural Resources, University of Freiburg, Freiburg im Breisgau, Germany (angela.avila@forst.bwl.de; ademir.ruschel@embrapa.br; silvanatalino734@gmail.com; lucas.mazzei@embrapa.br; olegario.carvalho@gmail.com; juergen.bauhus@waldbau.uni-freiburg.de)

Sustainable forest management is based on the assumption that forest ecosystems are resilient to silvicultural interventions so that their ecosystem functions can recover between felling cycles and thus be maintained in the long term. However, our understanding of responses to silvicultural interventions and factors driving tropical forest resilience is rather limited. Here, we investigated how management intensity and post-logging (remaining) biological legacies (basal area and species diversity) affect the resilience of important forest attributes and functions related to biodiversity conservation, carbon sequestration and timber provision within 30 years following initial logging. We analysed data from a unique long-term experiment located in the Tapajós National Forest, Pará, Brazil, where trees ≥ 5 cm DBH were measured on 8 occasions in 41 permanent sample plots including unlogged forest. Management intensities comprised logging (1982) with associated damage and follow-up thinning (1993-1994). An important finding was that the recovery of tree species composition, above-ground biomass and timber stocks was impaired when basal area was reduced by more than 20% relative to pre-logging stocks. In contrast to our expectations, remaining basal area and diversity had no effect, but management intensity determined the recovery of multiple functions over the first logging cycle. Thus, when managing for ecosystem resilience within current felling cycles, our findings indicate that management intensity will directly affect the recovery capacity and subsequent ability of continuous provision of goods and services in these managed tropical forests of the Eastern Amazon.

The main challenges of sustainable forest management in the Amazon: why sustainable forest management in the Amazon should be reinforced?

Plinio Sist¹, Lucas Mazzei², Camille Pionot¹, Bruno Hérault¹, Geraldine Derroire³, Euridice Honorio⁴, Milton Kanashiro², Marcus d'Oliveira⁵, Marielos Peña-Claros⁶, Ken Rodney⁷, Virginia Wortel⁸, Alexander Shenkin⁹

Since the last 50 years, tropical natural forests have been intensively logged in the tropics to supply the increasing demand of tropical timber. Unplanned logging operations caused forest degradation leading to their conversion due to the loss of their commercial value. Today, natural forests remain a major source of timber and tropical production forests worldwide are estimated to cover around 400 million ha. Studies carried out on the long term impact of logging on timber yield showed that at best about only 50% of the timber volume extracted during the first harvest will be available for the subsequent cycles. We estimated the potential of natural production of the Amazonian forest to supply the future wood demand using more than 200 permanent plots for monitoring the long term response after logging of the TmFO network. Our results clearly show that natural forests alone will not be able to supply the increasing demand of tropical timber in the region and that significant efforts in forest restoration through plantations as well as intensive silvicultural practices such as enrichment planting in gaps and liberation, must

be initiated immediately. Although natural forests will not be able to supply alone the timber market demand, they will play a major role in environmental services (including biodiversity protection and conservation, climate change mitigation rather than solely for timber provision while they will continue to provide necessary income to forest communities that depend on the forests for their livelihoods).

Population management of *Juniperus procera* tree from Ethiopia

Mindaye Teshome Legese^{1,2} ; Tesfaye Bekele¹, Patricia Póvoa de Mattos³ ; Aline Canetti⁴ ; Evaldo Muñoz Braz³ ; Carlos Moreira Miquelino Eleto Torres²
¹Ethiopian Environment and Forestry Research Institute, P. O. Box 30708 code 1000, Addis Ababa, Ethiopia; ²Universidade Federal de Viçosa, Departamento de Engenharia Florestal, Viçosa, Brasil; ³Embrapa Florestas, Colombo, Brasil; ⁴Universidade Federal do Paraná, Departamento de Engenharia Florestal, Curitiba, Brasil (mindayet@gmail.com; tebean77@yahoo.com; patricia.mattos@embrapa.br; alinecanetti@gmail.com; evaldo.braz@embrapa.br; carlos.eleto@ufv.br)

In this study we evaluated the sustainability of *Juniperus procera* timber management from two important dry afro-montane forests (Chilimo and Wofwasha) in Central Ethiopia. A total of 141 major sample plots were established. We used dendrochronological techniques and stand class projection model. The cutting cycle simulated was 30-year. Due to the higher population disturbance in Chilimo forest three scenarios were simulated: disturbance ceased; remain at the same intensity and increased by 25%. For Wofwasha forest we only considered the current situation. For both forests the diameter limit was simulated varying between 50 and 60 cm, seeking the optimal harvestable diameter and ensure a more sustainable structure. In Chilimo forest it would be possible to produce 0.76 m³ ha⁻¹ year⁻¹, stabilizing after 5 cutting cycles. The continuity of undue exploitation in the forest following the same pattern will lead to a reduction in 37% of timber volume production. And increasing the exploitation by 25% will lead to a 76% reduction, potentially destroying the capacity of the forest to recover, and it was considered unsustainable. In Wofwasha forest simulations resulted in 0.63 m³ ha⁻¹ year⁻¹ of timber production. The simulations also showed that population structures of both forests become similar after the sixth cycle, suggesting that these forests have the same forest formation. The differences today appear to be due to the disturbance level or interventions by local communities and history of logging in each forest.

Implications of silvicultural interventions for sustainable forest management: case study of Bobiri Forest in Ghana

Ernest Foli¹
¹Forestry Research Institute of Ghana, Kumasi, Ghana (efoli@hotmail.com)

Silvicultural interventions are necessary for regulating tropical forest growth and productivity. This paper describes experiments carried out in Bobiri forest in Ghana through the tropical shelterwood system (TSS), post-exploitation system (PES) and the girth limit selection system (GLS) to simplify the forest structure and species composition to enhance productivity. Stand basal area was reduced from about 30 m² ha⁻¹ to 12 – 15 m² ha⁻¹. After 40 years data on height, diameter and species were collected for all trees with DBH > 10 cm from six one-hectare plots in each treatment. The results showed that the forest was capable of recovery in terms of structure, species diversity, and productivity to the pre-intervention state. There was no significant difference between treated and unlogged forest ($\chi^2 = 26.3$; $df = 21$; $P = 0.196$). However, stand density was higher in the silviculturally-treated stands relative to unlogged forest ($F = 7.62$; $df = 3$; $P = 0.002$). A total of 176 tree species were recorded in 38 families; the 10 most common species between treatments accounted for > 50% of the species, but < 46% in unlogged forest, with no significant shifts in species composition. The treated stands attained structural and compositional attributes similar to unlogged forest after 40 years, but commercial basal area was higher in the treated forest. In conclusion, silvicultural interventions (including harvesting) can improve both commercial productivity and species composition, depending on intensity and frequency of interventions.

Population dynamics of *Mezilaurus duckei* van der Werff (Lauraceae) in a managed forest in the Eastern Amazon region / Dinâmica da população de *Mezilaurus duckei* van der Werff (Lauraceae) em uma floresta manejada na Amazônia Oriental

Jaqueline Macedo Gomes¹, João Olegário Pereira de Carvalho², Ademir Roberto Ruschel³, Nisângela Severino Lopes Costa¹
¹Universidade Estadual da Região Tocantina do Maranhão, Imperatriz, Brasil; ²Universidade Federal Rural da Amazônia, Capitão Poço, Brasil; ³Embrapa Amazônia Oriental, Belém, Brasil (jaquelinemacedogomes@hotmail.com; olegario.carvalho@gmail.com; ademir.ruschel@embrapa.br; nisangela.lopes@hotmail.com)

Estudos ecológicos são primordiais para avaliar a sustentabilidade do manejo florestal, pois indicam o estado de conservação das espécies exploradas. Com a finalidade de inferir sobre a conservação da população de *Mezilaurus duckei*, avaliou-se a sua dinâmica no período de 33 anos após a exploração. A pesquisa foi realizada na Área Experimental km 67, na Floresta Nacional do Tapajós (02° 53' 03,09" S; 54° 55' 30,10" W). Os dados são provenientes de inventário contínuo realizado em 36 parcelas permanentes (50 x 50 m) instaladas em 1981 em 64 ha que foram exploradas em 1979. Foram medidas as árvores com DAP ≥ 5 cm em 9 ocasiões no período 1981-2012. Analisou-se a abundância, dominância, distribuição diamétrica, taxas de ingresso e mortalidade. A abundância (1,1 indivíduo ha⁻¹ em 1981) aumentou 10% em 31 anos e a dominância (0,051 m² ha⁻¹) aumentou 39%. Não houve mortalidade no período, mas houve ingresso de 10%. Por isso, em relação à distribuição diamétrica houve acúmulo de indivíduos no período avaliado, sendo 54,5% na classe DAP < 25 cm, 36,4% na classe DAP 25-45 cm e 9,1% na classe DAP ≥ 45 cm. Comparando as distribuições diamétricas de 1981 e 2012, observa-se claramente a passagem de indivíduos das classes inferiores para as superiores. *M. duckei* aumentou gradativamente seu estoque na área explorada, demonstrando que pode se recuperar e garantir futuras colheitas de madeira. Recomenda-se a aplicação de tratamentos silviculturais na área para estimular o recrutamento, crescimento e evitar a sua extinção local. (Embrapa, CNPq, UEMASUL).

The influence of initial stand structure on plant community composition and diversity in eucalypt forest

Anu Singh¹, Craig Nitschke¹, Patrick Baker¹, Sabine Kasel¹
¹University of Melbourne, Melbourne, Australia (anu6@student.unimelb.edu.au; craign@unimelb.edu.au; patrick.baker@unimelb.edu.au; skasel@unimelb.edu.au)

Effective forest management and conservation require knowledge of the structure and composition of forest stands and how they change over time. Disturbances are important drivers of these forest stand dynamics, providing opportunities for recruitment, shifts in relative dominance of species, and changes in the trajectory of stand development especially in Southeastern Australia. The type of disturbance, its intensity, and any interactions with previous disturbances all influence how individual species respond and will shape the post-disturbance development patterns. Forest structure has a substantial influence on plant community composition. The structure of vegetation plays a vital role in shaping biodiversity. The recruitment of target species in managed forests following harvesting is a crucial objective of sustainable

forest management. The success or failure of managed forests in Southeastern Australia is dependent on the density of *Eucalyptus* stems after stand establishment. We studied the influence of density on the diversity of the understorey species and found that light has a bigger impact on the species composition of the forest rather than the density of the species.

Intact forest landscapes: how to conciliate forest management and conservation efforts under FSC certification in Brazilian Amazon

Edson Vidal¹, Nathalia Ribeiro², Isabel Garcia-Drigo², Marco Lentini³, Leonardo Sobral²

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo Piracicaba, Brasil; ²Instituto de Manejo e Certificação Florestal e Agrícola, Piracicaba, Brasil; ³WWF Brasil, Sao Paulo, Brasil (edson.vidal@usp.br; nathalia@imaflora.org; isabel@imaflora.org; marcolentini@wwf.org.br; leonardo@imaflora.org)

Maintenance of large natural forest landscapes is paramount to protect biodiversity, but also to reduce carbon emissions from deforestation and forest degradation. Intact Forest Landscapes (IFLs) are defined as unbroken portions of natural ecosystems within the current global forest extent, showing no signs of significant human activity, and vast enough to effectively maintain biodiversity. In 2015, the Forest Stewardship Council (FSC) has introduced the concept of IFLs in the new Principle, Criteria and Generic Indicators for certification. Hence, certified forest managers have to identify the IFL portion in their forest management units to design and apply specific management strategies. The present study analyzed spatial data to enlighten the scale and territorial domains where IFLs are found in Brazilian Amazon. We also demonstrate the proportion of IFLs within certified Forest Management Units (FMU). In addition to these analyses, we performed a survey to reveal the challenges to manage IFLs portions from FSC certificate holders and experts perspective. Results showed a significant proportion of IFLs within certified forests in federal or state forest concessions more than in private lands. The primary challenge is how to develop the IFL portions while maintaining its values and ensuring protection. While the market for ecosystem services and non-timber forest products are uncertain, a more stringent Reduced Impact Logging (RIL) model is defended as one of the best management strategies to conciliate sustainable forest management and conservation within IFL areas.

Development of dipterocarp rainforests after timber harvesting challenge the current slow recovery paradigm

Jan Falck¹, Daniel Lussetti¹, Petter Axelsson², David Alloysius³, Ulrik Ilstedt¹ 

¹Swedish University of Agricultural Sciences, Dept. of Forest Ecology and Management, Umea, Sweden; ²Forest Ecology and Management, Umea, Sweden; ³Yayasan Sabah, Tawau, Malaysia (jan.falck@slu.se; daniel.lussetti@slu.se; petter.axelsson@slu.se; david.alloysius@gmail.com; ulrik.ilstedt@slu.se)

Timber harvesting in tropical rainforests is under debate partly because of the natural recovery of stand structures are believed too slow to provide a sustainable provision of timber, and maintenance of biodiversity and carbon storage potential. We present a long-term study of selective logging in a virgin tropical rain forest in Sabah, North Borneo, Malaysia, starting in 1992 and re-measured every second year up to 2017; 25 years after logging operation, forest plots harvested with supervised logging and climber cutting (SLC) - which aim to minimize damage to the residual stand have improved stand recovery compared to the conventional practices, and restored the number of trees with DBH 10 cm and above, the number of harvestable trees (DBH 60 cm and above), as well as the number of germlings, seedlings and saplings, to a level almost equivalent to the mean numbers of trees in virgin control plots. The growth rate of dipterocarp species in SLC was 5 m³ha⁻¹yr⁻¹ and in 2017, the number of species recorded in all diameter classes was nearly the same as in control plots. In general, recovery was faster than expected after such logging operation, which usually kill or damage many trees for every tree logged. Our results stress the need for wider evaluation of economic and carbon potential of managed dipterocarp forests. Comparisons with other land use options should consider improved logging methods and the possibility of faster above ground volume and carbon recovery.

Economic and environmental potential benefits of charcoal production from logging residues in sustainable forest management in the Brazilian Amazon

Camila Thiemy Dias Numazawa¹, Dmitry Schepaschenko², Andrey Krasovskii², Stephan A. Pietsch²

¹Universidade de São Paulo, São Paulo, Brasil; ²International Institute for Applied Systems Analysis, Laxenburg, Austria (numazawacamila@gmail.com; schepd@iiasa.ac.at; krasov@iiasa.ac.at; pietsch@iiasa.ac.at)

Under sustainable forest management principles, primary data from 13 forest plots located in the western Brazilian Amazon were adopted to calibrate and estimate projected net primary productivity (NPP) and the net measure of ecosystem exchange (NEE) using the complex BioGeo Chemistry model (BGC-MAN) approach. The purpose of this study was to show the potential economic and environmental benefits associated with charcoal co-production from part of the logging residues (LR). The analysis was done for five scenarios: the legal reserves (reference scenario), one cutting cycle over the whole period, three timber rotation periods of 30-year, and the last two scenarios complemented with collecting part of the woody LR ≥ 10 cm for charcoal production. For each case, we simulated the NPP and the NEE over a time-horizon of 120 years. Results indicated an economic gain for charcoal production using woody LR ($\approx 77\%$ of total LR) which could reach $\approx 46\%$ of the total stem value. Additionally, we found that in scenarios where LR were harvested the biomass recovered faster. The benefits would not only consist of the generation of new income and promoting new jobs, but also lead to increased NPP and NEE by removing part of the LR to assist the forest regrowth. The Brazilian Forest Code strategy could focus on maximizing the economic gain to ensure exploitation viability while implementing the reduction of logging intensity necessary for full forest recovery within cutting cycles. This could be associated with carbon credit incentives.

Floristic analysis to subsidize forest management planning in the Amazon Forest region

Mariana Oliveira¹ , Marilice Cordeiro Garrastazu¹ , Evaldo Muñoz Braz² , Patricia Póvoa de Mattos² , Nelson Carlos Rosot¹ 

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil (marianaferraz.floresta@gmail.com; marilice.garrastazu@embrapa.br; evaldo.braz@embrapa.br; patricia.mattos@embrapa.br; nerosot@ufpr.br)

The objective of this study was to characterize the horizontal structure of a primary Amazon Forest, with emphasis on three commercial species, using conventional methods and Geographic Information System. The study area consists of an approved management plan, in Santa Carmem, MT, Sinop Microregion, with 1,024 ha, where all trees with a diameter of 1.30 m (DBH) ≥ 30 cm were measured. We calculated densities, frequencies and absolute and relative dominances, as well as the importance and coverage value indexes, using 1 ha plots. Kernel Density and Dispersion Analysis AT species level were obtained with ArcGIS. Among the 36 species observed, *Qualea* spp. presented the highest values for all analyzed parameters. *Goupia glabra* and *Dipteryx odorata* were, respectively, the fourth and sixth in importance index value. The area was classified as low diversity by Shannon Index. It was observed a higher concentration of individuals in commercial diametric classes (DBH 50 cm), concluding that the area presents potential to be sustainably managed. The estimates obtained by spatial analysis

for both density and dispersion were similar to those observed in the conventional estimatives, however, as the first method considers the geographic coordinates of each tree, it is suggested that it is more accurate than the second, that estimatives are generated at plot level.

B1e: TREES ON THE MOVE: SEED SOURCING, GERMINATION, GENETIC ADAPTATION AND ASSISTED MIGRATION IN A CHANGING CLIMATE

Origin, genetic variation and genetic change of non-native forest trees in their introduced range

Charalambos Neophytou¹ , Marcela van Loo^{1,2} , Elisabeth Pötzelberger¹ , Hubert Hasenauer¹ 

¹Institute of Silviculture, Department of Forest and Soil Sciences, University of Natural Resources and Applied Sciences (BOKU), Peter-Jordan Str; 82, 1190, Vienna, Austria, ²Department of Botany and Biodiversity Research, Faculty of Life Sciences, University of Vienna, Rennweg 14, 1030, Vienna, Austria (charalambos.neophytou@boku.ac.at; marcela.van.loo@univie.ac.at; elisabeth.poetzelberger@boku.ac.at; hubert.hasenauer@boku.ac.at)

Non-native tree species play an important role in European forestry which may even increase in future due to climate change. Environmental adaptation depends on genetic variation and this is true for non-native species, too. Here, we explore the origin, genetic variation and genetic change over time, observed in the introduced range of such species. First, we focus on Douglas-fir (*Pseudotsuga menziesii*), a species with a prominent position in Central European forestry. Marker based genetic analysis indicated that a relatively small part of the native range served as seed source for most of 67 European Douglas-fir study stands spread across Germany and Austria. Moreover, a comparison between adult trees and natural regeneration revealed a significant reduction of genetic diversity in the younger generation. Second, we examine the outcome of genetic analysis in populations of tree of heaven (*Ailanthus altissima*), a species with an invasive character. Whereas results from chloroplast DNA markers do not suggest multiple origins, we observed a significant population genetic structure at nuclear microsatellites in our study area in Eastern Austria. We attribute this pattern to repeated founder effects. Third, we present current results on the origin and genetic variation of Northern red oak (*Quercus rubra*) in introduced European populations. We conclude that drift is a major factor shaping the genetic variation in the introduced range. Since introduced populations constitute an important seed source, special caution should be exercised when establishing seed stands and seed orchards, but also during seed harvesting, in order to avoid genetic erosion.

Assisted migration of *Araucaria araucana* in Chile to safeguard genetic diversity of populations in the face of climate change / Migración asistida de la *Araucaria araucana*, en Chile, para salvaguardar la diversidad genética de sus poblaciones ante la presión del Cambio Climático

Roberto Ipinza¹, Jorge Gonzalez², Braulio Gutierrez², Hernan Soto², Marcos Barrientos¹, Maria Paz Molina², Andres Bello³, Patricio Rojas⁴, Sabine Muller-Using^{4,5}, Fernando Santibañez^{6,7}, Juan Andres Celhay⁸, Dante Corti¹, Richard Velasquez⁵

¹Instituto Forestal, Valdivia, Chile; ²Instituto Forestal, BioBio, Chile; ³Consultor, Concepcion, Chile; ⁴Instituto Forestal, Santiago, Chile; ⁵SIMEF, Valdivia, Chile; ⁶Universidad de Chile, Santiago, Chile; ⁷INFODEP Santiago Chile ⁸CMPC, Los Angeles, Chile (roberto.ipinza@infor.cl; jgonzalez@infor.cl; bgutierr@infor.cl; hsoto@infor.cl; mbarrientos@infor.cl; mmolina@infor.cl; beduan13@hotmail.com; patricio.rojas@infor.cl; smuller@infor.cl; fersantiba@gmail.com; juan.celhay@cmpec.cl; dcorti@infor.cl; richard.velasquez@simef.cl)

La *Araucaria araucana* (Molina) K. Koch (*Araucaria*) es una especie emblemática del bosque nativo chileno, se distribuye en la costa y en la cordillera de los Andes (desde los 37°30' a los 40°03' S). La *Araucaria* está asociada a prácticas ancestrales y alimentación del pueblo pehuenche, declarada monumento natural, protegida por la convención CITES y constituye un patrimonio nacional que contribuye a la belleza escénica del paisaje en las regiones de La Araucanía, Biobío y Los Ríos. La *Araucaria* está catalogada como una especie vulnerable y recientemente las poblaciones costeras han sido declaradas en vías de extinción en el actual escenario de cambio climático. El estrés integral del cambio climático, actúa como un factor de predisposición que disminuye la vitalidad y es luego atacada por innumerables poblaciones de microorganismos e insectos, lo que finalmente se expresa en un Daño Foliar de la *Araucaria* (DFA). Este fenómeno está amenazando su adaptación, su potencial evolutivo y por ende su supervivencia. Por esta razón, se realizó el rescate genético en toda el área de distribución a través de la técnica conocida como "Migración Asistida", donde se colectó semilla de 418 madres, se viverizaron y luego se plantan las familias, estructuradas como ensayos de progenies y procedencias, en lugares donde las proyecciones de cambio climático en los próximos 50 años le dan más posibilidades de supervivencia a la especie. Por otro lado, estas nuevas poblaciones podrán generar germoplasma para recuperar áreas afectadas por el DFA.

Stability of species and provenance performance following translocation into diverse restoration communities

Nicolò Camarretta¹ , Peter A. Harrison¹, Tanya G. Bailey^{1,2}, Neil Davidson², Arko Lucieer³, Mark Hunt¹, Brad M. Potts¹

¹University of Tasmania and ARC Training Centre for Forest Value, Hobart, Australia; ²Greening Australia, Hobart, Australia; ³University of Tasmania, Hobart, Australia (nicolo.camarretta@utas.edu.au; p.a.harrison@utas.edu.au; tanya.bailey@utas.edu.au; ndavidson@greeningaustralia.org.au; arko.lucieer@utas.edu.au; mark.hunt@utas.edu.au; b.m.potts@utas.edu.au)

Assisted migration is increasingly integrated into conservation and restoration strategies. For long-lived species such as trees, future climate models are being used to guide translocation decisions to develop resilient plantings better adapted to future climates. In restoration, this involves strategies such as climate-adjusted provenancing, aimed at enriching local plantings with seed genetically adapted to future climates predicted for the planting site. However, translocation decisions rarely consider the extent to which biotic interactions modify performance. This is particularly important as species and provenance translocations are not made in isolation but embedded in diverse and even novel communities. We here examined how species and provenance performance are affected by community composition using two focal eucalypt species planted under six community treatments, in a degraded agricultural landscape in Tasmania, Australia. These community treatments differed in the species planted as immediate neighbour to the focal plant, and co-plantings comprised of same species, same genus or one of three different genera. Six years after planting, there were significant differences between the focal eucalypt species and among their provenances for measured performance traits, while their interactions with community treatments were not significant. Provenance differences in both species were mainly due to non-local provenances experiencing greater insects and frost damage and having higher mortality than the local provenances. Home-site altitude predicted provenance performance, and the extent to which up-slope translocations impacted provenance performance differed between focal species, regardless of the community composition.

The importance of genetic variation and phenotypic plasticity for climate adaptation in *Pinus sylvestris*: conclusions from a continent-wide study in Europe

José Alberto Ramírez-Valiente¹ , Aida Solé¹, Raquel Benavides², Sandra Cervantes-Arango³, Darius Danusevicius⁴, Katrin Heer⁵, Eduardo Notivol⁶, Lars Opgenoorth⁵, Tanja Pyhäjärvi³, Outi Savolainen³, Juan José Robledo-Arnuncio¹

¹Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Madrid, Spain; ²Museo Nacional de Ciencias Naturales, Consejo Superior de Investigaciones Científicas, Madrid, Spain; ³University of Oulu, Oulu, Finland; ⁴Aleksandras Stulginskis University, Linkuva, Lithuania; ⁵Philipps University Marburg, Marburg, Germany; ⁶Centro de Investigación y Tecnología Agroalimentaria de Aragón, Zaragoza, Spain (josealberto.ramirezvaliente@gmail.com; aidasome@gmail.com; rbenavidescalvo@gmail.com; sandra.cervantesarango@oulu.fi; darius.danusevicius@asu.lt; katrin.heer@uni-marburg.de; enotivol@cita-aragon.es; opgenoorth@uni-marburg.de; tanja.pyhajarvi@oulu.fi; outi.savolainen@oulu.fi; jjrobledo@gmail.com)

Given the ongoing rapid climate change, the ability of species to respond to novel and changing environmental conditions is critical for long-term survival of populations. In forest trees, common gardens, reciprocal transplants and provenance trials have been widely used to assess the genetic composition and potential response to climate variation. However, such studies largely focus on juvenile or adult traits with little consideration on the early stages of development, which are crucial for niche regeneration. In this study, we explored the adaptive divergence and phenotypic plasticity in early fitness traits in *Pinus sylvestris* and examined the potential evolutionary response to the predicted future conditions of climate. We conducted a continent-wide series of experiments where 24,000 seeds from eighteen populations were established in common garden along a latitudinal gradient in Europe. In addition, geographically-closed populations with contrasting climates were included to evaluate the role of adaptation at small spatial scales. We monitored germination, survival, growth, phenology and ontogenic development over two years. Our results showed that populations largely differed in all studied traits and fitness components. Phenotypic differences were also observed between populations separated by a few hundred meters but with different altitudes. Interestingly, maternal families within populations exhibited a variation comparable with differences among long-distance populations. High plasticity to local environment was also found. Overall, our study suggests that climate has exerted strong selective pressures on *Pinus sylvestris*, driving the genetic differentiation of populations in traits important for fitness during the first stages of seedling development.

Production and quality of Caatinga dry forest seeds in a changing climate

Barbara França Dantas¹, Gilmar Moreira de Oliveira², Samara Elizabeth Vieira Gomes³

¹Embrapa Semiárido, Petrolina, Brasil; ²Universidade de Feira de Santana, Feira de Santana, Brasil; ³Universidade do Estado da Bahia, Juazeiro, Brasil (barbara.dantas@embrapa.br; gilmar_5@hotmail.com; samaraelizabethvg@yahoo.com.br)

The Caatinga dry forest has been experiencing, since 2010, the most severe drought ever recorded in the region, which has led to tree mortality, lack of seed production and/or quality and lower recruitment of seedlings. We aimed to correlate climate variations specifically, precipitation and temperature and seed quality of two important Caatinga species, *Anadenanthera colubrina* (Vell.) Brenan (Leguminosae – Mimosoideae) and *Myracrodruon urundeuva* Allemão (Anacardiaceae), in different harvest years from 2012 to 2018. Seeds were collected directly from mother-plants in a partially human-degraded Caatinga area. *Anadenanthera colubrina* seeds were sorted as small ($\emptyset \leq 1$ cm) and large ($\emptyset 1$ cm). Seeds of both species of each harvest and/or classification were weighed and germinated for physiological quality evaluation. The climatic data were obtained by nearby agrometeorological stations. With *A. colubrina* seed size evaluation of four consecutive years and the mean, minimum and maximum annual precipitation and temperature, it was possible to observe that the variation in seed size in the lots may be related to the low precipitation and the high temperatures. Seeds of *M. urundeuva* showed improved germination percentage when produced in years with more rain. Physiological quality of seeds of both species were affected not only by rainfall volume but also by high temperatures. Thus, one can predict poor seed production and quality in a future climate at the Caatinga region, for which is predicted temperature increase of 4.5 °C and 30% decrease in rainfall volume by 2100.

Genetic variation and evolutionary potential in a natural beech population

Marjana Westergren¹, Marko Bajc¹, Rok Damjanic¹, Domen Finzgar², Barbara Fussi³, Filippos A. Aravanopoulos⁴, Hojka Kraigher¹, Santiago C. González-Martínez⁵

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²University of Edinburgh, Edinburgh, United Kingdom; ³Bavarian Office for Forest Seeding and Planting, Teisendorf, Germany; ⁴Aristotle University of Thessaloniki, Thessaloniki, Greece; ⁵BIOGECO, INRA, Bordeaux, France (marjana.westergren@gozdis.si; marko.bajc@gozdis.si; rok.damjanic@gozdis.si; d.finzgar@sms.ed.ac.uk; barbara.fussi@asp.bayern.de; aravanop@for.auth.gr; hojka.kraigher@gozdis.si; santiago.gonzalez-martinez@inra.fr)

Local survival of natural populations of forest trees relies on standing genetic variation and their capacity for adaptation to changing environments. Selection gradients, heritability, evolvability and selection response was studied in a natural population of European beech (*Fagus sylvatica*) in Slovenia. Adult trees (250), saplings (200) and 400 seeds obtained from 20 mother trees, were genotyped with 16 nuSSRs. Adaptive traits related to growth and phenology were assessed for all adult trees. Effective reproductive success, a fitness proxy, was estimated via parentage analysis. Log-linear models were used to compute female and male selection gradients correlating adaptive traits with fitness. Heritability was estimated using mixed models based on pedigrees reconstructed using nuSSRs. The study revealed skewed effective reproductive success, with few parents contributing to successful regeneration, and significant selection gradients. Strong directional selection was found for growth, with bigger trees having more offspring; also, trees with earlier phenology had higher reproductive output; finally, both early and late trees in terms of bud burst mothered less offspring. Heritability was low (albeit significant) for all traits except leaf senescence. Low phenotypic variance for phenological traits and moderate selection gradients resulted in low responses to selection, but that could be larger under increased selection pressure, as suggested by high evolvability for flowering and fruiting phenology (~20%). In conclusion, our study suggests some capacity of populations of forest trees to adapt locally; however, pace and intensity of climate change will determine whether such evolutionary responses will suffice for unassisted population survival.

Genetic variation and phenotypic plasticity in early fitness traits across the range of a Mediterranean conifer: implications in a changing climate

Aida Solé^{1,2}, Agathe Hurel³, Juan José Robledo-Arnuncio¹, Santiago C. González-Martínez³, Eduardo Notivol⁴, Giovanni G. Vendramin⁵, Andrea Piotti⁵, Jose Alberto Ramirez-Valiente¹
¹INIA-CIFOR, MADRID, Spain; ²URJC, MADRID, Spain; ³Institut National de la Recherche Agronomique, BORDEAUX, France; ⁴CITA, Zaragoza, Spain; ⁵CNR-IBBR, FIRENZE, Italy (aidasome@gmail.com; agathe.hurel@inra.fr; jjrobledo@gmail.com; santiago.gonzalez-martinez@inra.fr; enotivol@aragon.es; giovanni.vendramin@ibbr.cnr.it; andrea.piotti@gmail.com; josealberto.ramirezvaliente@gmail.com)

Both standing levels of genetic variation and the potential for adaptive plastic responses are crucial to forecast the susceptibility of forest tree species to climate change and manage its impacts. Environmental heterogeneity across species' ranges produces differential selective pressures, resulting in intra-specific genetic variation and potential population-specific responses to climate change. Early seedling traits are subject to particularly strong selective pressures and, as determinants of the regeneration niche, may have a disproportionate contribution to future species' distributions. We present here an international field trial to elucidate patterns of intra-specific genetic variation at early fitness traits in Mediterranean *Pinus pinaster*, in the framework of the H 2020 European project GenTree. Seeds from 14 provenances were collected across the species range and sown at two sites with contrasting climates. Germination, developmental stage, growth and survival were monitored periodically. Results show significant among-population genetic variation in early fitness traits and in their plasticity, which were correlated with climatic and geographic variables of the site of origin of the seeds. There were evidences of local adaptive differentiation even over small spatial scales, in the cases of nearby populations growing over steep environmental gradients. The experiment results will help decision making for adaptive forest management and conservation, by improving our understanding of population-specific climate-change threats to early recruitment and therefore to population persistence.

Germination response to heat shocks in five legume species from Colombian tropical dry forests

Alejandro Hernandez Cobos¹, Angela Parrado-Rosselli¹
¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (jalhercobos@gmail.com; aparrado-rosselli@lycos.com)

Fire regimes of tropical dry forests of Colombia are not well known and there is still a debate if fire has been a frequent natural disturbance. Consequently, whether plant species of this ecosystem have specialized fire-response traits, such as heat-stimulated germination is also poorly understood. As germination of several legumes in fire-dominated ecosystems is stimulated by fire and heat shocks, the objective of this research was to evaluate, for five legume species common to the tropical dry forests of the Upper Magdalena River Valley in Colombia, the effect of heat shock on seed germination. We exposed 810 seeds per species to nine experimental heat shock treatments (i.e. 80 °C, 100 °C and 140 °C for 1, 3 and 5 minutes). We then incubated the seeds in an acclimatized germination chamber. Seeds were also classified into seed size classes (i.e. small, medium and large) in order to test if germination response was correlated with seed size. Results showed that germination of all seed species was stimulated by heat; however, germination percentages of *Albizia niopoides*, *Pseudosamanea guachapele* and *Piptadenia* sp were higher under less-intense heat treatments. In contrast, *Enterolobium cyclocarpum* and *Chloroleucon manguense* exhibited a better germination response under high temperatures (100 and 140 °C for 3 and 5 minutes). Seed size did not correlate with germination response. Our findings indicate that some tropical dry forest legumes might have an adaptive advantage to forest fires, which are expected to become more frequent and intense even in nonfire-prone environments due to climate change.

Effect of fertilization on stone pine (*Pinus pinea* L.) growth and cone yield in a young plantation located in a non-native habitat

Verónica Loewe-Muñoz¹, Claudia Delard¹, Rodrigo Del Río¹, Mónica Balzarini²
¹INFOR, Santiago, Chile; ²Universidad Nacional de Córdoba, Córdoba, Argentina (vloewe@infor.cl; cdelard@infor.cl; rdelrio@infor.cl; mbalzari@gmail.com)

Stone pine is a species of economic interest for its nutritious and highly demanded pine nuts. Despite this traditional use, cones are harvested mostly from natural forests; advances in techniques for its cultivation as a fruit tree have been limited. Fruit development is characterized by a long cycle (3.5 years), with one-, two- and three-year-old cones occurring simultaneously on the trees; this phenomenon makes the evaluation of management practices even more challenging than in other perennial crops. The objective of this work was to monitor the effect of fertilization on growth and fruiting over time. A fertilization trial with two treatments (fertilized and non-fertilized), was set up in a previously thinned and pruned 16-year-old stone pine plantation in central Chile. In spring 2009, trees of fertilized treatment were treated with macro- and micronutrients. All 3-year-old cones in each tree were harvested, weighed and counted annually for 10 years (2009-2018), diameter (DBH and crown) and height were repeatedly measured. Nine years after fertilization, significant differences were found for DBH and crown diameter growth, with a 32.3% and 20.8% higher annual growth, respectively, in fertilized trees. Significant effects of fertilization on fruiting were evident five years after application, and continued up to the end of the study, leading to cone yields up to 2.6 times higher than in non-fertilized trees. Fertilization also affected cone weight positively. Fertilization was a useful cultural practice to enhance stone pine fruiting and growth. Results suggest the convenience of repeating fertilization to enhance cone production and weight.

Assessing biodiversity change in the last 70 years by eDNA metabarcoding and pollen analyses of ice core from Adamello glacier, Italian Alps

Cristiano Vernesi¹, Alexis Marchesini¹, Matteo Girardi¹, Antonella Cristofori¹, Valter Maggi², Camilla Wellstein³, Nicola Alessi⁴, Stefan Zerbe³, Daniela Festi³, Klaus Oegg¹
¹Fondazione Edmund Mach, San Michele all'Adige, Italy; ²Università Milano Bicocca, Milano, Italy; ³Libera Università Bolzano, Bolzano, Italy; ⁴University of Innsbruck, Innsbruck, Austria (cristiano.vernesi@fmach.it; alexis.marchesini@fmach.it; matteo.girardi@fmach.it; antonella.cristofori@fmach.it; valter.maggi@unimib.it; camilla.wellstein@unibz.it; nicola.alessi@unibz.it; stefan.zerbe@unibz.it; daniela.festi@unibz.it; klaus.oegg@uibk.ac)

Forest ecosystems in mountain areas like the European Alps are particularly affected by climate and land use changes. Modern genetic technologies (e.g. NGS metabarcoding) are fostering new opportunities for extending biodiversity monitoring to the ecosystem level. Using a 45 m ice core extracted from the Adamello glacier (Alps, Italy) as biological archive, we propose a new approach for studying how taxonomic and functional diversity has changed through time. Taking advantage of the relatively precise ice core stratigraphy we can assume that our ice core covers the last about 70 years. This is the time period where in this area climate and land use changes dramatically impacted mountain areas, with glacier retreat as the most iconic event. By dividing the ice core in different layers, each approximately corresponding to one year, we aim at identifying the occurrence of major plant taxa in the last 70 years. From each layer environmental DNA (eDNA) is extracted and analysed using three different barcode markers: trnL, matK and rbcL. This eDNA metabarcoding analysis has been coupled with pollen

morphological investigation. Taxonomic assignment is accomplished by comparing the retrieved DNA sequences to a custom-made reference database and by morphological identification of pollen grains contained in each layer. eDNA metabarcoding and morphological investigation give complementary taxonomic information, able to reveal the overall floristic composition of the glacier catchment area across time. Results are discussed in light of methodological challenges (e.g. contamination) and biodiversity data gained by additional sources such as remote sensing data, vegetation surveys and maps.

Measures for “genetic protection of forests” need implementation, recording and monitoring

Hojka Kraigher¹, Paraskevi Alizoti², Marjana Westergren¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Aristotle University of Thessaloniki, Thessaloniki, Greece (hojka.kraigher@gozdis.si; alizoti@for.auth.gr; marjana.westergren@gozdis.si)

Silviculture can have profound effects on gene flow and selection processes, thus affecting the adaptability of future forests to the changing environment. The measures for the ‘genetic protection of forests’ to the environmental changes are mainly focusing on supporting and securing their adaptive potential to uncertain futures through, among others, adaptive thinning and cutting, support to and selection of diverse tree species composition, support to and accelerated enhancement of genetic diversity. This last can be achieved through combining natural regeneration with assisted migration and enrichment planting; that could be of particular interest in the case of highly diverse natural environments, where both climate change modelling, as well as forest reproductive material (FRM) translocation studies, are failing to provide accurate and reliable results. Hence an in situ long-term FRM inventorying system needs to be developed, based on: the choice of a high number of (predominantly native) tree and shrub species with different roles and interactions in the forest ecosystems, the choice of appropriate non-autochthonous provenances that could contribute to the genetic diversity enhancement and acceleration of selection processes, a well designed planning of enrichment planting, and long-term recording of all tending measures applied on stands established based on the strategy above, so that the initial forest reproductive material establishment success could be disentangled from the effect of silvicultural practices. However, all these measures need to be supported also by the long term monitoring of genetic diversity changes, as it is currently being developed in the implementation EU project LIFE GENMON, contributing to EUFORGEN.

BIF: SILVICULTURE AND MANAGEMENT OF TROPICAL NATURAL FORESTS IN AMAZON REGION: RESCUING CLASSIC SOLUTIONS TO ATTEND NEW DEMANDS - CLIMATE CHANGE, BIODIVERSITY AND BIOECONOMY

Opportunities for carbon emissions reduction from selective logging in Suriname

Zalman Joey¹, Peter W. Ellis², Sarah Crabbe³, Anand Roopsind⁴

¹Stichting voor Bosbeheer en Bostoezicht, Paramaribo, Suriname; ²The Nature Conservancy, Arlington, USA; ³Stichting voor Bosbeheer en Bostoezicht, Paramaribo, Suriname; ⁴Boise State University, Idaho, USA (joeyzalman92@gmail.com; pellis@tnc.org; sarah_crabbe@yahoo.com; aroopsind@gmail.com)

Improved forest management is a cost-effective intervention to reduce carbon emissions and mitigate climate change. Emissions reductions from the forestry sector are especially important in countries such as Suriname, a high forest cover low deforestation country, where large areas are allocated for logging. In this study we quantify carbon emissions from selective logging from three forest management systems applied in Suriname: (1) conventional timber harvests, which does not require pre-harvest inventories or planning of skid trails and roads prior to timber harvests; (2) controlled timber harvests, that requires forest management plans that include pre-harvest inventories and skid trail planning and; (3) controlled timber harvests that are Forest Stewardship Council (FSC) certified. Our carbon accounting method tracks emissions associated with the extracted log, unextracted portions of the felled tree, felling damage, as well as deforestation caused by logging infrastructure. Carbon emissions were highest from conventional timber harvests (3.23 mg C/m³), 40% lower in controlled harvests (1.96 mg C/m³), and lowest in FSC certified timber harvests (1.82 mg C/m³). The majority of carbon emissions were from the unextracted sections of felled trees (0.63-0.77 mg C/m³), followed by felling damage (0.41-0.70 mg C/m³). Based on the current scale of timber production under conventional timber harvests in Suriname, we estimate emissions from the forestry sector could be reduced annually by 0.39 million Mg C (37.1% of current forestry emissions) by switching to the controlled timber harvest system.

Forest degradation and restoration of carbon stocks in lowlands landscapes

Paul Eguiguren^{1,2}, Sven Günter^{1,2}

¹Technical University of Munich, TUM School of Life Sciences Weihenstephan, Munich, Germany; ²Thünen Institute of International Forestry and Forest Economics, Hamburg, Germany (paul.eguiguren@thuenen.de; sven.guenter@thuenen.de)

Latin America’s tropical forests contain 49% of the total biomass carbon in the tropics, influencing the global carbon cycle. Despite this, are heavily impacted by anthropogenic activities, such as timber extraction and forest conversion. We analyzed total carbon stocks (aboveground biomass, dead organic matter and soil carbon) in five lowland ecosystems (old growth forest-OGF, logged forest-LF, successional forest-SF, agroforestry systems-AF and plantations-PL), in order to generate inputs to reduce forest degradation and promote landscapes restoration. As logging is an important driver of degradation we evaluated the impact of this activity on OGF. In addition, we assessed different restoration strategies (active-passive) for carbon recovery. We used a stratified random sampling design to establish 156 plots of 1600 m² between Esmeraldas and the Amazon Region in Ecuador. Analysis of variance using general mixed models was conducted. We found that OGF accumulate between 237 mg C·ha⁻¹ in Amazonia and 206 mg C·ha⁻¹ in Esmeraldas. LF present up to 25% of degradation in terms of carbon contents when they are contrasted with OGF. Regarding to restoration strategies, SF (between 12 to 30 years) can store among 143 and 153 mg C·ha⁻¹. In the long term, SF is an adequate alternative for carbon recovery, since they store almost 69% of a mature forest at a low cost. Meanwhile, AF can store around 42% and PL 54% in contrast with the OGF. Although AF and PL only represent half of the OGF carbon, these restoration strategies are important not only to maintain carbon stocks but for climate change mitigation and local livelihoods.

Disentangling the drivers of fruit production in a long-lived tropical tree: What drives Brazil nut (*Bertholletia excelsa*) production?

Christina Staudhammer¹, Karen Kainer², Thiago da Cunha³, Lúcia Helena de Oliveira Wadt⁴

¹University of Alabama, Tuscaloosa, Alabama, USA; ²University of Florida, Gainesville, Florida, USA; ³Universidade Federal do Acre, Rio Branco, AC, Brasil; ⁴Embrapa Rondônia, Porto Velho, Brasil (cstaudhammer@ua.edu; kkainer@ufl.edu; etsfor@yahoo.com; lucia.wadt@embrapa.br)

Brazil nut is an important non-timber forest product (NTFP), and widely recognized as the cornerstone species of the Amazonian extractive economy. It is the only commercial nut collected almost entirely from natural populations in mature forest; however, fruiting varies both among trees and among years, with 8-10% of mature trees not producing any fruit in a given year. Despite this observed variability, and its important links to Amazonian forest conservation, few studies have quantified the factors explaining long-term Brazil nut fruit production variation. Our objective is to address knowledge gaps in explaining production variation over time, while providing insights to the larger ecological question of fruit production variation and its causes. We utilized long-term data collected in two extractive reserves in Acre, Brazil, which have similar climate but differ in soil characteristics and land use legacies, to address hypotheses about the role of site- and tree-level characteristics, as well as climate, in fruit production. We found that fruit production was significantly higher for trees growing at higher elevations in both sites. The site with a longer, more intense history of management and extractivism had significantly higher fruit production, and was less affected by other tree-level characteristics and climate. In the poorer site, production was significantly lower with greater vegetative competition, as well as higher dry season temperatures and vapor pressure deficit. These results indicate that long-term observation is important to adequately quantify the response of this and other NTFP species to future climate and development pressures.

Evaluation of Swidden fallow potential to increase landscape-level Brazil nut (*Bertholletia excelsa*) productivity in the Western Amazon

Eduardo Bongioiolo¹, Karen Kainer¹, Wendell Cropper¹, Christina Staudhammer², Lúcia Helena de Oliveira Wadt³

¹University of Florida, Gainesville, USA; ²University of Alabama, Tuscaloosa, USA; ³Embrapa Rondônia, Porto Velho, Brasil (eduardosbongioiolo@gmail.com; kkainer@ufl.edu; wcropper@ufl.edu; cstaudhammer@ua.edu; lucia.wadt@embrapa.br)

Brazil nut (*Bertholletia excelsa* Bonpl.) is considered the 'cornerstone non-timber species of Amazonian conservation'. Nuts (or seeds) of this massive tree are harvested by local people living in and near old growth forests, supporting local livelihoods and regional economies. Secondary forests, however, particularly plots previously used for agriculture (swidden fallows), present better *B. excelsa* seedling and sapling recruitment than mature forest. This study examines the extent to which forest residents could increase nut productivity by allowing their fallows to grow into Brazil nut rich forests. We conducted *B. excelsa* inventories in the Brazilian state of Acre in abandoned swidden fallows. We also conducted interviews to determine landowner perspectives on fallow potential for increasing nut production. An individual-based model estimated growth, survivorship and production from the 250 inventoried trees in 18 fallows of varying sizes (from 0.41 to 4.18 ha) and different regrowth stages (12 to 60 years old). Model predictions showed that after 10 years, 2.4% of existing trees will be productive, with an average of 68.6 ± 21.5 fruits per reproductively mature tree in the four fallows that most quickly yielded productive trees. By the final projected time interval (40 years), all fallows were predicted to produce fruits with cumulative production averaging 1475 ± 359 fruits ha⁻¹, suggesting an increase in landowner income of US\$55.1 \pm 13.4 per hectare of fallow. Our model likely underpredicts *B. excelsa* growth and nut production, considering that swidden fallows provide better resource availability than the forest-derived datasets used to construct model equations.

Predicting clearing sizes in floodplain areas under forest management: a case study in the Mamirauá Sustainable Development Reserve, Amazonas, Brazil / Predição do tamanho de clareira em área de várzea sob regime de manejo florestal: estudo de caso na Reserva de Desenvolvimento Sustentável Mamirauá, Amazonas

¹Universidade Federal do Amazonas, Manaus, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil; ³Universidade de São Paulo, Piracicaba, Brasil; ⁴Instituto de Desenvolvimento Sustentável Mamirauá, Tefé, Brasil; ⁵Centro de Estudos Integrados da Biodiversidade Amazônica, Manaus, Brasil (mvmarcio82@hotmail.com; celso.azevedo@embrapa.br; claudio@mamiraua.org.br; emilio.higashikawa@gmail.com; katia.emidio@embrapa.br)

O objetivo do estudo foi desenvolver modelos matemáticos capazes de relacionar o tamanho das áreas de clareiras de espécies florestais exploradas com dados dendrométricos e características morfométricas de copa, gerando parâmetros para planejamento de exploração e estimativas de área impactada aperfeiçoados. Este estudo foi conduzido em áreas de manejo florestal da Reserva de Desenvolvimento Sustentável Mamirauá, estado do Amazonas. Os inventários florestais foram realizados pelas associações comunitárias que desenvolvem as atividades em suas respectivas áreas de manejo florestal, entre janeiro e fevereiro nos anos de 2012 a 2014. Os dados morfométricos da copa foram coletados em janeiro de 2018 e analisados por meio da análise de variância, coeficiente de correlação de Pearson e análise de regressão linear múltipla. A exploração sob regime de manejo florestal ocasionou a abertura de 89,76% de clareiras de categoria pequena. Os testes mostraram diferença significativa entre as clareiras de espécies exploradas, sendo que a espécie Açacú (*Hura crepitans*) apresentou os maiores valores, com área de clareira de $341,88 \text{ (m}^2 \pm 99,09 \text{ (m}^2 \text{))}$. As variáveis diâmetro a altura do peito (DAP) e volume (V) apresentaram forte correlação com áreas de clareira, DAP ($r = 0,85$) e volume ($r = 0,697$), indicando que as áreas de clareiras (m²) aumentam proporcionalmente a estes parâmetros. A equação CL = $-626,5439 + 6,6645 \cdot \text{DAP} - 127,3025 \cdot G + 69,295 \cdot \text{IS} - 1,9302 \cdot \text{IEV} + 292,765 \cdot \text{IA} - 4,3849 \cdot \text{VSH}$ foi a que apresentou os melhores valores de R²ajust (0,9358), de Cp mallows (7,000), AIC (238,38) e Syx% (19,7), permitindo indicar para predição de área de clareira a equação CL = $-134,5395 + 2,8028 \cdot \text{DAP} + 13,266 \cdot \text{IS}$.

Aspects of agroforestry and agroextractivist production in the Amazonian Hinterlands / Aspectos da produção agrosilvicultural e agroextrativista na Hinterlândia Amazônica

Maria Isabel Araújo¹, Silas Garcia Aquino de Sousa², Evandro de Moraes Ramos¹, Márcio A. O. de Menezes³

¹Universidade Federal do Amazonas, PPGSCA, Manaus, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil; ³Universidade Federal do Amazonas, PPGCASA, Manaus, Brasil (miar@terra.com.br; silas.garcia@embrapa.br; evandro.ramos@ufam.edu.br; mzmario@yahoo.com)

Sob a auto-gestão dos agricultores familiares, a produção agrosilvicultural e agroextrativista na hinterlândia amazônica apresenta resultados eloquentes sob a ótica da oferta de produtos regionais e a preocupação e o respeito ao meio ambiente. Objetiva-se neste trabalho, discutir os aspectos da produção agrosilvicultural e agroextrativista pela agricultura familiar, ofertados nas feiras regionais do Amazonas. Utilizou-se a abordagem do método pesquisa-ação etnográfica, com visita de campo na Comunidade São Francisco de Assis e feira de produtos regionais, do município de Rio Preto da Eva/AM. A comunidade reúne 15 agricultores familiares que manejam diferentes sistemas de produção, combinando plantios agrícolas e espécies florestais, manejo de produtos florestais madeireiros (PFM) e não madeireiros (PFNM) voltados para o mercado local e o consumo da família. Os resultados demonstraram a utilização de boas práticas do manejo da floresta e do solo, com base nos princípios do desenvolvimento rural sustentável. Com referência as ofertas de produtos da agrosilvicultura destacam-se as frutíferas regionais: *Theobroma grandiflorum*, *Annona muricata*, *Spondias mombin*, *Bactris gasipaes*, dentre outras frutíferas; os PFNM: *Euterpe oleracea*; *E. precatória*,

Myrciaria dubia, *Bertholletia excelsa*, *Caryocar villosum*, *Astrocaryum aculeatum*, dentre outras espécies; bem como, uma variedade de espécies hortícolas, flores, raízes, plantas alimentícias não convencionais (PANC) e medicinais. Conclui-se que agricultores familiares da hinterlândia amazônica ofertam grande variedade de produtos da agrosilvicultura e do manejo florestal, combinando benefícios das dimensões sociais, culturais, econômicas e ambientais, com base nos princípios da sustentabilidade.

Natural regeneration of commercial species in areas subjected to multiple-cycle forestry systems in Central Amazonia / Regeneração natural de espécies comerciais em áreas submetidas ao sistema silvicultural policíclico na Amazônia Central

Alexsandro da Silva Silveira¹, Celso Paulo de Azevedo^{1,2}, Cintia Rodrigues de Souza²

¹Universidade Federal do Amazonas, Programa de Pós-Graduação em Ciências Florestais e Ambientais, Manaus, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil (alexandro.cheff@gmail.com; celso.azevedo@embrapa.br; cintia.souza@embrapa.br)

Para que o manejo florestal seja considerado sustentável é necessário que haja a renovação de quotas, das espécies exploradas comercialmente, em vários aspectos em um determinado período de tempo preestabelecido. Neste sentido destaca-se a importância de buscar compreender como funciona a renovação de quotas e a dinâmica, do principal alicerce do manejo florestal em regime sustentado, a regeneração natural. O objetivo deste estudo foi avaliar os efeitos de curto e médio prazos do sistema silvicultural policíclico, na dinâmica e no estoque da regeneração natural ($5\text{cm} \leq \text{DAP} < 15\text{ cm}$) do povoamento total e as espécies comerciais/potenciais, considerando três UPAs da Mil Madeiras Preciosas em Itacoatiara/AM, em 820 subparcelas de 100 m² pertencentes a 41 parcelas permanentes de 1 hectare. Calculou-se as taxas de ingresso e mortalidade, estoque (DAP, G, V, N e S), e IPAs. Avaliou-se, também, o nível de recomposição da floresta utilizando variáveis categóricas. Observou-se efeito positivo da exploração para espécies, DAP, N, G e V. O povoamento total apresenta balanço dinâmico positivo e o comercial/potencial ainda é negativo. Os IPAs decrescem com o tempo. O teste de Scott-Knott agrupou as espécies em três grupos considerando o IPADAP. A classe de floresta mostrou que o povoamento está em construção. Considerando o período de 17 anos, conclui-se que a regeneração natural recuperou ao estado antes da intervenção, no entanto, é necessário cuidado uma vez que o balanço dinâmico das espécies comerciais/potenciais é negativo.

Biometry of *Bertholletia excelsa* Bonpl. seeds in two regions in the state of Amazonas, Brazil / Biometria de sementes de *Bertholletia excelsa* Bonpl. em duas regiões produtoras no estado do Amazonas

Ana Lorena da Silva Aguiar¹, Kátia Emídio da Silva², Thais Carla Vieira Alves³

¹Universidade Nilton Lins, Manaus, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil; ³Universidade Federal do Amazonas, Manaus, Brasil (aguiarz.ana@gmail.com; katia.emidio@embrapa.br; thais.vieira.alves@hotmail.com)

A castanheira (*Bertholletia excelsa*) é uma das árvores símbolo da Amazônia por sua importância no contexto social, econômico e ecológico para a região. Sua semente, também chamada de castanha, é um produto florestal não madeireiro-PFNM de relevante importância para famílias de agroextrativistas, que têm neste produto uma fonte de renda complementar. Este estudo objetivou contribuir com informações sobre a biometria de sementes da castanheira, avaliando-a em dois segmentos da cadeia produtiva (produtor e intermediário). Desta forma, avaliou-se o comprimento, largura e espessura, de sementes oriundas de amostras adquiridas na Reserva de Desenvolvimento Sustentável (RDS) Piagaçu-Purus – Anori/AM e na Comunidade Lago das Pedras Reserva Extrativista (RESEX) do Rio Unini – Barcelos, AM. Três representantes de cada segmento foram amostrados, onde sete latas de 20 litros de sementes in natura de cada representante foram amostradas, sendo que de cada lata foram obtidas 10 sementes, as quais foram utilizadas nos estudos biométricos. Os resultados indicaram que há maior variabilidade entre o segmento de produtores dentro de cada localidade, onde as variáveis que apresentaram diferenças significativas foram comprimento (p-value = 1.472e-07), largura (p-value = 0.0119) e espessura (p-value = 1.409e-05) na RESEX Unini e comprimento (p-value = 0.04212) e largura (p-value = 0.00031) na RDS Piagaçu Purus, quando comparados aos intermediários que apresentaram apenas diferença significativa na espessura (p-value=0.0066) na RESEX Unini. Quando se comparou de forma global o tamanho das sementes entre as duas áreas, estas não mostraram variações significativas nos valores médios das variáveis estudadas, apesar das áreas estarem localizadas em regiões muito distantes entre si.

B1p: MONITORING AND RESTORING DEGRADED FORESTS

The Matas Legais program: integrating sustainability on rural properties and expanding areas of native vegetation / Programa Matas Legais: integrando a sustentabilidade nas propriedades rurais e ampliando as áreas de vegetação nativas

Maurício Batista Reis¹, Samantha Nazaré de Paiva², Gabriela Sanches Dolenc², Ana Cristina André²

¹Apremavi, Telêmaco Borba, Brasil; ²Klabin, Telêmaco Borba, Brasil (mauricio@apremavi.org.br; snpaiva@klabin.com.br; gabrielasdolenc@gmail.com; ana.andre@klabin.com.br)

O Programa Matas Legais, uma parceria entre a Associação de Preservação do Meio Ambiente e da Vida - Apremavi e Klabin, implementa ações de desenvolvimento sustentável tendo como base o planejamento de propriedades e paisagens dos pequenos produtores localizados na área de atuação da empresa. As metodologias de restauração das áreas de preservação permanente e reservas legais são: o plantio de mudas nativas em áreas com pouca ou sem resiliência e a regeneração natural quando há fragmentos florestais próximos às áreas degradadas. Em 13 anos de parceria estão sendo atendidas 998 propriedades. Já foram restaurados 380 hectares com plantio de mudas nativas, 1.390 hectares em processo de regeneração natural e doadas cerca de 1,4 milhões de mudas nativas. Este trabalho tem o objetivo de apresentar como as ações do Projeto, mesmo que atuando em uma propriedade de cada vez, impactam positivamente o desenvolvimento de uma região, criando conectividade entre os fragmentos nativos ao passar do tempo. Um dos estudos de casos mostra a evolução de imóveis localizados no bairro José Lacerda, Reserva – PR. As ações do Projeto iniciaram em 2013 em 07 propriedades, identificando 101,71 ha degradados. Em cinco anos de atuação a área foi convertida para 80,56 ha que estão em processo de restauração com plantio de 23.880 mudas nativas e 21,15 ha em processo de regeneração natural. Nesses imóveis foram identificadas 136 nascentes sendo que 37 escoam para bacia hidrográfica do Rio Ivaí e 99 para a bacia do Rio Tibagi.

Analyzing ecological processes in projects to remediate degraded areas within the Matas Legais program / *Análise dos processos ecológicos nos projetos de recuperação de áreas degradadas dentro do Programa Matas Legais*

Maurício Batista Reis¹, Samantha Nazaré de Paiva², Gabriela Sanches Dolenc², Ana Cristina André²

¹Apremavi, Telêmaco Borba, Brasil; ²Klabin, Telêmaco Borba, Brasil ((mauricio@apremavi.org.br; snpaiva@klabin.com.br; gabrielasdolenc@gmail.com; ana.andre@klabin.com.br)

O Programa Matas Legais, uma parceria entre a Associação de Preservação do Meio Ambiente e da Vida - Apremavi e Klabin, implementa ações de desenvolvimento sustentável como: recuperação com plantio de mudas nativas ou regeneração natural de áreas de preservação permanente e reservas legais, sistemas agroflorestais, enriquecimento ecológico de florestas secundárias e agricultura orgânica em propriedades de pequenos produtores localizados na área de atuação da empresa. O programa iniciou em 2005 em Santa Catarina e em 2008 foi ampliado para o Paraná. Em 13 anos de parceria estão sendo atendidas 998 propriedades. Já foram restaurados 380 hectares com plantio de mudas nativas, 1.390 hectares em processo de regeneração natural e doadas cerca de 1,4 milhões de mudas nativas. O objetivo deste trabalho é apresentar os resultados de uma análise dos projetos de restauração realizada em 232 dos projetos do programa. A avaliação dos projetos foi feita de forma qualitativa e quantitativa onde os resultados indicam a qualidade e quantidade de mudas plantadas que sobreviveram, bem como na qualidade e quantidade de plântulas regenerantes no local. Para avaliar a evolução dos processos ecológicos, nos projetos de recuperação de áreas degradadas, foram adotados quatro critérios, que compreendem a mortalidade da mudas plantadas, a chance de sucesso para que essas mudas sobrevivam ao longo do tempo, a quantidade de regenerantes na área de plantio e o sucesso da regeneração natural. Além da análise de todas as propriedades foi feita uma comparação entre proprietários certificados e não certificados FSC.

Arthropod fauna in the leaf litter: improvement monitoring techniques for ecological restoration, knowledge on biodiversity and ecosystem services in the Serra do Itajaí National Park, Brazil / *Artrópodo-fauna de serapilheira: utilização no aperfeiçoamento de técnicas de monitoramento da restauração ecológica, conhecimento da biodiversidade e serviços ecossistêmicos do Parque Nacional da Serra do Itajaí, Brasil*

Taise Cristina Plattau Arenhardt^{1,2}, Guilherme Alan Klunk², Joice Adriana Rezini², Marcelo Diniz Vitorino²

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Fundação Universidade Regional de Blumenau, Blumenau, Brasil (taise.arenhardt@hotmail.com; guilhermeklunk@hotmail.com; joice_rezini@hotmail.com; dinizvitorino@gmail.com)

Artrópodes de serapilheira representam grande porção da biodiversidade e podem ter aplicação no monitoramento de iniciativas de restauração ecológica. Assim, o objetivo deste trabalho foi avaliar a influência de técnicas de restauração e o potencial de aplicação de famílias da Classe Collembola e Insecta e espécies da família Formicidae (Hymenoptera) como indicadores da restauração ecológica no Parque Nacional da Serra do Itajaí (PNSI). As coletas foram realizadas com uso de armadilhas pitfall e funil de Berlese-Tüllgren, entre agosto/2014 e agosto/2015. Para análise de dados foram utilizados parâmetros de abundância, riqueza, diversidade, composição, similaridade, grupos funcionais e também a estrutura vegetacional. Foram coletados 128.957 artrópodes, sendo 80,25% de Collembola e 19,75% de Insecta. A riqueza total de Formicidae foi de 102 espécies, sendo que destas, 37 foram exclusivas em floresta nativa. Os potenciais grupos bioindicadores foram as famílias Ptiliidae (Coleoptera), Cicadellidae e Cercopidae (Hemiptera) e espécies *Pheidole sarcina*, *Hypoponera* spp., *Solenopsis* sp., *Linepithema* sp. e *Camponotus rufipes* (Formicidae). As famílias mais representativas de Collembola foram Entomobryidae, Paronellidae, Isotomidae, Dicyrtomidae, Katiannidae e Neanuridae, sendo este o primeiro levantamento deste grupo no PNSI. Os resultados demonstram que as famílias e espécies de Insecta respondem de forma diferenciada aos processos de restauração e de que isso está fortemente associado à cobertura vegetal. A utilização conjunta de parâmetros ecológicos da comunidade de artrópodes mostrou-se eficiente para a aplicação no monitoramento das técnicas de restauração ecológica. Além disso, o levantamento dos artrópodes servirá de base para avaliação do retorno de serviços ecossistêmicos nas áreas no PNSI.

Ecological restoration in a brazilian Atlantic Forest hotspot - Project Restaurar / *Restauração ecológica em um hotspot de Mata Atlântica brasileira - Projeto Restaurar*

Marcelo Diniz Vitorino¹, Eduardo Adenesky Filho¹, Taise Cristina Plattau Arenhardt^{1,2}

¹Fundação Universidade Regional de Blumenau, Blumenau, Brasil; ²Universidade Federal de Viçosa, Viçosa, Brasil (dinizvitorino@gmail.com; eduardo_forestal@hotmail.com; taise.arenhardt@hotmail.com)

A Floresta Tropical Atlântica brasileira é um hotspot de maior biodiversidade do mundo, detém elevada diversidade de espécies endêmicas e ameaçadas. Iniciativas para a restauração e conservação desse bioma estão distribuídos pelo país. Entretanto, poucas ações são implementadas em unidades de conservação. O Parque Nacional da Serra do Itajaí (SC), abrange cerca de 57 mil hectares de Floresta Atlântica. Em 2013, um projeto de restauração ecológica (Restaurar) foi implantado para recuperar 300 ha de 1.500 ha, de áreas degradadas com pastagens abandonadas, no interior do parque. Primeiramente foi realizado o diagnóstico abiótico do ambiente e posteriormente, foram amostrados diferentes grupos de fauna (insetos, aves, répteis, anuros, mamíferos) e caracterizado a vegetação por meio do estudo fitossociológico, método de parcelas (20 parcelas - 400 m² cada). A descrição vegetal foi utilizada como referência para futuras comparações, marcação de árvores matrizes produtoras de sementes (2.500 árvores marcadas) e subsidiar os plantios. Após o diagnóstico, três técnicas de nucleação (poleiros artificiais, transferência de serapilheira e instalação de rugosidade do solo) foram selecionadas e implementadas isoladamente e em associação com mudas produzidas no viveiro (germoplasma autóctone), totalizando 51 ha. A semeadura direta foi implantada em 60 ha e o plantio de mudas em 123 ha, utilizando módulos circulares adaptados de Anderson, em uma densidade de 1.100 mudas/ha. A seleção das espécies para o plantio foi orientada pelo valor de importância e grupos ecológicos, resultantes do estudo fitossociológico. Monitoramentos estão sendo efetuados para descrever a trajetória da restauração, e subsidiar projetos de restauração para o bioma.

Effect of temperature on germination of *Poincianella pluviosa* (sibipiruna) seeds / *Efeito da variação da temperatura na germinação de sementes de Poincianella pluviosa* (sibipiruna)

Dayane Lopes Pinto¹, Ana Cláudia Nogueira Silva¹, Gumercindo Souza Lima¹, Lydiane Lúcia de Sousa Bastos¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (dayanelopesp@gmail.com; anasilvanogueira@yahoo.com.br; gslima@ufv.br; lydilucia@gmail.com)

A intensificação da restauração florestal e da arborização urbana vem resultando no aumento da demanda por sementes e mudas de espécies arbóreas nativas. A *Poincianella pluviosa* var. *peltophoroides* (Benth.) L.P. Queiroz, popularmente conhecida como Sibipiruna, é uma espécie da família Fabaceae que se distribui pela maioria dos biomas brasileiros. Considerando a importância da temperatura na germinação, o objetivo deste trabalho foi estudar o efeito desse fator na germinação de sementes de *P. pluviosa* afim de definir a temperatura ideal de germinação da espécie. Foi realizada a avaliação da protusão da raiz primária sob quatro temperaturas constantes (25, 30, 35 e 40 °C) em laboratório, com cinco repetições de 20 sementes cada, durante 10 dias. A temperatura de 25 °C resultou

em uma maior germinação em menor tempo (média de 7,4 dias), comparada a de 30 °C. A temperatura de 35 °C não apresentou germinação e a de 40 °C foi letal, revelando que esta espécie é sensível à mudança térmica em até cinco graus centígrados da sua temperatura ideal. A temperatura ótima para germinação da espécie é, portanto, 25 °C. Variações na temperatura podem diminuir o poder germinativo da *P. pluviosa* ou até impossibilitar sua germinação, o que torna esta espécie sensível às mudanças climáticas previstas em cenários mais drásticos para o futuro.

Planning optimized ecological restoration using drones in the Pirai do Sul National Forest, Paraná, Brazil / Planejamento da restauração ecológica otimizado pelo uso de VANT na Floresta Nacional de Pirai do Sul, PR

Patricia Portela Feldmann¹, Marlon Prestes¹, Leonardo Gomes Glir², Carolina Mesquita², Maria Vitória Yamada Müller¹, Alessandra Xavier de Oliveira¹
¹Instituto de Pesquisa em Vida Selvagem e Educação Ambiental, Curitiba, Brasil; ²Notus Topografia, Curitiba, Brasil (patricia.feldmann@spvs.org.br; sig@spvs.org.br; leonardo@notustopografia.com.br; carolina@notustopografia.com.br; vitoria.consultoria@spvs.org.br; alessandra.xavier@spvs.org.br)

Este trabalho apresenta o estudo de caso realizado na Floresta Nacional de Pirai do Sul (FLONA) – PR, elaborado no contexto do Projeto Conexão Araucária em curso pela SPVS, financiado pelo BNDES. A FLONA tem 150 hectares (ha) e está inserida no bioma Mata Atlântica. O projeto tem como proposta iniciar o processo de restauração ecológica em 36 ha de áreas que antes eram recobertas por reflorestamento de pinus. Para agilizar o planejamento da restauração e obter um refinamento do diagnóstico ambiental foi realizado um sobrevoo com veículo aéreo não tripulado (VANT) multirrotor (drone), que forneceu informações com precisão geográfica, imagens de alta resolução e planialtimetria da área. As cinco Zonas de Restauração definidas no Plano de Manejo da FLONA, foram subdivididas em polígonos de acordo com a sua heterogeneidade física e ecológica. A visita de campo e o mapeamento oferecido pelo DRONE possibilitaram identificar as técnicas de restauração mais adequadas para cada situação. Os dados permitiram a análise da paisagem e dos solos, como: proximidade de remanescentes de florestas nativas, existência de fluxo de água, regeneração natural, erosão, exposição e compactação do solo, deficiência hídrica, e declividade. O mapa gerado otimizou tempo e recursos para a restauração, e o modelo digital de elevação propiciou o monitoramento do crescimento e altura da vegetação com menor esforço de campo.

Intensity and cutting cycle of a population of *Protium altsonii* Sandwith (breu vermelho) in the upper Capim River region of Paragominas, Pará, Brazil / Intensidade e ciclo de corte de uma população de *Protium altsonii* sandwith (breu vermelho) na região do alto Rio Capim, Paragominas, Pará

Kenia Brito¹, Fabrício Gomes², Esther Castro², Lucas Mazzei³

¹Universidade de Brasília, Brasília, Brasil; ²Universidade Estadual da Região Tocantina do Maranhão, Imperatriz, Brasil; ³Embrapa Amazônia Oriental, Belém, Brasil (keniaribeiro@hotmail.com; freisflorestal@gmail.com; ebandeiradecastro@gmail.com; lucas.mazzei@embrapa.br)

As espécies arbóreas comerciais mais exploradas na Amazônia necessitam ter suas populações estudadas em termos dinâmicos pois os incrementos diamétricos e os ciclos ótimos de corte variam por espécie e por sítio. O objetivo deste trabalho foi estimar uma intensidade e um ciclo de corte para uma população de *Protium altsonii* Sandwith em uma área de 100 ha na Fazenda Rio Capim. Os dados foram obtidos em 18 parcelas permanentes de 100 x 100 m, que foram medidas em oito ocasiões (2004, antes da exploração, e 2005, 2006, 2008, 2010, 2012, 2014 e 2016 após exploração), considerando os indivíduos com DAP (diâmetro a 1,30 m do solo) ≥ 20 cm. Foi calculado o incremento em volume no período considerado (após exploração) e transformado em valor percentual (IPAv%), intensidade e o ciclo de corte com base na teoria de crescimentos relativos anuais volumétricos seguindo a regra dos juros compostos, considerando os indivíduos com DAP ≥ 55 cm. A intensidade de corte obtida para população de árvores comerciais vivas de *P. altsonii* com DAP \geq DMC, foi de 23,9 m³ ou 1,3 m³.ha-1, a partir de uma taxa de crescimento volumétrico de 14,1 % a.a. e ciclo de corte de 35 anos. Observou-se na área de estudo que, uma exploração considerando uma taxa de corte de até 99% do volume disponível, permite a produção madeireira continuada da espécie no ciclo de corte de 35 anos. Assim, para uma produção sustentada da espécie é necessário considerar a intensidade de corte mediante o volume comercial disponível.

Case study: reparatory activities in a brownfield area of Ribeirão Santo Antônio do Grama in Minas Gerais, Brazil / Estudo de caso: ações reparatórias em um trecho antropizado do Ribeirão Santo Antônio do Grama em Minas Gerais

Elizabeth Neire da Silva¹, Rogério Vasconcellos Pinto², Gabriel Vargas Mendonça², Vanessa Pataro Maffia¹, Luana Oliveira Caló¹

¹Agroflor Engenharia e Meio Ambiente, Viçosa, Brasil; ²Anglo American, Belo Horizonte, Brasil (elizabeth@agroflor.com.br; rogerio.vasconcellos@angloamerican.com; gabriel.mendonca@angloamerican.com; vanessa.maffia@agroflor.com.br; luana.calo@agroflor.com.br)

Em função de dois vazamentos de um mineroduto em Santo Antônio do Grama, foram propostas ações de estabilização e recuperação de áreas de preservação permanente (APPs) do ribeirão, como forma e medidas mitigatórias e compensatórias. As ações de recuperação contemplam proprietários rurais e abrangem aproximadamente 8 km de calha do ribeirão. Todas proposições foram fundamentadas na Lei Federal nº 12.651/12 para definição da largura das APPs que variam de acordo com a extensão em módulos fiscais, que resulta em faixas estreitas e isoladas em uma matriz de campos antrópicos. Utilizando-se dessa premissa, utilizou-se métodos diversos e diferentes do convencional, propostos especificamente para a área de estudo, e testando métodos alternativos com a priorização de higrófilas, heliófilas, pioneiras e ruderais, especialmente não arbóreas, com predomínio de herbáceas e arbustivas. Primeiramente, fez a remoção de todo minério do leito e margens do rio. Posteriormente, utilizou-se resgate, transplante e reintrodução de flora, semeio manual de nativas e plantio de mudas para recobrimento das bordas, calha e APP's. O término das atividades ocorreu em janeiro de 2019, quando iniciaram-se as atividades de monitoramento das áreas que irão durar pelo menos 30 meses e gerarão novos dados científicos. Os resultados já alcançados demonstram que a área apresentará no futuro qualidade ambiental superior ao cenário antes do ocorrido.

B1q: FORESTS AND CLIMATE CHANGE

Proposed governance for landscape recovery in two regions in Chile / Una propuesta de gobernanza para la restauración de paisajes en dos regiones de Chile

Roger Villalobos¹, Natalia Ruiz-Guevara¹, Leonardo Duran Gárate²

¹Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba, Costa Rica; ²Universidad Mayor de Chile, Santiago de Chile, Chile (rvillalo@catie.ac.cr; natalia.ruiz@catie.ac.cr; leonardo.duran@umayor.cl)

La ocurrencia de los megaincendios forestales del periodo 2016-2017, que afectó más de 500 mil hectáreas, se concentró en las regiones de O'Higgins y del Maule. Para abordar el desafío de la restauración a escala de paisaje, el Ministerio de Medio Ambiente solicitó elaborar una propuesta de gobernanza, que oriente a

actores clave de nivel regional y nacional para su articulación, bajo una visión integrada. Para construir las bases de la propuesta se realizaron entrevistas, revisión bibliográfica y talleres para el diagnóstico de las bases técnicas, organizativas, de conocimiento y experiencias relacionadas a restauración en ambas regiones; así como un análisis institucional y de lecciones aprendidas de otros contextos. Como resultado, se propuso la conformación de estructuras descentralizadas para la participación, aprendizaje y toma de decisiones en las escalas local, regional y nacional, que trabajen de manera colaborativa en cuatro ejes centrales: coordinación, participación y promoción, gestión del conocimiento y fortalecimiento de capacidades, y financiamiento. En torno a estos ejes se propusieron estrategias para la puesta en marcha de las estructuras y acciones para la implementación, tales como la identificación de territorios prioritarios para la restauración, la definición de roles y funciones, la toma de acuerdos y compromisos de acción por parte de actores clave, y el diseño conjunto de indicadores para el monitoreo. La estructura se vinculará con el Comité Nacional de Restauración con el objetivo de replicar en otras regiones los procesos de participación integrada, para abordar las necesidades de restauración bajo una visión nacional.

Survival and growth of Brazil-nut (*Bertholletia excelsa* Humb. & Bonp.) seedlings in tree-fall gaps and forest understory

Jorge Santiago Garate Quispe^{1,2} , Rosel Quispe-Herrera², Percy Zevallos-Pollito¹

¹Departamento Académico de Ingeniería Forestal, Universidad Nacional Amazónica de Madre de Dios, Puerto Maldonado, Madre de Dios, Peru; ²Herbario Alwyn Gentry, Universidad Nacional Amazónica de Madre de Dios Puerto Maldonado Peru; ³Departamento Académico (jgarate@unamad.edu.pe; roquihe@yahoo.es; pazpollito@yahoo.com.br)

This study aimed to evaluate the influence of canopy openness on survival and growth of *Bertholletia excelsa* seedlings, through experimental plantings in tree-fall gaps and forest understory in Madre de Dios, Perú. Sixty-four seedlings were planted within the experimental design, with eight repetitions each with four seedlings in two treatments of canopy openness. Basal diameter, height, and incidences of mortality and regrowth of seedlings were evaluated for twelve months. The survivorship, the annual increase in height and diameter were significantly higher in gaps than in the understory (P-value < 0.05). The regression analysis showed a direct and highly significant relationship between canopy openness and diameter increment ($r^2 = 0.61$) and between canopy openness and height increment ($r^2 = 0.34$). We recommend the use of Brazil-nut seedlings in enrichment planting of forests in Madre de Dios, using large gaps and guarantee high growth rates.

Aboveground biomass quantification and tree-level prediction models for the Brazilian Subtropical Atlantic Forest

Heitor Felipe Uller¹, Laio Zimemann Oliveira¹, Aline Renata Klitzke¹, Jackson Roberto Eleotério¹, Alfredo Celso Fantini², Alexander Christian Vibrans¹

¹Fundação Universidade Regional de Blumenau, Blumenau, Brasil; ²Universidade Federal de Santa Catarina, Florianópolis, Brasil (heitor.uller@florestral@gmail.com; laiozoliveira@gmail.com; klitzkealine@gmail.com; eleoterio@furb.br; alfredo.fantini@ufsc.br; acv@furb.br)

Forests are the largest biological reservoir of biomass and carbon on the planet. This turns them into the main tool to neutralize the CO₂ emitted by human activities. Despite such importance, the uncertainties associated with biomass estimates in forests, especially in (sub)tropical forests, are enormous. Facing this scenario, the objectives of this study were: (i) to quantify through destructive sampling the aboveground biomass (AGB) of 105 trees of 47 species occurring in a secondary subtropical evergreen rainforest in Brazil; (ii) to investigate the AGB distribution in different tree compartments; and (iii) to fit tree-level models to improve biomass estimates for the referred forest type. The results revealed that most of the AGB was stored in the compartments stem and large branches (diameter ≥ 5 cm). There was an increase in the proportion of biomass—in relation to the total tree AGB(kg)—allocated in the large branches as tree diameter at breast height (DBH) increased; this pattern was not observed for the compartments stem, thin branches (diameter < 5 cm), and leaves. The compartments thin branches and leaves represented between 5.4% and 17.0% and 1.3% and 2.9% of the total tree AGB, respectively. From the 10 fitted biomass models, the linearized power models yielded the smallest errors. The best performance model, which returned a mean bias of 1.7%, may be written as $AGB = \exp(-8.9807 + 2.1642 \cdot \ln(DBH) + 0.5072 \cdot \ln(h) + 0.9999 \cdot \ln(pbas))$; Baskerville's factor = 1.0175.

Replanting Lives: convicts helping to restore forests / Replantando Vida: presidiários contribuindo para a restauração florestal

Alan Henrique Marques de Abreu^{1,2}, Elton Luis da Silva Abel^{1,2}, Paulo Sérgio dos Santos Leles², Alcione Duarte Ferreira¹, Jorge Makhouta Alonso²

¹Companhia Estadual de Águas e Esgotos, Rio de Janeiro, Brasil; ²Universidade Federal Rural do Rio de Janeiro, Seropédica, Brasil (alan.abreu@cedae.com.br; elton@cedae.com.br; pleles@ufrjr.br; alcione@cedae.com.br; j_makh@hotmail.com)

O Programa Socioambiental Replantando Vida, desenvolvido no Rio de Janeiro, pela Companhia Estadual de Águas e Esgotos (CEDAE), emprega presidiários em atividades da cadeia produtiva da restauração florestal, com oportunidade de trabalho digno, capacitação profissional e geração de renda, sendo uma alternativa interessante de integrar a necessidade de proteção de mananciais hídricos com a necessidade de promover a ressocialização de apenados, em uma relação ganha-ganha, com reflexos sociais, econômicos e ambientais. Os apenados atuam desde a coleta de sementes, produção de mudas, até o plantio e manutenção dos reflorestamentos. O objetivo deste trabalho é apresentar o modelo de fomento a restauração florestal, desenvolvido pelo Programa. A CEDAE emprega atualmente 439 apenados, em diferentes frentes de trabalho e um quarto desta mão de obra é utilizada na área ambiental. Os apenados recebem capacitação profissional, salário mínimo nacional, auxílio transporte e alimentação, além do direito garantido por lei de remissão de um dia de pena a cada três dias trabalhados. O Programa possui sete viveiros florestais estruturados, com capacidade instalada de 1,8 milhão de mudas ano⁻¹. Parte das mudas produzidas nos viveiros florestais são plantadas em projetos de recuperação de nascentes e matas ciliares pelos próprios apenados, e o restante é disponibilizado gratuitamente para projetos voluntários de restauração florestal em todo o estado do Rio de Janeiro. De 2015 a 2018, o programa já disponibilizou 518.000 mudas florestais para projetos de restauração florestal, em 47 municípios do estado, desenvolvidos por instituições públicas, privadas, organizações sociais, pessoas físicas e produtores rurais.

Analysis of ecological resilience and resistance in temperate forest systems in central Mexico / Análisis de resiliencia y resistencia socioecológica en sistemas forestales templados del centro de México

Lesly Elizabeth Solis Mendoza¹ , Leopoldo Galicia Sarmiento¹

¹Instituto de Geografía, Universidad Nacional Autónoma de México, Ciudad de México, Mexico (l.solis@ciencias.unam.mx; lgalicia@igg.unam.mx)

Los ecosistemas forestales templados se enfrentan al aprovechamiento intensivo-extensivo, baja cobertura de áreas forestales de conservación, políticas de intensificación de extracción de madera y bajo capital social, comprometiendo su resistencia y resiliencia. El aprovechamiento sostenible de la producción forestal es imprescindible para asegurar la resiliencia socioecológica que permita conservar sus funciones, capacidad autorganizativa, de aprendizaje y de adaptación al cambio bajo las nuevas presiones antropogénicas. El objetivo de este trabajo fue comparar la resiliencia socioecológica de dos sistemas de manejo

forestal (un sistema intensivo y otro semi-intensivo) a través de indicadores de resiliencia en bosques templados del centro de México. Se construyó un modelo socioecológico teórico y se definieron indicadores de resiliencia socioecológica. Los indicadores de capacidad de resiliencia fueron biomasa arbórea, fertilidad, diversidad e ingreso de las familias productoras. Los indicadores de autoorganización fueron afiliación a organizaciones productoras, nivel de dependencia económica en la producción, rendimientos e ingreso familiar anual. La habilidad de construir capacidades para el aprendizaje y resiliencia se evaluó a partir de la disposición de los ejidatarios hacia la transición de un aprovechamiento forestal multipropósito. Los resultados muestran que en ambos sistemas de manejo la biomasa arbórea se recupera, pero en el método intensivo las tasas de fertilidad se reducen drásticamente en cada ciclo. Por otro lado, en el sistema de aprovechamiento intensivo la capacidad autorganizativa y diversificación de aprovechamiento en recursos forestales fueron mayores. Finalmente, el sistema de aprovechamiento intensivo resulta tener una mayor resiliencia social y menor resiliencia ecológica con relación al sistema semi-intensivo.

Volume equations for Southern Amazonas, Brazil / Equações de volume para região Sul do Estado do Amazonas

Érico Trevisan¹, Alberto Pinto¹, Joaquim Santos², Adriano Lima², Niro Higuchi², Victor Andrade³

¹Universidade Federal do Amazonas, Manaus, Brasil; ²Instituto Nacional de Pesquisa da Amazônia, Manaus, Brasil; ³Universidade Estadual do Centro-Oeste, Irati, Brasil (ericotrevisan@hotmail.com; albertocarlos@ufam.edu.br; joca@inpa.gov.br; adrianolmf@gmail.com; higuchi.niro@gmail.com; victorhugofandrade@gmail.com)

A exploração madeireira em regime de manejo florestal sustentável tem sido fundamental no desempenho econômico da região. Para utilizar os produtos da floresta, por lei, é necessário Plano de Manejo Florestal Sustentável – PMFS com informações técnicas e específicas com dimensionamento volumétrico do local. Atualmente, o volume comercial é calculado por equação com o uso do fator de forma 0,7 proposto por Heinsdijk (1963), beneficiando o mercado de madeira ilegal por meio da homologação de créditos virtuais no Sistema Nacional de Controle do Origem dos Produtos Florestais – SINAFLO. Portanto, foram testados seis modelos de regressão, sendo três de simples e três com dupla entrada, visando selecionar a equação que melhor representa o volume de madeira comercial das árvores em pé numa área de manejo florestal licenciada no município de Novo Aripuanã-AM. Foram geradas 6 equações de volume com base nos modelos selecionados, utilizando dados da cubagem rigorosa de 323 árvores de espécies comerciais com diâmetros acima de 0,5 metros. Adotando os critérios estatísticos, Syx(%), R²ajustado, Incerteza(%), Critério de Informação de Akaike (AIC), elencados no ranking de seleção sugerido por Bartoszeck (2000) e validação pela estatística do Qui-quadrado (X²), foi possível afirmar que a equação $V = 0,8643 * 0,0007 * DAP^2$ (R²aj. = 0,82) gerada pelo modelo de Kopecky e Gehrhardt apresentou melhor resultado com simples entrada e a equação $V = 7,3035 + (-0,1045 * DAP) + 0,0004 * DAP^2 + 0,0145 * (DAP * Hc) + 0,0000 * (DAP^2 * H) + (-0,7813 * Hc)$ (R²aj. = 0,88) gerada com base no modelo de Meyer apresentou melhor ajuste dentre os modelos com dupla entrada.

Assessment of cashew production potentials and ComCashew contributions for restoring the productive capacity of degraded lands and forests in Sierra Leone

Mintah Agyarko¹, Abraham Conteh², Mohamed Salifou Issaka¹, Rita Weidinger¹, Medgar Brown³

¹GIZ, Accra, Ghana; ²Ministry of Agriculture and Forestry, Freetown, Sierra Leone; ³Balmed Holdings Ltd, Freetown, Sierra Leone (agyarko.mintah@giz.de; abratu2006@gmail.com; issaka.salifou@giz.de; rita.weidinger@giz.de; med@balmedholdings.com)

Sierra Leone is a post-conflict and post-Ebola country in West Africa. Large scale land degradation caused by unsustainable use of forest resources and mining practices have resulted in low productivity of agricultural lands. With a low requirement of inputs, Cashew is a crop for smallholders and also a tree crop for soil conservation, restoration of degraded lands and climate change mitigation. After having built a basis for the cashew sector in the five African project countries, ComCashew aims now to consolidate its achievements and scale up its interventions to other countries. To get started in Sierra Leone, the project conducted a baseline study in 2017 to assess the potential of cashew cultivation as a crop for restoring the degraded lands and forests. Data from 231 households in 10 districts have been collected to determine the extent to which farmers are involved in cashew production, their production and selling practices and also to understand the knowledge gaps for future intervention strategies. The findings show that 22% of the responded households have been growing cashew for more than 10 years, while 75% have been growing it for less than 5 years. Only 9% of the households have had some training on cashew whilst 60% of them have a yield of no more than 100 kg/ha. Planting degraded, deforested and new lands with improved planting materials, agroforestry, capacity building and access to market are key intervention areas for the project activities. Project interventions will concern a total of 30,000 farmers.

Small islands with big ideas: systems using traditional resources and resistance to climate change in the South Pacific / Islas pequeñas con ideas valiosas: sistemas del uso de los recursos consuetudinarios y la resiliencia al cambio climático en el Pacífico Sur

Dan Orcheron¹

¹UNSCHE, Pichari (Cuzco), Peru (orchertonandsudario@gmail.com)

Comprender la resiliencia de los sistemas socio ecológicos al cambio climático es uno de los asuntos más cruciales del mundo en la actualidad. Revisamos el estado de los sistemas de conocimiento en cuanto a resiliencia y adaptación, y destacamos las necesidades críticas de investigación para abordar las áreas interrelacionadas de: (1) Experiencia local y observaciones de cambio con respecto al clima, historia de vida ciclos y procesos ecológicos; (2) Instituciones y prácticas consuetudinarias de gestión de recursos (es decir, con agroforestales y el entorno marino costero); y (3) los roles de los líderes, las instituciones sociales y las redes sociales en el contexto de la perturbación y el cambio. Se llegó a la conclusión de que estos sistemas de conocimiento pueden aportar observaciones de alta resolución, datos de referencia y conocimientos sobre prácticas que mejoran la resiliencia y la capacidad de adaptación en sistemas terrestres y marinos integrados. Los enfoques basados en la participación comunitaria pueden complementar y establecer modelos climáticos fundamentales y dirigir las medidas de gestión, investigación y adaptación de recursos culturalmente apropiados. Aunque la mayoría de las islas del Pacífico son geográficamente pequeñas, sus sistemas de conocimiento incluyen valiosa información sobre los ciclos estacionales, los procesos ecológicos y la gestión de la diversidad biocultural que son relevantes a gran escala para comprender la resiliencia y la adaptabilidad a los efectos socio-ecológicos del cambio climático.

B1r: SILVICULTURE**Major bottlenecks for the restoration of natural forests in Chile**

Jan R. Bannister¹, Rodrigo Vargas-Gaete², Juan F. Ovalle³, Manuel Acevedo¹, Andrés Fuentes-Ramírez², Pablo J. Donoso⁴, Alvaro Promis³, Cecilia Smith-Ramírez^{4,5,6}

¹Instituto Forestal, Castro, Chile; ²Universidad de La Frontera, Temuco, Chile; ³Universidad de Chile, Santiago, Chile; ⁴Universidad Austral de Chile, Valdivia, Chile; ⁵Universidad de Los Lagos, Osorno, Chile; ⁶Instituto de Ecología y Biodiversidad, Santiago, Chile (jbannister@infor.cl; rodrigo.vargas@ufrontera.cl; juan.ovalle@uchile.cl; macevedo@infor.cl; andres.fuentes@ufrontera.cl; pdonoso@uach.cl; alvaro.promis@gmail.com; ceciliasmithramirez@gmail.com)

International agreements combined with the recent Chilean Forestry Policy (2015-2035) represent a challenge and an opportunity for forest landscape restoration (FLR) in Chile. Nevertheless, restoring over 500,000 ha using mainly native species seems like a daunting task by 2035. Here, we discuss the three major bottlenecks that currently constrain the restoration efforts of forest ecosystems in Chile. First, Chile urgently needs a national strategic plan for FLR, which should take into account mid- and long-term goals. There is also a need to prioritize resource allocation for an efficient use, promoting the creation of economic subsidies for restoration that consider different types of forest ecosystems. Second, there is a great need for better nursery protocols in plant production as well as to strengthen educational programs for professional and technical training, given the lack of high-quality personnel in Chilean nurseries. This would help increase the currently limited national plant supply, improving quality and increasing the diversity of native species suitable for forest restoration. Lastly, taking advantage of novel eco-technological tools and promoting innovative plantation design would help to overcome the usually deficient results in the establishment phase, leading to higher survival rates and promoting better performance of native species. Beyond current experiments that are relatively efficient on a small spatial scale, the practice of forest restoration needs to become massive and successful at a landscape scale. More and better applied research is crucial for improving the impact of FLR, so that Chile can achieve its forest restoration challenge in the next decade.

Effects of tending on the species and functional diversity of woody plants in a secondary tropical lowland rain forest

Yi Ding¹, Runguo Zang¹

¹Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China (dingyi@caf.ac.cn; zangrungg@caf.ac.cn)

The function and productivity of secondary forests are relatively low compared with old growth forests. Therefore, it may prove important to enhance the recovery rate and related ecosystem services of these forests through forest tending practices. Here, we explored the effects of tending measures on species and functional diversity of woody plants in a secondary tropical lowland rain forest in Bawangling forest region on Hainan Island. We logged trees which hindered the growth of the target species in 30 plots (50 m × 50 m). The result showed that stem density in overstory (dbh ≥ 5cm) and understory (1cm ≤ dbh < 5cm) reduced by 24.9% and 59.9%, and the basal area decreased by 13.1% and 54.9% after tending. The stem size distribution structure was not significantly changed after tending. Both the community species compositions in overstory and understory did not significantly change. Species diversity of overstory trees did not change significantly, but the effect of tending on understory trees was more significant. The specific leaf area, leaf dry matter content, leaf nitrogen content and leaf potassium content significantly decreased, but woody density and the maximum potential height significantly increased. Leaf chlorophyll content, leaf phosphorus content did not change significantly after tending. Functional richness decreased significantly, and functional evenness and functional divergence significantly increased, while functional dispersion did not change significantly after tending. Our results point to the various ways in which tending can change the trajectory of a secondary forest as it succeeds towards an old growth forest.

Patterns and influencing factors for natural regeneration of *Sorbus pohuashanensis* in Eastern forest region of Northeast China

Ling Yang¹, Hailong Shen¹

¹State Key Laboratory of Tree Genetics and Breeding, School of Forestry, Northeast Forestry University, Harbin, China (yangling082477@yahoo.com; shenhl_cf@nefu.edu.cn)

Mountain ash (*Sorbus pohuashanensis*) is an endemic accompanying broad-leaved species in boreal coniferous forest and mountain dark coniferous forest distributed in single-scattered or contagious patterns in the Northeast and north China. As an important non-timber tree species, mountain ash has been over-developed recently and its population declined or even disappeared in some areas. We investigated the wild seedlings establishment, seed natural dispersal, soil seed bank and seedling emergence for the purpose of understanding the natural regeneration characteristics of this species and its influencing factors. We conclude that habitats have certain effect on seedlings establishment types of mountain ash, and human disturbance could significantly reduce the establishment ratio of root sprouts. Adequate seedling bank was not a limiting factor of mountain ash natural regeneration, but the transfer rate from diameter class II to diameter class III was very lower and was the key limit factor for mountain ash natural regeneration. The temporal and spatial pattern of soil seed bank had significant effect on mountain ash natural regeneration. Temperature may be a limiting factor for mountain ash natural regeneration. Soil moisture and burial depth were the crucial factor in mountain ash natural regeneration. Insects and birds were the main predators for fruits on tree crown layer. The intensive predation of fruit and seeds decreased seed resources and limited natural regeneration of mountain ash. But the predation promoted the dispersal of seeds of mountain ash that favored the natural regeneration and extension of population of mountain ash.

Ecological and social barriers to successful restoration of mangrove forests under a community-based management regime

Daniel Schoenig¹, Manon Davies²

¹Centre for Forest Research, Université du Québec à Montréal, Montréal, Canada; ²Schutzwaldverein e.V., Radolfzell, Germany (schonig.daniel@courrier.uqam.ca; manondavies@rocketmail.com)

A major part of the mangrove forests in the Gulf of Guayaquil (Ecuador) was converted to shrimp aquaculture throughout the 20th century. The remaining forests are crucial for supporting the livelihoods of local communities, coastal protection and carbon sequestration. What are the decisive ecological and social barriers that restoration efforts have to overcome to restore mangrove forests and their ecosystem services? How relevant are social barriers compared to ecological ones? To investigate these questions we analyzed restoration trajectories within a community-managed area that is part of the Ramsar site "Don Goyo". We traced natural regeneration and institutional change over a five-year period by integrating forest inventories and regeneration assessments of nine abandoned shrimp ponds with interviews of key stakeholders. Contrary to our expectations, ecological barriers could be easily identified and overcome. In eight of the nine ponds, established natural regeneration far exceeded a minimum density of 1500 trees per hectare. Ecological barriers also were regarded as

less important by local stakeholders. Rather, safe access to restored areas, a functioning management council including all communities of the area, adaptive institutions within the communities, and education efforts appeared to be most relevant to restore mangrove ecosystem services. Our analysis thus emphasizes that these social factors must explicitly be accounted for as they may be decisive for success of restoration efforts, especially in a community-based management context and under low-input conditions. In addition, we consider the most influential factors within our study also potential targets for efforts to enhance resilience and adaptive capacity.

Rooting of *Apuleia leiocarpa* (Vogel) J. F. Macbr. minicuttings

Deborah Barroso¹, David Siqueira¹, Giovanna Carvalho¹

¹Universidade Estadual do Norte Fluminense Darcy Ribeiro, Campos dos Goytacazes, Brasil (deborah@uenf.br; pessanhasdavid@hotmail.com; giovannacampos85@yahoo.com.br)

The *Apuleia leiocarpa* is a Brazilian Atlantic Forest species valued for its timber and medicinal uses. There is a growing seedlings demand for reforestation, environmental adequacy of rural properties in accordance with laws, and to commercial purposes. This study aimed to evaluate the *A. leiocarpa* minicuttings rooting aiming the vegetative propagation. Sprouts of mini-stumps produced by seeds were collected for mini-cuttings production. Minicuttings of the apical and intermediate segment of these sprouts were made. The work was carried out in completely randomized design with 10 plots per treatment, composed of 15 minicutting each. After staking in 280 cm³ polyethylene tubes, the minicuttings were taken into the nebulization chamber and at 40 days they were evaluated for survival, percentage and quality rooting, and then transferred to greenhouse. At 165 days after staking the seedlings were evaluated for survival, base diameter, height, leaf area and rooting, using WinRhizo software. There was a greater survival of intermediate minicuttings in relation to the apical ones, both in the expedition of the rooting sector (58 and 85%, for apical minicuttings and intermediate ones, respectively), and in the final evaluation of the seedlings (13% apical mini-cuttings and 42% intermediate). There was no difference in the rooting percentage between the propagules in the nebulization chamber, reaching on average 49%. However, the intermediate minicuttings had a higher number of roots. At the end of the cycle, the mean height was higher in the clonal seedlings originated from intermediate minicutting (21cm).

Rooting of *Paratecoma peroba* (Record) Kuhl. and *Amburana cearensis* (Allemão) A. C. Sm. minicuttings

Deborah Barroso¹, David Siqueira¹, Giovanna Carvalho¹, José Gabriel Silva¹

¹Universidade Estadual do Norte Fluminense Darcy Ribeiro, Campos dos Goytacazes, Brasil (deborah@uenf.br; pessanhasdavid@hotmail.com; giovannacampos85@yahoo.com.br; jgabrielshs@gmail.com)

The minicutting can be an alternative for species of difficult access, irregularity in seed production, and a short shelf life when stored, limiting supply of seedlings. The aim of this work was to establish an optimal time in a nebulization chamber for rhizogenesis in juvenile *Paratecoma peroba* and *Amburana cearensis* minicuttings. The staking was carried out in polypropylene tubes (120 cm³), with commercial forest substrate. After staking of 192 minicuttings of *A. cearensis* (96 apical and 96 basal) and 70 minicuttings of *P. peroba*, the tubes were taken to the nebulization chamber with sprays of 30 seconds, every 15 minutes. At 30 days the rooting evaluation was started, and 10 live minicuttings were taken at random. The procedure was repeated every 10 days, up to 70 days after staking. Rooting (%) and total length of roots per clonal seedlings were evaluated. The *A. cearensis* began rooting at 40 days after staking, with a higher rooting of apical minicuttings. Up to 70 days, 60% rooting was observed in apical minicuttings and 30% in basal, with an average length of 27.7 cm and 14.45 cm, respectively. The *P. peroba* presented calluses in 90% of the minicuttings and 80% of rooting, which starts from 40 days after the staking. The adventitious roots of the *P. peroba* reached 24 cm of total length per seedling. Both species can be removed from the nebulization chamber from 50 days after staking, and studies are necessary to increase the rooting percentage of the basal minicuttings of *A. cearensis*.

Innovative systems for large-scale environmental governance in agrarian reform settlements in Brazil: the Radis-Project Platform

Iris Roitman¹, Tamiel Khan Baiocchi Jacobson¹, Rômulo José da Costa Ribeiro¹, Nívea Jorgia Silva Marcondes¹, Luciana Silva Estevam¹, Raimundo Fagner Vansconcelos¹, Carla Silva Souza¹, Paula Daniella Prado Ramos¹, José Tito Lima Neto¹, Reinaldo José de Miranda Filho¹, Mário Lúcio de Ávila¹

¹Radis Project, Faculdade Unb Planaltina (FUP), Universidade de Brasília, Planaltina, Brasil (irisroitman01@gmail.com; tamiel@unb.br; rjcribeiro@unb.br; marcondes.nivea@gmail.com; luestevam@hotmail.com; raimundofagner83@gmail.com; carlassousa.css@gmail.com; dannyprado8@gmail.com; ljostito@gmail.com; rjmiranda@unb.br; unbavila@gmail.com)

In Brazil, there are 9,373 Agrarian Reform Rural Settlements (ARRS), comprising more than 87 million ha. Many of them have deforestation liabilities. The National Institute for Colonization and Agrarian Reform (Incra) is responsible for the environmental regularization of settlements in which farmers haven't obtained land tenure yet. The challenge for such large-scale environmental governance requires innovative solutions for big data collection and management. Therefore, the Radis Project, a partnership between Incra and the University of Brasília, developed a platform to collect and integrate environmental and social data toward the environmental regulation (including the rural environmental registry) and sustainable development of ARRS in the state of Mato Grosso. The platform, developed with Open Data Kit, allows the collection of social, economic and environmental field data (text, numbers, media, geodata), with cloud-based storage, and its integration with satellite and other GIS-based data. We also developed a user-friendly platform to include restoration dynamics data in those areas, according to monitoring indicators (eg. morphotypes tree density, and tree cover) defined by state law. The system allowed the environmental assessment of 12,105 rural family units from 101 ARRS (991,843 ha) in 28 municipalities. Besides social and economic data, we identified native vegetation and consolidated areas (deforested areas in which restoration is not mandatory) and deforested areas in which restoration is mandatory. The platform proved effective for large-scale environmental monitoring and governance and research purposes and, thus, has been extended nationwide to other ten states.

Deforestation and carbon dynamics between 2008 and 2016 and potential for ecosystems services in 55 agrarian reform settlements in Southeastern Amazon, Mato Grosso, Brazil

Iris Roitman¹, Rômulo José da Costa Ribeiro¹, Tamiel Khan Baiocchi Jacobson¹, Luciana Silva Estevam¹, Nívea Jorgia Silva Marcondes¹, Reinaldo José de Miranda Filho¹, Mário Lúcio de Ávila¹

¹Radis Project, Faculdade Unb Planaltina, Universidade de Brasília, Planaltina, Brasil (irisroitman01@gmail.com; rjcribeiro@unb.br; tamiel@unb.br; luestevam@hotmail.com; marcondes.nivea@gmail.com; rjmiranda@unb.br; unbavila@gmail.com)

In the Amazon region, 80% of rural properties should be preserved as Legal Reserves. However, in small properties, restoration is not mandatory in areas deforested before July 2008. We evaluated deforestation and carbon (C) dynamics in 55 agrarian reform settlements in 23 municipalities of Mato Grosso, Brazil, between 2008

and 2016. We used Sentinel images and field campaigns to determine settlements' perimeters and land-use changes. Carbon emissions were calculated using the Radam-IBGE CCSIVAN vegetation map (1:250,000) and carbon reference values from the FREL-Amazonia. The 55 settlements comprise 689,614.70 ha of which 0.68% is made up of water bodies and rocky outcrops and 33.70 % is covered with native vegetation, which represents 35 Tg of C. Total deforestation was 454,133.93 ha (66.30%), corresponding to 68.07 Tg of C. However, most of which (77.69%) was deforested before June 2008 (352,825.34 ha, 52.43 Tg of C). Deforestation and associated carbon-emission rates between 2008 and 2016 were 12,663.57 ha y⁻¹ and 1.96 Tg y⁻¹. Most of the deforested areas comprise pastures with low productivity rates. Besides, competition with large-scale agribusiness farming is difficult. Although restoration of areas deforested before July 2008 is not mandatory, it can provide revenue from carbon credits, environmental reserve quotas, forest management and agroforestry. Besides small-scale livestock and farming, restoration efforts may provide ecosystem services, additional income and, thus, improve the livelihood of farmers.

B1s: SILVICULTURE

Rehabilitation of mined-out and waste-dump areas using pre-selected forest tree species in Bagacay, Hinabangan, Samar, Philippines

Angelito Exconde¹, Albert Piñon¹, Alan Castillo¹, Analyn Pasagdan¹, Maria Theresa de Alday¹

¹Ecosystems Research and Development Bureau, Department of Environment and Natural Resources, Los Baños, Laguna, Philippines (erdb.excondelito@gmail.com; alpinon@yahoo.com; alan.castillo@usq.edu.au; arpasagdan@gmail.com; mtvdealday@gmail.com)

The destructive method of harnessing the mineral resources of Bagacay, Hinabangan in Western Samar, Philippines from 1956 to 1992 left tons of mine tailings containing toxic heavy metals that pollutes the water ways and surrounding landscapes. With the aim of rehabilitating the area using various tree species, ascertain the most suitable soil amelioration, and identify the best-performing tree species in terms of growth and survival, the study investigates the phytoremediation capacity of pre-selected trees in rehabilitating the mined-out and waste dump site. In 2009, the experiment was established using split-plot in Randomized Complete Block Design replicated three times with six soil amendments (main plot) and four pre-selected tree species (*Pterocarpus indicus* Willd., *Acacia auriculiformis* A. Cunn. Ex Benth, *Acacia mangium* Willd. and *Gymnostoma rumphiana* L. A. S. Johnson) for sub-plot. A total of 900 seedlings were planted in holes measuring 0.125 m³ at 3 m x 3 m spacing with replanting for mortality applied only within a year after planting. Measurements of height, diameter and percent survival were undertaken in 2010, 2011, 2013 and 2016. After a year, growth and percent survival of trees treated with forest soil + chicken dung + lime were found significantly different compared to control (forest soil), but not in 2011, 2013 and 2016. In 2011, *P. indicus* performed best in terms of growth and percent survival, while *A. mangium* outperformed the other species in 2013. Finally, *A. auriculiformis* stand out after seven years.

Mixing Silver fir (*Abies alba*) and European beech (*Fagus sylvatica*) leads to faster and more complete growth recovery following drought

Julia Schwarz¹, Jürgen Bauhus¹

¹Chair of Silviculture, University of Freiburg, Freiburg, Germany (julia.schwarz@waldbau.uni-freiburg.de; juergen.bauhus@waldbau.uni-freiburg.de)

In Europe, replacing drought-sensitive monocultures of spruce (*Picea abies*) with mixtures of European beech (*Fagus sylvatica*) and Silver fir (*Abies alba*) promises to be an effective forest management strategy as the latter two are expected to be more drought tolerant compared to spruce. This study investigates the influence of mixing Beech and Fir on the tree response to extreme drought stress using neighbourhood-analyses. We derived basal area increment (BAI) series from increment cores of 160 trees from 3 sites in south-western Germany and from 1 site in Croatia. In addition, for all trees, we determined the carbon isotope composition ($\delta^{13}C$) of latewood in a wet and dry year. At most sites, fir trees growing in mixed neighbourhoods exhibited higher BAI compared to firs from monospecific neighbourhoods while growth of beech trees was less affected by neighbourhood composition. Results of mixed models suggest that mixing benefits depend on tree size and neighbourhood density but not on species identity: Mixing improved growth of large trees from both species irrespective of neighbourhood density while for smaller trees benefits of mixing appeared only in trees from denser neighbourhoods. For either species, there was no benefit of mixing for growth resistance during the 2003-drought. Yet, trees in mixed neighbourhoods exhibited a smaller increase of $\delta^{13}C$ in the dry compared to the wet year as trees in monospecific neighbourhoods indicating complementary water-use of these 2 species under drought. Trees from both species showed higher growth recovery and resilience following drought in mixed compared to monospecific neighbourhoods.

Effect of stump height on sprouting capacity of native tree species from Northeast Brazil

Antonio Carlos Ferraz Filho¹, Andressa Ribeiro¹, Rodolfo Molinário de Souza¹, Helionai Pereira da Silva¹, Lucas de Souza Silva¹, Lailla Sabrina Queiroz Nazareno¹

¹Universidade Federal do Piauí, Bom Jesus, Brasil (acferrazfilho@ufpi.edu.br; andressa.florestal@ufpi.edu.br; molinariodesouza@gmail.com; helionai_2012@hotmail.com; lucas045furtado@gmail.com; sabrinaaqueiroz@hotmail.com)

Wood extraction from native forests in Brazil is responsible for 15% of the total industrial wood produced in the country. However, great care must be taken to ensure that managed areas are adequately restored. Stump height is an important variable to achieve this, since higher stumps might facilitate sprouting, but leave larger quantities of wood in the field. The objective of this study is to determine the impact of the stump height (10, 20 and 30 cm) on the sprouting capacity of native tree species. The study area is located in Cristino Castro, Piauí, and is a transition vegetation between savannah (cerrado) and dry forest (caatinga); 9 sample plots (10 m x 10 m) were clear cut (January 2017) installing 3 stump height treatments (T¹⁰, T²⁰, T³⁰). The plots were installed in a forest managed for fire wood production, clear-cutting followed by restoration through coppicing. Six months after cutting, all stumps were evaluated for the following traits: presence, number and height of the sprouts. Leaf area index (LAI) was measured in each plot using an AccuPAR LP-80 ceptometer. The results showed that stump height did not affect the percentage of sprouted stumps (83.9%), height of the dominant sprout (111.4cm) or LAI (1.2 m²/m²). The only statistically different variable was number of sprouts per stump, being double for T¹⁰ (24.5 sprouts/stump) than for the other two treatments (12.3 sprouts/stump). These results are preliminary, additional plots are being implemented and will be monitored during a complete harvest cycle (15 years). Acknowledgements: TAESA, Gurguéia Manejo Florestal.

CO₂ removal by forest restoration in Amazon

Carlos Sanquetta¹, Alexis Bastos², Mateus Sanquetta¹, Marcelo Ferronato³, Ana Corte¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Centro de Estudos Rioterra, Porto Velho, Brasil; ³ECOPORÉ, Rolim de Moura, Brasil (carlossanquetta@gmail.com; alexis@rioterra.org.br; mateus.sanquetta@gmail.com; marcelo@ecopore.org.br; anapaulacorte@gmail.com)

Deforestation rates in the Amazon remain alarming, implying high levels of emission of greenhouse gases (GHG) into the atmosphere. Rondônia is one of the Brazilian states with the highest rates of deforestation in the country. Forest restoration is a concrete action to recover its biodiversity and ecological functions, as well as to mitigate GHG emissions, especially in protection zones and legal forest reserve as defined by law. CO₂ removal of mixed young stands with native species implanted in family farms, aged between 5 and 7 years, was quantified. A forest inventory was carried out by establishing 40 permanent plots and the biomasses of 40 sample trees were determined by the destructive direct method. Laboratory analyzes of plant tissues were carried out. The total dry biomass was estimated at 65.77 t.ha⁻¹, which has the following order of partitioning: stems> branches>roots foliage> miscellaneous. The carbon stock stored in the stands was calculated at 29.60 t.ha⁻¹, which corresponds to 16% of the average stock of mature natural forest in the region. Carbon dioxide removal was estimated at 108.52 t CO₂eq.ha⁻¹, which corresponds to the annual rate 16.99 t CO₂eq.ha⁻¹.year⁻¹. It was concluded that, in spite of being young, these restoration stands store large amounts of carbon and promote GHG mitigation and help in recovering forest cover affected by deforestation. In addition to this role, the restoration stands in question play an important role in the recovery of biodiversity in this tropical region highly affected by the human perturbation.

Forest regeneration challenges in a changing climate

Alaba Emmanuel Gbadamosi¹

¹Adekunle Ajasin University, Department of Forestry & Wildlife Management., Akungba-Akoko, Nigeria (alaba.gbadamosi@aaua.edu.ng)

Extreme conditions of cold or heat are known to exclude trees. Fluctuating temperatures and unpredictable rainfall regimes which are hallmarks of changing climatic conditions, on the long run, will alter the composition of plants on the earth's surface. Forest helps to mitigate these unpleasant consequences when grown and managed sustainably. Forest trees are raised vegetatively or from seeds which engender variability. Seeds are propagules which carry genetic information from one generation to the other but these are impacted by inherent challenges of dormancy—a natural time clock, which is presently aggravated by unfavourable environmental conditions which promote irregular fruiting patterns. Dormancy of seeds is a major problem in artificial and natural regeneration process. Anthropogenic activities of unregulated forest conversions, uncontrolled exploitation and incessant fire outbreaks, and the economics matrix which precludes biological and ecological considerations have combined to limit the natural regeneration process of forest. Therefore, in order to combat the consequences of a changing climate on natural regeneration of forest trees especially in the tropics where forest are mainly revenue generating units; conservation and domestication of useful species, reinforcement of forest reserve boundaries, novel dormancy breaking mechanism, enrichment plantings of tree species with complex dormancy mechanism, seeding of forest floors and knowledge-driven storage system of recalcitrant seeds must be a priority in the new-look management of forest estate and resources. Conclusively, reforestation and afforestation projects must be re-initiated, re-invigorated and encouraged with adequate funding by governments, local and international agencies to arrest the diminishing forest estates.

Quantifying growth response of trees to drought: a critique of the Lloret-concept and recommendations for future studies

Julia Schwarz¹, Jörg Kunz¹, Martin Kohler¹, Florian Schnabel², Valentina Vitali³, Jürgen Bauhus¹

¹Chair of Silviculture/University of Freiburg, Freiburg, Germany; ²German Centre for Integrative Biodiversity Research (iDiv), Leipzig, Germany;

³Université du Québec à Montréal (UQAM), Montréal, Canada (julia.schwarz@waldbau.uni-freiburg.de; joerg.kunz@waldbau.uni-freiburg.de; martin.kohler@waldbau.uni-freiburg.de; florian.schnabel@idiv.de; valentina.vitali89@gmail.com; juergen.bauhus@waldbau.uni-freiburg.de)

The components of tree resilience, as originally proposed by Lloret et al. in 2011, have been widely applied to assess the drought tolerance of (radial) growth of trees for different purposes. The majority of studies calculated indices of resistance, recovery, and resilience to quantify the potential of silvicultural management, i.e. thinning or mixing of tree species, to improve drought tolerance. In other cases, they were used to compare the drought tolerance of trees of different species, populations, age, or dimension. Despite its wide application, the current concept exhibits some major drawbacks and limitations, which may lead to spurious results or misinterpretations of observed patterns. In this study, we, therefore identify and discuss several shortcomings of the Lloret-indices based on re-analyses of different datasets. In addition, we present a new approach that allows synthesizing the entire drought-related growth deviation of trees while considering the growth level of a given tree. In addition, we give recommendations for future studies that employ the Lloret concept concerning 1) the type of input data to be used (raw ring-widths, basal area increment, or standardized growth series), 2) objective selection procedures for the number of years included in pre- and post-drought periods and 3) cases where one should refrain from calculating indices of recovery. Finally, we propose that future studies should aim at relating short-term responses of trees to drought (i.e., the resilience indices) to the temporal stability of tree growth.

Non-timber forest products and climate change adaptation by forest adjacent communities in selected forests in Kenya

Roxventa Ongugo¹, Jonah Kipsat¹

¹KEFRI, Nairobi, Kenya (rongugo@gmail.com; jonahkipsat@gmail.com)

Non-timber forest products (NTFPs) are products other than timber, extracted from the forest for the human use (Wiersum, 2003). The most commonly used NTFPs are medicinal plants, wild vegetables, fuelwood, and edible fruits. In this study, NTFPs were both direct benefits like food and healthcare and indirect benefits like biodiversity and ecotourism. The poor depend on economic activities sensitive to the climate; eg, agricultural and forestry activities that depend on local climate conditions; a change in those conditions could directly impact productivity levels and diminish livelihoods. Majority of the forest dependents have reduced opportunity to cope with the adversities of climate change due to low capabilities, poverty, weak institutional mechanisms and lack of access to resources (Brooks et al., 2005). Therefore, the main objective of the study was to assess the role of NTFPs to forest dependent communities as a strategy to cope/adapt with the impacts of climate change. The study was conducted among communities in the selected forests. Questionnaires were the main methods of data collection. Tentative results showed that communities identified different NTFPs of importance to them. Majority of them also perceived changes in climate pattern due to increased temperatures and unpredictable rainfalls. The respondents admitted to use of NTFPs for subsistence and source of income as a climate change coping strategy. The study concluded that NTFPs still play a safety role in assisting communities cope with the current climate change.

Carbon sequestration associated with alternative strategies for the reforestation of degraded areas: an analysis of analog forests, plantation forests, and degraded pastures

Raul Ramos¹, David MacFarlane², Lauren Cooper²

¹Escuela Superior Politécnica de Chimborazo, Riobamba, Ecuador; ²Michigan State University Department of Forestry, East Lansing, USA (raulramos@gmail.com; macfar24@msu.edu; lcooper@msu.edu)

In European countries and the United States, the ability of ‘analog’ forestry – a unique silvicultural approach which undertakes restoration of degraded land by focusing on high biodiversity and resiliency, but avoids agrochemicals and fossil fuels – to provide an alternative land restoration and carbon sequestration technique has been demonstrated. However, there has been little analysis comparing the potential for above- and below-ground carbon sequestration and storage in analog forests, monoculture forest plantations, and degraded pastures. Taking place in degraded farmland in the Cumaná, Ecuador, this study estimated the storage potential of organic soil carbon up to 1 meter in depth and in aboveground biomass in the three types of land use listed above. The study used a randomized split-plot design and evaluated the following variables: apparent density and organic carbon of the soil, diameter at breast height (DBH) and total height of the trees, and biomass estimated by use of allometric equations. The study found that analog and plantation forests stored higher quantities of total carbon (178 and 141 t ha⁻¹, respectively) compared to degraded pasture (124 t ha⁻¹). These findings show that the analog forest system presents a high potential for intentional carbon sequestration. Furthermore, this approach generates other ecosystem products and services that provide economic resources for producers and communities. With planning, the analog forestry approach could be utilized in a transformative reforestation strategy for restoration of degraded areas at the farm and landscape levels to deliver high-impact carbon storage and human development benefits.

B2b: ABIOTIC STRESSORS AND THEIR INTERACTIVE IMPACTS ON FORESTS

Population dynamics of endophytic fungi in monsoon forests of Cape York Peninsula, Northern Australia: water stress and biogeographical host affinities

Jed Calvert¹, Alistair McTaggart¹, Lilia Costa Carvalhais¹, Paul Dennis¹, Andre Drenth¹, Roger Shivas¹

¹University of Queensland, Brisbane, Australia (j.calvert@uq.net.au; a.mctaggart@uq.edu.au; l.carvalhais@uq.edu.au; p.dennis@uq.edu.au; a.drenth@uq.edu.au; r.shivas@uq.edu.au)

Fungal endophytes play important ecological roles in relation to their host plants, including promotion of plant growth, inhibition of plant pathogens and drought tolerance, which are all characteristics that have potential far-reaching applicability in the forestry sphere. However, the way in which massively diverse endophyte communities across the major terrestrial plant lineages respond to seasonal water stress is a question that has not yet been examined in tropical endophytes using culture-independent methods. The lowland rainforests of the Iron Range in north-eastern Australia experience extreme seasonal fluctuations in water availability due to the monsoon cycle. The aims of this study are to (a) establish how fungal endophyte diversity and community composition differ during the dry and wet seasons in the monsoon tropics, and (b) whether endophytes of host plants that evolved on the Sunda and Sahul continental plates exhibit differing community-level patterns of fungal colonisation. This information has the potential to direct agriculture-focused bioprospecting efforts to isolate beneficial fungal endophytes from the Australian tropics, and to clarify the degree to which land plants have developed divergent microbiomes over deep evolutionary time. We used high-throughput internal transcribed spacer (ITS) sequence analysis to compare the fungal endophyte communities in leaves and stems of plants in Cape York Peninsula sampled from wet and dry seasons. Twelve plant taxa were evaluated, including representative members of angiosperms, monocots, magnoliids and bryophytes.

Change of gas exchange characteristics and chlorophyll fluorescence of three dominant tree species during the vegetation season in European hemi-boreal zone, Lithuania

Vitas Marozas¹, Ainis Pivoras¹, Algirdas Augustaitis¹

¹Vytautas Magnus University, Kaunas, Lithuania (vitas.marozas@vdu.lt; ainis.pivoras@vdu.lt; algirdas.augustaitis@vdu.lt)

Current climate scenarios predict rising air temperature along with increasing frequency and intensity of summer drought in the Central and Eastern Europe. Severe drought episodes affect physiological processes in trees such as transpiration, photosynthesis and carbon allocation. Understanding gas exchange between plants and the atmosphere is important in woody plant research. The aim of this study was to evaluate differences in gas exchange characteristics and chlorophyll fluorescence of tree species prevailing in Lithuania (Scots pine, Norway spruce and Silver birch and their physiological response to water stress. The study was conducted in Aukštaitija integrated monitoring station, Lithuania. Gas exchange parameters and chlorophyll fluorescence was measured during the vegetation season of 2016–2018. Meteorological parameters were obtained from the monitoring station. Under moderate drought conditions all investigated tree species demonstrated reduced photosynthetic rates, lower stomatal conduction transpiration rates, water use efficiency, instantaneous carboxylation efficiency. During moderate drought, intercellular CO₂ concentration of Norway spruce was higher and this species demonstrated the highest decrease in instantaneous carboxylation efficiency. No significant changes of maximal chlorophyll fluorescence (Fv/Fm) among species were detected during different weather periods. The investigated tree species reacted differently to weather conditions. The study confirmed the sensitivity of Norway spruce to drought conditions. The Silver birch was the least sensitive to temperature and humidity conditions variation. The Scots pine demonstrated the highest tolerance to different weather conditions.

Waterlogging affected the production, mortality and longevity of fine roots in Scots pine saplings

Tapani Repo¹, Timo Domisch¹, Jouni Kilpeläinen¹, Sirpa Piirainen¹, Ji Qian^{1,2}, Marja Roitto¹, Ai-fang Wang^{1,2}, Leena Finér¹, Samuli Launiainen³, Tarja Lehto⁴

¹Natural Resources Institute Finland, Joensuu, Finland; ²Agricultural University of Hebei Baoding China; ³Natural Resources Institute Finland, Helsinki, Finland; ⁴University of Eastern Finland, Joensuu, Finland (tapani.repo@luke.fi; timo.domisch@luke.fi; jouni.kilpelainen@luke.fi; sirpa.piirainen@luke.fi; qianji167@163.com; mroitto@saunalahti.fi; wangai82@126.com; leena.finer@luke.fi; samuli.launiainen@luke.fi; tarja.lehto@luke.fi)

Excess soil water limits tree growth especially on peatlands but also on fine-textured mineral soils. Predictions for global change effects include increasing flooding events which may worsen the situation. Elevated water table impairs root functioning through oxygen deficiency but the implications for fine root dynamics are known poorly. We studied the effects of waterlogging (WL) on the phenology, longevity and mortality of short (1st order) and long (1st order) roots of Scots pine (*Pinus sylvestris* L.) saplings in two controlled laboratory experiments. Tree roots were monitored by minirhizotron imaging and their responses

were compared with the aboveground physiology and growth. In the first experiment, five-week WL starting at the time of cessation of shoot elongation killed most of the saplings. Trunk sap flow decreased within a few days after WL onset. Short root mortality started to increase and root production and photosynthesis to decrease after three weeks of WL. Waterlogging decreased fine root longevity. In the second experiment, three weeks of WL in the beginning of growing season affected both roots and shoots. Interrupted WL alternating at one week intervals decreased root longevity more than continuous WL, whereas shoot elongation was affected more by continuous WL. In conclusion, elevated water table changed the fine root dynamics of Scots pine. Changing soil water table by changes in distributions of rainfall events may affect carbon cycle of trees through roots in boreal forest ecosystems more than previously envisaged.

Drought reduces carbon storage and soil respiration: results from throughfall exclusion experiment in moso bamboo stand in Southeast China

Benzhi Zhou¹, Xiaogai Ge¹, Yonghui Cao¹, Qian Li¹

¹Research Institute of Subtropical Forestry, Chinese Academy of Forestry, Hangzhou, China (benzhi_zhou@126.com; gexiaogai2006@163.com; ffcyh77@sina.com; sxczliqian@163.com)

Drought can severely affect alteration of carbon sink-source relationships through impacts on carbon storage and carbon emission in forest ecosystems. On-site field experiment is very rare on drought effect on forest carbon cycle, especially in subtropical forest ecosystems. In this study, we imposed drought to a moso bamboo stand by excluding throughfall to the forest floor beginning in July 2012, and measured biomass carbon, soil carbon, and soil respiration during specific period over the drought duration. Bamboo shoot number, new culm number, and their height and diameter at breast height were significantly lower in throughfall exclusion (TE) plots than in control (CK) plots, with decrease of 64.6, 70.8, 10.6 and 11.3%, respectively. Annual carbon sequestration for TE plots was 58.1% lower than that for CK plots. Soil carbon storage in the 0–60-cm layer in CK and TE plots decreased by 3.7 and 12.2%, respectively, during the 10-month experiment period. Drought led to ~10% decrease for ecosystem carbon storage in moso bamboo stand. On the other hand, drought caused a significant decline (~25%) in annual soil respiration rate and CO₂ emission (~26%), with the significant difference occurring in growing seasons. Drought does not change the exponential relationship between soil respiration and temperature, but decreases the temperature sensitivity, and the correlation coefficient between soil respiration and temperature/moisture. Our findings should provide a better understanding of carbon sequestration potential and determination of how future climate change may impact carbon budgets.

Toward the definition of epidemiologically-based stomatal-flux critical levels for forest protection against ozone: the MOTTLES approach

Elena Paoletti¹, Ovidiu Badea², Elisa Carrari¹, Laurence Dalstein-Richier³, Alessandra de Marco⁴, Silvano Fares⁵, Ionel Popa², Pierre Sicard⁶, Yasutomo Hoshika¹

¹CNR, Sesto Fiorentino, Italy; ²INCDS, Bucharest, Romania; ³GIEFS, Nice, France; ⁴ENEA, Casaccia, Italy; ⁵CREA, Arezzo, Italy; ⁶ARGANS, Sophie Antipolis, France (elena.paoletti@cnr.it; badea63@yahoo.com; elisa.carrari@ipsp.cnr.it; ldalstein-richier@departement06.fr; alessandra.demarco@enea.it; silvano.fares@crea.gov.it; popaicas@gmail.com; psicard@argans.eu; yasutomo.hoshika@cnr.it)

European directives for the protection of vegetation from phytotoxic ozone (O₃) are based on atmospheric exposure (AOT40) while O₃ effects on forests depend on gas uptake through stomata (stomatal flux). MOTTLES is a LIFE project establishing a permanent network of forest sites based on active O₃ monitoring, in order to define new standards based on stomatal flux, i.e. PODY (Phytotoxic Ozone Dose above a threshold Y of uptake). Based on the first year of MOTTLES data, we describe the typical monitoring station, together with measure protocols and index calculation methods. AOT40 and PODY are then compared and correlated with plant-response indicators (radial growth, crown defoliation, leaf visible injury). For 2017, the average AOT40 calculated according with the European Directive was almost twice the EC legislative standard of 5,000 ppb h. The metrics calculated by EC protocols (EC Directive, ICP-Vegetation) resulted well correlated to those calculated from the real duration of the growing season (MOTTLES method) and are thus representative of the actual exposure/flux. AOT40 showed an opposite trend compared to PODY, hence it cannot be recommended as an optimal metric for forest protection. Visible foliar injury was the best plant-response indicator of tree responses to O₃ under field conditions and more easily detected at the forest edge than inside the forest. These results help the set-up of further long-term forest monitoring networks for O₃ assessment. This is recommended in Europe where stomatal O₃ fluxes shall now be monitored in different habitats according with the new National Emission Ceiling directive.

Interactive effects of climate and land-use on tree diversity in three ecological zones of Ghana

Reginald Tang Guuroh^{1,2}, Gloria K. Adeyiga¹

¹Council for Scientific and Industrial Research, Forestry Research Institute of Ghana, Kumasi, Ghana; ²University of Cologne, Range Ecology and Range Management Group, Botanical Institute Cologne, Germany (rguuroh@gmail.com; gloriaadeyiga@gmail.com)

Ecosystem health and functioning is closely related to plant diversity. Plant diversity is interactively driven by biotic and abiotic environmental factors. The importance of these drivers for tree diversity is still poorly understood particularly within the context of ongoing global changes. This knowledge gap affects ecosystem management and services provision. The study uses a combined gradient approach with area comprising a gradient of climatic aridity from the forest-savannah transition zone to the sudanian savannah of Ghana, in combination with local gradients of soil and land-use (distinguishing between protected areas with and without fire). Using species richness and Shannon diversity index as response variables, linear mixed-effect models and model selection were applied to test the links between environmental variables and diversity. In total, 180 species were recorded. Highest species richness was recorded in the forest-savannah transition (123), while the guinea and sudan savannah had 50 and 41 species respectively. In the drier savannah zones, species richness was highest in protected areas without fire followed by communal areas while protected areas with fire had the lowest species richness. In the wetter forest-savannah transition zone, species richness was highest in protected areas without fire followed by protected areas with fire and then communal areas. We found that climate and land-use were more important than soil for tree diversity. Precipitation was the most important driver of species richness and Shannon diversity index (> 50% explained variance). These results are useful for land managers and can be used as a guide for management and conservation planning.

Analysis of wind effect on trees in riparian areas

Oscar Bustos¹, Carlos Mena¹

¹Universidad de Talca, Talca, Chile (obustos@utalca.cl; cmena@utalca.cl)

The natural fall of trees in riparian areas is an important source of coarse woody debris for mountain streams, improving fish habitat and influencing stream morphology. This research presents the results of a physical and probabilistic model to estimate the probability of a tree falling into the stream including the effects of tree lean and wind direction of conifers near a stream in a stand in the Maule's Coast Range, Chile. Two hundred trees were measured in this study area. A systematic sampling method was applied in each stream. The sample plots were defined as a rectangle of 20 m x 50 m located each 30 m on both sides of the stream. The total area sampled was 3 ha. In every sample plot all trees were measured. Results of this study indicate that tree lean is not a major factor with respect to influencing tree blowdown for the range of tree lean data collected from coniferous trees along streams in the study area.

Sensitivity of stomatal conductance to soil moisture: implications for tropospheric ozone

Alessandra de Marco¹, Alessandro Anav¹, Elena Paoletti²

¹ENEA, Rome, Italy; ²CNR, Sesto Fiorentino, Italy (alessandra.demarco@enea.it; alessandro.anav@enea.it; elena.paoletti@cnr.it)

Plants remove a large amount of atmospheric compounds from the lower troposphere through stomata; however the role of water availability was often neglected in atmospheric chemistry modelling studies as well as in integrated risk assessments. The aim of this study is to evaluate the effect of soil water limitation on stomatal conductance and assess resulting changes in atmospheric chemistry testing various hypotheses of water uptake by plants in the rooting zone; following the main assumption that roots maximize water uptake, we improve the dry deposition scheme within the chemistry transport model CHIMERE. Results highlight how dry deposition significantly declines when soil moisture is used to regulate the stomatal opening, mainly in the semi-arid environments: over Europe the amount of ozone removed by dry deposition in one year without considering any soil water limitation to stomatal conductance is about 8.5 TgO₃, while using a dynamic layer that ensures plants to maximize the water uptake from soil, we found a reduction of 10% in the amount of ozone removed by dry deposition (~7.7 TgO₃). Despite dry deposition occurs from top of canopy to ground level, it affects concentration of gases remaining into the lower atmosphere with a significant impact on ozone concentration (up to 4 ppb) extending from surface to upper troposphere (up to 650 hPa). Our results shed light on the importance of improving parameterizations of processes occurring at plant level (i.e. from the soil to the canopy) as they have significant implications on concentration of gases in the lower troposphere.

B2c: NOVEL ADVANCES IN GENOMICS AND TREE BREEDING FOR SUSTAINABLE FORESTS

The status of forest trees breeding in Sweden and realized genetic gain in Norway spruce breeding program

Mateusz Liziniowicz¹, Mats Berlin², Bo Karlsson¹, Andreas Helmersson¹

¹Skogforsk, Ekebo, Sweden; ²Skogforsk, Uppsala, Sweden (mateusz.liziniowicz@skogforsk.se; mats.berlin@skogforsk.se; bo.karlsson@skogforsk.se; andreas.helmersson@skogforsk.se)

The forest tree breeding has started in Sweden in 1950's. The species of interest have been Norway spruce (*Picea abies*), Scots pine (*Pinus sylvestris*), lodgepole pine (*Pinus contorta*) and silver birch (*Betula pendula*). The breeding aim for all species is to combine intensive breeding, gene conservation and preparedness for future climate change. The test strategy is based on multiple breeding populations formed from tested plus-trees selected in wild populations. The breeding cycle is repeated generation by generation and expected genetic gain in growth is estimated to be between 10% and 15% per generation. The deployment into operational forestry is mainly by mass propagation in seed-orchards. Soon, seed orchards from tested material will start to produce seeds with expected gain of 25% in areal production. The realized gain trails have been established for Norway spruce in southern and central Sweden to demonstrate effects of ongoing breeding program. The planted genetical material, ranged from unimproved local seedlings up to the best clones from breeding front. The results showed that the differences between material matched the predictions and increased with an increase in breeding level. Moreover, an early height measurement gave reliable estimations of genetic gain in areal production in the time of first commercial thinning. Finally, it was shown that planting clonal bulk is a reasonable to spread the production risk as there is a great clonal variation for areal growth.

Genomic selection for half-sib family using exome capture as genotyping platform in Norway spruce

Linghua Zhou¹, Zhiqiang Chen¹, John Baison¹, Bo Karlsson², Sven-Olof Lundqvist³, María Rosario García-Gil¹, Harry Wu^{1,4}

¹Swedish University of Agriculture Science, Umeå, Sweden; ²Skogforsk, Ekebo, Sweden; ³IIC, Stockholm, Sweden; ⁴National Research Collections Australia NRC, Canberra, Australia (linghua.zhou@slu.se; zhiqiang.chen@slu.se; john.baison@slu.se; bo.karlsson@skogforsk.se; svenolof.lundqvist@indic.se; m.rosario.garcia@slu.se; harry.wu@slu.se)

Genomic selection (GS) is considered a promising approach to accelerate tree breeding and enhance genetic gain. We investigated the predictive ability of GS based on 484 progeny trees from 62 half-sib families in Norway spruce (*Picea abies* (L.) Karst.) for density, modulus of elasticity and microfibril angle (MFA) scored with SilviScan technology and two indirect methods, Hitmann (a proxy to MFA) and Pylodin (a proxy to density). GS predictive ability (PA) was comparable with that based on pedigree-based selection. PA assessment for each cambial age and calendar age showed the possibility to train the GS model at an early stage. In this study, we also tested PA based on different ratio between the training and validation sets and different statistical models. Different statistical models have no significant impact on the estimated PAs. Taking into account the cost of wood property assessment, the two indirect methods could be considered a cost-efficient alternative for the implementation of GS for solid wood properties into operational breeding.

Advances in genetic improvement in three *Acacia* species in Cuba / Avances en el mejoramiento genético en tres especies del género *Acacia* en Cuba

Sandra Herrera Soler¹, Arnaldo Fabian Álvarez Brito¹

¹Instituto de Investigaciones Agro-Forestales, La Habana, Cuba (sherrerass1992@gmail.com; archie@forestales.co.cu)

Los programas de mejoramiento genético en las especies forestales son esenciales para elevar rendimientos de productos madereros y no madereros, así como la tolerancia a factores bióticos y abióticos adversos. Sobre este último aspecto los registros climáticos disponibles indican que la pluviosidad media de Cuba

ha disminuido 200 mm en los últimos 50 años y los escenarios climáticos evidencian que tal tendencia aumentará, extendiéndose de oriente a occidente, por lo que disponer de material de elevados rendimientos de madera y tolerante a la sequía constituye un objetivo central del programa forestal al 2030. El objetivo de este trabajo es analizar los avances del mejoramiento genético con el género *Acacia*: *A. mangium*, *A. auriculiformis* y el híbrido interespecífico, basado en el total de áreas dedicadas a las plantaciones, los experimentos establecidos y las investigaciones realizadas. Desde principios de los años 90 hasta el 2000 fueron establecidos siete experimentos con ambas especies parentales, en los que se desarrollaron ocho investigaciones sobre su introducción en Cuba, una relacionada con la introducción de procedencias y otra con la obtención del híbrido interespecífico. La superficie destinada para las especies del género *Acacia* incrementó en seis años, hasta fines de 2016, en 65 %, mostrando su relevancia en el sector productivo. El análisis de esos resultados condujo a la elaboración del programa de mejoramiento genético a seguir para cumplir los objetivos de obtención de semilla híbrida para la producción de madera en rollo y tolerante a la sequía.

Breeding for resistance to *Teratosphaeria nubilosa* on *Eucalyptus globulus*

Gustavo Balmelli¹, Sofía Simeto¹, Alicia Castillo², Pilar Gasparri¹, Danilo Cabrera³, Ignacio Aguilar³, Marianella Quezada³, Cecilia da Silva⁴, Facundo Giorello⁴

¹Programa Nacional de Investigación en Producción Forestal, Instituto Nacional de Investigación Agropecuaria, Tacuarembó, Uruguay; ²Unidad de Biotecnología, INIA, Montevideo, Uruguay; ³Programa Nacional de Investigación en Producción Frutícola, Instituto Nacional de Investigación Agropecuaria, Montevideo, Uruguay; ⁴PDU Biología Vegetal del Noreste, Centro Universitario de Tacuarembó, Universidad de la República, Montevideo, Uruguay (gbalmelli@inia.org.uy; ssimeto@inia.org.uy; acastillo@inia.org.uy; pgasparri@inia.org.uy; dcabrera@inia.org.uy; iaguilar@inia.org.uy; mquezada@inia.org.uy; cecilia.dasilva@cut.edu.uy; fagire@gmail.com)

The devastating damage caused by *Teratosphaeria nubilosa* in plantations of *Eucalyptus globulus* is forcing the replacement of this species in Uruguay. As there is no local availability of resistant genotypes, INIA reoriented its Tree Breeding Plan to the specific aim of developing clones with good performance against this disease. Genetic variation in disease resistance (% defoliation) and precocity of phase change (% of adult foliage) at 14 and 21 months of age was analyzed in five progeny tests (comprising 87 full-sib families) naturally infected by *T. nubilosa* in Southeastern Uruguay. The narrow-sense individual tree heritability for disease severity was low or moderate (0.05 at 14 months and 0.15 at 21 months) and was moderate to high (0.21 at 14 months and 0.38 at 21 months) for precocity of phase change. The genotype x environment interaction for disease severity and precocity of phase change was moderate at 14 months (Type B $rg = 0.56$ and 0.67 , respectively) and low at 21 months (Type B $rg = 0.90$ and 0.86 , respectively). Based on these parameters, the main selection criterion currently used, both in the selection of parents for controlled pollination and candidates for cloning, is the proportion of adult foliage at 21 months. Currently, the capture and multiplication of clones is underway, both from intraspecific crosses and from interspecific crosses with *E. grandis*, and the incorporation of Genomic Selection is in process through the development and validation of selection models for the characteristics of interest.

Applications of nuclear technologies in conservation and forest genetic improvement under a climate change scenario

Patricio Rojas¹, Paulina Aguirre², Oscar Duran², Adriana Nario², Ethel Velasquez², Daniel Villegas², Jorge Gonzalez¹

¹INFOR, SANTIAGO, Chile; ²CCHEN, SANTIAGO, Chile (parojas@infor.cl; paulina.aguirre@cchen.cl; oscar.duran@cchen.cl; adriana.nario@cchen.cl; ethel.velasquez@cchen.cl; eldanvillegas@gmail.com; jgonzalez@infor.cl)

Chilean forestry sector represents 2.1% of GDP and is the third industrial sector for export (US \$ 5,271 million), after copper mining and agricultural and food sector. The forest area of native forest is 13.4 million hectares and plantations (*Pinus*, *Eucalyptus*, others) reaches 2.4 million hectares. Recent research shows that climate change is altering the distribution of forest species, growth rates, susceptibility to insects and fungi, causing mortality of trees (*Araucaria araucana*) because of decrease in rainfall and increase in temperatures in last decade. Application of gamma rays in agricultural crops has generated enormous economic benefits and better living standards in the world, however there are few global experiences of application of in forest species. There is a challenge to generate new genotypes that does not exist in nature through mutagenesis to reforest with more adapted species to climate change, like more drought tolerant and resistant to pests and diseases. Chile has nuclear reactors (CCHEN) and advanced tree improvement programs (INFOR) for propagation of trees by seeds, clones and micro propagation. However, for the selection of short-term valuable M1 mutants equipment for assisted selection by molecular markers (DNA) will be required. In the first phase dosimetry in sublethal doses will be determined to improve germination on *Peumus boldus* and rooting of *Eucalyptus nitens* and hybrids clones. In later stage, protocols will be developed for genotypic screening based in Next-Generation Sequencing (NGS) for mutations targeted discovery species and Genome-Wide Association Study (GWAS) in species where genetic information is lacking.

Genetics, epigenetics and metabolomics of *taxus baccata* for the selection of antineoplastic taxol/taxane-producing plant material in Greece

Filippos Aravanopoulos¹, Evangelia Avramidou¹, Aliko Xanthopoulou¹, Eleftheria Dalmaris¹

¹Aristotle University, Thessaloniki, Greece (aravanop@for.auth.gr; aevaggelia@yahoo.com; aliko.xanthopoulou@gmail.com; edalmaris@gmail.com)

The demand for taxol a promising cancer chemotherapeutic agent exceeds supply, hence expanding its potential sources to the European yew species *Taxus baccata*. Natural marginal populations, especially at the xerothermic edge where stresses are more frequent and profound, may possess particular gene complexes reflected in the quantitative and qualitative profile of European yew taxol. We study the distribution and magnitude of genetic and non-genetic sources of variation in taxol content marginal south-eastern natural populations of *T. baccata* in Greece. The goals of this study are: to develop taxol plantations that would contribute to the supply of an important antineoplastic agent, to increase the quantity and quality of produced taxol by applying methods of classical and molecular breeding, and to provide genetic conservation guidelines for natural populations. Demographic data were recorded and needles from genetically isolated natural populations (30 trees per population) were collected for genetic (SSRs; 14 primers), epigenetic (MSAP; EcoRI rare cutter, HpaII and MspI frequent cutters) and metabolomic (LC-MS/MSMRM; taxol, taxanes, alkaloids, phenolic profile) analyses. Preliminary data demonstrate that height, diameter and volume index distribution curves in the natural populations are not generally normal, while effective population sizes are generally low ($N_e < 30$). Results are examined against the available literature for *T. baccata*, *T. brevifolia* and *T. canadensis*. To the best of our knowledge, this is the first study using Greek populations and the first study that combines genetic, epigenetic and metabolomic analyses in *Taxus* worldwide. This work is funded by project NSRF5004922/TAXOL-GR

Genomic prediction of complex traits: genomics and quantitative genetics converge to innovate *Eucalyptus* breeding in Brazil

Dario Grattapaglia^{1,2}, Rafael Resende^{1,3}, Barbara Müller⁴, Bruno Lima⁵, Biyue Tan⁶, Elizabete Takahashi⁷, Regiane Estopa⁸, Carla Garcia⁹, Leonardo Rosse¹⁰, Orzenil Silva-Junior¹

¹Embrapa Recursos Genéticos e Biotecnologia, Brasília, Brasil; ²Universidade Católica de Brasília Brasília Brasil; ³Universidade Federal de Goiás Goiania Brasil; ⁴University of Florida, Gainesville, USA; ⁵Fibria Celulose, Jacareí, Brasil; ⁶Stora Enso AB, Nacka, Sweden; ⁷Cenibra Celulose, Ipatinga, Brasil; ⁸Klabin S.A., Telemaco Borba, Brasil; ⁹Veracel Celulose S.A., Eunápolis, Brasil; ¹⁰Eldorado Brasil Celulose, Três Lagoas, Brasil (dario.grattapaglia@embrapa.br; rafael.tassinari@gmail.com; mullerbsf@gmail.com; bruno.lima@fibria.com.br; biyue.tan@storaenso.com; elizabete.takahashi@cenibra.com.br; restopa@klabin.com.br; carla.garcia@veracel.com.br; leonardo.rosse@eldoradobrasil.com.br; orzenil.silva@embrapa.br)

Genetically improved seeds or clonal stocks have been successfully delivered by systematic tree breeding, but several challenges remain. Long life cycles, late flowering, poor juvenile-mature correlations and changes in market demands and climate, frequently make the progress of tree breeding slow and uncertain. Following the largely fruitless attempts to develop MAS (Marker Assisted Selection) for forest trees, based on the unrealistic concept of dissecting a complex trait in its individual components, the convergence of high-throughput genomics and quantitative genetics has established the paradigm of genomic prediction of breeding values as a way to accelerate breeding of complex traits. Additionally, the adoption of realized genomic relationships, provide innovations in breeding approaches and genetic parameters' estimation by accounting for the random Mendelian segregation in pedigrees. Using the *Eucalyptus* genome sequence we developed a breeder-friendly and cost-effective SNP genotyping "chip" that provides high-density genotyping for eucalypts. Using this platform in several breeding programs in Brazil, we have shown that genomic selection (GS) matches the accuracy of phenotypic selection for growth and wood traits, nevertheless enhancing the rate of genetic gain by increasing selection intensity, radically reducing generation interval and improving the accuracy of breeding values. Yet, predictive abilities are impacted by GxE interaction and driven mainly by relatedness, such that population-specific predictive models are necessary. We are on the brink of adopting GS in operational eucalypt breeding in Brazil. Strategic and logistics aspects for the adoption of GS are now the challenges to fully integrate this new breeding technology into routine tree improvement.

The *Eucalyptus* SNP array initiative: second-generation SNP arrays for low-cost operational genomic selection and very high-density genotyping for advanced genomic and breeding applications

Orzenil Silva-Junior¹, Rafael Tassinari², Dario Grattapaglia¹

¹Embrapa Recursos Genéticos e Biotecnologia, Brasília, Brasil; ²Universidade Federal de Goiás, Goiânia, Brasil (orzenil.silva@embrapa.br; rafael.tassinari@gmail.com; dario.grattapaglia@embrapa.br)

Following the development and worldwide adoption of the *Eucalyptus* EuCHIP60K SNP, we have now advanced a new initiative to build second-generation SNP arrays. The objective of the ESAI (Eucalyptus SNP Arrays Initiative) was to provide an improved performance 65k SNP genotyping array with wider applicability and significantly lower cost for operational genomic selection and a very high-density (HD) array with 500,000 to 1,000,000 SNPs for advanced genomic investigation and breeding applications. The new arrays were developed on the Axiom myDesign technology platform and provide a larger number of SNPs than the previous chip. A total of 1.3 million SNPs with coordinates to *Eucalyptus grandis* genome sequence assembly v2.0 were screened bioinformatically, including previously validated SNPs and a large set of newly discovered ones from new sequencing data for *Eucalyptus* species of subgenus *Symphomyrtus* and genus *Corymbia*. This screening was carried out with 960 samples, including germplasm sources of 18 *Eucalyptus* and 3 *Corymbia* species contributed by the 17 ESAI participating organizations, allowing selection of an optimized set of SNPs. The newly developed ESAI65K SNP array includes a set of ~10,000 SNP for *Corymbia*, a set of cpDNA SNPs for inferring maternal lineages and a set of SNPs making the previous SNP chip data fully portable to this new one. The ESAIHD array with > 500,000 SNPs was used to genotype parents of breeding populations, subsequently allowing SNP imputation to high-density for offspring individuals genotyped with the ESAI65K to improve accuracy and longevity of prediction models along generations of genomic selection.

Cooperative research effort for the production of pine solid wood and resin in Brazil

Ananda Virginia de Aguiar¹, Jarbas Y. Shimizu², Edilson Batista Oliveira¹, Valderês Aparecida Sousa¹, Carlos Mendes³, Gilson Geronasso⁴, Mauro Murara Junior⁵
¹Embrapa Florestas, Colombo, Brasil; ²Autonomo, Curitiba, Brasil; ³Associação Paranaense de Empresas de Base Florestal, Curitiba, Brasil; ⁴Empresa Remasa, Bituruna, Brasil; ⁵Associação Catarinense de Empresas Florestais, Lages, Brasil (ananda.aguiar@embrapa.br; shimizu@jy@gmail.com; edilson.oliveira@embrapa.br; valderes.sousa@embrapa.br; carlosmendes@apreflorestas.com.br; gilson@remasa.com.br; mauro.murara@acr.org.br)

Companies working with pines in the solid wood and resin segments in Brazil highlight scientific developments in the areas of gene conservation, genetic improvement and silviculture as basic priorities. However, the required long term research activities in forestry are costly and companies usually face budgetary and structural limitations. High investments are necessary and routine activities are complex, involving procurement of genetic material, specialized personnel, laboratory facilities and establishment and maintenance of both short- and long-term field experiments. In a quest to reduce costs and optimize efficiency in the implementation of research with support from Embrapa Florestas, forest companies associated with APRE (Associação Paranaense de Empresas de Base Florestal) and ACR (Associação Catarinense de Empresas Florestais) set up PCMP (Projeto Cooperativo de Melhoramento de Pinus), a cooperative project for the improvement of pines, and Funpinus (Fundo Cooperativo para Melhoramento de Pinus), a cooperative fund for the improvement of pines. Funpinus provides the administrative structure and financial organization for the implementation of PCMP. The cooperative currently has ten associated companies (resin and solid wood production) from the states of Santa Catarina, São Paulo, and Paraná. The objective of PCMP is to focus efforts on the development of improved pine genetic material, including interspecific hybrids to meet growing demands for high-quality raw material and higher productive efficiency. The PCMP began operations in 2017, with the basic premise to offer an addition to the work developed by individual companies, so that independence and autonomy of each participant company's particular work is honored.

B2d: WOOD AND TREE-RING STUDIES OF FOREST ADAPTATION TO CLIMATE CHANGE; IMPLICATIONS FOR WOOD PRODUCTION

Functional role of *Eucalyptus* wood in terms of drought resistance traits: trends at interspecific and intraspecific levels

Multispecies surveys have showed that there is a weak but significant tradeoff between xylem efficiency and safety in woody species, and that there are no species occupying the space with high efficiency and high safety. Large vessels and tracheids result in high vulnerability to xylem cavitation (VC) due to tension. Moreover, relationships between xylem structure and function are studied mostly at the interspecific level, with few studies considering the relationships at the intraspecific level, particularly in angiosperms. Recent studies in *Quercus* species, finding opposite trends in wood anatomy-function relationships considering the interspecies and the intraspecific levels, raises the question about the value of multispecies studies to shed light over what is adaptive within a given species. *Eucalyptus* species share with *Quercus* a xylem anatomy composed by solitary vessels surrounded and connected to imperforate tracheary cells and parenchyma, a type of wood anatomy which is poorly understood in functional terms. Contrary to results in that genus, our results in four *Eucalyptus* species revealed that the trends observed between vessel size (mean and distribution) and VC are similar at the interspecific and intraspecific (*E. globulus*) levels. No tradeoff was observed between xylem efficiency and safety: the largest the vessels, the lower the VC. The amount of cells around different size-vessels could be involved in this phenomenon. Trends observed in this important forestry genus challenge what we already know about xylem anatomy and function, and may help to widen our vision about the role of wood in adaptation to drought stress.

Wood anatomical traits reveal water constraints on black spruce xylem formation in the Boreal ecosystem

Paulina Puchi¹, Daniele Castagneri², Sergio Rossi³, Marco Carrer¹

¹Università degli Studi di Padova, Padova, Italy; ²Swiss Federal Research Institute, Birmensdorf, Switzerland; ³Université du Québec à Chicoutimi, Chicoutimi, Canada (paulinafernanda.puchigonzalet@phd.unipd.it; daniele.castagneri@unipd.it; sergio_rossi@uqac.ca; marco.carrer@unipd.it)

One of the most evident effects of the rapid warming occurring recently in cold and high-latitude forests is the lengthening of the growing season, with the concurrent extension of the period of wood formation. In addition, the increase of evapotranspiration demand is starting to induce drought-stress conditions. By selecting the same black spruce (*Picea mariana*) trees (20 trees in 4 sites along a latitudinal gradient in Quebec, Canada) where xylogenesis analyses were performed in the last years, we investigated long-term series of wood anatomical traits and compare them to previous short-term findings. Time series of wood anatomical traits were correlated to chronologies of daily temperature, VPD and precipitation during the period 1936-2010. In all sites, tracheid area correlated negatively with June-September temperature and VPD, and positively with precipitation. Meanwhile, cell-wall thickness and the number of cells per ring in the northernmost site were positively affected by spring and summer temperature. While previous monitoring studies evidenced temperature as the key climate variable influencing the timing of xylogenesis phases, our results show that water availability plays a central role in shaping xylem cell features in boreal black spruce. This stresses the importance of an integrate approach to better understand the relationships between wood formation and climate variability at both intra-annual and long (decadal) time scales. This approach will hopefully reduce the uncertainties and skewed interpretations of models on how boreal forest will perform in the future.

Impact of drought on *Eucalyptus* wood chemistry by near infrared hyperspectral imaging

Gilles Chaix^{1,2}, Mariana Pires Franco², Roger Chambi Legoas², Nathalie Gorretta³, Celio Pasquini⁴, Cristiane Vidal⁴, Jean-Michel Roger³, Mario Tomazello-Filho²

¹Cirad, Montpellier Cedex, France; ²Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ³IRSTEA, Montpellier, France; ⁴Universidade Estadual de Campinas, Campinas, Brasil (gilles.chaix@cirad.fr; ma.pires@hotmail.com; rogerchl86@hotmail.com; nathalie.gorretta@irstea.com; pasquini@iqm.unicamp.br; cristiane.vidal@iqm.unicamp.br; jean-michel.roger@irstea.fr; mtomazel@usp.br)

The aim is to study tree development submitted to different water and mineral constraints. The objective is to correlate spatial distribution of wood chemistry with wood density, secondary growth. We sampled wood discs from 54 trees in rainfall exclusion design with *Eucalyptus grandis* at Esalq-USP, Itatinga Station, Brazil. We felled the 5 years old trees growing under different water availability. For each disk, we acquired an image with a near infrared (nir) hyperspectral camera (hsi, specim, pixel size 625 x 625µm). The challenge here was to transfer our previous nir calibrations for total extractives built with a benchtop spectrometer (vector, bruker) to a hsi camera by using standard sample set measured on the two devices. An efficient model were built for the hsi camera with a prediction error of 10.3% compared to the prediction error of 11.6% for our previous calibration with benchtop spectrometer. Then, based on spectra from his image, we predicted extractive contents and built images. These allow us to compare their spatial distributions according to the growth conditions. In the absence or absence of fertilization, trees with higher water stress showed a higher heterogeneous distribution, from pith to bark, for the total extractive contents and a higher average mean value. In perspective, these data will allow us to study and refine the knowledge on cambium activity according to climatic variations by crossing variability of the chemical properties, x-ray micro-density and anatomy of wood, and diameter growth rate measured by electronic dendrometers.

Spatial variation of wood density for *Eucalyptus grandis* by near infrared hyperspectral imaging combined with X-ray analysis

Roger Chambi-Legoas¹ , Mario Tomazello-Filho², Nathalie Gorretta³, Celio Pasquini⁴, Cristiane Vidal⁴, Jean-Michel Roger³, Gilles Chaix^{3,6}

¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Departamento de Ciências Florestais, Montpellier, Brazil; ²Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ³IRSTEA, UMR ITAP, Montpellier, France; ⁴UNICAMP, Department of Analytical Chemistry, Campinas, Brasil; ⁵CIRAD, UMR AGAP, Univ Montpellier, INRA, Montpellier SupAgro, Montpellier, France; ⁶Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil (rogerchl@usp.br; mtomazel@usp.br; gilles.chaix@cirad.fr; gilles.chaix@cirad.fr; cristiane.vidal@iqm.unicamp.br; gilles.chaix@cirad.fr)

Most near-infrared spectroscopy (NIRS) studies for wood density use multiple spectral acquisitions taken manually at several points from pith to bark. Recently the use of near-infrared hyperspectral imaging (NIR- HSI) has shown good performance in predictions of wood properties, allowing build high spatial resolution predictive images. The combined use of NIR- HSI and X-ray microdensity imaging (X-ray MDI) could be more practical for evaluation of spatial variation of wood density. The aim was to develop a wood density calibration model for NIR- HSI (625 μm pixel size) from X-ray MDI (30 μm pixel size) and evaluate the spatial variation of wood density along stem cross-section in *Eucalyptus grandis* trees. Wood discs were collected from 18 trees of 6 years old, submitted to two different water availability, located in São Paulo, Brazil. The challenge here was to match the pixels of X-ray MDI to pixels of NIR- HSI (in 2 mm width radial region) to transfer accurate values of wood density to each pixel of NIR- HSI. The R^2 of the model was 0.72, while the root mean squared error was and $4.8 \times 10^{-2} \text{ g cm}^{-3}$ for the validation group. The prediction model allows comparing their spatial distributions according to the growth conditions. Trees with higher water stress showed higher wood density. Treatments showed a similar spatial variation of wood density, increasing from pith to bark. In perspective, these data will allow evaluating the spatial distribution of wood density inter and intra-tree rings in relation to meteorological variability.

A novel approach to understanding the formation of tree rings in tropical species by analyzing traces of elements

Daigard Ricardo Ortega Rodriguez¹, Luiz Santini¹, Hudson Carvalho², Mario Tomazello-Filho¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ²Universidade de São Paulo, CENA, Piracicaba, Brasil (dai.ricardo.or@gmail.com; luizsantini82@gmail.com; hudson@cena.usp.br; mtomazel@usp.br)

After the initial division of the cambium and tree-ring formation, derivative cells are subject to cell expansion and secondary wall deposition. In this process, different chemical elements are allocated and translocated as part of tree metabolism and physiology. Both anatomical and chemical events, vary among the xylem cells according to their transport or storage functions. Here we analyze the anatomical and chemical pattern at the intra and inter ring level of two tropical species extensively used for dendrochronological studies, *Cedrella fissilis* and *Hymenaea coubaril*. The samples were them cut transversely (1.5 mm, thickness) with a parallel double circular saw for chemical analysis by X-ray fluorescence. And the rest of wood samples were used to prepare histological slides to evaluate the microscopic anatomical structure. Simultaneous multielemental and anatomical evaluation for each species-wood sample at different positions (five rings close to pith, in the sapwood and heartwood transition and close to bark) were performed. Elements such as Ca and K stood out in both samples. The highest K presence are observed in the developing xylem (rings close to the bark). While the highest Ca presence were found near to the pith. Furthermore, both elements were observed related to parenchymatic tissue. Elements content differences were observed between the rings of sapwood and heartwood. Altogether, this work shows interesting clues to understand the tree-physiology based on element traces related to their anatomical structures.

A simple and new method for enhance tree-ring visualization using fluorescence

Milena Godoy-Veiga¹, Paula Alecio¹, Gregório Ceccantini¹, Marcos Buckeridge¹, Giuliano Locosselli¹

¹Universidade de São Paulo, Institute of Biosciences, São Paulo, Brasil (milena.gveiga@gmail.com; pcalecio@gmail.com; gregorio@usp.br; msbuckeridge@gmail.com; locosselli@yahoo.com.br)

Tropical forests harbor about 50.000 tree species, out of which only few hundreds are used for dendrochronological purposes. One of the reasons is because only few species are known to produce annual tree rings. The other reason is the proportional diversity of wood anatomy that may result in less than clear tree-ring boundaries. In order to improve tree-ring visualization we evaluated the suitability of using fluorescence to enhance the contrast among wood cells. We tested three sets of fluorescence filters: GFP (green fluorescent protein), RFP (red fluorescent protein) and UV and compared with visualization under natural light. Overall, fluorescence enhanced the contrast among fibres, parenchyma and vessels on different tree species improving tree-ring visualization. For a few species tree-ring boundaries were highlighted by the presence of fibrous zones, by the presence of parenchyma bands, by presence of early-wood large vessels and/or narrow late-wood vessels, or by highlighting the content of secretory canals. For species known to have clear tree ring boundaries, fluorescence may aid visualization of false tree-rings. We also found this technique suitable for qualitative and quantitative wood anatomy studies. Therefore, tropical dendrochronologists may find this method useful for tree-ring counting, cross-dating and to expand the available set of species suitable for tree-ring investigations.

Geographical patterns and drivers of regeneration and growth dynamics of *Quercus variabilis*

Gao Wen-Qiang¹, Lei Xiang-Dong¹

¹Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Key Laboratory of Forest Management and Growth Modelling, State Forestry and Grassland Administration, Beijing, China (gwq9975@ifrit.ac.cn; xldlei@ifrit.ac.cn)

Impending climate warming is expected to influence plant regeneration, growth and distribution ranges. However, synchronous comparisons of regeneration and growth dynamics associated with biotic factors across latitudinal, longitudinal and altitudinal gradients at a single species' level have received little attention. In the present study, we investigated regeneration (seedling and sapling) and growth variations (radial and height growth) of *Quercus variabilis* along latitudinal, longitudinal and altitudinal gradients; meanwhile, the effects of environmental factors (climate, soil and stand conditions) on regeneration and growth across the three geographical gradients were ranked and apportioned using linear mixed-effects models. Our results indicated that the regeneration of Chinese cork oak decreased from middle to the range limit, the radial growth of ringwood and latewood increased with latitude, and latewood and height growth decreased with longitude; furthermore, the growth sensitivity to climate were less in the southern and eastern populations than the northern and western. When pooling all sites' data, we found that climate variables were not solely decisive factors to drive the geographic variations in the regeneration and growth of *Q. variabilis*, stand conditions (stand density and total basal area) and soil properties (pH, Ca, Mg, N and N/P) also played important roles in shaping large geographical patterns of the oak regeneration and growth.

B2f: WOOD AND TREE-RING STUDIES OF FOREST ADAPTATION TO CLIMATE CHANGE; IMPLICATIONS FOR WOOD PRODUCTION - 1

The relationships between functional, adaptive, and technological characteristics of cypress wood from the Cordillera / Relaciones entre caracteres funcionales, adaptativos y tecnológicos de la madera en ciprés de la cordillera

Eventos de mortalidad han sido registrados en los bosques de ciprés de la cordillera (*Austrocedrus chilensis*), una conífera endémica cuya distribución abarca un marcado gradiente ambiental. Estudios recientes asocian los eventos de mortalidad a decaimientos previo del crecimiento, coincidiendo con eventos extremos de calor y sequía, los cuales son cada vez más recurrentes en el marco del cambio climático. Dado los múltiples procesos biológicos en los cuales la madera se encuentra involucrada, ciertas propiedades determinantes de la calidad de la madera para usos sólidos, pueden ser utilizadas para estudiar el potencial de adaptación de los árboles a eventos de estrés abióticos. El presente estudio propone un abordaje interdisciplinario del análisis conjunto de las propiedades físicas, mecánicas, hidráulicas y de la dinámica de formación de la madera, a lo largo del área de distribución natural de la especie. Perfiles de microdensidad permitieron establecer diferencias significativas de crecimiento y densidad entre árboles vivos y muertos. El estudio de los mecanismos de respuesta a la sequía permitió relacionar los ajustes funcionales con las condiciones ecológicas. El estudio de la dinámica de la formación de la madera, mediante el empleo de dendrómetros, permitió determinar como el clima afecta el crecimiento. Métodos sónicos permitieron determinar la aptitud tecnológica de la madera para usos estructurales. El análisis conjunto de los resultados permitirá determinar la existencia de un compromiso entre las propiedades físicas y función biológica, que condicione la producción de madera y el potencial de adaptación al estrés abiótico en el marco del cambio climático.

Shoots length growth dynamics and dendroclimatology of dwarf shrubs in treeline of Eastern Carpathians

Ionel Popa¹, Anca Semeniac¹, Mihai Balabasciuc¹

¹National Institute for Research and Development in Forestry Marin Dracea, Campulung Moldovenesc, Romania (popaic@gmail.com; semeniac@yahoo.ro; mihaibalabasciuc@yahoo.ro)

High altitude mountain ecosystems are ones of the most vulnerable and sensitive to climate change effects. In high mountain ecosystems, the trees and dwarf shrubs growth is assumed to be limited by temperature, and most scientists expect a significant increase of growth due to recent and future warming. The main aim of this study is to fill the gaps on data and knowledge about the response of dwarf shrubs growth (tree ring and shoots length) to climate from ecotone of Carpathians region. To highlight the shoots length growth dynamics and dendroclimatic patterns, six dwarf shrubs species and two slope aspects (sunny and shade) in two high altitude location from Eastern Carpathians (Romania) were analysed and monitored weekly in 2018 and 2019, during the growing season. The results reveal a differentiation at species and slope aspects level in the dynamics of the growth processes in shoots length and phenophases. A 5-10-day delay was observed between the shaded slopes compared to the sunny ones on the dynamics of the shoot length growth phenology. The length of the shoot length growing season varies from species to species, ranging from 60 to 90 days. Generally, the maximum length is observed on the sunny slope 70-90 days, and the minimum on the shaded 60-70 days. The general dendroclimatic pattern of climate-growth (radial growth and shoots length) relationship is characterised by a positive and significant influence of the summer temperature, but species specific.

Analysis of growth rings in *Bulnesia sarmientoi* Lorentz ex Griseb in its climate gradient in Argentina / Análisis de anillos de crecimiento de *Bulnesia sarmientoi* Lorentz ex Griseb, en su gradiente climático en Argentina.

Vanina Chifarelli¹, María Senilliani¹, Natalia Bonel², Erwin Bartel¹, Juana Moglia¹, Ana Gimenez¹

¹Universidad Nacional de Santiago del Estero, Santiago del Estero, Argentina; ²Servicio Meteorológico Nacional, Buenos Aires, Argentina (vaninachifarelli@yahoo.com.ar; senilliani@yahoo.com.ar; nataliabonel@gmail.com; matiasbartel@yahoo.com.ar; vimog@unse.edu.ar; amig@unse.edu.ar)

Esta investigación busca determinar el crecimiento de la especie y si hay diferencia entre sitios donde se distribuye, ya que la especie *Bulnesia sarmientoi* Lorentz ex Griseb. (Zigophyllaceae) presenta un área de distribución restringida en la región norte de Argentina. Esta especie está incluida en el apéndice II Convención Internacional de Tráfico de Especies Amenazadas de Fauna y Flora Silvestres, incluye especies que, aunque no se encuentran necesariamente en peligro de extinción están amenazadas. El trabajo pretende determinar el crecimiento en función de la edad, la evolución del incremento radial (IR), estimar el incremento medio (IMA) y anual (IA), con la finalidad luego de establecer la relación entre los espesores de anillos por sitio. El estudio se realizó en tres provincias Formosa (Las Lomitas e Ingeniero Juárez), Salta (Rivadavia) y Chaco (las Hacheras), abarcando un amplio gradiente climático. Se estudiaron 35 individuos, de posición sociológica dominantes, buen estado sanitario. La marcación y medición de anillos se efectuó con el programa Image-Pro-Plus. Los datos se analizaron con el software estadístico INFOSTAT. El espesor promedio de anillos determinado fue 3.03 mm. El incremento medio anual en Las Hacheras y Las Lomitas es mayor que en los demás sitios.

Ecological adaptations of endemic trees from two biodiverse hotspots of India

Deepa Bisht¹, Sangeeta Gupta¹

¹Forest Research Institute, Dehradun, India (deejyala@gmail.com; sangeeta.fri@gmail.com)

The variations in climatic conditions of India has made it one of the most biodiverse regions in the world with four biodiversity hotspots viz. The Eastern Himalayas, Indo-Burma, Western Ghats & Sri Lanka and Sundaland. These biogeographical regions are well-known for high level of endemism and have

cultural, socio-economic and ecological roles. Several sacred groves are also documented in these areas. They provide various ecosystem services and serve as life supporting system of native communities. The present study was carried out to elucidate the adaptive responses of trees in two tropical hotspots of India: Western Ghats and North-Eastern region (Indo-Burma). The wood microstructure of selected endemic trees was examined as per the IAWA terminology. The study reflected variations and similarities in wood microstructure, especially, vessel characters for the successful establishment of different taxa. Values of hydraulic conductivity based on vessel dimensions reflected the efficiency of water transport while values of mesomorphy and vulnerability indices represented the ecological adaptations of different trees. The study further depicted that the adaptation was governed by water transport efficiency and drought resistance or hydraulic safety supported by the negative relationship between vessel diameter and vessel frequency.

Radial growth response to climate change of populations of *Pinus halepensis* Mill., *Pinus pinea* L. and *Pinus canariensis* C.Sm. ex DC in the Collserola Natural Park (Barcelona)

Jorge Santiago Garate Quispe^{1,2} , Cristina Valeriano², Emilia Gutiérrez²

¹Departamento Académico de Ingeniería Forestal, Universidad Nacional Amazónica de Madre de Dios-UNAMAD, Av. Jorge Chavez 1160, 17001 Puerto Maldonado, Peru; ²Dept. Biología Evolutiva, Ecología i Ciències Ambientals, Universitat de Barcelona, Av. Diagonal 643, 08028 Barcelona, Spain (jgarate@unamad.edu.pe; cristinavaleriano@ub.edu; emgutierrez@ub.edu)

Increasing temperatures, hotter and more frequent droughts and climate variability in western Mediterranean Basin are causing tree dieback episodes, high mortality rates and reduction in tree recruitment in southeastern Spain. The forests of two of the most drought resistant Mediterranean species, *Pinus halepensis* and *Pinus pinea*, do show forest die-off. The aim of this study was to evaluate tree growth trends of *P. halepensis*, *P. pinea* and *Pinus canariensis* populations in the Natural Park of Collserola (Barcelona) located in the Northeast of Spain. We also analyze the effect of climate on radial growth of these species and the trend and proportions of the late-wood and early-wood growth. The results show that only *P. canariensis* increased its basal area, while *P. pinea* and *P. halepensis* show a significant growth decrease since 1970. In all tree species, precipitation showed a positive effect while the effect of temperatures is mainly negative; growth was limited by water stress early in spring and summer due to the lack of available water because of the joint effect of temperature and precipitation. All the three species show an increasing trend the latewood proportion, but it was not significant, although *P. pinea* showed a change in the trend of this ratio since 1950 affected by rising temperatures. Our results suggest that *P. canariensis* has got adapted to the Mediterranean climate and shows higher annual growth rates in basal area increment (BAI, cm²/year) and its response to climate is similar to *P. pinea* and *P. halepensis* in Collserola.

Formation of growth rings, radial increment, and the relationship between growth and climate: assessing two potential species used in projects to restore the Atlantic Forest / Formação dos anéis de crescimento, incremento radial e relação crescimento-clima: avaliando duas espécies potenciais usadas em projetos de restauração da Mata Atlântica

Rafael P. Albuquerque¹, Arno F. N. Brandes², Claudio S. Lisi³, Luiz Fernando Duarte de Moraes⁴, Claudia Franca Barros¹

¹Instituto de Pesquisas Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brasil; ²Universidade Federal Fluminense, Niterói, Brasil; ³Universidade Federal de Sergipe, Aracaju, Brasil; ⁴Embrapa Agrobiologia, Seropédica, Brasil (albuquerque.perpetuo@gmail.com; arnofritz@id.uff.br; clcslisi@gmail.com; luiz.moraes@embrapa.br; claudiafrancabarros@gmail.com)

Avaliar projetos de restauração de áreas degradadas é um passo importante na conservação de biomas ameaçados como a Mata Atlântica. Através da dendrocronologia é possível investigar as dinâmicas de crescimento de espécies usadas em plantios de restauração e indicar espécies potenciais para estudos posteriores. O objetivo do presente trabalho foi estudar a formação dos anéis de crescimento, as tendências de crescimento radial e a relação crescimento-clima de *Pseudobombax grandiflorum* (Cav.) A. Robyns and *Citharexylum myrianthum* Cham. em remanescentes de Mata Atlântica e plantios para restauração na Rebio de Poço das Antas, Rio de Janeiro, Brasil. Para entender a periodicidade de formação dos anéis de crescimento, foram realizados experimentos de lesão no câmbio vascular e análises microscópicas diretas do câmbio e dos tecidos adjacentes. A largura dos anéis de crescimento foram usadas para investigar o incremento radial das espécies e para construir cronologias. Foi observado que o crescimento radial de ambas as espécies ocorre durante as estações chuvosas e de transição, passando por um período de dormência cambial na estação seca. A relação entre crescimento radial e chuva foi reforçada ao observar que as cronologias da largura dos anéis de crescimento possuem correlação positiva com a precipitação, no entanto, as espécies respondem a precipitação em períodos diferentes do ano. As taxas e tendências de crescimento foram semelhantes nos plantios e nos remanescentes florestais, mostrando que a situação de plantio não afeta o crescimento potencial das espécies. Esse dado reforça o sucesso da restauração ecológica desenvolvida na Rebio de Poço das Antas.

Impacts of edge effects on the growth of an emergent tree species in a tropical forest fragment

Milena Godoy-Veiga¹, Gregório Ceccantini¹, Philipp Pitsch², Stefan Krotenthaler², Dieter Anhuf², Giuliano Locosselli¹

¹Universidade de São Paulo, Institute of Biosciences, São Paulo, Brasil; ²University of Passau, Department of Physical Geography, Passau, Germany (milena.gveiga@gmail.com; gregorio@usp.br; philipp.pitsch@uni-passau.de; gruenermann@googlemail.com; dieter.anhuf@uni-passau.de; locosselli@yahoo.com.br)

Climate change and deforestation are affecting trees worldwide. Intensive deforestation in tropical regions is raising fragmentation to alarming levels, leading to losses of forest area. Abiotic and biotic changes on forest edge areas alter the development of the remaining trees. We aimed to evaluate the effects of forest fragmentation on the growth of the emergent tree species *Aspidosperma polyneuron* (Apocynaceae) at forest edge and interior in the endangered Brazilian Atlantic Forest. We sampled increment cores of each tree along with their current levels of liana infestation and data about tree and surrounding canopy heights. We used tree-ring analyses to estimate age and growth rate of trees. Both sampled trees and surrounding canopy were taller at the forest interior than at the edge. Nonetheless, trees DBH and age were similar between forest interior and edge. Trees at forest interior display lifetime growth trends common to shade-tolerant species, with a peak of growth rate at 120 years. Such growth trends are shared by all trees before fragmentation. However, growth rates are constantly slow for all diameter classes after fragmentation. The dominance of lianas at forest edge prevents trees from experiencing the expected growth releases during life, probably by keeping the leaves of *A. polyneuron* under conditions similar to the forest understory. Therefore, the management of lianas at the forest edge is an effective procedure to promote the growth of emergent trees, guarantying their role on forests structure, carbon storage, and ecosystem functioning

B2p: ABIOTIC STRESSORS AND THEIR INTERACTIVE IMPACTS ON FORESTS

Centenarian Brazilian pines may enter into decline due to climate change effect

Alvaro Bosen de Castro Faria¹, Fagner Goes Conceição¹, Solon Jonas Longhi¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (alvarob@utfpr.edu.br; fagnerconceicao@utfpr.edu.br; longhi.solon@gmail.com)

Forest health needs to be considered in the in situ conservation strategies for *Araucaria angustifolia*, and climate changes anomalies may be influencing drought-induced tree mortality in the mature trees, with low recovery power. We present a phytosanitary assessment for a native forest in Palmas (State of Paraná), with centenarian trees, for future comparisons over the dead ones. It was verified the behavior of meteorological variables between 2008 and 2018. The data series were organized by ANOVA and by average tests. A Grouping Analysis was performed, using the Euclidean distance as a similarity pattern, obtaining the groups. A Principal Component Analysis was performed to order the variables. The changes reported here were for the winter months, where in southern Brazil, rainfall is mainly caused by the interaction between the polar air masses, with the continental masses conditioned to ENSO events. The changes were cyclical and standards were verified. Air heat and dryness needs long-term monitoring for climatic warming statement, but, it was verified that overconcentrated rainfall in short periods may have influenced the devitalization and conditioned trees to wilt by dryness, due to hydraulic failure, which would increase mortality in the long term. There are indications that 2009 and 2015 winters were stressful to the Brazilian pine, due to the irregular distribution of the rains and the droughts periods. Still, that a next prolonged drought could be verified until the winter of 2021.

Is climate change adaptation in alpine mountain forests constrained by forest seed production and its climatic triggers?

Katharina Lapin¹, Martin Braun², Peter Schwarzbauer^{2,3}, Theo Koller³, Franziska Hesser³, Christoph Dobeš¹, Silvio Schueler¹

¹Federal Research and Training Centre for Forests, Natural Hazards and Landscape, Vienna, Austria; ²Institute of Marketing & Innovation, Department of Economics and Social Sciences, University of Natural Resources and Life Sciences, Vienna, Austria; ³Team for Market Analysis and Innovation Research, Wood K plus - Kompetenzzentrum Holz GmbH, Linz, Austria (katharina.lapin@bfw.gv.at; martin.braun@boku.ac.at; peter.schwarzbauer@boku.ac.at; theo.koller@boku.ac.at; franziska.hesser@boku.ac.at; christoph.dobes@bfw.gv.at; silvio.schueler@bfw.gv.at)

Climate change (CC) will considerably alter environmental conditions like temperature and precipitation patterns affecting Central European tree species, especially in alpine regions. To reduce CC-related risks for forests, the planting of different tree species and provenances better adapted to the expected climate has been suggested. However, the amount of seeds produced by temperate tree species varies between years and depends on numerous factors including site and weather conditions during and preceding the year of seed maturation. This study aims to identify the most important climate factors affecting variable seed production in order to estimate the need for forest plantations of key tree species in Austria under different adaptation strategies. Historical data on mast seeding and seed harvest from 1960 to 2016 were collected and analyzed for the currently main tree species. The main climatic conditions and regimes affecting their reproductive features were determined and the occurrence of mast fruiting in each species clustered and mapped at the district level to allow the application of predictive models for all Austrian regions. The results show that the climatic variables affecting mast seeding vary between species and geographical areas and that elevation likewise influences seed production. A heterogeneous distribution of mast fruiting clusters was found for all key tree species. Forest seed producers and forest nurseries are key stakeholders for the implementation of adaptation measures to reliably meet forest seed & seedling demand. Results of this study can support the development of a transnational CC adaptation management strategy in Austria and Central Europe.

Responses of photosynthesis and component processes to temperature: are Mediterranean trees fit for climate change?

Dominik Sperlich¹, Chaoting Chang², Josep Penuelas³, Santi Sabaté⁴, Juan Carlos Zamora⁵

¹Albert-Ludwig University, Freiburg, Germany; ²CREAF, Barcelona, Spain; ³CSIC, Global Ecology Unit CREAF-CSIC-UAB, Cerdanyola del Valles, Spain; ⁴University of Barcelona, Barcelona, Spain; ⁵University of Freiburg, Freiburg, Germany (dominik.sperlich@ife.uni-freiburg.de; r91625045@gmail.com; josep.penuelas@uab.cat; santi.sabate@ub.edu; juan.zamora@ife.uni-freiburg.de)

Global warming is raising concerns about the acclimatory capacity of trees and forests, especially in Mediterranean-type ecosystems. The sensitivity of photosynthesis to temperature is a key uncertainty for projecting the magnitude of terrestrial feedbacks on future climate change. While boreal, temperate and tropical species have been comparatively well investigated less attention has been paid to the Mediterranean trees. We quantified seasonal changes in the responses of net photosynthesis (Anet), stomatal conductance (gs), mesophyll conductance (gm), and electron-transport rate (Jcf) and investigated their sensitivity to drought and thermal stress in sunlit and shaded leaves of *Quercus ilex*, *Q. pubescens*, *Pinus halepensis*, and *Arbutus unedo*. All four species showed a remarkably dynamic acclimation of Topt characterised by high thermal tolerance. Seasonal changes in Topt were consistent in all four species, whereas the shape of the response curves was highly species-specific. Surprisingly, severe drought decreased Topt (similar to winter) accompanied by narrower response curves above all in *P. halepensis*, reducing the optimal range for photosynthesis to the cooler morning/evening periods. In contrast, less strict stomatal control under severe drought led to leaf shedding in *Q. ilex* and *Q. pubescens* and additionally branch dieback in *A. unedo*. Water availability was thus a key factor, in addition to growth temperature to explain acclimation of photosynthetic responses to temperature. More frequent and severe drought periods as predicted by climate change may disrupt the acclimatory capacity of Mediterranean trees, which could lead to reduced growth and, for some species such as *A. unedo*, increased mortality risk.

Climate, genetic variability and natural distribution of yerba mate in Southern Brazil

Elenice Fritzsos¹, Marcos Silveira Wrege¹, Márcia Toffani Simão Soares¹, Ananda Virgínia de Aguiar¹, Valderês Aparecida de Sousa¹

¹Embrapa Florestas, Colombo, Brasil (elenice.fritzsos@embrapa.br; marcos.wrege@embrapa.br; marcia.toffani@embrapa.br; ananda.aguiar@embrapa.br; valderes.sousa@embrapa.br)

It is believed that very little of the genetic variability of yerba mate (*Ilex paraguariensis* S. T. Hill) is being explored in breeding programs and in commercial plantations. It is also believed that climate affects the phenotype of plants and models the genetic variation among populations. The aim of this work was to determine differences between specific climates where yerba mate naturally occurs in southern Brazil. A database of 195 natural occurrences of mate (one of the largest databases of yerba mate in Brazil) was set up. These data was applied to multivariate analysis, georeferencing and modelling. As a result, four climatic groups had being obtained using eleven climatic parameters in addition to altitude. Although these groups feature spatial geographic contiguity, it has being found that yerba mate occurs in several lithologic substrates, in different ecosystems (Mixed Ombrophylous Forest, Ombrophylous Dense Montana Forest, Deciduous and Semideciduous Seasonal Forest), and in Atlantic Forest biome and in Pampa biome. Such a distribution indicates great adaptive plasticity of

yerba mate, greater than those of *Araucaria*, a symbol species of the Mixed Ombrophilous Forest. The group located in the most temperate climate of Brazil was isolated from the others. This isolated group can be verified in genetic studies that aim to know whether the populations are also genetically different. The output of this study may be used to support further improvement in breeding and conservation of species programs, currently and future use, considering the climatic changes and the anthropic pressures.

Tree-ring and response to climate variability and carbon sequestration using dendrochronology in the Sahelian Agroforestry of Niger

Moussa Massaoudou¹, Larwanou Mahamane²

¹National institute for Agricultural Research, Maradi, Niger; ²International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Niamey, Niger (mmassaoudou13@gmail.com; larwanou, mahamane (icrisat-ne))

Agroforestry Parklands are the predominant agro-ecosystems in West Africa where *Prosopis africana* and *Faidherbia albida* are some of key species for rural population. While these trees are resistant to external stress, their growth and regeneration depend strongly on local conditions. Meanwhile, characterizing tree response to climate variability and carbon sequestration is limited in the Sahelian Agroforestry Parklands. This study was carried out in two agroforestry parklands in the South Central Niger and purports at characterizing the response to climate variability and carbon sequestration of *P. africana* and *F. albida* trees using modern dendrochronology methods. The methodological approach consisted of sampling discs using standard dendrochronology techniques, LINTAB 6 system for ring width measurements, COFFECHA and ASTAN for respectively crossdating and standardization of chronological series. There was no significant difference in mean ring-width between the two tree species ($P \geq 0.05$). However the dynamic of cambial growth varied with tree age for both species indicating strong influence of environmental factors. *P. africana* ($r1 = 0.50$) expresses more dependence on annual rainfall than *F. albida* ($r2 = 0.63$). There was a significant difference in carbon sequestration between the two species ($P \leq 0.05$). These results can guide policy makers in the choice of adapted species to climate variability and other anthropogenic pressures in the Sahelian belt of Niger.

Estimating the impact of climate change on Brazil's planted forests sector

Marluce Scarabello^{1,2}, Aline Soterroni^{1,3}, Marcia Zilli¹, Hugo Valin³, Aline Mosnier³, Florian Kraxner³, Fernando Ramos¹

¹Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil; ²Instituto de Pesquisa Econômica Aplicada, Brasília, Brasil; ³International Institute for Applied Systems Analysis, Vienna, Austria (mascarabello@gmail.com; soterr@iiasa.ac.at; marciatz@gmail.com; valin@iiasa.ac.at; mosnier@iiasa.ac.at; kraxner@iiasa.ac.at; fernando.ramos@inpe.br)

Brazil has 9.85 million hectares of planted forests, grown mainly in the South and Southeast regions. These forests have species of the genera *Eucalyptus* and *Pinus*, which represent 93% of the total. In 2017, 139.83 million cubic meters of log wood for paper, cellulose and other purposes were produced, with a production value of several billions of US dollars. However, projected advances of the planted forests sector in Brazil can be directly impacted by climate change and resulting biophysical effects. Here, we quantify these impacts using GLOBIOM-Brazil, a global bottom-up partial equilibrium model of competition for land use between agriculture, forestry, and bioenergy sectors, which includes various refinements reflecting Brazil's specificities. It computes consumption and trade for 30 regions of the world; and production and land use at a 50 km grid resolution in Brazil and 250 km in other regions for the most important crops, wood, and animal products. Land use change depends on the feedback between agricultural demand and biophysical and regulatory constraints on land. Climate change impacts are incorporated in the model by climate shocks on future crop, grass and biomass productivities as projected by Global Gridded Crop Growth Models simulated for five Global Climate Models (HadGEM-ES, MIROC-ESM-CHEM, IPSL-CM5A-LR, GFDL-ESM2M, NorESM1-M) and two climate change scenarios (RCP 2.6 and RCP 8.5). Simulations through the year 2050 indicate a slight decrease of the biomass of planted forests in all Brazilian biomes but the Pampa, where the conditions for planted forests are projected to improve.

Dry of Brazil nut trees at Resex Cajari: new evidence that climate anomalies are affecting Amazonian biodiversity

Marcelino Guedes¹, Dayane Pastana², Érica Modena³

¹Embrapa Amapá, Macapá, Brasil; ²Embrapa Amapá, CNPq, fellowship of scientific initiation, Macapá, Brasil; ³CAPES/FAPEAP, fellowship of post doctoral, Macapá, Brasil (marcelino.guedes@embrapa.br; dayanepastana@gmail.com; erimodena@yahoo.com.br)

The Brazil nut (*Bertholletia excelsa* Bonp.) is among the largest trees in the Amazon. It has big canopy area, and is a deciduous species, indicating high water dependence. In order to investigate Brazil nut trees dry, after strong "2015 el nino", we evaluated occurrence and possible explanations of this drought, and relationships with climatic anomalies and nut production. We conduct semi-structured interviews with agroextractivists, and we analyzed leaves and soil near at 15 trees, with and without symptoms of dry. In the years 2015/2016, was registered the strongest El Niño in the Amazon, with an increase of more than 2 °C in the average temperature, reduction of precipitation and prolongation of the dry period. Probably, the water deficit and temperature stress caused the dry (burn) of the leaves and thin branches of the higher Brazil nut trees, observed in the Santa Rosa region, Resex Cajari-Amapá, Eastern Amazonia. The same did not occur in the young trees, in other species and in other regions. There was a drastic fall in fruit production in 2017, and negative correlation of the production with positive anomalies in the Pacific temperature, demonstrating that this species has sensitivity to climate change. Brazil nut trees can recover and sprout new leaves, but the next harvest is it impaired. The nutritional variables did not present significant relationships with trees dry. The hypothesis raised is that this may be related with hydraulic conductance problems, when occurs cavitation and loss of water molecules adhesion, after physiological stress in large trees.

For the assessment of ozone and climate change impacts on southern European forests: MITIMPACT PROJECT

Yasutomo Hoshika¹, Alessandra De Marco², Pierre Sicard³, Elisa Carrari¹, Elena Paoletti¹

¹CNR, Sesto Fiorentino (FI), Italy; ²ENEA, Roma, Italy; ³ARGANS, Biot, France (yasutomo.hoshika@cnr.it; alessandra.demarco@enea.it; psicard@argans.eu; eli.carrari@gmail.com; elena.paoletti@cnr.it)

Climate change and air pollution are two significant stressors affecting forest health and vitality of European forests. Mediterranean area has been identified as one of the most prominent "Hot-Spots" in future climate change projections and is seriously affected by air pollution, in particular ozone (O₃). The MITIMPACT ALCOTRA project aims to quantify ozone impacts on forest test sites distributed in South East France and Northwest Italy, by evaluating ecosystem health and ecosystem services. The project area can be considered as a case study for the assessment of global change impacts in Mediterranean forests. This innovative aspect of the project can be useful to provide cost-effective measures for forest management in preparation to future climate conditions. Here we will introduce a new monitoring station to measure in real time O₃ concentrations together with meteorological parameters in MITIMPACT project. Based on the data obtained here, calculated several O₃ indices, especially the effective dose of O₃ entering into the stomata so called phytotoxic ozone dose with a threshold Y (PODy), will be shown. We will discuss new appropriate thresholds to protect Mediterranean forest against the negative effect of O₃ for future climate change.

B2q: ABIOTIC STRESSORS AND THEIR INTERACTIVE IMPACTS ON FORESTS

Derivation of flux-based critical levels for European forest protection against ozone

Unique in the world, the project MOTTLES takes place in the main European areas at highest and medium risk of ozone injury, relative to human well-being and vegetation impacts, i.e. Southern and Central Europe and combines field epidemiology with plant-responses to ozone. A standard for forest protection is considered biologically relevant when it translates into real-world forest impacts. For this reason, epidemiological investigations where large-scale biological responses (e.g. radial growth, crown defoliation and visible foliar ozone injury) are compared with ambient data in the field provide useful information for establishing the best standards and thresholds for forest protection from ozone. Ozone effects on vegetation depend on the air concentrations but also on the ozone uptake through the stomata, i.e. phytotoxic ozone dose above a threshold Y of uptake (PODY). With the effort of implementing permanent new-generation monitoring stations across Europe, capable to return continuous hourly ozone concentrations with meteorological and environmental parameters in real-time, PODY is estimated and correlated to measured forest-response indicators to develop flux-based critical levels (CLef) for forest protection against ozone. Based on real-world flux-effect relationships, derivation of suitable species-specific epidemiologically-based ozone critical levels for European tree species represents a considerable progress in the development of methods for quantifying ozone effects on vegetation at the regional scale. This work was carried out with the contribution of the LIFE financial instrument of the European Union (LIFE15 ENV/IT/000183) in the framework of the MOTTLES project "Monitoring ozone injury for setting new critical levels".

Seasonal growth of a clonal *Eucalyptus* plantation in soil fertilized with class b sewage sludge

Cassio Hamilton Abreu-Junior¹, Paulo Henrique Silveira Cardoso¹, Thays da Silva Mandu¹, Anibal Deboni Neto¹, Antonio Leite Florentino², Rhayra da Silva Paiva Branco¹, Marcelo Gomes de Oliveira¹, Thomas Gamper Feitoza¹, Clayton Alcarde Alvares³, José Luiz Stape³

¹Universidade de São Paulo, Centro de Energia Nuclear na Agricultura, Piracicaba, Brasil; ²Universidade de São Paulo, Piracicaba, Brasil; ³Suzano Papel e Celulose, Itapetininga, Brasil (cahabreu@cena.usp.br; paulohscardoso@usp.br; thaysmandu@usp.br; anibaldeboni@gmail.com; antonio.florentino@usp.br; rhayra.branco@usp.br; magoliveira102@hotmail.com; thomasfeitoza@gmail.com; calcarde@suzano.com.br; stape@suzano.com.br)

The objective of this work was to evaluate seasonality of trees growth of a *Eucalyptus* plantation fertilized with sewage sludge (SS) and K, complemented or not with P and/or B, and their respective response to meteorological variables. Therefore, in February 2015, a randomized block experiment was set up using clones of *Eucalyptus* (SP5727), with ten treatments and four replications, in a commercial area with water restriction (Cwa, Köppen scale) and low soil fertility of the company Suzano Papel e Celulose S.A. The treatments were two levels of mineral fertilization, seven treatments with SS and K, supplemented or not with P and/or B, and one control. From 23 to 35 months after planting, a biweekly monitoring was carried out, using dendrometer bands, in five trees per plot. The treatments with application of 50%LE+86%P-B+K, 100%LE+66%P-B+K, 100%LE+66%P+B+K, 150%LE-P-B+K and the highest level of mineral fertilization presented a volume of wood (139 m³ ha⁻¹) higher than the control (125 m³ ha⁻¹). There was a smaller increase of transversal area in the period of low rainfall (July to October), with a high growth rate in October, after precipitation of 50 mm. The variables minimum temperature and potential evapotranspiration were the ones that most influenced the increment of the cross-sectional area, positively and negatively, respectively. The precipitation, although significant, showed low growth influence. There were no differences due to climatic variables between treatments. The fertilization of *Eucalyptus* with sewage sludge promoted growth equivalent to the application of mineral fertilizer for high productivity.

Intra-annual radial growth patterns of four species of *Larix decidua* and *Abies alba* in relation to water limitations

Adriana Lestianska¹, Peter Fleischer Junior¹, Peter Fleischer¹, Katarina Strelcova¹, Katarina 18¹

¹Technical University in Zvolen, Faculty of Forestry, Zvolen, Slovakia (adriana.lestianska@tuzvo.sk; p.fleischerjr@gmail.com; p.fleischer@tuzvo.sk; katarina.strelcova@tuzvo.sk; katarina.merganicova@tuzvo.sk)

Climate change is expected to increase the frequency and intensity of droughts and heatwaves in Europe, leading to effects on forest growth. This study aims at increasing the understanding on species-specific effects of climate factors on radial growth, which is necessary to assess the responses of tree radial growth to anticipated climate changes. We monitored radial growth response to climate fluctuation of four mature coniferous species (*Larix decidua* and *Abies alba*) located at altitudes from 290 m a.s.l. to 377 m a.s.l., Zvolen valley, Central Slovakia. Based on continuous monitoring of stem radial variation of coniferous species using dendrometers within the growing season, daily changes in stem radial variation (ΔR) and extracted water deficit (ΔW), maximum daily shrinkage (MDS) and radial growth were extracted. Diurnal cycles were divided into the three phases of contraction, expansion and stem radius increment. We used Morlet wavelet analysis to assess the differences in cyclic radial stem variations between coniferous species. Stem radial variation and extracted variables (ΔW) were compared among coniferous species and the influences of environmental variables were evaluated by applying correlation analysis and moving correlation analysis (MCA). *L. decidua* showed more pronounced variability in seasonal course of stem radius variations than *A. alba*.

Biochemical responses to stresses water and light in *Cecropia pachystachya* Trécul. and *Myroxylon peruiferum* L.F. used for Tropical forest restoration

Marcela Aparecida de Moraes¹ , Daniele Ribeiro Contin¹, Eduardo Habermann¹, Mario Luiz Teixeira de Moraes², Carlos Alberto Martinez¹

 (marcela.apmoraes@gmail.com; danibyog@gmail.com; eduardohabermann@gmail.com; mario.moraes@unesp.br; carlosamh@ffclrp.usp.br)

In the tropics, plants are exposed to various abiotic stress conditions and suffer mainly from photoinhibition by high levels of solar radiation, compromising their survival. In the present study, the biochemical characterization was done in two native tree species used in forest restoration projects, one pioneer (*Cecropia pachystachya*) and one late succession (*Myroxylon peruiferum*), submitted to two light conditions (full sun and shade) and two water conditions (irrigated and progressive water deficit). Subsequently, plants grown under shade conditions were transferred to sun simulating the opening of a clearing to induce light stress. The concentrations of photosynthetic pigments, carotenoids and enzymatic activity of superoxide dismutase, catalase, ascorbate peroxidase and lipid peroxidation were determined. In all species there was a greater decrease in total chlorophyll content in the sun condition, and water stress accelerated the degradation of this pigment. In rehydration the species didn't present photosynthetic pigment contents similar to the control, suggesting that there wasn't complete biochemical restoration. The highest enzymatic activity was observed in *C. pachystachya*, indicating greater efficiency in the biochemical defense system. On the other hand, *M. peruiferum* presented greater lipid peroxidation, mainly under light stress, indicating the occurrence of oxidative damages. Therefore, independent of the successional classification of the species, these present greater damages when there is a clearing opening in the forest, than to a long period of drought. Thus, the present study contributed to a better understanding of the defense mechanisms of the species the photoinhibition, from the biochemical evaluations under abiotic stresses.

Interactions between urban tree-based biogenic volatile organic compounds (BVOCs) emissions and O₃

Jong Kyu Lee¹, Su Young Woo¹, Myeongja Kwak¹, Ji Eun Kim¹, Sang Hee Park¹, Han Dong Kim¹, Yea Ji Lim¹
¹University of Seoul, Seoul, Republic of Korea (gpl90@naver.com; wsy@uos.ac.kr; 016na8349@hanmail.net; amarg@naver.com; parksanghee0930@gmail.com; blasterkhd92@gmail.com; oxlfl@naver.com)

Volatile organic compounds (VOCs) has become a big issue, and urban trees can play critical roles in reducing air pollution including gas-phase VOCs by means of the absorption. But plants also may emit a considerable amount of biogenic volatile organic compounds (BVOCs) into the air. BVOCs can contribute to ozone (O₃) and second organic aerosol (SOA) formation. Air pollution, such as O₃, SO₂ and NO_x, may induce or decrease BVOCs emissions by affecting metabolism of plants in different ways. Interaction between BVOCs and air pollution is a key factor of characteristics of the atmospheric environment. This research aimed to study BVOCs emission on five major urban trees (*Pinus densiflora*, *Ginkgo biloba*, *Taxus cuspidata*, *Prunus yedoensis* and *Zelkova serrata*) under elevated O₃ (100 ppb), which is one of the most serious air pollutants. The experiment was conducted by using O₃ controlled phytotron chamber. Many BVOCs, including isoprene, α -pinene, β -pinene and limonene, are investigated; 100 ppb of O₃ induced change of BVOCs, either increasing or decreasing emission. With 100ppb O₃ for 6 weeks, the content of α -pinene from *Pinus densiflora* and *Ginkgo biloba* was significantly increased compared to control chamber (10 ppb of O₃). The emission of other BVOCs under 100 ppb of O₃ presented significant difference compared to 10 ppb. Also, the change of BVOCs emission under elevated O₃ was also depending on species. Acknowledgment: This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (No; 2018R1D1A1A02044683).

Artificial night lighting causes photosynthetic downregulation and incomplete stomatal closure in *Liriodendron tulipifera* L.

Myeongja Kwak¹, Jongkyu Lee¹, Yeaji Lim¹, Handong Kim¹, Sanghee Park¹, Suyoung Woo¹, Saenggeul Back²
¹University of Seoul, Seoul, Republic of Korea; ²Baekdudaegan National Arboretum, Bonghwa-gun, Republic of Korea (016na8349@hanmail.net; gpl90@naver.com; oxlfl@naver.com; blasterkhd92@gmail.com; parksanghee0930@gmail.com; wsy@uos.ac.kr; bsg1175@bdna.or.kr)

Light pollution generated by artificial night lighting can alter natural light patterns and have a negative impact on living organisms, including plants. This study determined the impact of artificial night lighting on yellow-poplar (*Liriodendron tulipifera* L.) seedlings using artificial street lighting (high-pressure sodium lamp). Seedlings were exposed to either natural night lighting (control) or artificial night lighting (treatment) with a photoperiod of 13 h day/11 h night over two years. Yellow-poplar seedlings were evaluated for their nighttime light response strategies, including photosynthetic light harvesting relative to daytime gas exchange parameters, nighttime stomatal opening, photosystem II photochemistry, and photosynthetic function. Yellow-poplar seedlings exposed to artificial night lighting showed functional dynamics in their photosynthetic capacity, including night lighting inhibition of photosynthesis, reduced photochemical efficiency of photosystem II, and increased stomatal limitation, especially at the highest level of artificial night lighting. Furthermore, nighttime stomatal opening was frequently observed in yellow-poplar leaves grown under artificial night lighting. Results of this study advance our understanding of the interrelationship between photosynthetic downregulation and incomplete nighttime stomatal closure, via modification of photoperiod perception by circadian dysfunction. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (N° 2012R1A1A2005498).

Bioindicators to evaluate the impact of industrial plants on urban settlement: a case study in Southern

Giuseppe Colangelo¹, Giovanni Sanesi¹
¹University of Bari, Bari, Italy (giuseppe.colangelo@uniba.it; giovanni.sanesi@uniba.it)

Atmospheric pollution of industrial areas near to urban centre play a crucial role in contamination and degradation of the urban health and safety. This study analysed the chemical composition of tree rings and lichens to investigate: 1. ranging impact of pollutant according to the distance from pollutant sources; 2. spatial and temporal variability of pollutants in relation with the sprawling and transformation of industrial activities; 3. potential use of bioindicators as passive samplers in monitoring of the urban environment. The study area consists of an industrial area with different pollutants sources (steel factory, oil refinery) close to the city centre of Taranto (Italy). The city is mentioned among the Italian national sites with documented contamination and associated potential health impacts (National Priority Contaminated Sites-NPCSS). Field data collection was performed in a 36 km circular buffer with 8 concentric areas assuming the industrial site as the centre of the study area. Were sampled 42 sites collecting tree corers and lichens. All samples were analysed to detect trace element index (Cr, Be, As, Cd, Pb, Hg, Sn, Ni, V, and Zn). The initial hypothesis focused on the spatial variation of the pollutants on such bioindicators according to the proximity of the industrial plants. Moreover, chemical patterns were detected to assess the suitability of results in reflecting the variations of industrial activities over time. Results show that the analysis is a suitable methodology to investigate past and recent diffusion of pollutants and to support the management of such areas.

B2r: ABIOTIC STRESSORS AND THEIR INTERACTIVE IMPACTS ON FORESTS

Evaluation of real options: strategy in the allocation of resources for planting of *Ochroma pyramidale*

Rafaele Almeida Munis¹ , Ricardo Hideaki Miyajima¹ , Gislaine Cristina Batistela² , Douglas Henrique da Fê² , Danilo Simões¹ 

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agronômicas, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Campus de Itapeva, Itapeva, Brasil (rafaele.munis@gmail.com; richidetoshimiyajima@hotmail.com; gislaine.batistela@unesp.br; douglas.fe@unesp.br; danilo.simo@unesp.br)

The real options approach makes it possible to integrate the uncertainties and management flexibilities of investment projects into real assets, that is, it allows explicit calculation of the value of strategic decisions that can be contemplated during the life of the project, which does not occur with the traditional form calculation of net present value. The objective of this study was to evaluate a forest investment project for the *Ochroma pyramidale* planting in the Center-West region of the State of São Paulo, to quantify the strategic value based on a binomial pricing model. The project aims to plant *Ochroma pyramidale* established in an area of five hectares, spaced 3 m² x 1.5 m², which required an CAPEX of USD40,521.92. The cash flow was projected for a five-year horizon, discounted through the capital asset pricing model (CAPM). The underlying asset was modeled using a binomial tree, and the behavior of the asset value was described by the multiplicative values of increase and decrease. Consequently, the relevant options (American Call) were the deferral and expansion, that is, from the focal date the forest producer can wait two years to realize the investment until uncertainties are resolved and the project becomes feasible and, in the fourth year of the useful life the planted area can be expanded by 30%. The results revealed that by integrating the option value of USD43,151.13 to the capital budget, an expanded (strategic) NPV of USD46,155.13.

Effects of soil nitrogen (N) deficiency on photosynthetic N-use efficiency in N-fixing and non-N-fixing tree seedlings in subtropical China

Zuomin Shi¹, Ruimei Cheng¹

¹Institute of Forest Ecology, Environment and Protection, CAF, Beijing, China (shizm@caf.ac.cn; chengrm@caf.ac.cn)

Soil nitrogen (N) deficiencies can affect the photosynthetic N-use efficiency (PNUE), mesophyll conductance (gm), and leaf N allocation in many plant species. However, there is a lack of information about how these physiological characteristics in N-fixing trees could be affected by soil N deficiency and the difference in adaptations to N deficiency between N-fixing and non-N-fixing trees. In this study, we choose seedlings of two N-fixing (*Dalbergia odorifera* and *Erythrophleum fordii*) and two non-N-fixing trees (*Castanopsis hystrix* and *Betula alnoides*) as study objects, and we conducted a pot experiment with three levels of soil N treatments (high nitrogen, HN; medium nitrogen, MN; and low nitrogen, LN). Our results showed that soil N deficiency significantly decreased the leaf N concentration and photosynthesis ability of the non-N-fixing trees, but it had less influence on these indices in the two N-fixing trees. The LN treatment had lower gm in *D. odorifera* and lower leaf N allocated to Rubisco (PR), leaf N allocated to bioenergetics (PB), and gm in *B. alnoides*, eventually resulting in low PNUE values. *D. odorifera*, *B. alnoides*, and *C. hystrix* seedling leaves had improved leaf N allocated to the cell wall (PCW) and (or) the leaf mass per area (LMA) to adapt to a low-N soil environment. Our findings suggested that the *D. odorifera* and *E. fordii* seedlings could grow well in N-deficient soil and adding N may increase the growth rates of *B. alnoides* and *C. hystrix* seedlings and promote the growth of artificial forests.

Geographic clines in genetic diversity and variation in adaptive traits of two major pine species, *Pinus densiflora* and *Pinus thunbergii*, in Japan

Masakazu G. Iwaizumi¹, Yoshiaki Tsuda², Yoshihiko Tsumura², Makoto Takahashi³, Tomonori Hirao⁴, Atsushi Watanabe⁵

¹Kansai Regional Breeding Office, Forest Tree Breeding Center (FTBC), Forestry and Forest Products Research Institute (FFPRI), Forest Research and Management Organization (FRMO), Katsuta, Japan; ²Faculty of Life and Environmental Sciences, University of Tsukuba, Tsukuba, Japan; ³Genetic Resources Department, FTBC, FFPRI, FRMO, Hitachi, Japan; ⁴Forest Bio-research Center, FFPRI, FRMO, Hitachi, Japan; ⁵Department of Forest Environmental Science, Faculty of Agriculture, Kyushu University, Fukuoka, Japan (ganchan@ffpri.affrc.go.jp; tsuda.yoshiaki.ge@u.tsukuba.ac.jp; tsumura.yoshihiko.ke@u.tsukuba.ac.jp; makotot@ffpri.affrc.go.jp; hiratomo@ffpri.affrc.go.jp; nabeatsu@agr.kyushu-u.ac.jp)

Pinus densiflora (Japanese red pine) and *P. thunbergii* (Japanese black pine) are two major economically and ecologically important pine species in Japan. Because of serious population size reduction throughout Japan due to the extensive damages from pine wilt disease, appropriate design for conserving and managing their regional genetic resources is essential. In the present study, geographic patterns of genetic diversity of 62 *P. densiflora* natural populations (in total of 1,883 trees) and 49 *P. thunbergii* old planted populations (2,755 trees) were examined using nuclear microsatellite markers. As adaptive traits, geographic variations in cone characteristics were also investigated for 28 and 24 genotyped populations, respectively. We found that allelic diversity was significantly lower in northeastern populations for both species. Structure analyses revealed a clinal genetic structure from southwestern to northeastern populations. For *P. densiflora*, the northeastern cluster showed the highest F value; whereas, for *P. thunbergii*, some populations showed quite a different local proportion of cluster memberships from nearby populations. These results indicated species-specific backgrounds; genetic drift through recent population expansion in northeastern Japan suggested by anthropological and paleoecological studies (*P. densiflora*) and historical seed pool transfer to develop coastal forest against land erosion (*P. thunbergii*). We also found that cone size (length, width) of trees was significantly larger in northern populations for both species. Results obtained in these variations would provide fundamental information for designing nematode-resistant breeding zones and also for evaluating adaptive genetic variations against climate changes in future studies.

Estimating the biomass of *Guadua weberbaueri* inside and on the edge of forests in the Western Brazilian Amazon / Estimativa de biomassa e anatomia de *Guadua weberbaueri* no Interior e Borda de Floresta na Amazônia Ocidental Brasileira

Berenice Silva¹ , Yasmin Rodrigues¹, Sebastião Santos¹, Vitor Andrade¹, Moisés Lobão¹

¹Universidade Federal do Acre, Rio Branco, Brasil (bernicekaj@gmail.com; iasmimalves.ro2011@gmail.com; kennonsantos@gmail.com; vitorjg.andrade@gmail.com; moiseslobao6@gmail.com)

A floresta Amazônica, no estado do Acre, Brasil, se destaca como uma região rica em diversidade de espécies de bambus lenhosos, visto que 38% da composição florística dessa região é constituída por bambuzais. A cultura do bambu, embora milenar, tem sua utilização e pesquisas em sua maioria restritas aos países orientais, sendo, portanto, interessante que haja o fomento de projetos de estudo para as espécies de bambu nativos da Amazônia tendo em vista a sua

versatilidade. Neste trabalho, foram avaliados dados biométricos de *Guadua weberbaueri* (popularmente conhecido como taboca) que se desenvolveu em borda de floresta (ambiente antropizado) e no interior da floresta. Valores de DAP (diâmetro na altura do peito) foram usados para calcular a biomassa de acordo com modelos específicos para a espécie e região. Observou-se que os tabocais que cresceram na borda obtiveram menores valores de biomassa em comparação aos tabocais crescendo no interior da floresta, observando-se uma média de 1,76 kg vs; 4,59 kg por indivíduo, respectivamente, o que mostra um efeito negativo do estresse abiótico causado por diversos fatores antrópicos característicos da borda da floresta (desmatamento, danos mecânicos, efeitos do vento etc). Além dos dados biométricos, este trabalho irá correlacionar a biomassa com as características anatômicas dos colmos e raízes de bambu de forma a entender como esses fatores de estresse abiótico interferem na anatomia do bambu.

Flowering phenology and pollen characteristics of *Quercus* species growing in Korea

Myeongja Kwak¹, Jongkyu Lee¹, Handong Kim¹, Yeaji Lim¹, Sanghee Park¹, Suyoung Woo¹

¹University of Seoul, Seoul, Republic of Korea (016na8349@hanmail.net; gpl90@naver.com; blasterkhd92@gmail.com; oxll2l@naver.com; arksanghee0930@gmail.com; wsy@uos.ac.kr)

Recently, the incidence of major allergic diseases has increased by the conversion of coniferous forests to deciduous broad-leaved forest in Korea. Oaks such as *Quercus serrata*, *Q. acutissima*, and *Q. mongolica*, which are typical broad-leaved species of Korea, are allergen-inducing pollen species. Furthermore, identification of the dynamics between the flowering time and pollen dispersal under elevated CO₂ is very important in the establishment of health monitoring system. The present study aimed to assess bud development stages and pollen dispersal of *Q. acutissima* according to elevated CO₂. The pollen dispersal and production of oak species can be predicted by the interaction between temperature and other climatic factors as well as the complexity of overlapping plant seasonality. The pollen production increased in *Q. acutissima* grown under elevated CO₂ compared with the atmospheric CO₂. The pollen dispersal of *Q. serrata* tends to be different depending on the climatic factors, and the climate change due to the increase of CO₂ concentration is expected to increase the air pollen dispersal. Climate change and global warming are the main cause of plant phenology, but these phenological patterns can also affect by other factors including precipitation and CO₂ concentration. Plant phenological patterns are an important biomarker of ongoing ecosystem changes and can provide a general idea that future climate change can be a key driver of biodiversity changes. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (No; 2018R1D1A1A02044683).

Effects of potassium/sodium fertilization and water availability on wood properties of *Eucalyptus grandis* trees

Roger Chambi-Legoas¹, Gilles Chaix^{1,2}, Mario Tomazello-Filho¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ²CIRAD, UMR AGAP, Montpellier, France (rogerchl@usp.br; gilles.chaix@cirad.fr; mtomazel@usp.br)

In Brazil, most *Eucalyptus* plantations are located in regions experiencing periods of water shortage where fertilizers such as potassium (K) are intensively used to achieve high productivity. Recently, sodium (Na) has also been considered a potential nutrient. As well as tree growth, wood properties are also an important factor to consider in order to measure the impacts of silvicultural practices and water deficit on forest productivity, since they are determinants for quality and yield of pulp and paper. In a split-plot experimental design with 4-year-old *Eucalyptus grandis* trees, located in São Paulo State, Brazil, we evaluate the effects of K and Na supply compared with a control treatment, under two water supply regimes (37% throughfall reduction versus no throughfall reduction) on stem volume, heartwood proportion, basic density, fiber, and vessel properties. K and Na fertilization increased stem volume 2.7 and 1.9 fold, respectively, with a non-significant effect of 37% throughfall reduction. Na fertilization was more detrimental to wood properties than K fertilization, affecting heartwood proportion, basic density, and fiber wall thickness. K fertilization affected only heartwood proportion and basic density. The 37% throughfall reduction only affected wood basic density, increasing it. Effects of fertilization treatments did not change regardless changes in water supply. Despite the detrimental effects of fertilizers (stronger with Na supply) in wood properties there is a large beneficial effect on stem volume (stronger with K supply), even under a water availability reduction, that would be compensates the loss of wood quality for pulp and paper production.

Urban and industrial air pollution effects on a native specie of Atlantic Rainforest

Daniel Rodrigues da Silva¹, Luzimar Campos da Silva¹, Silvia Ribeiro de Souza², Larisse de Freitas Silva³

¹Plant Anatomy Laboratory, Department of Plant Biology, Federal University of Viçosa, Viçosa, Brasil; ²Ecology and Physiology Research Center; Botanical Institute, São Paulo, Brasil; ³Federal University of Recôncavo da Bahia, Center for Agricultural, Env (silvabiodaniel@yahoo.com.br; luzimarcampos@yahoo.com.br; souzasrd@gmail.com; larisse_bio@yahoo.com.br)

The large Brazilian urban centers are located in the Atlantic Rainforest domain, an important global biome, and urban air pollution contributes to forest decline. In the Ipatinga's city, Minas Gerais - Brazil, exist a steel mill and a circulating fleet of vehicles responsible for atmospheric pollutants emissions that contribute to the reduction of environmental quality. The objective was to evaluate the urban and industrial air pollution effects of Ipatinga in *Joannesia princeps* Vell. (Euphorbiaceae), a native Atlantic Rainforest specie. For this, we analyzed the visual foliar damages and the anatomical and micromorphological effects in extrafloral nectaries (EFNs) of this species. During 126 days, *J. princeps* seedlings were exposed in stand systems at Bom Retiro, Cariru, Cidade Nobre and Veneza points in the Ipatinga's city. The leaf symptomatology was evaluated monthly. For the anatomical analysis, EFNs were collected and processed for analysis in light microscopy and scanning electron microscopy. At Bom Retiro and Cariru points, the highest concentrations of NO, NOX, SO₂, O₃, benzene and naphthalene were recorded. The highest concentrations of hydrocarbon pollutants were recorded in the Cidade Nobre and Veneza points. In plants exposed at the Cariru point, more visual damage was observed. Regarding the anatomical and micromorphological damages in the EFNs, tissue necrosis, wound healing formation and cell hyperplasia, intense superficial damage such as epidermal rupture, fungal colonization, disarrangement and trichome fall were observed. Thus, our data suggest that the urban air pollution of Ipatinga's city promotes changes in the morphology and micromorphology of native plant species.

Mangrove species of *Rhizophora apiculata* BL. and *Avicennia alba* BL. in responses to the changes in sediment condition impacted by processes of deposition and erosion in coastal areas, Vietnam

Linh Nguyen Thuy My^{1,2}, Pil Sun Park²

¹Vietnamese Academy of Forest Sciences, Hanoi, Vietnam; ²Seoul National University, Seoul, Republic of Korea (linh.ntm@rcfee.org.vn; pspark@snu.ac.kr)

Mangrove forests are one of important estuarine ecosystems, controlling the formulation, stabilization and development of coastal muddy banks. Mangrove species are naturally adaptive to normal disturbances but sensitive to stressors. *Rhizophora apiculata* BL. and *Avicennia alba* BL. are the most abundance mangrove species distributed in the South areas of Vietnam. Unbalance in the deposition and erosion processes within this area have been strongly affecting

mangrove lost. Two species were hypothesized to respond differently corresponding with soil condition variations between contrasting sites of deposition and erosion. Relative abundance, regenerative status and root morphology were analyzed in correlations with changes in elevation and sediment properties of soil salinity, acidic, porosity, organic matter and water content. *Avicennia alba* BL. and *Rhizophora apiculata* BL. remained the dominance from seedlings to matures in deposition and erosion area, respectively. To be better adaptation to soil condition variation, higher number of primary stilt roots and root spread distance of *Rhizophora apiculata* BL. were detected in erosive substrate. Pneumatophores of *Avicennia alba* BL., however, showed lower values of root density, length and coverage, associated with the weak adaptation in erosion area. Our results suggested that the restoration of mangrove forests should use appropriate species that are adapted to erosion and deposition processes in coastal areas.

B2s: NOVEL ADVANCES IN GENOMICS AND TREE BREEDING FOR SUSTAINABLE FORESTS

Early selection efficiency for growth in two half-sib population of *Eucalyptus grandis* Hill ex. Maiden

Paola Molina^{1,2}, Jorge Franco³, Ariel Castro⁴

¹Lumin, Tacuarembó, Uruguay; ²Centro Universitario de Tacuarembó, Universidad de la República Tacuarembó Uruguay; ³Departamento de Biometría, Estadística y Computación, Facultad de Agronomía, Universidad de la República, Paysandú, Uruguay; ⁴Departamento de Producción Vegetal, Facultad de Agronomía, Universidad de la República, Paysandú, Uruguay (paolamleon@gmail.com; jfranco@fagro.edu.uy; vontruch@fagro.edu.uy)

Reducing the time in each cycle on breeding programs is one strategy to increase genetic gains. The objective of the study was to estimate the efficiency of early selection in *Eucalyptus grandis* Hill ex Maiden half-sib families selected prior to year 5 based on diameter at breast height (DBH), total height (HT) and cylindrical volume (VOL) in a solid wood genetic improvement program. Progeny trials, grouped in two populations according to the seed source (Population 1 and Population 2), were planted in 2009 in the departments of Tacuarembó and Cerro Largo, Uruguay, with randomized complete block design (BCA) and single tree plot (STP). Genotype by environment interaction was identified in Population 2 for DAP and VOL. Mean heritability increased as they approached year 5, DAP 0.21 to 0.36, HT 0.42 to 0.54 and VOL 0.20 to 0.36. Age-age genetic correlations were high (> 0.70) from year 3. DAP was the variable that presented the highest genetic correlation with VOL (> 0.60) from year 3. The selection efficiency (E) was higher in years 3 and 4. The genetic parameters, the percentages of G/year and the E for DAP, HT and VOL showed similar behaviors within each trial and variations between trials which indicate the potential for early selection prior to year 5 in populations of *E. grandis* and shorten the time of the material evaluation phase to reduce the cycle of improvement.

Variety testing and selection of the intersectional poplar hybrids for industrial plantation forests in the Central Chernozem region of Russia

Tsarev Vadim Anatol'evich¹ 

¹All-Russian Research Institute of Forest Genetics, Breeding and Biotechnology, Voronezh, Russian Federation (vad.tsareff@yandex.ru)

The urgency of the problem of variety testing and hybridization of poplars is due to the need to develop and select the most productive and sustainable hybrids of fast-growing tree species in order to create plantations which cover the ever-growing shortage of wood in the densely populated but low-forest South-Eastern part of the European territory of Russia. The objectives of research were to summarize the results of long-term variety testing of the intersectional hybrids obtained from controlled crosses of balsamic poplars with black and black poplars with balsamic ones and to select the best of them. The object of research was the testing site (populetum) on the area of 4 ha made in 1974 on Typical Chernozem soil by stem cuttings with arrangement place 5×4 m in Semiluki situated in Voronezh region; 13 clones of intersectional poplar hybrids were introduced into the test. The results of 40-year studies of their survival, height and diameter growth, trunk volume and wood stock dynamics have been allowed identifying the most promising poplars' intersectional hybrids proposed in the assortment for the creation of the most fast-growing and sustainable forest and shelter belt plantations in the region. By the age of quantitative timber maturity of intersectional poplar hybrids (i.e; 25 years) their survival was 83-100%, the wood stock – 462-641 m³/ha and the average increment – 18.5-25.6 m³/ha/yr. Further by the age of 40 their productivity and sustainability also remained quite high (survival 63-96%, wood stock – 417-764 m³/ha and average increment – 10.45-19.1 m³/ha/yr).

Genetic variation for growth traits in progenies of *Eucalyptus pellita* F. Muell / Variação genética para caracteres de crescimento em progênies de *Eucalyptus pellita* F. Muell

Darlin Gonzalez Zaruma¹, Jose Carlos de Oliveira², Jory Alvarado Chamba³, Ney Quezada Cabrera³, Henry Cuenca Suing³, Daniele Fernanda Zulian², Maiara Ribeiro Cornacini¹, Paulo Henrique Müller da Silva⁴, Mario Luiz Teixeira de Moraes²

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil; ³Universidad Nacional de Loja, Loja, Ecuador; ⁴Instituto de Pesquisas e Estudos Florestais, Pir (dgzaruma@gmail.com; ze0897@gmail.com; jory.andres1993@gmail.com; quezadaney@gmail.com; henrycuenca93@gmail.com; danizullian@gmail.com; maiaracornacini@gmail.com; paulohenrique@ipef.br; teixeira@agr.feis.unesp.br)

Eucalyptus pellita é uma espécie arbórea que possui atributos silviculturais promissoras que a tornam atraente para o estabelecimento de plantações, contudo, a melhor compreensão do controle genético do crescimento é necessária para apoiar os esforços de melhoramento genético. Nesse sentido, o objetivo do estudo foi avaliar a variação genética para caracteres silviculturais, em um teste de progênies. O teste foi instalado em maio de 2016, na Fazenda de Ensino, Pesquisa e Extensão (FEPE/Unesp), em Selvíria-MS. O delineamento experimental foi de blocos casualizados, com uma planta por parcela, 20 repetições, no espaçamento de 3,0 m × 1,5 m. Foram utilizados 206 tratamentos (progênies). Aos dois anos de idade foi avaliado: altura total (ALT) diâmetro a altura do peito (DAP) e sobrevivência (SOB). As estimativas de componentes de variância e parâmetros genéticos foram obtidas pelo método da máxima verossimilhança restrita e melhor predição linear não viciada (REML/BLUP). Os indivíduos apresentaram boa adaptação ao local com 77% de SOB e a média para ALT e DAP foi de 8,14 m e 6,35 cm, respectivamente. Foram detectadas diferenças significativas a 1% de significância na análise de deviance (LRT). O coeficiente de herdabilidade, em nível de média de progênies, foi de 0,77 (ALT) e 0,64 (DAP) resultando em acurácia elevada. O coeficiente de variação genética, em nível de progênies, foi de 13,8% (ALT) e 10,7% (DAP). Assim, a presença de variação genética e a acurácia encontradas, para os caracteres nas progênies, indicam boas perspectivas de ganho na seleção nessa população de *E. pellita*.

Genotype characteristics of *Eucalyptus benthamii* in developing clonal cultivars / Caracterização de genótipo de *Eucalyptus benthamii* no desenvolvimento de cultivar clonal

Paulo Eduardo Telles dos Santos¹, Estefano Paludzyszyn Filho¹, Washington Luiz E. Magalhães¹

¹Embrapa Florestas, Colombo, Brasil (paulo.telles@embrapa.br; estefano.filho@embrapa.br; washington.magalhaes@embrapa.br)

A formação de plantações florestais com eucaliptos em regiões propensas a fortes geadas, comuns no Sul do Brasil, ainda está grandemente vinculada à utilização de sementes de um reduzido número de espécies, havendo pouca disponibilidade de clones comerciais. Nesse contexto, *E. benthamii* é particularmente estratégica para a obtenção de madeira, principalmente para atender finalidades energéticas e utilização na forma roliça. A matriz denominada “brs 203” foi selecionada em um amplo teste de progênies instalado em 2007 na localidade de Candói, PR, Brasil (25°36'S; 52°04'O; 870m), sendo os parentais originários de Kedumba Valley, NSW, Austrália (33°49'S; 150°23'E; 140m). A alta taxa de crescimento e o elevado padrão silvicultural foram os critérios iniciais de seleção. Os valores encontrados para diversos caracteres avaliados aos 9 anos de idade foram os seguintes: DAP 48,7 cm; altura total 33,7 m; altura comercial 29,5 m; volume de tronco com casca 2,60 m³; volume de tronco sem casca 2,14 m³; porcentagem de casca 17,8%; densidade básica 537 kg/m³; teor de cinzas 0,28%; teor de extrativos 2,20%; teor de lignina Klason 24,25%; teor de lignina solúvel em ácido 1,89%; teor de holocelulose 71,38%. Um dos aspectos de destaque desse genótipo é o fato de estar demonstrando em viveiro resultados iniciais bastante favoráveis quanto à formação de raízes a partir de estacas, fundamental para se ter sucesso na estratégia de desenvolvimento de clones comerciais. Muito embora haja necessidade, na sequência dos trabalhos, de se realizar inúmeros testes adicionais de campo comprobatórios de desempenho e qualidade, as perspectivas são promissoras.

Genetic parameters in seed characters of *Stryphnodendron pulcherrimum* under different temperature levels

Ivinne Nara Lobato dos Santos¹, Maria Teresa Gomes Lopes¹, Mágnó Sávio Ferreira Valente¹, Manuel de Jesus Vieira Lima Junior¹

¹Universidade Federal dos Amazonas, Manaus, Brasil (ivinne.lobato@gmail.com; mtglopes@hotmail.com; magnosavio@yahoo.com.br; mjlimajunior@gmail.com)

The *Stryphnodendron pulcherrimum* (Fabaceae) is Amazonian tree species also found in Atlantic Forest, Guianas, Venezuela and Colombia. It has a potential for urban afforestation use, reforestation, ecological recovery of degraded areas and extraction of tannin. However, genetic and physiologic traits of its seeds are poorly studied. This work aimed to estimate genetic parameters in *S. pulcherrimum* seeds under different temperatures of germination, proposing superior matrices in seedlings production and subsidize strategies for domestication as well as to genetic enhancement of this specie. Seeds of 21 matrices of the species were collected in Apuí, Amazonas. The design was completely randomized, with four replicates of 25 seeds per matrices. The germination tests were conducted at temperatures of 25, 30 and 35°C. Whereas genetic parameters, selection gain for germination percentage, mean germination time, synchronization and germination rate indexes were subjected to analysis of variance (ANOVA) in order to examine the difference among matrices or warming level. The genetic variability and high values of heritability and selective accuracy (> 69%) for all germination traits suggest that the phenotypic value can provide a reliable measure for selection of superior genotypes. The highest percentage of germination was obtained in the environment of 25 °C (92%) with decreasing of twinned seeds and mean germination time with increasing temperature. Progenies 11, 14 and 15 presented good germination characteristics for all analyzed environments.

Biometric parameters in seed characters of *Stryphnodendron pulcherrimum*

Ivinne Nara Lobato dos Santos¹, Maria Teresa Gomes Lopes¹, Mágnó Sávio Ferreira Valente¹, Manuel de Jesus Vieira Lima Junior¹

¹Universidade Federal do Amazonas, Manaus, Brasil (ivinne.lobato@gmail.com; mtglopes@hotmail.com; magnosavio@yahoo.com.br; mjlimajunior@gmail.com)

The species *Stryphnodendron pulcherrimum* is a Fabacea. In Brazil it grows in the Amazon region and in the south of Bahia and has importance for the recovery of degraded areas, however, it is difficult to obtain seedlings. The objectives of this work were to estimate biometric parameters of seeds of 21 *S. pulcherrimum* matrices located in Apuí, AM, in order to the selection of those that present the characteristics desirable for future generations. The matrices were selected according to their phenotypic characteristics as plant productivity and sanity. For each matrix, 30 seeds were randomly selected and measured weight, length, width and thickness of each seed. All statistical analyzes were performed using the Genes program. Progenies of *S. pulcherrimum* presented significant genetic variability for all high-heritability (> 87%) traits, as well as mean values for the wet weight of 0.061 g (ranged from 0.046 to 0.081 g), length of 7.11 mm (ranged from 6.47 to 7.78 mm), width of 4.47 mm (ranged from 3.82 to 5.18) and thickness of 2.96 (ranged from 2.68 to 3.24 mm). The repeatability coefficient presented median values, except thickness that assumed low values. The coefficients of determination were higher than 80%, demonstrating that the evaluation of the characteristics can be performed with high reliability. The results show that with only 14 seeds it is possible to evaluate the characteristics with good accuracy in the selection of superior genetic material.

From phloem to xylem: a metabolomic overview of wood formation in hybrid aspen

Ilara Budzinski¹, Ilka Abreu¹, Thomas Moritz¹

¹Swedish University of Agricultural Sciences, Umea, Sweden (ilara.frasson.budzinski@slu.se; ilka.abreu@slu.se; thomas.moritz@slu.se)

Wood (secondary xylem) is a valuable resource for the generation of renewable energy and it is an important feedstock for fiber, pulp and cellulose production. The process of wood formation is strongly affected by environmental conditions such as water, nutrient and light availability. Despite the importance of secondary growth to trees, the metabolic profile underlying wood formation still poorly understood. Here, we present a metabolomics approach (GC-TOF-MS and LC-QTOF-MS) performed to identify both (a) the metabolic distribution from phloem towards wood-forming tissues, (b) key metabolites with specific roles during wood formation. To this purpose, hybrid aspen (*Populus tremula* x *P. tremuloides*) trees were cultivated under greenhouse conditions and supplied four different levels of nitrogen, to obtain trees with different secondary growth. The stems from four-month-old trees were cryo-sectioned (20 µm) in: bark, inner bark, phloem, expanding phloem, cambium, expanding xylem, xylem, mature xylem and pith. Trees treated with high nitrogen concentration showed higher diameter, height and biomass, compared to the others treatments. By multivariate analysis, we could discriminate tissues and treatments. A gradient of metabolites belonging to different chemical classes (sugars, amino acids, phenolics) was identified along the differentiated wood tissue and towards phloem. The results obtained here represent the metabolic overview of secondary growth and highlighted the powerful combination of cryosectioning and metabolomics analysis in forestry research.

B2t: NOVEL ADVANCES IN GENOMICS AND TREE BREEDING FOR SUSTAINABLE FORESTS

The variation of genotypes in natural forest populations: an important variable to precision silviculture

João Antonio Pereira Fowler¹

¹Embrapa Florestas, Colombo, Brasil (joao-antonio.fowler@embrapa.br)

The term precision silviculture can mean the selection of individuals of a species in a natural population with characteristics suitable for a particular purpose of use. As each individual of the population occupies a specific site, in addition to the soil variables, it is fundamental to genotype characterization to identify genotype environment interactions. To access of DNA of each individuals, we adapted a method of extraction of the genomic DNA of these samples. An improved protocol for the isolation of DNA from sapwood of *Astronium fraxinifolium* Schott, *Cariniana legalis* (Mart.) Kuntze, *Pterocarpus rohrii* Vahl, *Handroanthus serratifolius* (Vahl) S.Grose, *Astronium graveolens* Jacq., *Cedrela odorata* L., *Lecythis pisonis* Cambess., *Manilkara salzmanii* (A.DC.) H.J.Lam., *Handroanthus riococensis* (A.H.Gentry) S.O.Grose, native species of Mixed Ombrophilous Forest is described. The isolated DNA is suitable for RAPD and SSR for DNA analysis. Different DNA protocols were examined to determine which might yield DNA from sapwood of the studied species. The protocols tested were Cationic hexadecyl trimethyl ammonium bromide (CTAB), CTAB modified, and the commercial kits Quiagen® - DNeasy Plant Mini Kit, MoBio®, Noren Biotek® and Himedia®. None of these protocols produced yielded DNA suitable purity for RAPD analysis. We established a new procedure involving CTAB protocol varying the incubation time and the concentration of proteinase K, denominated CTAB modified. The recovery of DNA with an average yield of 20 and 100 µL of sapwood samples, using protocol CTAB modified.

Evaluation of growth traits as selection indicators for *Phyllostachys pubescens* seedlings in radiation-induced breeding programs

Zhihua Cao¹, Zhongneng Wu¹, Hongfei Zhao²

¹Anhui Academy of Forestry, Hefei, China; ²Zhejiang Shuren University, Hangzhou, China (308457017@qq.com; 312412679@qq.com; 971660891@qq.com)

Deriving novel germplasm of the bamboo *Phyllostachys pubescens* from tradition approaches to plant breeding is problematic, due to its indeterminate growth, however radiation-induced breeding represents a potential solution. Here, seeds of *P. pubescens* were radiation-treated with 60 Co γ -ray irradiation, from which 16 superior seedlings were screened and planted in an experiment from 2011 to 2017 and found variation in the traits among the phenotypes within and across years, and principal components analysis showed that growth of the phenotypes was more accurately described using a combination of growth traits, rather than a single trait. Using our trait analysis, we found that growth in a phenotype derived from seed irradiated with 10 Gy of 60 Co γ -ray irradiation was superior; these results supported a previous study of growth of this phenotype in an afforestation experiment. This study provides a feasible method and foundation for the selection and screening of superior *P. pubescens* genotypes in radiation-induced breeding programs.

Ecology and evolution of a tree species challenged by dual threats

We are studying the ecological and evolutionary processes affecting the geographical distribution of southwestern white pine (SWWP; *Pinus strobiformis*), an important tree species of the Southwestern USA and Mexico. Southwestern white pine viability is threatened by changing climate and an invasive tree disease, white pine blister rust (caused by the fungal pathogen, *Cronartium ribicola*). Rapid climate change is negatively affecting SWWP by increasing heat and drought stress, and thus challenging its ability to adapt. White pine blister rust causes extensive tree decline and mortality, including in SWWP. The dual threats of climate change and invasive species make forecasting future tree distributions at continental scales an urgent challenge. The goal of our project is to determine how gene movement among populations, adaptation to disease and drought, heritable changes beyond DNA mutations, and a changing environment interact to govern the success of SWWP. We are utilizing and developing tools to help forecast and manage the future of the species, including those from genomics, common gardens, tree disease resistance testing, engineering and technology innovation to measure drought tolerance and physiological response. Results will be synthesized and included in cutting-edge landscape genomics models to meet our overarching goal. We will present our framework and current project status, including results. Completed products include development of landscape genomic models, a species distribution model incorporating climate change, and adaptive trait, phenotype plasticity and genomic variation analyses. Continuing work incorporates these aspects in addition to transgenerational plasticity research and a genome-wide association study.

Artificial neural networks for predicting the genetic value of *Eucalyptus* progenies

The main goal of researchers in genetic breeding programs is to select superior genotypes and recommend varieties through effective selection methods. Thus, the objective of this study was to evaluate the performance of Artificial Neural Networks (ANN) in predicting genetic values for progeny selection of *Eucalyptus* sp. For the training of ANN, 64 experiments were simulated that varied among means (5, 10, 15 and 20), heritability (10, 20, 30 and 40%) and coefficient of variation (10, 20, 30 and 40%). For validation of ANN, data from a progeny test of *Eucalyptus camaldulensis* was used. The genetic values of both the simulated and progeny data were obtained by the REML / BLUP procedure. The ANN used was a multiple layer type with three inputs (phenotype value, block means, and progeny mean), a hidden layer containing four neurons and one exit layer. The algorithm used was backpropagation. The correlation between genetic values predicted by the BLUP methodology and those obtained by ANN was 99% in the training phase and 91% in the validation stage. The good performance of ANN in the validation stage reflected in the correlation of the ordering of individuals (92%) and families (99%) of *E. camaldulensis* by the two methods. Thus, multiple layer ANN showed good performance in predicting genetic values in progeny tests of *Eucalyptus* sp. for DBH which are promising tools for selection of progenies in forest breeding programs.

A genotyping array of 3,400 Single Nucleotide Polymorphisms (SNPs) advances the genetic analysis of the iconic tree *Araucaria angustifolia*, showing that the natural populations are more differentiated than previously reported

Pedro Tanno¹, Orzenil Silva-Junior², Lucileide Resende², Valderês Aparecida de Sousa³, Dario Grattapaglia^{2,4}

¹Universidade de Brasília, Brasília, Brasil; ²Embrapa Recursos Genéticos e Biotecnologia, Brasília, Brasil; ³Embrapa Florestas, Colombo, Brasil;

⁴Universidade Católica de Brasília, Brasília, Brasil (tanno.pedro@gmail.com; orzenil.silva@embrapa.br; lvilelar@gmail.com; valderes.sousa@embrapa.br; dario.grattapaglia@embrapa.br)

We have developed a genotyping “chip” for the iconic and endangered *Araucaria angustifolia* tree containing 3,400 SNPs, discovered from RNAseq and RAD-sequencing data. Of these, 1,643 were polymorphic in a sample of 192 individuals from a provenance/progeny collection involving 15 populations from Brazil (SP, MG, PR and SC). These same 192 individuals were genotyped with 30 microsatellites (SSR). Analysis of the population genetic structure with SSR and SNPs revealed substantial differences in the magnitude of population differentiation: F_{st} was 0.13 with SSR and 0.28 with an equivalent number of SNPs. This pattern was maintained with different estimators (G_{st} , G_{st}^* , D_{st}) or R_{st} for microsatellites. Using all 1,643 SNPs covering the entire spectrum of allelic frequencies F_{st} was slightly higher (0.31). These results corroborate the recognized fact that the multiallelism of SSR restricts the maximum F_{st} value even in the absence of gene flow, and allele homoplasy tends to overestimate gene flow and homogeneity among populations resulting in largely underestimated population differentiation. Conversely, although bi-allelic and less informative individually, SNPs have a considerably lower mutation rate and a negligible mutation reversal rate, providing robust, accurate, genome-wide estimates of genetic differentiation. These results raise important questions about the validity of the low levels of genetic differentiation between natural populations typically reported for *Araucaria* based on microsatellites. An underestimated F_{st} has critical repercussions on inferences of genetic structure and gene flow and, more importantly, on strategic decisions about the conservation of natural populations and enrichment of germplasm banks of this ecologically keystone tree.

Determining genotype-environment interactions for precedents and progeny of *E. nitens* established in 3 trials in 2 growth areas for this species in Chile at 4 years of age / Determinación interacción genotipo-ambiente para procedencias y progenies de *E. nitens* establecidas en 3 ensayos en 2 zonas de crecimiento para la especie en Chile a los 4 años de edad

Maria Paz Molina¹, Roberto Ipinza²

¹Instituto Forestal de Chile, Bio Bio, Chile; ²Instituto Forestal de Chile, Valdivia, Chile (mmolina@infor.cl; robertoipinza@infor.cl)

Eucalyptus nitens Deane & Maiden originaria del sudeste australiano y de alto interés para el sector forestal chileno, dada su resistencia al frío y a plagas y enfermedades forestales. Actualmente hay aproximadamente 255.000 hectáreas en Chile, establecidas en su gran mayoría para la producción de pulpa. Es la especie forestal de mayor tasa de crecimiento, alcanzando hasta 400 m³/ha a los 8 años. Dados los efectos del cambio climático en Chile, se analiza la interacción genotipo-ambiente con el fin de optimizar el uso del material genético en distintas zonas de alta productividad para la especie. De modo de conocer la interacción genotipo – ambiente entre pares de ensayos se determinó la correlación tipo B, la cual era significativa entre los pares de ensayo. Luego para profundizar la interacción Sitio-Familia se seleccionó un grupo de 30 progenies para cada ensayo siendo las de mayor Ganancia Genética para la variable D2H. Posteriormente se verificó que todas estas familias estuvieran representadas en cada uno de los ensayos, encontrándose un subgrupo de 21 familias que cumplían con esta condición. Mediante gráficos se comparó el comportamiento de las familias en cada uno de los ensayos. En las variables analizadas hay una fuerte interacción de sitios sobre las familias y gráficamente se visualiza la no coincidencia de las mejores familias para los tres ensayos e incluso, se detecta que familias que son de mejor desempeño en un ensayo tienen el desempeño menor en otro.

Estimated genetic gains in bolaina blanca (*Guazuma crinita*) in forest plantations within Peruvian Amazonia / Estimación de la ganancia genética esperada de bolaina blanca (*Guazuma crinita*) en plantaciones forestales de la Amazonía Peruana

Guillermo Eduardo Gorbiz Dupuy¹, Lino Ríos¹, Victor Cornejo²

¹DIPTERYX SAC, Pucallpa, Peru; ²Restaura Peru S.A.C., Lima, Peru (guillermo@dipteryx.org; lino@dipteryx.org; victorcornejobadillo@gmail.com)

Bolaina blanca (*Guazuma crinita*) es la especie forestal maderable más plantada en la Amazonía baja del Perú, además, su madera es la principal fuente de ingresos para cientos de pequeños agricultores. Sin embargo, la productividad de *G. crinita* se mantiene aún muy por debajo de su potencial. El trabajo de investigación tuvo como objetivo estimar la ganancia genética esperada de árboles plus seleccionados para su introducción en un programa de mejoramiento genético forestal. Siguiendo la metodología propuesta por Vallejos et al. (2010), se seleccionaron 36 árboles plus según caracteres de volumen comercial y calidad de las cuatro primeras trozas. La superioridad de estos árboles plus fue validada luego de la evaluación fenotípica de cada árbol en relación a sus cuatro mejores vecinos en un radio inmediato de 15 m. Posteriormente, los árboles plus fueron clasificados en dos listas, la lista A para el árbol que presenta superioridad en volumen comercial y calidad de troza, y la lista B para aquellos árboles que presenta sólo superioridad en uno de los dos caracteres. La ganancia genética esperada, entendida como el producto del diferencial de selección del árbol plus por un valor esperable de heredabilidad en el sentido amplio (H₂), para el total de árboles candidatos se estimó en 14.94% y 3.99% de ganancia para los caracteres de volumen comercial y calidad de troza respectivamente, mientras que si solo se toma la lista A, la ganancia genética sería de 20.05% para volumen comercial y 6.20% para calidad de troza.

Dendrochronological study of *Brosimum utile* (Kunth) Oken from Timbiquí, Cauca, Colombia / Estudio dendrocronológico de *Brosimum utile* (Kunth) Oken procedente de Timbiquí, Cauca, Colombia

Claudia Parada¹, Cesar Polanco Tapia¹, Mario Tommasiello²

¹Universidad Distrital Francisco Jose de Caldas, Bogotá D. C., Colombia; ²Universidade de São Paulo, São Paulo, Brasil (cparada.r@gmail.com; cpolanco@udistrital.edu.co; mtomazel@usp.br)

Brosimum utile es una especie con una amplia distribución sobre zonas tropicales, posee alto potencial maderable y altas tasas de aprovechamiento y movilización sobre el territorio colombiano, de acuerdo al IDEAM, el pacífico Colombiano movilizó 364.227 m³ en el periodo 2008-2010. Esta especie es comercializada de forma importante en el distrito de Buenaventura, Valle del Cauca. Con el ánimo de aportar elementos de manejo silvicultural al bosque natural desde las técnicas dendrocronológicas, que propendan por el aprovechamiento sostenible de la especie, fueron muestreados en Buenaventura, diez discos de madera usando trozas basales con diámetros de entre 394 y 881 mm y 3000 mm de longitud. Estas trozas tradicionalmente son utilizadas para la obtención de chapas para fabricación de plywood. La procedencia del material fue Timbiquí, Cauca. Una vez el material llegó al equilibrio en la ciudad de Bogotá, D.C. las trozas fueron preparadas en la superficie, se visualizaron y marcaron los anillos de crecimiento verificando las fluctuaciones del crecimiento. Con la ayuda de técnicas de cofechado y el análisis de valores de densitometría con rayos X, realizados en La ESALQ-USP, Brasil. Se realizó la construcción de las cronologías y su correlación con la intensidad de la precipitación, en una serie de 44 años. Se identificaron señales ambientales incitadoras del cambium. Adicionalmente, se obtuvo el crecimiento medio anual y corriente anual, permitiendo el cálculo del diámetro mínimo de corta ajustado, que podrá contribuir al aprovechamiento adecuado de la especie y al manejo forestal sostenible en esta región del país.

B4b: DATA FUSION FOR IMPROVED FOREST INVENTORIES AND PLANNING

Double calibration estimation of forest wood volume for exploiting Airborne Laser Scanning and satellite auxiliary variables

Piermaria Corona¹, Sara Franceschi², Gherardo Chirici³, Francesca Giannetti⁴, Lorenzo Fattorini⁴

¹CREA Research Centre for Forestry and Wood, Arezzo, Italy; ²University of Calabria, Rende, Italy; ³University of Florence, Firenze, Italy; ⁴University of Siena, Siena, Italy (piermaria.corona@unitus.it; sara.franceschi@unical.it; herardo.chirici@unifi.it; francesca.giannetti@unifi.it; lorenzo.fattorini@unisi.it)

Under-coverage is present in many forest surveys when only a portion of the forested area is surveyed but the estimation of the total of a forest attribute for the whole area is the target. Under frequent circumstances Airborne Laser Scanning (ALS) information is available for the surveyed portion and satellite information is available for the whole area. In these cases, two-stage least-squares or hierarchical model-based estimation are usually adopted to estimate totals for the whole area. The purpose of this paper is to propose an alternative, completely design-based estimation strategy based on a two-step calibration. The first calibration exploits auxiliary variable arising from ALS metrics to improve the precision of the crude design-based estimation of the total over the sampled portion. The second calibration exploits the set of auxiliary variables arising from satellite information to expand the total estimate achieved for the sampled portion to the total estimate over the whole area. The two calibrations are unified in a double-calibration estimator. Mean and variance of the estimator are derived up to the first order of approximation. Conditions ensuring approximate unbiasedness are derived and discussed. The strategy is empirically checked by a simulation study performed on an artificial forest. A large-scale case study is considered to assess the total wood volume and basal area in a forested land of Central Italy.

Estimates of biomass that use the global ecosystem dynamics investigation lidar mission waveform Data

Paul Patterson¹, Sean Healey², Göran Ståhl³, Svetlana Saarela³, Sören Holm³, Ralph Dubayah⁴, Laura Duncanson⁴, Steven Hancock⁴, John Armston⁴, Jim Kellner⁵, Hans-Erik Andersen⁶, Warren Cohen⁷, Zhiqiang Yang²

¹United States Forest Service, Fort Collins, USA; ²United States Forest Service, Ogden, USA; ³Swedish University of Agricultural Sciences, Umeå, Sweden; ⁴University of Maryland, College Park, USA; ⁵Brown University, Providence, USA; ⁶United States Forest Service, Seattle, USA; ⁷United States Forest Service, Corvallis, USA (paul.l.patterson@usda.gov; seanhealey@fs.fed.us; goran.stahl@slu.se; svetlana.saarela@slu.se; soeren.holm@gronstensen.se; dubayah@umd.edu; lduncans@umd.edu; hancock@umd.edu; armston@umd.edu; james_r_kellner@brown.edu; andersen@fs.fed.us; warren.cohen@oregonstate.edu; zhiqiangyang@fs.fed.us)

In December 2018 the NASA GEDI (Global Ecosystem Dynamics Investigation) mission installed a full-waveform lidar instrument on the International Space Station for the purpose of measuring global forest structure. The waveforms are collected in “footprints” that are spatially discontinuous; the waveform data is expected to be strongly correlated with aboveground forest biomass (AGB). Using simulated GEDI waveforms models have been constructed for the footprints by plant functional types within the six continental regions. The estimates for the discontinuous footprint level AGB will be combined to estimate the AGB within geographical regions, e.g., 1 km grid cell, administrative unit, national park, etc. using a hybrid estimator. The precision of the hybrid estimator depends on both the sample strategy and the model uncertainty. Using a diverse set of global sites a simulation study was conducted to empirically assess the statistical properties of hybrid estimator and the proposed variance estimator for 1 km grid cells using the plant functional type within continental regional footprint models. The results show the performance in terms density of the GEDI overpasses. It is possible to decompose the variance estimator into model and sample components. The relative contributions to the variance and variance estimator are assessed.

An imputation/copula approach for fusing and analyzing multiple, large datasets in forestry

John Kershaw¹, Ting-Ru Yang¹, Yung-Han Hsu¹, Elizabeth McGarrigle²

¹University of New Brunswick, Fredericton, Canada; ²Nova Scotia Department of Natural Resources, Truro, Canada (kershaw@unb.ca; tyang1@unb.ca; yhsu@unb.ca; emcgarrigle@gmail.com)

Big data analytics are rapidly becoming the norm in many disciplines in forest resource evaluation and modeling. While these machine learning algorithms are very good at shifting through large datasets and building robust predictions for the “here and now,” they have very limited capabilities of predicting the “then and there.” We propose an alternative approach to data fusion and big data analytics that applies an iterative cycle of multiple imputation and copula sampling to develop predictions. The multiple imputation step narrows the range of data used to model or predict a given observation through a nearest neighbor selection process. Empirical or distribution-based copulas are derived from the set of nearest neighbors, and copula sampling is used to develop a probability distribution of predictions. Because of the iterative process of imputation and copula sampling, the model can be run multiple times and uncertainties directly assessed. Applications to stand and tree modeling and LiDAR analyses are presented. Implications of bandwidth selection (number of nearest neighbors) and sample sizes (number of copula samples) are explored.

Towards a global standard of digital forest representation and monitoring. How airborne and terrestrial LIDAR combined with artificial intelligence and blockchain technology will change traditional forest inventory concepts

Guenther Bronner¹, Mathias Schardt²

¹Umweltdata, Vienna, Austria; ²Joanneum Research, Graz, Austria (g.bronner@umweltdata.at; mathias.schardt@joanneum.at)

LIDAR is the most dynamic segment in the development of forest assessment. In Styria 1Mio hectares forest resources have been mapped using only 2000 well distributed sample plots. Swiss Neuchatel has already time series of single-tree segmentation. Umweltdata has several years experience in designing 2-phase inventories based on aerial laserscanning and traditional terrestrial fieldwork where the number of sample plots was reduced by factor 4 while maintaining statistical accuracy. As enhancement an intermediate layer with stripes of high density aerial LIDAR point-clouds is added. This new dataset allows 3D-segmentation of trees, determining basal and tree top coordinates and the distance to competing trees. Despite this surplus of information, the fieldwork assessment effort is again significantly reduced. Regarding fieldwork we now introduce a new concept of terrestrial LIDAR. Mounting a small LIDAR sensor on a slowly moving eccentric arm, occlusion of trees far from sample plot centre can be avoided; in one single scan more than 99% of the basal area is recorded. The future implementation of blockchain technology on different stages of data recording and data processing will generate certified snapshots of the forest, which could be a basis for an international trade with CO₂ certificates based on cryptocurrency. Deep learning algorithms will enhance single tree forest growth modelling sensitive to climate change. All proposed methods work within existing NFI designs and allow wall-to-wall interpolation of NFI-results being ready for Forest Management Planning. The presentation will include results from operational and research projects as well as concepts for future developments.

Interrelation and interchangeability of Sentinel-2 and Landsat 8 data for burnt areas mapping

Maria Prodromou¹, Miltw Miltiadou¹, Diofantos Hadjimitsis¹

¹Cyprus University of Technology, Limassol, Cyprus (ml.prodromou@gmail.com; milto_miltiadou@hotmail.com; diofantos@cut.ac.cy)

Forest monitoring has benefited from the technological advancement and the increased availability of open remotely sensed data. Issues like cloud covered areas and the desired of increased temporal resolution has been solved by combining Sentinel-2 and Landsat-8 data. This research exploits whether these two datasets are interrelated and whether they can be used interchangeably for burnt area mapping, since fires destroy vegetation and chlorophyll, affect soil moisture and lead to the creation of leave bare areas. Two study areas in Cyprus were selected: Solea and Ora-Vavatsinia, which were burnt in June 2016 and July 2017 respectively. Solea contains pine forests, plantains, shrubs and Mediterranean vegetation, while Ora contains wild vegetation, pines and olive trees. This study explores the relationship between three spectral indices (Normalized Difference Vegetation Index NDVI, the Normalized Burn Ratio NBR and the Burn Area Index BAI) derived from Sentinel 2 and Landsat-8 OLI imagery. The Pearson correlation for NBR index was 0.89 and 0.91, for NDVI was 0.85 and 0.89 and for BAI was 0.76 and 0.80 for the Ora and Solea areas. Furthermore, the deviation between the estimated burnt area using the different datasets was less than 0.6%. It is therefore shown that the two datasets can be used interchangeably for burnt area mapping and the most interrelated index is the NBR, while BAI was the least correlated.

Estimating wood quality in standing timber with the fusion of point cloud - based forest inventory data and saw mill measurements

Jiri Pyörälä¹, Ville Kankare², Ninni Saarinen¹, Xinlian Liang³, Yunsheng Wang³, Markus Holopainen¹, Juha Hyypä³, Mikko Vastaranta²

¹University of Helsinki, Helsinki, Finland; ²University of Eastern Finland, Joensuu, Finland; ³Finnish Geospatial Institute, Masala, Finland; ³Finnish Geospatial Institute, Masala, Finland (jiri.pyoral@helsinki.fi; ville.kankare@uef.fi; inni.saarinen@helsinki.fi; xinlian.liang@nls.fi; yunsheng.wang@nls.fi; markus.holopainen@helsinki.fi; juha.coelars@gmail.com; mikko.vastaranta@uef.fi)

Changes in climate and silviculture are altering forest growth globally, including adverse effects to wood properties that may limit timber usage as long-term carbon storage. Forest industries could better adapt to these challenges if wood quality was more precisely accounted for in wood procurement planning. Because wood properties are a consequence of tree's adaptation to the environment by regulating wood formation, the tree phenology, e.g. stem geometry and branching reflect wood quality. In this study, we studied the wood quality of Scots pine (*Pinus sylvestris* L.) in Southern Finland. We recorded geometrical tree attributes using terrestrial laser scanning (TLS) and compared them firstly with wood quality measured at sawmill by means of X-ray scanning for 180 trees, and secondly with upper canopy features delineated from airborne laser scanning (ALS) data for a separate set of ca. 300 trees. Ultimately, we used the ALS and TLS data to produce tree lists with detailed stem and branching attributes for harvestable forest stands, and estimated the tree-specific wood quality using the TLS and sawmill data. We will evaluate the accuracy of our tree lists by comparing the predicted wood quality against stand-specific sawmill measurements of over 2000 trees harvested from six Scots pine forest stands within the same geographic region. We aim at assessing the potential gains of pre-harvest wood quality estimation that utilized existing sawmill databases and point cloud based - forest inventory data and the implications to the sustainability of industrial wood procurement in the future.

Using heterogeneity indices to adjust basal area: leaf area index relationship in managed coniferous stands

Alex Appiah Mensah¹, Svetlana Saarela¹, Hans Petersson¹, Emma Holmström², Martin Goude²

¹Swedish University of Agricultural Sciences, Umea, Sweden; ²Swedish University of Agricultural Sciences, Alnarp, Sweden (alex.appiah.mensah@slu.se; svetlana.saarela@slu.se; hans.petersson@slu.se; emma.holmstrom@slu.se; martin.goude@slu.se)

The structure of contemporary managed forests are complex which can be described with indices of heterogeneity. To apply theoretical growth functions on managed forests, adjustments are required, especially for leaf area index (LAI) which is a key biophysical variable in process-based growth models. The performance of canopy LAI in modelling the basal area (BA) of managed boreal forests dominated by Norway spruce (*Picea abies* (L.) Karst) and Scots pine (*Pinus sylvestris* L.) was investigated by heterogeneity analysis. The heterogeneity was studied in two parts: (a) ground-based stand structural heterogeneity (SSH) described by coefficient of tree diameter variation, tree social status and height-diameter ratio, and (b) spectral heterogeneity (SPH) by vegetation and textural indices developed from Sentinel-2. Species-specific final (with heterogeneity metrics) and base (without heterogeneity metrics) models were fitted for BA-LAI relationships by nonlinear least squares regression functions. For both species, BA-LAI final models (FMs) accounting for heterogeneity resulted in larger explained variance (RMSE, m² ha⁻¹) than the base models (BMs). Compared with the BMs, FMs with SSH reduced the variance by 55% in Norway spruce (RMSE = 3.330, relative-RMSE = 15.398%) and 43% in Scots pine (RMSE = 3.701, relative-RMSE = 17.377%). The fit between BA-LAI with SPH also showed an improvement in the RMSEs for Norway spruce and Scots pine over the BMs, suggesting the potential use of Sentinel-2 in future growth models. The study concludes that when extrapolating theoretical growth functions to managed forests, there is a need to calibrate the models with the forest structural heterogeneity.

Experiences from stand level applications of data assimilation based on combinations of remotely sensed and field data

Håkan Olsson¹, Anton Grafström¹, Nils Lindgren¹, Kenneth Nyström¹, Mattias Nyström¹, Göran Ståhl¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden (hakan.olsson@slu.se; anton.grafstrom@slu.se; nils.lindgren@slu.se; kenneth.nystrom@slu.se; mattias.nystrom@slu.se; goran.stahl@slu.se)

Data assimilation has found widespread application in fields such as meteorology and robotics. The basic idea is to use data from multiple time points for improving the accuracy of estimates of current state of a system. The baseline alternative would be to utilize only data from the last time point. Through data assimilation all sources of data are, ideally, used in a way so that best possible estimates are obtained by combining the different sources, considering their uncertainties. Since 2012 studies on data assimilation for improving stand level estimates of characteristics such as growing stock volume, biomass, and mean height have been carried out at the Swedish University of Agricultural Sciences (SLU), by combining multiple sources of remotely sensed data with field reference data. During this presentation the experiences from these studies will be summarized. Some important findings and conclusions are that (i) data assimilation offers great potential to utilize all new sources of remotely sensed data that are becoming available today, (ii) theoretical studies point at substantial improvements in the precision of estimators of stand level characteristics, (iii) several practical obstacles are faced when data assimilation is applied in practice implying that, (iv) the gain in precision obtained in practice is typically modest compared to what theoretical studies suggest. However, in addition to slightly improving the precision of estimators, data assimilation systems provide benefits in terms of identifying stands where changes have occurred and through growth updates based on remotely sensed data.

B4c: ESTIMATION OF STATUS AND CHANGE IN FOREST CARBON POOLS BASED ON INVENTORY DATA: GOING BEYOND TREE CARBON

The carbon mitigation potential of European forests

Hubert Hasenauer¹, Adam Moreno², Mathias Neumann¹, Frits Mohren³

¹University of Natural Resources and Life Sciences, Vienna, Austria; ²California Air Resource Board, Sacramento, USA; ³Wageningen University, Wageningen, Netherlands (hubert.hasenauer@boku.ac.at; adam.moreno@arb.ca.gov; mathias@neumann@boku.ac.at; frits.mohren@wur.nl)

European forests, covering one third of the land surface in Europe, have recently sequestered more than 700 million tones CO₂ every year. Biomass functions in combination with forest inventory data allow estimating the carbon stocks of European forests. In this study we collate consistent information on coarse and fine roots, above-ground litterfall and above ground biomass. A gap-filled map based on harmonized forest inventory data from 13 countries is applied to produce pan European gridded datasets derived from a single methodology to inform researchers, policy makers and conservationists on the state of forest structures would improve our ability to study forests independent of political boundaries and along various gradients. Although National Forest Inventory (NFI) data provide information on the characteristics of forests, including carbon content, volume, height, and age, such spatial data is not available across Europe. We produced a pan European map for each of the four key variables on a 0.133° grid representing the time period 2000–2010. The results of the study are that European forests exhibit an annual average carbon uptake of 577 gC/m²/year, which can be considered of the average carbon sequestration potential.

Forest inventories in a systems approach to understanding the carbon cycling of forest ecosystems

Anatoly Shvidenko^{1,2}, Dmitry Schepaschenko^{1,3}, Florian Kraxner¹

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²Institute of Forest SB RAS, Krasnoyarsk, Russian Federation; ³Forestry Faculty, Bauman State Technical University, Mytischki, Russian Federation (shvidenk@iiasa.ac.at; schepd@iiasa.ac.at; kraxner@iiasa.ac.at)

System theory considers full and verified account (FCA) of carbon budget of forests as underspecified (fuzzy) system. The major methodological consequence of this is understanding that any method of the FCA (i.e., landscape-ecosystem approach as aggregation of different inventories, eddy covariance, inverse modelling, diverse models, “direct” estimates of FCA components by remote sensing) used individually is not able to assess structural uncertainty, thus the calculated uncertainties of FCA (e.g. Net Ecosystem Carbon Budget, NECB) are inevitable incomplete. Elimination of this requires complimentary use of all available methods of FCA with following mutual constraints of both results and uncertainties. National forest inventories (NFI) present unique information for such an approach, although a number of unresolved questions exist, including 1) incomplete identity of basic definitions used by forest inventories and other sources; 2) incompatible classifications; 3) lack of spatially distributed models of structure of forest ecosystems, especially for assessing forest parameters unobservable by remote sensing; 4) unsatisfactory quantification of other than trees ecosystems’ components etc. Much more complicated problems arise in countries which have no operational NFI yet. The presentation considers problems, challenges and opportunities for Russian forests (above 20% of the world forests) which inherited the previous soviet system of forest inventory, but political, social and economic changes of the last decades have led to a dramatic decline of forest inventory. Use of official inventory data results in a significant (> 2 times) bias of the forest NECB. We present a system of updating forest inventory information and its use in FCA.

Assessment of the amount of fine woody debris

Jan Merganic¹, Katarina Merganicova², Martin Mokros², Zuzana Allmanova¹, Michal Ferencik¹, Maria Vlckova¹, Vladimir Jusko¹

¹Technical University Zvolen, Faculty of Forestry, Zvolen, Slovakia; ²Czech University of Life Sciences Prague, Prague, Czech Republic (j.merganic@forim.sk; k.merganicova@forim.sk; martin.mokros@gmail.com; zuzana.allmanova@gmail.com; ferencik@tuzvo.sk; maria.vlckova@tuzvo.sk; jusko@tuzvo.sk)

Deadwood material is an important component of forest ecosystems. Within national forest inventories monitoring of its amount and spatial distribution started in many countries only recently. Moreover, frequently only coarse woody debris is accounted for, while fine deadwood is often omitted although it can make a substantial proportion of carbon stock in woody debris. Here we evaluate several different inventory methods of downed fine deadwood applied to five windthrown areas of the Forest School Enterprise of the Technical University Zvolen, Slovakia. For the inventory of fine woody debris on these disturbed areas we applied a randomised systematic sampling design. In total, 536 quadratic sampling plots, each 1 m², were established in the field in the year 2018. The situation on the ground of the plots was documented with the photos taken using Panasonic DMC-FZ1000 camera. The relative cover of fine deadwood was first visually estimated, after which the lengths and the mid-diameters of individual pieces of fine woody debris within the sample plot were measured and recorded.

The photographs of the 124 randomly selected plots were transformed to orthophotos with Agisoft Photoscan Professional software. On the orthophotos, the relative cover of fine woody debris was visually estimated on the computer screen. Then, fine deadwood pieces were measured by operators in QGIS software. The comparison of the outputs of all applied methods revealed that the measurements of the amount of fine woody debris on the orthophotos had a systematic negative bias.

Quantification of tree stems and soil carbon stocks in Omo Biosphere Reserve, Nigeria

Oladele F. Falade¹, Rosemary E. Ubaekwe¹

¹Department of Forest Production and Products, University of Ibadan, Ibadan, Nigeria (faladedele@yahoo.com; rosemary.ubaekwe@gmail.com)

Omo Biosphere Reserves (OBR) contributes to mitigation of climate change through provision of carbon sinks. Tree stems and soil are major carbon stocks in (OBR). There is partition and transfer of carbon among the components of stocks. However, rate of carbon transfer between stocks is hindered because knowledge on carbon distribution among components is limited. Therefore, this study quantified carbon stocks of Omo Biosphere Reserve. Twenty (30 m x 30 m) plots were randomly demarcated within OBR. The reserve was stratified into close and open canopy structures. Fourteen and six plots were demarcated in close and open canopy structures, respectively. Tree stems with diameter-at-breast-height ≥ 10 cm were identified and enumerated. The diameter-at-breast-height and merchantable height were measured for carbon estimation. Profile pits were dug at the centre of plots and soil core samples were collected to 100 cm depth with 20 cm interval. Soil core samples were oven dried at 105°C to constant weight and 100g of soil sample was sieved into five aggregate sizes (> 2 , 2-1, 1-0.5, 0.5-0.05, < 0.05 mm) and carbon contents were determined. Data collected were analyzed using descriptive statistics. The carbon stocks of above-ground and below-ground stem were 140.56 mg/ha and 28.11 mg/ha and 30.79 mg/ha and 6.15 mg/ha in close and open canopy structure, respectively. *Ceiba pentandra* and *Terminalia superba* contributed highest carbon stock density in close and open canopy structure, respectively. Aggregate (< 0.05 mm) contributed highest proportion to soil carbon at all depths in both canopy structures. The conservation of soil carbon stock and regeneration of *Ceiba pentandra* should be encouraged in Omo Biosphere Reserve.

The estimation and modelling of carbon stocks from harvested wood products in New Zealand

Anne Wekesa¹, Bruce Manley¹, David Evison¹

¹University of Canterbury, Christchurch, New Zealand (anne.wekesa@pg.canterbury.ac.nz; bruce.manley@canterbury.ac.nz; david.evison@canterbury.ac.nz)

End use categories such as buildings, furniture, pallets and paper are the main stores of carbon in the harvested wood products (HWP) pool. Nonetheless, information on the actual carbon stocks, the contribution of the different semi-finished wood products to these carbon stocks and the duration of carbon storage for these products is little known and understood and not explored in relation to New Zealand. This information is very important as it allows for robust estimates of carbon stored in this pool to be reported. In this research, a survey is being carried out of wood processing companies across New Zealand, namely, sawmills, plywood, veneer, laminated veneer lumber (LVL), cross laminated timber (CLT), pulp and paper, paper board, newsprint, furniture and pallet manufacturers. The aim is to collect information on the material flow of roundwood logs to the end use products. Roundwood flow data is being collected using a country specific approach. It tracks wood flow from log grades that are harvested and processed domestically. In addition, the information on conversion efficiencies, waste flows during the manufacturing process and the service lives of the end use products will also be gathered in order to improve carbon stock estimates from HWP in New Zealand.

CO₂ dynamics from harvested wood products in Brazil during 1900-2016

Carlos Sanquetta¹, Margarida Tomé², Ana Dias³, Greyce Maas¹, Felipe Sanquetta¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²University of Lisbon, Lisbon, Portugal; ³University of Aveiro, Aveiro, Portugal (carlossanquetta@gmail.com; magatome@isa.ulisboa.pt; acdias@ua.pt; greyce.maas@gmail.com; felipe_sanquetta@hotmail.com)

How relevant is the role of carbon dioxide (CO₂) from harvested wood products (HWP) for the Brazilian greenhouse gas (GHG) emission balance? We evaluated the C stocks and CO₂ emissions and removals in the HWP in Brazil in the period 1900-2016 using three IPCC methodological approaches: stock-change, production, and stock change of domestic origin. Data from the FAOSTAT system on the production, import and export of semi-finished products (sawn wood, wood panels and paper) were analyzed, considering afforestation/reforestation (A/R), forest management (FM) and deforestation (D) activities. Two scenarios to evaluate the effect of HWP from D were evaluated. The stock of C in HWP in 2016 reached 252 Mt C, by the stock-change approach, that was considered the most complete to report HWP. Contributions on C storage historically were higher in lumber, but wood panels and paper have recently outperformed it. The A/R activity is the major responsible for the storage of C in the HWP throughout the period. The mitigation by HWP was 521 Mt CO₂ in 1990-2016, representing 1.1% of the country's GHG emissions in that period. It was concluded that Brazil has become a major producer and consumer of wood and the HWP are allies for a positive C balance and fulfillment of the commitments assumed by the country regarding climate change.

Estimating potential carbon storage of domestic harvested wood products in Republic of Korea

Eun-Kyung Jang¹, Youn Yeo-Chang¹

¹Seoul National University, Seoul, Republic of Korea (mentaka1209@gmail.com; youn@snu.ac.kr)

Korea Forest Services has set the plan to increase HWP carbon pool to increase quantities of domestic harvest wood and sawn wood production. However, if the use of domestic wood resources has an unsustainable way, the policy effect of increasing the amount of carbon stored in the HWP carbon pool will not be high, no matter how much the volume is increased. In this context, this study aims to identify major material flow of primary products including sawnwood, plywood, wooden-based panel, woodchip etc. and its flow into industries including construction, civil engineering (temporal structural materials), transportation and household of domestic harvested wood products, to evaluate of carbon storage efficiency in Korea using Material Flow Analysis (MFA) and estimate potential carbon reduction of policy scenario (a. increasing production of sawnwood, b. increasing production of panel and c. increasing recycling rate). As a result, Korea has a small amount of sawn wood production as a lumber for building construction, but a lot of domestic wood flows to wood chips used as paper and board materials. From a point of carbon view, it shows low efficiency as a HWP carbon storage, using wood resources for period of 30 years. Policy scenario to encourage long-term use of wood products may increase the using time and efficiency of HWP carbon pool in Korea. This study can provide information for decision making in establishing and implementing policies to increase carbon stocks in HWP and the utilization efficiency of wood resources.

Carbon storage in harvested wood products for a selected number of countries worldwide, based on FAO country data

Frits Mohren¹, Ashley Steel², Federico Alice³

¹Forest Ecology and Forest Management Group, Wageningen University and Research, Wageningen, Netherlands; ²Forestry Department, Food and Agricultural Organization (FAO), Rome, Italy; ³School of Environmental Sciences, Universidad Nacional de Costa Rica (frits.mohren@wur.nl; ashley.steel@fao.org; federico.alice@wur.nl)

Forests make a strong contribution to meeting the Sustainable Development Goals (FAO's The State of the World's Forests, 2018), and are of paramount importance in storing carbon and mitigating CO₂ emissions. We estimate the climate change mitigation potential of carbon storage in harvested wood products. Our estimates, based on Tier 1 methods from the IPCC Guidelines, use FAO country statistics and a first order decay model with default half-lives. We focus on the development of estimates of carbon storage in harvested wood products for developing countries and incorporate uncertainties in default assumptions about half-lives and carbon content. Overall carbon storage in harvested wood products is compared with carbon storage in forest ecosystems. For select countries, trends in carbon storage in harvested wood products are compared to trends in related phenomena, e.g., greenhouse gas emissions, change in forest area, and gross domestic product (GDP). We also discuss carbon storage accounting related to forests more generally, including carbon losses from managed lands and the effects of forest management on overall carbon storage.

B4d: GLOBAL MONITORING NETWORK OF TREE MORTALITY PATTERNS AND TRENDS

Global monitoring network of tree mortality patterns and trends: a new IUFRO task force

Henrik Hartmann¹, Aster Gebrekirstos², Nadine Ruehr³, Tanja Sanders⁴, Bernhard Schuldt⁵

¹Max-Planck Institute for Biogeochemistry, Jena, Germany; ²World Agroforestry Center, Nairobi, Kenya; ³Karlsruhe Institute for Technology, Garmisch-Patenkirchen, Germany; ⁴Thuenen Institute of Forest Ecosystems, Eberswalde, Germany; ⁵University Wuerzburg, Wuerzburg, Germany (hhart@bgc-jena.mpg.de; a.gebrekirstos@cgiar.org; nadine.ruehr@kit.edu; tanja.sanders@thuenen.de; bernhard.schuldt@uni-wuerzburg.de)

Forests cover about 31% of the Earth's land surface and the sustainable provision of resources and ecological services from forests, such as carbon storage, hosting biodiversity, and climate regulation ensures human welfare. Yet, recent observations in temperate, boreal, and tropical forests indicate that this sustainable provision may be threatened by increasing tree mortality and forest decline from environmental change. There currently is, however, no global assessment of forest condition that could validate a global general trend in climate change-induced forest decline. Given the importance of global forests for biogeochemical cycles and human welfare there is an urgent need to understand forest responses to changing climate and to predict future forest conditions. Assessments of forest condition at the global scale are challenging. Although recent remote sensing products can identify large-scale changes in forest cover, the spatial resolution is often too coarse to detect climate change-induced tree mortality. Field observations from forest inventories or research plot networks can detect individual tree mortality but are often not openly accessible and spread across different ownerships. The new IUFRO Task Force 'Global monitoring network of tree mortality patterns and trends' aims to overcome these limitations by facilitating sharing of knowledge and data and promoting international collaborations between different disciplines concerned with forest assessment, tree physiology and ecological modelling. Here we present how this task force was created, its goals and objectives and discuss future activities. We encourage anyone who is interested in making progress in assessments of global forest conditions to join our initiative.

Mortality trends of old-growth trees and forests under global change stresses: Global monitoring needs and opportunities

Craig Allen¹

¹US Geological Survey, Los Alamos, USA (craig_allen@usgs.gov)

Many tree species and forest landscapes globally are noticeably adjusting in diverse (sometimes contrasting) ways to changing temperature and precipitation climate conditions, particularly including warming temperatures and changing precipitation patterns. Significant theoretical and empirical evidence indicates that larger (and thus often older) trees and forest stands may be disproportionately vulnerable to increased growth stress and mortality under hotter drought conditions. The responses of the world's largest, oldest trees and forests to global change are of particular interest, given that such ancient trees and forests are valued as: a) disproportionately large carbon sinks; b) among the most biodiverse and rare terrestrial ecosystems; c) irreplaceable archives of ecological history; and d) venerated for spiritual and cultural reasons. Development of improved global forest monitoring capabilities is vital to broadly interpret spatially and temporally contrasting observations of forest responses to emerging climate changes, and to foster integrated multidisciplinary understanding of climate-induced tree mortality and forest die-off. This presentation addresses global forest monitoring needs and opportunities, with a particular emphasis on the needs and opportunities associated with determining the broad-scale status and trends of the world's remaining large ancient trees and old-growth forests.

Long-term, large-scale harmonized monitoring to detect changes in forest health and mortality: the ICP Forests experience

Marco Ferretti¹

¹Swiss Federal Research Institute WSL, Birmensdorf, Switzerland (marco.ferretti@wsl.ch)

Concern generated from observation of poor forest condition and tree death in some parts of central Europe prompted the set-up of international forest monitoring initiatives in Europe in the 1980s. The similarity with today's concern on tree mortality makes it interesting to look at the development of forest health monitoring (FHM) in Europe over the past decades. International FHM in Europe is carried out within the International Co-operative Programme on Assessment and Monitoring Air Pollution Effects on Forests (ICP Forests) under the auspices of the UN ECE Convention on Long-Range Transboundary Air Pollution (CLRTAP). Today ICP Forests monitors forest health on ca; 5000 plots on a 16 x 16 km grid (Level I), and on ca; 600 plots purposively selected (Level II). FHM is carried out annually since the 1980s, and consists of a visual inspection of sample trees carried out according to SOP and QA/QC. At the beginning FHM concentrated on defoliation, discoloration and most obvious categories of damaging agents. Now it includes many attributes related to foliage, branches and stem, and attempt to identify causes of damage (when present). Subsequent changes in attributes/scoring system, however, caused some noise in the data series. Long-term mortality assessment, in particular, was constrained by several factors, including the difficult separation between removals (management) and actual mortality. Here I will provide an overview of the ICP Forests, its FHM methods, achievements, advantages and disadvantages, as well as possible contribution to a global assessment of tree mortality.

A nation-wide analysis of tree mortality under climate change: forest loss and its causes in Israel 1948–2017

Tamir Klein¹

¹Weizmann Institute of Science, Rehovot, Israel (tamir.klein@weizmann.ac.il)

Is tree mortality increasing? Are recent mortality events related to climate change? Which tree species are the most affected? Many case studies have been published in the last decade, but the necessary large-scale and long-term knowledge is still missing. Here we combined data from forest surveys and satellite imagery, to create the first spatial tree mortality history at the national scale. Israel is a small country with only 7% forest cover, but its large environmental diversity and mosaic of many, small, forest areas makes it a good 'miniature model' for the task. Tree mortality events have been increasing significantly since 1991 and correlated well with drought. Among mortality events, 24% of the loss was directly related to drought, and 58% to fire, with 69% of fires occurring over a drought background. Conifers were disproportionately more affected than native broadleaved trees. This is the first national-scale study of tree mortality dynamics, and it confirms the suspected increase in this phenomenon in recent decades, and the dominant role of drought. Our study opens a way to a better, multi-source monitoring future for forest management and ensuring forest sustainability under climate change.

One century of forest monitoring data in Switzerland reveals species - and site - specific trends of climate-induced tree mortality

Sophia Etzold¹, Kasia Ziemińska¹, Brigitte Rohner¹, Alessandra Bottero¹, Arun K Bose¹, Nadine Ruehr², Andreas Zingg¹, Andreas Rigling¹

¹WSL Swiss Federal Research Institute, Birmensdorf, Switzerland; ²Institute of Meteorology and Climate Research IMK, Garmish-Partenkirchen, Germany (sophia.etzold@wsl.ch; kasia.zieminska@wsl.ch; brigitte.rohner@wsl.ch; alessandra.bottero@wsl.ch; arun.bose@wsl.ch; nadine.ruehr@kit.edu; andreas.zingg@wsl.ch; andreas.rigling@wsl.ch)

Climate-induced tree mortality became a global phenomenon during the last century and is expected to further increase in many regions. However, our current understanding of forest mortality trends is limited by the short time span of majority of studies, small number of species or narrow geographical ranges. Here, we present an overview of mortality trends of five common European tree species (Norway spruce, Scots pine, silver fir, European beech, and oak), using a unique data set of monitoring records from 127 unmanaged forest stands across broad climatic gradients in Switzerland, covering a time span of over one century (1898-2013). Species-specific annual mortality rates did not consistently increase over the entire study period nor the last decades, except for pine forests at lower altitudes, which exhibited a clear increase of mortality since the 1960s. Mixed effects models revealed that gradual changes in stand parameters (stand basal area and stand age) had the strongest impact on mortality rates, further modulated by climate, especially during the last decades. However, climate had highly variable effects on tree mortality rates, depending on the species, abiotic and biotic factors, and stand and site conditions. We complement these results with a synthesis of several case studies, conducted at species' range edges such as the upper tree line or at very dry hot-spots, where mortality trends are clearly visible. Overall, our findings highlight the complexity of forest dynamic processes such as long-term, gradual changes of forest structure, demography and species composition, which together with climate determine mortality rates.

Towards a realistic representation of disturbance events in Global vegetation models

Thomas Pugh^{1,2}, Nezha Acil¹, Mats Lindeskog³, Benjamin Poulter⁴, Rupert Seidl⁵, Cornelius Senf⁵

¹School of Geography, Earth and Environmental Sciences, University of Birmingham, Birmingham, United Kingdom; ²Birmingham Institute of Forest Research, University of Birmingham, Birmingham, United Kingdom; ³Department of Physical Geography and Ecosystem Science, Lund University, Lund, Sweden; ⁴Biospheric Sciences Laboratory, NASA Goddard Space Flight Center, Greenbelt, USA; ⁵Institute for Silviculture, University of Natural Resources and Life Sciences (BOKU), Vienna, Austria (t.a.m.pugh@bham.ac.uk; nxa807@student.bham.ac.uk; mats.lindeskog@nateko.lu.se; benjamin.poulter@nasa.gov; rupert.seidl@boku.ac.at; cornelius.senf@geo.hu-berlin.de)

Stand-replacing disturbances, including those from fire, wind-throw, bark beetles and harvest, are a cornerstone of forest dynamics, defining the age structure of forests across the landscape, with significant implications for carbon fluxes and species composition. Their extent, frequency and type are believed to have changed substantially over the last few centuries and are expected to further change over the next century. In order to realistically capture the effects of stand-replacing disturbances, dynamic global vegetation models (DGVMs) need to move beyond the current paradigm of representing all natural disturbances as fire, by explicitly representing the effects of multiple disturbance types on forest age structure. This, however, requires a range of observation-based constraints to effectively implement. Here, we will present recent efforts drawing on space-based and ground-based observations to improve the representation of these disturbance events within a DGVM. Using a model-data fusion approach with satellite forest loss products, we will show an estimate of the total contribution of all large-scale disturbance types to recent forest dynamics. We will compare this with the results of forest inventory-based approaches to determining stand age and assess what this implies about disturbance size and the equilibrium of forests with respect to current disturbance regimes. Finally, we will present work implementing relationships of disturbance frequency as a function of forest composition and climate variability from protected forest areas into a DGVM. We will conclude by highlighting key knowledge and data gaps which constrain further progress on this topic.

Characterising and quantifying forest disturbance patches using Global satellite-derived data

Nezha Acil^{1,2}, Thomas A. M. Pugh^{1,2}, Jonathan P. Sadler^{1,2}

¹School of Geography, Earth and Environmental Sciences, University of Birmingham, Birmingham, United Kingdom; ²Birmingham Institute of Forest Research, University of Birmingham Birmingham, United Kingdom (nxa807@student.bham.ac.uk; t.a.m.pugh@bham.ac.uk; j.p.sadler@bham.ac.uk)

Earth Observation imagery has permitted major advances in the detection and quantification of forest loss across the globe. However, discerning what agents caused these losses and understanding how the disturbance regimes vary over time and space remain challenging. Based on global geospatial data products for the period 2001-2018, this study seeks to (i) identify the disturbance agents causing tree cover loss at the stand scale through a process of patch analysis and classification, and (ii) comparatively assess how the frequency and severity of different disturbance agents vary across the globe. Using the 30-m resolution Global Forest Change dataset, the structural patterns of forest loss patches were explored and quantified inter-annually across biomes. Derived patch-level landscape indices will be combined with putative explanatory data to establish process links and attribute likely agents. The global distribution of stand-replacing disturbances over the period studied will be used to examine linkages between occurrence rates and environmental factors. The results will contribute to enhanced disturbance representation within a dynamic Global vegetation model, leading to better constrained simulations of forest structure and function, particularly with regard to carbon cycling.

Large scale assessment of forest attribute dynamics in Southern Brazil

Alexander Christian Vibrans¹, André Luís de Gasper¹, Laio Zimmermann Oliveira¹, Débora Vanessa Lingner¹

¹Fundação Universidade Regional de Blumenau, Blumenau, Brasil (acv@furb.br; algasper@furb.br; laiozoliveira@gmail.com; deboravanessa.ef@gmail.com)

Tropical secondary forests play important roles as carbon sink, stepping stone for biodiversity conservation, provider of ecosystem services and multiple forest products. Notwithstanding, uncertainties about increment and biomass/carbon accumulation, as well as legal restrictions are still hindering innovative practices of sustainable use within Brazilian Atlantic Forest Biome. Reliable data on secondary forest dynamics may contribute to overcome traditional paradigms and subsidize public forest land use policies. We discuss methodologic aspects of large-scale continuous tree plot measuring and present results of a systematically designed, spatially unbiased statewide forest and floristic inventory (IFFSC). We analyzed data from 418 field plots, with sample area of 4,000 m² each, covering the entire territory of Santa Catarina state (95,000 km²), in Southern Brazil, measured at two occasions with mean interstice of 7.1 years (2007-2011 and 2014-2019). We present overall and forest type mean annual change rates of tree (DBH >10 cm) recruitment and mortality (human induced and natural), of gain and loss of basal area, stem volume and biomass, as also regeneration (DBH <10cm, height >1,30cm) dynamics. Annual tree mortality is about 2.5%, while recruitment is about 3,6%; in a similar way basal area gain (3,6%) is greater than loss (2,2%). Stem volume and biomass changes present the same trend, unfolded by species and species groups. Species composition is significantly changing, with decrease of pioneer/early secondary and increase of shade-tolerant species, regarding both tree density and basal area level. Our data-sets are open for data-sharing and integrated with Global Forest Diversity Initiative (GFBI) and sPlot (iDIV) data-bases.

On modelling individual-based tree mortality: dealing with unequal period lengths and hierarchical effects

Christian Salas-Eljatib¹, Aaron Weiskittel², Joaquin Riquelme¹

¹Universidad Mayor, Santiago, Chile; ²University of Maine, Orono, USA (csejlatib@gmail.com; aaron.weiskittel@maine.edu; joaquin.riquelme@umayor.cl)

Tree mortality is a critical ecological phenomenon shaping forest ecosystem dynamics, structure, and composition, and its effects are of global relevance due to its relationship with forest conditions and environmental changes. Both density-dependent and environmental factors strongly influence tree mortality, but there are challenges associated with individual-based mortality data, particularly observations with uneven measurements intervals. In this analysis, we develop and examine several individual-based mortality modelling strategies that simultaneously account for unequal period lengths and the hierarchical structure of the data in long-term, permanent plot data from the mixed *Nothofagus* forests in southern Chile. These strategies depend on: the data structure to be used (traditional or all multiple combinations of the time series), the functional form (logit and Gompit), and the period length adjustments (annualized, covariate, and exposure). Our findings indicated that the Gompit functional form outperforms the traditional logit link function. In addition, considering the period length as an exposure in the generalized linear mixed-effects model offered better goodness-of-fit than the other examined period length adjustments. Using all the possible combinations of the dynamic data did not improve the prediction capabilities of the model variants, but important differences were found in the statistical inferences of the fitted models. Our results highlighted that understanding tree mortality strongly relies on a suitable model being able to both capture and assign the sources of variation to the corresponding variables, which was best accomplished using a multi-level binary Gompit-exposure modelling framework.

Effects of extreme storms in the Portuguese forest: assessment of damages and development of a storm catalogue

Teresa de Jesus Fidalgo Fonseca^{1,2}, Stéphanie Lopes Ribeiro¹, Irene Pereira Cascarejo³, Ana Paula Alves Neves², Margarida da Conceição Rasteiro Magano Lopes Rodrigues Liberato^{1,4}

¹Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal; ²Centro de Estudos Florestais, Universidade de Lisboa, Lisboa, Portugal; ³Instituto da Conservação da Natureza e das Florestas, IP, Porto, Portugal; ⁴Instituto Dom Luiz, Universidade de Universidade de Lisboa, Lisboa, Portugal (tfonseca@utad.pt; ribeiro.stephanie.lopes@gmail.com; irene.cascarejo@icnf.pt; ana.neves@icnf.pt; mlr@utad.pt)

Extreme storms are an important abiotic disturbance factor with a negative impact in forest systems across the world. Disturbances strongly affect the forest resources, their dynamics and have a negative impact on forest carbon budget. In Europe's forests, more than 130 storms causing notable damage to forests were identified since 1950 (FORESTORMS database). Forest damages are likely to increase further in the frequency and in the damages in coming decades due to more extreme weather conditions associated with the effects of climate change. Moreover, storms are predicted to affect wider areas and penetrate further east across Europe (Gardiner et al; 2010). The information on the storm damages is not equally balanced across European countries, with a paucity of information available for countries of the Mediterranean area being reported. In Portugal, partially due to the historical importance of wildfires, little prominence has been given to data collection of the storm's damages in the forests. Known exceptions refer to the cyclone of 1941 and to the Gong depression in 2013. This communication aims to present information gathered under the umbrella of WEx-Atlantic project and to share the results achieved so far, on the preparation of a catalogue of storms and forest wind damage for Portugal. The catalogue, by providing appropriate and up-to-date information will help to understand storm risk and to promote adequate national strategies. Moreover, the results of the research can be integrated into the monitoring of damage studies that are being promoted across Europe, enhancing post-storm coordination between countries.

Climate-induced forest mortality in the Pacific islands: What do we really know?

Hans Juergen Boehmer¹, Stephen Galvin¹

¹University of the South Pacific, Suva, Fiji (neobiota@web.de; stephen.galvin@usp.ac.fj)

In 1991, Allan N. D. Auclair submitted a report to the US Environmental Protection Agency that discussed the widespread forest dieback of the 1970s and 1980s in the Pacific Rim in the context of extreme climatic fluctuations. Auclair's work was based on over 20 years of intense and complex research on the causes of forest dieback in Hawaii and other islands across the Pacific, carried out by multiple research groups, in particular on the effects of pathogens, nutrient limitations, and potential climatic triggers like droughts and other extreme events. After careful consideration of all available knowledge he concluded that region-wide, persistent episodes of forest dieback are incited by extreme moisture stresses. Ironically, perception of this spectacular phenomenon and related ground-breaking research vanished while the awareness of climate change and its potential impact on the World's forests started to grow, rapidly becoming a major focus of forest mortality-related research in recent years. In this paper, we reinforce memory of the World's first complex discussion on the natural causes of forest dieback as a showcase for the complexity of forest mortality research, and try to summarize what science has added to our knowledge on the links between tree mortality, forest dynamics and climate change in the Pacific islands in the meantime.

Monitoring urban forest mortality and change globally

David Nowak¹

¹USDA Forest Service, Syracuse, USA (dnowak@fs.fed.us)

Urban forests provide numerous benefits to society, but face numerous threats due to development, insects and diseases, climate change and other environmental pressures. To better manage this important resource, it is essential to inventory and monitor changes in forest composition and value through time. To this end, a free suite of forest assessment and monitoring tools have been developed that can be applied in cities across the world. These tools provide an easy and standardized means to monitor tree cover change using Google images and establish permanent plots to monitor urban forest change and mortality. This presentation will discuss these monitoring protocols and tools. In addition, it will present results on: a) urban forest change and mortality in Syracuse, NY and Baltimore, MD, and b) recent urban tree and impervious cover change globally using random paired-point analysis of Google aerial images. These monitoring protocols can be used globally to assess forest mortality and change.

An assessment of tree health in Brazil / Diagnóstico sobre a sanidade das árvores do Brasil

David Fagner de Souza e Lira¹, Raquel Leao¹, Doádi Antônio Brena¹, Claudia Maria Mello Rosa¹, Roberto Veloso de Freitas¹

¹Serviço Florestal Brasileiro, Brasília, Brasil (liradfs@gmail.com; raquel.leao@florestal.gov.br; dabrena@gmail.com; claudia.rosa@florestal.gov.br; roberto.freitas@florestal.gov.br)

As florestas estão suscetíveis à influência de fatores que podem ser causados por eventos naturais, influenciados pelo clima, por pragas e doenças ou ainda por ações do homem, como o uso de fogo. A influência desses fatores pode levar a alterações na composição, estrutura e funções das florestas, afetando sua saúde e vitalidade. De acordo com o processo de amostragem do Inventário Florestal Nacional do Brasil (IFN-BR) para a coleta de dados em campo seguindo grade nacional de pontos amostrais equidistantes 20 x 20 km entre si estabelecida pelo Serviço Florestal Brasileiro, uma enorme gama de informações é coletada. As variáveis coletadas foram classificadas de forma a facilitar o seu entendimento, como por exemplo, as biofísicas, que no caso de inventários florestais correspondem às informações mais diretamente ligadas aos recursos florestais e por isso são consideradas de fundamental importância nos levantamentos de campo. Dados sobre árvores sadias, árvores mortas, com podridões, com cupins e com ocos foram registrados e analisados em 21 estados mais o distrito federal até o início de 2019 nos levantamentos do IFN-BR em 650.181 indivíduos. Os resultados da análise conjunta dos dados demonstram que aproximadamente 53% dos indivíduos foram classificados em estágio sadio, 30% estão classificados em estágio inicial e 16% em estado avançado de deterioração ou são indivíduos mortos em pé. Pode-se dizer que é de extrema importância a continuidade do IFN-BR utilizando-o como ferramenta efetiva de classificação de padrões qualitativos e quantitativos sobre as florestas do Brasil.

B4e: FOREST TREE AND STAND GROWTH PROCESSES UNDER DIFFERING ENVIRONMENTS: CONCEPTS, METHODS AND EVIDENCE

Transport and distribution characteristics of photoassimilates of *Pinus massoniana* seedlings

Wenfa Xiao¹, Xiuxiu Deng¹, Lixiong Zeng¹, Lei Lei¹, Zheng Shi¹

¹Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, State Forestry Administration Key Laboratory of Forest Ecology and Environment, Beijing, China (xiaowenf@caf.ac.cn; dengxxiu@163.com; zlxcaf@163.com; lei19860123@163.com; sz481@126.com)

Exploring the transport and distribution of photoassimilates in *Pinus massoniana* would deepen our understanding of its productivity formation. The 1.5-year-old *P. massoniana* seedlings were feeding with pulse-chased ¹³C labeling for 4 h, and different organs were collected at 0, 2, 5, 17, 24, 72, 120, 168, 216 and 360 h after labeling to analyze ¹³C levels, to investigate the transport and distribution of recent photoassimilates in the seedlings; meanwhile, total carbon and non-structural carbohydrate were determined in various organs. The amount of photoassimilates transport from source to sink gradually decreased until completing. Concretely, after the end of marked time within 0-24 hours, the value of recently photoassimilates transport was the most, within 24-216 hours the transport decreased gradually, and was completed after 216 hours, and more than 59% of photoassimilates completed transport to sink organs within 0-24 hours; After the photoassimilates completed transport, the distribution of recently photoassimilates was ordered as 1-year leaves> current-year leaves>roots>stem>1-year branches> current-year branches, same as the distribution of the biomass. The sink activity was ordered as current-year leaves> current-year branches>1-year leaves> roots>1-year branches>stem. The distribution of total carbon and NSC accumulation in various organs was in accordance with the distribution of recently photoassimilates. The photoassimilates transport rate of *P. massoniana* seedlings was greater than 0.1 m/h. More than 59% photoassimilates was exported to each sink organ within 0-24 h. The accumulation of photoassimilates in various organs was mostly functional organs. This distribution pattern is conducive to the growth of *P. massoniana* in the seedling stage.

Changes in biomass allocation in *Eucalyptus* rootstock induced by forest rotation

Humberto Eufraide-Junior¹, Carla Brito¹, Renan Mangialardo¹, Julio Horta², José Marcos Freitas³, Saulo Guerra¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Universidade de São Paulo, Botucatu, Brasil; ²Ámbar Energia, São Paulo, Brasil; ³Florena, Negócios Florestais Eireli, Uberlândia, Brasil (hdjejunior@gmail.com; cmbunesp@gmail.com; rsmangialardo@gmail.com; julio.horta@ambarenergia.com.br; josemarcos@florenaflorestal.com.br; saulo.guerra@unesp.br)

Studies about trees root growth have gained importance, moreover due to the recent climate change. The seek for a sustainable forest conditions to require deepening the knowledge of belowground biomass dynamic. This work had as objective to identify patterns of biomass allocation in eucalypt rootstock induced by forest rotation. Thus, four *Eucalyptus* clones were managed in first and second rotation at Midwest region of Brazil. Rootstock *Eucalyptus* biomass (5.7 to 13.1 years old) were removed from the underground with a front wheel loader and was cut with a chainsaw into three different fractions: stump (above-ground biomass); root crown (below-ground biomass) and; coarse and fines roots (below-ground biomass). The fractions were weighted and the dry biomass was obtained after analyzing the moisture content of the material in the laboratory. Results showed that rootstock biomass varied of 30.4 to 105.3 kg per tree and the crown root is the most representative fraction (67.3%) of the *Eucalyptus* rootstock followed by fines and coarse roots (25.8%) and stump (6.9%). It was observed for all clones a higher biomass allocation in crown root compared to the others fractions which can be related with maturity of tree, either for support above-ground structure or nutritional reserve accumulation.

The contribution of fine roots to net primary production in temperate broadleaved and coniferous forests

Ji Young An^{1,2}, Akira Osawa², Byung Bae Park^{1,3}, Si Ho Han¹, Woo Bin Youn¹, Jeong Min Seo¹

¹Chungnam National University, Republic of Korea Daejeon; ²Kyoto University, Kyoto, Japan; ³Korean Society of Forest Science, Seoul, Republic of Korea (ajy2656@cnu.ac.kr; aosawa@kais.kyoto-u.ac.jp; bbpark@cnu.ac.kr; bupleurumhan@cnu.ac.kr; dsdnqls95@naver.com; jmseo3@naver.com)

Net primary production (NPP) is one of the key indices describing carbon fixation capacity of terrestrial ecosystems. Estimates of forest NPP is of importance to understand carbon and nutrient cycling because forest ecosystems are major carbon sink on land. One of essential parts of NPP is assimilated carbon and nutrients translocated to belowground for growing fine roots which take a role of acquiring soil resources such as water and nutrients. However, there is still no consensus on how fine roots contribute to forest NPP in terms of quantitative assessment. In this study, we investigated patterns and quantities of fine roots in relation to forest NPP estimation in temperate broadleaved and coniferous forests of Korea and Japan. We used sequential soil core and ingrowth core methods to estimate fine root biomass and production, and the flat-bed scanner method was used to investigate seasonal dynamics of fine roots. Annual fine root production ranged from 93 to 1342 g m⁻² across 13 stands, accounting for 10-44 % of NPP. The estimates of fine root production by sequential cores were higher than that by ingrowth cores. Relatively high fine root production in spring was observed in broadleaved forests where *Quercus serrata* dominates. Fine root production was positively correlated with NPP, suggesting that high belowground carbon allocation in forests leading to high productivity. Further, we will review the literature regarding the relationship between fine roots and forest productivity for better understanding of the contribution of fine roots to carbon and nutrient dynamics in ecosystem processes.

A two-year defoliation experiment in *Pinus radiata* grafts: does the lower canopy matter?

Mireia Gomez Gallego¹, Nari Williams¹, Sebastian Leuzinger², Peter Scott¹, Martin Bader²

¹Scion, New Zealand Forest Research Institute, Rotorua, New Zealand; ²Institute for Applied Ecology New Zealand, School of Sciences, Auckland University of Technology, Auckland, New Zealand (mireia.gomez@scionresearch.com; nari.williams@scionresearch.com; sebastian.leuzinger@aut.ac.nz; peter.scott@scionresearch.com; martin.bader@aut.ac.nz)

Biotic and abiotic stressors can lead to different defoliation patterns within trees. Foliar pathogens of conifers commonly prefer older needles and infection frequently progresses from the bottom canopy to the top. During mild defoliation episodes, only old foliage in the lower canopy is affected, which represents a defoliation pattern that has received little attention in past research. A two-year artificial defoliation experiment was performed using 2-year-old *Pinus radiata* grafts to investigate the effects of lower-canopy defoliation on carbon assimilation and allocation. Sixty-two grafts received the following treatments in consecutive years: Control-Control, Control-Defoliated, Defoliated-Control and Defoliated-Defoliated. Stomatal conductance, A/Ci curves, diameter, height, biomass and non-structural carbohydrate concentrations in needles, stems, and roots were measured before and after each treatment. No upregulation of photosynthesis was observed in response to defoliation. Root: shoot ratio and leaf mass were not affected by any treatment, suggesting prioritization of canopy regrowth following defoliation. In genotype B, defoliation appeared to impose carbon shortage and also reduced sugar storage in roots, while in genotype A, neither growth nor storage was altered. Root carbon storage in genotype B recovered over the second growing season. Our results suggest genotype-specific defoliation tolerance in *P. radiata*. In genotype A, the contribution of the lower canopy to the whole-tree carbon uptake appears to be negligible presumably conferring resilience to foliar pathogens affecting the crown base. Redundancy of lower-canopy foliage in terms of carbon assimilation is shown, raising a fundamental question on the role of the lower canopy in plants' carbon budget.

Functional responses of *Gmelina arborea* Roxb seedlings, bring under to contrasting light environments in tropical dry forest areas in Colombia

Omar Melo¹, Carolina Betancourt¹

¹Universidad Del Tolima, Ibagué, Colombia (omelo@ut.edu.co; acbetancourt@ut.edu.co)

The research was conducted in areas of tropical dry forest in Colombia and shows the behavior of the relative growth rate (RGR), functional and morphological components in *G. arborea* seedlings, bring under to different lighting conditions. The evaluation period was 120 days. The lighting conditions were expressed as the relative proportion of the Photosynthetically Active Radiation (PAR), established in umbracles within the nursery. The illumination values correspond to 40, 60 and 100%. The total biomass and its components of stem, root, leaves and leaf area were generated from the seedling harvest and the determination of its dry weights for six evaluation periods (0, 15, 30, 60, 90 and 120 days). A foliar analysis was carried out and the contents of nitrogen, total proteins and total phenols were evaluated. The growth components evaluated were net assimilation rate, specific leaf area and shoot/root ratio. The results showed that seedlings that grow in environments with light restrictions have higher RGR than those that grow at full exposure, for which the seedlings adjust their morphological and physiological characters in these environments. The results show a high plasticity in the populations of the species that prioritize the distribution of its biomass and its functionality according to the lighting conditions of the growing environment. These results contribute to the optimization of agroforestry systems and pure plantations, to maximize their conditions of competition or adaptation.

Ideotype competition dynamics in clonal *Pinus taeda* stands with contrasting crown attributes

Timothy Martin¹, Tania Quesada¹, Gary Peter¹, Jason Vogel¹, Salvador Gezan¹, Eric Jokela¹

¹University of Florida School of Forest Resources and Conservation, Gainesville, USA (tamartin@ufl.edu; tquesada@ufl.edu; gfpeter@ufl.edu; jvogel@ufl.edu; sgezan@ufl.edu; ejokela@ufl.edu)

Competition is central to forest stand structure and function. Competition has been conceptualized as ideotypes, conceptual models which hypothesize suites of traits which may contribute to varying competitive dynamics among genotypes. We examined competition from an ideotype perspective in a *Pinus taeda* clonal block plot experiment planted in 2010 in Gainesville, Florida. The design was a split-plot randomized complete block with treatment factors of planting density (741 trees/ha vs; 1483 trees/ha) and genetic type (three clones), with three replicates. Plot size ranged from 0.05 to 0.16 ha, depending on treatment. The three clones in the experiment differ in crown architecture, with one clone having significantly narrower crowns than the other two clones. By the second year of stand development onward, a significant ($P < 0.05$) spacing x clone interaction manifested for several variables (DBH, height, individual tree stem volume, stand-level stem volume). This interaction was due almost entirely to the differential response of the narrow-crowned clone to spacing. At age 7 at 741 trees/ha, the narrow-crowned clone had similar mean height, DBH, and individual tree stem volume to other clones. However, at 1483 trees/ha, the narrow-crowned clone showed a smaller decrease in DBH and stem volume (5% decrease vs; 19% decrease in other clone) and increased height (increase of about 1m vs. no increase in other clones), resulting in rank changes among the clones depending on competitive environment/spacing. We will report on the results of an allometric harvest designed to elucidate the mechanism of the differential responses.

B4f: LEGACIES OF DISTURBANCES ON FOREST FUNCTIONS**How can tree rings help to detect past forest disturbances and understand their legacy?**Paolo Cherubini^{1,2}, Andreas Rigling¹¹WSL Swiss Federal Research Institute, Birmensdorf, Switzerland; ²University of British Columbia, Vancouver BC, Canada (paolo.cherubini@wsl.ch; andreas.rigling@wsl.ch)

Tree rings have a tremendous power for reconstructing environmental conditions. In temperate climates, cambial activity of trees stops during the cold season and annual tree rings are formed. Tree rings have been widely used for reconstructing past climate, and can be used as indicators of the environmental (not only climatic) conditions in which trees have been growing, because their characteristics depend on the environmental conditions in which they grew. Within a forest stand, tree rings can provide information about the occurrence and impact of past disturbances such as insect infestation, fungal disease, wildfire, snow avalanche, windstorm or drought and frost. Reading tree rings in a proper way, tree and stand age can be determined with annual resolution. Past tree-growth trends, and abrupt decreases or releases after suppression can be identified, and information on the spatiotemporal occurrence of past disturbances (natural and anthropogenic), and their impact on tree growth, can be inferred for periods of time for which there are no historical records. It is more difficult to use tree rings to assess forest stand biomass. Some attempts have been made, but almost all the studies have been subject to some form of sampling bias. Using tree rings as indicators of tree biomass accumulation through time is possible but a sampling design that deals with all these issues adequately has yet to be developed, and represents a major challenge for dendroecology.

Management of bark beetle outbreaks: a carbon perspectiveLaura Dobor¹, Tomáš Hlásný¹, Soňa Zimová¹, Werner Rammer², Rupert Seidl²¹Czech University of Life Sciences, Faculty of Forestry and Wood Sciences, Prague, Czech Republic; ²University of Natural Resources and Life Sciences, Department of Forest- and Soil Sciences, Vienna, Austria (dobor.laura@gmail.com; hlasny@nlcs.org; zimova.sona@seznam.cz; werner.rammer@boku.ac.at; rupert.seidl@boku.ac.at)

Bark beetle outbreaks have recently disturbed substantial amounts of timber worldwide and triggered diverse management responses. These have ranged from the absence of active intervention to unprecedented intensities of salvage and sanitation logging, beetle trapping and insecticides application. Some responses included modified silviculture regimes, which aimed to reduce the share of vulnerable overmature stands or host trees. Synergistic impacts of bark beetle disturbance and subsequent management responses on ecosystem functioning, however, remain insufficiently understood. We used the forest landscape and disturbance model iLand to explore the effects of management efforts to prevent or suppress outbreaks of the European spruce bark beetle in a forest landscape in central Europe. We described the implementation of bark beetle disturbances in the iLand modelling framework and used simulations to disentangle the impacts of disturbance and management on forest carbon. We investigated trade-offs between excessive carbon removal by sanitation logging and premature harvesting of host trees, and the potentially positive effects of these measures via reducing outbreak risks. The overall effect of sanitation logging on landscape carbon was negative, though aboveground carbon benefited from reduced bark beetle disturbance. Long-term outbreak prevention, however, increased forest vulnerability to wind, and had an overall negative impact on forest carbon. A reduced rotation period reduced both bark beetle and wind disturbance; however, the amount of carbon in the landscape decreased sharply. We showed how ecosystem models can quantify a cascade of processes triggered by bark beetles and their management, and thus help better understand their impacts on ecosystem functioning.

Effects of forest fires on the fluxes of carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O) in permafrost and non-permafrost soils of Boreal ForestsChris Ribeiro-Kumara¹, Kajar Köster¹, Frank Berninger², Jukka Pumpanen³, Egle Köster¹¹University of Helsinki, Helsinki, Finland; ²University of Eastern Finland, Joensuu, Finland; ³University of Eastern Finland, Kuopio, Finland (christine.ribeiro@helsinki.fi; kajar.koster@helsinki.fi; frank.berninger@uef.fi; jukka.pumpanen@uef.fi; egle.koster@helsinki.fi)

Approximately half of the carbon entering the boreal forest ecosystem through photosynthesis is allocated belowground, where it can be stored for millennia. This reservoir is notably significant in boreal peatlands and areas of permafrost. Boreal soils may act as source and sink of greenhouse gases (GHGs) (e.g., CO₂, CH₄, and N₂O), with the net balance resulting from a multitude of dynamic processes. Fire disturbance is an integral part of boreal forests and impacts GHG fluxes and emission rates. However, studies comprising fluxes of CH₄ and N₂O are still scarce for boreal soils, especially when combined with post-fire succession. Our study introduces a network of fire chronosequences throughout boreal forests, including study sites in permafrost areas (Canada and Siberia) and in non-permafrost areas (Finland and Estonia), where we investigate GHG fluxes using a closed chamber system. The chamber is equipped with a diffusion-type CO₂ probe that measures soil respiration instantaneously. The CH₄ and N₂O fluxes are sampled simultaneously from the chamber headspace and further analysed via gas chromatography. We found that in permafrost and non-permafrost areas, soil was a source for CO₂ and a sink for CH₄. CO₂ emissions were lowest in the first years after fire, stabilizing around 60 years after fire. In Finland, the highest CH₄ uptake occurred a few years after fire, whereas in Canada it happened a few decades after fire. We could not identify a consistent pattern in N₂O flux among our study areas.

Is it possible to affect browsing pressure, food availability, and visitation rates of *Alces alces* with fire? A comparative study between wildfire and prescribed burning in the Swedish Boreal ForestEmelie Fredriksson¹, Märtha Wallgren², Therese Löfroth¹¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²Skogforsk, Uppsala, Sweden (emelie.fredriksson@slu.se; martha.wallgren@skogforsk.se; therese.lofroth@slu.se)

Land use conflicts between maximizing forest production, conservation and maintaining ecosystem services is an urgent challenge for sustainable forest management today. In the boreal forest, fire is a fundamental natural disturbance that has been replaced by timber harvest in Fennoscandia. These changes have had negative impacts on biodiversity, however, prescribed burn for restoration purposes is currently being implemented to counteract the reduction of natural fire disturbance. Another important disturbance is herbivory where large ungulates play a central role. Studies of the interactions between fire and herbivory in the boreal forest ecosystems of Fennoscandia are almost absent. The aim of this project is to quantify the long-term effects of forest fire and

browsing by moose (*Alces alces*), as well as the possible interaction between the two disturbances, on food availability, tree damage, and moose habitat use. We sampled three large wildfires and five prescribed burns 12 years post-fire. There were higher visitation rates (based on pellet counts) in the wildfire areas compared with the unburnt controls, however, the pattern was not significant for the prescribed burns. Possible due to the lower intensity of the fire in the prescribed burns, the effects on food availability and browsing damage differs both from the control and the wildfire areas with wildfire areas having both the highest food availability and browsing damage. These results are important to better understand the differences between prescribed burns and wildfires and their interaction with herbivory so that negative impacts of browsing can be reduced in managed stands.

Projecting future aboveground biomass and productivity of managed Eastern Canadian mixedwood Boreal Forest in response to climate change

Eliana Molina¹, Osvaldo Valeria¹, Louis de Grandpre², Jorge Ramirez³, Dominic Cyr⁴, Yan Boulanger²

¹Forest Reserach Institute, UQAT, Rouyn-Noranda, Canada; ²Natural Resources Canada, Canadian Forest Service, Sainte-Foy, Canada; ³Faculty of Agrarian Science, University of Cauca, Popayan, Colombia; ⁴Environment and Climate Change Canada, Pollutant Inventories and Reporting Division, Montreal, Canada (ecmolinag@gmail.com; osvaldo.valeria@uqat.ca; louis.degrandpre@canada.ca; j.ramirez@unicauca.edu.ca; dominic.cyr@canada.ca; yan.boulanger@canada.ca)

Eastern Canadian Boreal Forests are modulated by wildfires and forest management. To evaluate forest dynamics under possible interactions among fire and timber harvest in a future climate warming scenario (RCP 2.6, RCP 4.5 and RCP 8.5) we simulated with LANDIS II the dynamic of the 78000 km² of boreal forests. Forest management intensity was modeled considering changes in total harvested area (0.5%, 1%, and 2%) and the age that conifers and hardwoods can be harvested (5030, 7050, and 9070). The model projections showed that both forest management intensity and climatic scenarios explained most of the variability in aboveground biomass, productivity (ANPP), and forest composition. Forest management was the most important factor in the southern forests because there were more stands with the age and composition required by each harvesting prescription to deal with the annual prescription. On the contrary, in the northern forests, there was a mixed effect of climate change and forest management because many of the areas suitable for harvesting were previously burned limiting the forests available for harvesting. Although an increase in burned area due to climate change is expected, the intensification of forest management seems to be the most important driver of the increase of hardwoods and mixed stands and the decrease of conifers stands, as well as the decrease of the aboveground biomass and ANPP on the landscape. These results suggest that timber supply would be at risk in the Eastern Canadian, therefore, some strategies should be applied to adapt forest management to climate change.

Linking ecosystem and disturbance simulation models for enhancing the resilience of Alpine protection forests

Peter Antkowiak¹, Rasoul Yousefpour¹, Peter Bebi², Perry Bartelt², Adrian Ringenbach², Werner Rammer³, Manfred J. Lexer³, Marc Hanewinkel¹

¹Chair of Forestry Economics and Forest Planning, University of Freiburg, Freiburg, Germany; ²WSL Institute for Snow and Avalanche Research SLF, Davos, Switzerland; ³Institute of Silviculture, Department of Forest- and Soil Sciences, University of Natural Resources and Life Sciences (BOKU), Vienna, Austria (peter.antkowiak@ifef.uni-freiburg.de; rasoul.yousefpour@ifef.uni-freiburg.de; bebi@slf.ch; bartelt@slf.ch; adrian.ringenbach@slf.ch; werner.rammer@boku.ac.at; mj.lexer@boku.ac.at; marc.hanewinkel@ifef.uni-freiburg.de)

Alpine forests fulfill an important protective function against gravitational hazards such as landslides, avalanches or rockfall. At the same time they are subject to a variety of disturbances such as storms or insect outbreaks. As disturbances are expected to increase with climate change, forest resilience will be increasingly important for maintaining sufficient levels of protection. We study how an altered disturbance regime would affect the provision of protection ecosystem services in alpine forests in the future and whether it is possible and economically beneficial to increase forest resilience by targeted management measures. To disentangle the dynamic interaction of forest growth, disturbance events and management measures in alpine forests, we simulate future forest development in two valleys in Switzerland that are highly exposed to gravitational natural hazards. We use the hybrid forest simulator PICUS for simulating climate effects, storms and biotic disturbances. For simulating rockfall and avalanche impacts, we couple PICUS with the RAMMS mass movement simulation software. An intermediate software layer schedules management actions and disturbance events and feeds the effects of gravitational mass movements back into the main forest simulation. We quantify management costs, timber revenues and the value of disaster risk reduction resulting from different management scenarios to develop management strategies that are optimally adapted to future disturbance regimes and stakeholder preferences in the case study areas. For encouraging forest owners to invest into resilience-enhancing measures, we develop and test an approach to integrate protection forest management with the current system of financial property insurance.

Identifying areas of stable habitat in dynamic landscapes: implications for the management and conservation of forests

Craig Nitschke¹, Raphael Trouve¹, Lindy Lumsden², Lauren Bennett³, Melissa Fedrigo¹, Andrew Robinson⁴, Patrick Baker¹

¹The University of Melbourne, Richmond, Australia; ²Arthur Rylah Institute for Environmental Research, Heidelberg, Australia; ³The University of Melbourne, Creswick, Australia; ⁴The University of Melbourne, Parkville, Australia (craign@unimelb.edu.au; raphael.trouve@unimelb.edu.au; lindy.lumsden@delwp.vic.gov.au; lb@unimelb.edu.au; mel.fedrigo@gmail.com; apro@unimelb.edu.au; patrick.baker@unimelb.edu.au)

Effective conservation planning for species that require multiple structural features depends on vegetation models that can capture the dynamics of each habitat element across both spatial and temporal scales. Incorporating these dynamics at landscape scales is essential to identifying areas of habitat that will be stable over time in response to disturbances, management, and climate change. Using a critically endangered species, the Leadbeater's possum (LBP; *Gymnobelideus leadbeateri* McCoy) as a case study, we explored the effects of a range of management and climate scenarios upon the structure and availability of habitat within a 280,000 ha landscape in southeast Australia. We used a spatially explicit landscape-simulation model, LANDIS-II, linked to habitat suitability and patch modelling, to identify areas of temporal stability or transience in habitat for LBP. Using boosted regression trees and general additive modelling we explored the impact of resource availability, wildfire, forest management, and climate change on LBP habitat with the goal of understanding the importance of these factors on future habitat availability. Wildfire was the main factor determining all habitat components for LBP, both alone and in interaction with climate change and forest management. We identified stable habitat patches that will likely persist under future conditions, and that might be prioritised for conservation. We highlight how the current reserve network could be augmented to improve the future conservation status of LBP. Our approach provides conservation planners with a spatially and temporally explicit framework for incorporating the key dynamic processes that are typically omitted in conservation planning.

Burning for biodiversity? Decadal effects of wildfire on saproxylic communities in Northern Boreal Forest with a long history of fire suppression

Therese Löfroth¹, Emelie Fredriksson¹, Isak Vahlström¹, Roger Pettersson¹

¹SLU, Umeå, Sweden (therese.lofroth@slu.se; emelie.fredriksson@slu.se; isak.vahlstrom@gmail.com; roger.b.pettersson@slu.se)

Wildfire is an important disturbance in Boreal ecosystems, restarting succession and creating habitat for species dependent on fire for their survival. In Fennoscandia, efficient fire suppression during the last century has almost eradicated fire from the forest landscape, resulting in population declines for several species. However, active reintroduction of fire as an ecological restoration tool has been introduced the last decades and climate change has increased the frequency of wildfires. It is still unclear how these prescribed fires differ from wildfires and how species are affected by fire in landscapes with a long history of fire suppression. We studied the ecological decadal (>10 years) effects of wildfire and prescribed burnings on biodiversity of invertebrates and wood decay fungi. The study focused around three large wildfires in Northern Sweden that burnt the same year and are located in landscapes with different management intensity. Prescribed burnings and unburned stands were included as comparison. We show that fire impact the biodiversity of wood living beetles and fungi for more than a decade. The turnover of beetles was fast the first few years after fire and differences in assemblage composition still remained after 12 years. Wood decay fungi communities shifted towards generalist species favoured by early successional habitat after fire but several rare species occurred only in burned areas. The abundance of microarthropods was also affected with significantly lower densities of both mites and springtails in burned areas 12 years after fire. Thus, fire is an important ecological restoration tool in boreal landscapes.

Sustainable forest management: a simulation case-study on fire resilience

Susana Barreiro^{1,2}, João Rua¹, Akli Benali¹, Margarida Tomé¹

¹Universidade de Lisboa, Instituto Superior de Agronomia, Centro de Estudos Florestais, Lisboa, Portugal; ²Forest Ecology and Forest Management Group, Wageningen University and Research, Wageningen, Netherlands (smb@isa.ulisboa.pt; jcrua@isa.ulisboa.pt; aklibenali@gmail.com; magatome@isa.ulisboa.pt)

The supply of forest products and services depends on forest area, forest productivity and on a set of management choices. StandsSIM.md, a management driven forest simulator, was used in a practical exercise aiming to assess the impact of different management scenarios on wood supply and profitability of eucalypt plantations. A small parish in the center of Portugal, struck by a large wildfire in 2017, was selected as the case-study area. The objective was to show local forest owners that by reducing forest degradation and improving management eucalypt plantations could become more productive, economically viable and eventually more fire-resilient. Before the fire, around 90% of the parish was forested mainly with eucalypt (52%). Local stakeholders were deeply engaged in identifying and characterizing the forest management approaches (FMAs) defining five main forest owner types. Simulation scenarios were defined by assigning different shares of forest area to the five owner types/FMAs. A business-as-usual (BAU) scenario and three additional scenarios (S0, S1, S2) reflecting a reduction in forest area (for creating a fuel-break network) combined with increasing levels of management intensification were created. Estimates of eucalypt standing volume and of net present value were obtained for the parish running StandsSIM.md simulator under the four scenarios for a period of 36 years considering an interest rate of 4%. Preliminary results indicated that despite reducing forest area, for creating the fuel-breaks, standing volume increased from the BAU towards the S2 scenario, proving that implementing sustainable forest management makes a difference.

Elevated nitrogen (N) deposition can cause substantial changes in forest ecosystems. In Europe, N deposition increased for several decades until it peaked around 1990. Since then, moderate decreases in N deposition have been observed especially in Central and Western Europe where deposition levels are highest. We reviewed observational studies on the responses of forest ecosystems in Europe to the decrease in N deposition. We focused on five indicators, i.e. soil acidification and eutrophication, understory vegetation, tree nutrition (foliage concentrations), tree vitality and tree growth. We found a limited decrease in soil solution nitrate concentrations and a potential reaction in foliar N concentrations but no broad-scale responses in understory vegetation, tree growth, or vitality. Results from experimental studies supported the observation of a greater sensitivity of soil solution and foliar element concentrations to changes in N supply. Despite the decline in N deposition in the last 30 years, deposition rates are still high compared to pre-industrial levels in most parts of Europe and future decreases are expected to be small. We hypothesize that the past and future decline in N deposition alone is unlikely to reverse the effects of N saturation in Europe's forests. Instead, the reaction of soil N pools to climate change and forest management might be decisive for forest ecosystem N cycling in the future.

Environmental and host filtering of ectomycorrhizal fungi at large scales

Understanding the large-scale diversity and distribution of soil organisms that drive biogeochemical processes and responses to environmental change remains a contentious field of study; there is a generally acknowledged lack of consistent drivers of diversity and abundance at large spatial scales. Here we investigate ectomycorrhizal fungi at unprecedented scale and resolution across European forests to test for key biotic and abiotic environmental predictors, identify dominant responses and thresholds across complex gradients of environmental variables, and investigate whether there is plasticity in traits. Across Europe we sampled 137 level II plots of ICP Forests; one of the most extensive biomonitoring networks on Earth in which the effects of pollution and changes in forest soil quality have been closely monitored. We show the effect of 38 host, environment, climate and geographical variables on ectomycorrhizal diversity, and define thresholds of community change for key variables. We quantify host specificity and reveal plasticity in functional traits involved in soil foraging across gradients. We conclude that environmental and host factors explain most of the variation in ectomycorrhizal diversity, that the environmental thresholds used as major ecosystem assessment tools need adjustment and that the importance of belowground specificity and plasticity has previously been underappreciated.

Ozone concentrations and foliar symptoms on European forests

Marcus Schaub^{1,2} , Maxime Cailleret^{1,2}, Elena Gottardini^{3,4}, Matthias Häni^{1,2}, Marco Ferretti^{1,2}

¹Swiss Federal Research Institute WSL, Birmensdorf, Switzerland; ²Swiss ForestLab, Birmensdorf, Switzerland; ³Research and Innovation Centre, Fondazione Edmund Mach (FEM), San Michele all'Adige, Italy; ⁴IRSTEA Aix-en-Provence, France (marcus.schaub@wsl.ch; maxime.cailleret@irstea.fr; elena.gottardini@fmach.it; matthias.haeni@wsl.ch; marco.ferretti@wsl.ch)

Specific visible foliar symptoms have been widely used to detect the impact of tropospheric ozone (O₃) on vegetation. Here, April–September O₃ concentrations and O₃-induced visible foliar symptoms have been assessed across Europe in 2002–2016 according to ICP Forests standardized methods. This activity provided bi-weekly mean O₃ concentrations from over 18,000 passive samplers on 206 plots in 15 countries and over 29,000 symptom records from 285 woody plant species on 169 plots, in 19 countries. Data were evaluated for the period 2005–2016, excluding a calibration phase during the initial three years of the monitoring program. A linear-mixed-effects modeling approach was applied to analyze the temporal trends in O₃ concentrations and symptoms and their inter-correlation while accounting for the heterogeneity and incompleteness of the datasets. We also used re-sampling procedures (focus on different subsets, bootstrap, and jackknife) to test for the robustness of our results. The long-term mean O₃ concentrations in the growing season (April–September) showed an increasing trend from north to south in forests across Europe. The highest concentrations occurred in Italy, southern Switzerland, the Czech Republic, Slovakia, Romania and Greece. Trend analysis reveals a slight but significant decrease in growing season (April–September) O₃ concentrations. There were no clear spatial or temporal trends in mean O₃ symptoms, but we found differences among biogeographical regions using the EEA stratification. These first results demonstrate the potential of the survey on visible foliar symptoms to detect the possible impact of ozone on European vegetation.

The role of pollen in forest throughfall biochemistry

Pollen from wind-pollinated forest trees, beside by dry gravitational settling, is washed out from the atmosphere by precipitation, but little is known about the effects of this pollen on throughfall biochemistry. We analysed long-term data from five UNECE ICP Forests intensive monitoring (Level II) plots in Flanders, Belgium, and nearby pollen monitoring stations. Preliminary results indicate a positive relationship between airborne pollen concentrations and both throughfall dissolved organic carbon (DOC) flux in May and biomass of fruiting/seeds in the same year. The complete opposite happens with throughfall nitrate (NO₃⁻) flux in May that is reduced in most years, particularly in deciduous trees. Dissolution experiments using commercially available birch (*Betula pendula* L.) pollen in a 50 mg/L NO₃⁻ solution showed that pollen can remove NO₃⁻ and release DOC, nitrite, potassium, calcium, magnesium, sulphate and phosphate in throughfall samples. Pollen from wind-pollinated forest trees clearly is an important in-canopy source of nutrients during spring, which should be considered in the quality control of analytical results of for example throughfall measurements and in the calculation of nutrient budgets. The observed effects are further examined in ongoing studies at larger spatial scale using long-term data from ICP Forests Level II plots and pollen monitoring stations in 13 European countries, and throughfall samples and pollen collected in precipitation, from a subset of plots sampled during spring 2018.

Forest ecosystems are subject worldwide to anthropogenic impacts, directly through land-usechanges, and indirectly via the atmosphere, e.g. through elevated CO₂, warming and drought, soil acidification, dry and wet depositions (e.g. nitrogen, particulate matter) or precursor emissions of tropospheric ozone. After decades of transcontinental forest ecosystem research, few questions are still open and gaps in our understanding identified. For example, what is the influence of the increase of the tree growing seasons, and what is the inhibitory potential of ozone stress on forests? Does warming increase carbon storage, in particular in cool climates, besides promoting risks for drought? Research aims to establish mechanistic understanding of inter-related feedbacks between climate change, air pollution and forest ecosystem responses. To overcome these issues, a concept, i.e. supersites for forest research, was developed and proposed within the COST Action FP0903 and the Task Force IUFRO on Climate Change and Forest Health. The forest supersites are global operational platforms to be established by networking and upgrading of existing highly-equipped sites. The apparent novelties are interlinked i) by clarifying climate change - air pollution - forest ecosystem interactions, ii) by cross-linking experimenting - monitoring - modelling at same sites, and iii) by operating studies across key forest sites worldwide under a long-term perspective.

The COST Action CLIMO: a network on climate-smart forestry in mountain regions to face environmental threats in a changing climate

Roberto Tognetti^{1,2}, Pietro Panzacchi^{1,3}, Cost Action Climo¹

¹Università del Molise, Campobasso, Italy; ²Fondazione Edmund Mach, San Michele all'Adige, Italy; ³Università di Bolzano, Bolzano, Italy (tognetti@unimol.it; pietro.panzacchi@gmail.com; climo@unimol.it)

Mitigation goals fixed by the Paris Agreement cannot be met without a significant contribution from forests (sequestration lever) and increasing use of biomaterials and bioenergy (substitution lever). Natural climate solutions (conservation, restoration, improved land management) may provide cost-effective climate mitigation to stabilize warming to below 2 °C. Terrestrial GPP is the largest global CO₂ flux, and carbon stored in forest land represents 60% of total carbon stock contained in terrestrial carbon pools. The central role of forests in the carbon cycle can be enhanced through climate-smart forest management. Nevertheless, climate benefits from carbon sequestration through forest management can also be offset by concurrent management-induced changes in surface albedo, land-surface roughness, emissions of BVOCs, transpiration and sensible heat flux. Therefore, the role of forest management in the coming decades should focus on the adaptation of the forest cover to future climate and disturbances (drought spells, forest fires, heat waves, pest outbreaks, wind storms), moving forward climate mitigation objectives. The capacity to forecast the thresholds of irreversible transformation of forest ecosystems needs geographically distributed research infrastructures and long-term observation programs designed to monitor climate change, better understand its impacts, and evaluate possible mitigation and adaptation strategies. The COST Action CLIMO aims to identify a coordinated network of climate-smart forests for challenging ecological change throughout European mountain ranges. Variety of European mountains and local circumstances is an opportunity to test the resilience of forest systems to climate change and the role of forestry in the climate targets, in systems at climate risk.

The CzeCOS ecosystem stations network

Manuel Acosta¹, Marian Pavelka¹, Eva Dařenová¹, Jiří Dušek¹, George Jocher¹, Ina Kyselova¹, Natalia Kowalska¹, Lenka Foltynová¹, Ladislav Šigut¹, Caleb Mensah¹, Dalibor Janouš¹, Michal V. Marek¹, Pavel Cudlin¹

¹Global Change Research Institute, CAS, Brno, Czech Republic (acosta.m@czechglobe.cz; pavelka.m@czechglobe.cz; darenova.e@czechglobe.cz; dusek.j@czechglobe.cz; jocher.g@czechglobe.cz; kyselova.i@czechglobe.cz; kowalska.n@czechglobe.cz; foltynova.l@czechglobe.cz; sigut.l@czechglobe.cz; mensah.c@czechglobe.cz; janous.d@czechglobe.cz; marek.mv@czechglobe.cz; cudlin.p@czechglobe.cz)

The Global Change Research Institute of the Czech Academy of Sciences (CzechGlobe) has established a well-equipped network of ecosystem stations, with modern instrumentation for eco-physiological, plant physiological and micrometeorological studies, and estimation of GHG emissions. The research

infrastructure CzeCOS is included in the national roadmap of major research infrastructures. The network covers the main terrestrial ecosystems of the Czech Republic (coniferous forests, deciduous forest, mixed floodplain forest, grassland, wetland and cropland). The floodplain forest have been influenced by anthropological impact of water management the last decades. The 40-aged coniferous forest is located in high latitude, typical for Central European coniferous forest, while, the 110-aged coniferous forest is located at low latitude (influenced by drought period). The wetland station is located in UNESCO Man and Biosphere reservation. The deciduous forest is managed even-aged European mature beech stand with tree species composition close to natural. Further two ecosystems are part of the typical managed ecosystem, grassland (mowed one per year) and cropland (intensively used). Three stations of the network are proposed as ICOS stations. The network enables detailed research to be conducted on topics such as: the carbon balance of different ecosystems, energy balance closure, the impact of current climate conditions on production and ecosystem disturbances during extreme weather conditions (drought, floods, winter storms, etc). In the poster we show specific results from the sites and outline the importance of the regional/national network for improving our knowledge about the exchange of matter and energy fluxes at different ecosystems.

Optimising observation networks for the early detection and unequivocal attribution of environmental effects on European forests

Virginie Moreaux^{1,2}, Dario Papale^{3,4}, Bert Gielen^{4,5}, Denis Loustau⁶

¹INRA, UMR ISPA, Villenave d'Ornon, France; ²UMR IGE, Grenoble, France; ³University of Tuscia, Viterbo, Italy; ⁴ICOS Ecosystem Thematic Centre, Viterbo, Italy; ⁵University of Antwerpen, Antwerpen, Belgium; ⁶ICOS Ecosystem Thematic Centre, Antwerpen, Belgium (virginie.moreaux@inra.fr; darpap@unitus.it; bert.gielen@uantwerpen.be; denis.loustau@inra.fr)

The world forests are being observed and monitored by inventory and observatory systems organised mainly at country level and deployed across a wealth of temporal and spatial resolutions, making it difficult to coordinate and to interoperate the data collected. We demonstrate why the standardisation and coordination of such in situ monitoring networks such as ICOS are a prerequisite to detect the effects of environmental changes on forests and disentangle their causal chain. The ICOS network is monitoring the greenhouse gas fluxes, carbon, energy and water balances and phenology on the long term (20 years) at an hourly resolution with a high level of standardisation. We projected across Europe three different climate and pollution scenarios and estimated their impacts on forests functioning using both models and literature analysis. In parallel, the performances in terms of accuracy, standardisation and precision of the ICOS ecosystem network have been evaluated. Afterwards, we related the projected impacts of changing environmental forcings to the sensitivity and metrological performances of the station network. We show how the station network of ICOS in combination with companion forest networks (ICP Forests, ANAEE-RI, eLTER-RI) can be optimised to detect and attribute the effects of ozone and nitrogen deposition, temperature increase, CO₂ concentration and diffuse radiation on forests: which variables are most meaningful, how precise and accurate should they be measured, which observations should be added and where and how much stations is requested to detect expected changes and identify their driver(s).

Forest ecosystems biodiversity assessment and inventory based on ICP-Forests grid of sample plots

Alexander Alekseev¹, Iurii Belenkii¹

¹Saint-Petersburg State Forest Technical University, Saint-Petersburg, Russian Federation (a_s_alekseev@mail.ru; rector@spbftu.ru)

Regular grid of permanent sample plots (PSP) of ICP-Forests monitoring system was used for forest ecosystems biodiversity assessments and inventory. The supplementary features were added to the PSP structure to conduct biological diversity census: eight sample plots 1 x 1 m for geo-botanical description; two sample plots of 5x5 m each for description of the PSP's undergrowth; one 25 x 25 m plot for coarse woody debris estimations; four soil inventory pits. The total number of PSP amounted to 248. General statistical indicators of α -diversity characterizing forest land cover diversity were calculated. β – diversity of forest ecosystems as well as γ – diversity also was studied on the base of information collected on the same regular grid of sample plots. It appears that sample plots distribution by species diversity gradation is well described by the standard curve of normal distribution for the entire Karelian Isthmus forest (determination coefficient of the curve being 95.2%) as well as for each type of forest. Hence, the criterion (standard) of biodiversity for forest ecosystems can be defined as the mean value of alpha diversity for each forest type group – m ; and the standard deviation – σ , as a tool for assessing deviations from the standard biodiversity. Indication of man-made effects on forest ecosystems using occurrence of species of 5 different phyto-ecological groups was done; 5 phyto-ecological groups of species were distinguished: forest, bogged forest, forest-meadow, meadow, weed and ruderal. Estimated non-forest species presence (meadow, weed and ruderal) was used as indicators of the man-made effect on forest ecosystem.

Methodological issues and outputs of the REINFFORCE network: a unique transnational infrastructure of tree species arboreta for the adaptation of planted forests to future climate

Christophe Orazio¹, Hernan Serrano-León¹

¹European Forest Institute, Cestas, France (christophe.orazio@efi.int; hernan.serrano@efi.int)

Predicting the future responses of productive forests and choosing the best-adapted regeneration material to climate change requires transnational infrastructures that provide evidence-based knowledge of the response of multiple tree species under a wide range of climatic conditions. This is why REINFFORCE was established as a unique network of demonstration sites to test the field performance and adaptation of 32 tree species from all over the world, including currently established and alternative productive species/provenances. The network made of 38 arboreta with common genetic material distributed along the European Atlantic arc (latitudes 37° to 58° N). This latitudinal gradient, covering a large diversity of climate and soil conditions, allows assessing the response of 120,000 tested trees from 176 provenances to current and anticipated future climatic conditions outside their current distribution range. We present methodological issues for the establishment, maintenance and coordination of the transnational network between the multiple partners, based on the common protocols and consolidated database for long-term monitoring and knowledge sharing. The latest outputs in methodological innovation include a harmonized field protocol for phenology assessment, height measurements with drone technology, and the use of the arboreta network as sentinels for emerging pests and diseases. The successful experience of the REINFFORCE network provides a strategic research platform for transnational cooperation and creates synergies with other research initiatives on forest adaptation to climate change. The latest research findings provides evidences and decision support for multiple forest stakeholders to increase the adaptation of the planted forests facing future climate uncertainty.

Relationship between forest ecosystems capacity to provide regulating ecosystem services and their structural and biodiversity attributes in Romanian forest LTER sites

Diana Pitar¹, Stefan Leca¹, Carmen Iacoban¹, Marius Curca¹, Ovidiu Badea^{1,2}

¹National Institute for Research and Development in Forestry "Marin Dracea", Voluntari, Romania; ²"Transilvania" University, Brasov, Romania (diana.silaghi@icas.ro; stefan.leca@icas.ro; carmeniacoban@gmail.com; c.marius83@yahoo.com; badea63@yahoo.com)

Forests provide a wide range of ecosystem services (ES), including timber production, local climate air quality and water regulation, carbon storage, and many cultural services associated with recreational activities and nature experience. Traditionally, forest management has targeted only few of these benefits, particularly timber production. In forest protected areas, where wood logging is forbidden, regulating and cultural ES are the main benefits provided by forests. In order to investigate forest ecosystems capacity to provide regulating ES, particularly air quality regulation, through nitrogen and sulphur retention, we studied the relationship between dry deposition of N-NO_x, N-NH₃ and S-SO₄ fluxes and different forests attributes (forest type, number of trees per hectare - N, mean height - Hm, mean DBH, mean defoliation - def_med, Shannon diversity index of the tree layer - H') in 11 plots placed in 2 Romanian forest LTER sites (Retezat and Bucegi-Piatra Craiului). Our results show that only sulphur retention is significantly different (F(2,94)=5.9, p<0.05) in different forest types (coniferous, broadleaves and mixed); 12.9% of the N-NH₄ variation in Bucegi-Piatra Craiului LTER site is explained by N (8.6%) and H' (4.3%). N, mean DBH and H' explain 9.5% and 31% of the N-NO₃ variation in all plots and coniferous stands, respectively. Regarding S-SO₄, 30% of its variation is explained by H' in mixed forests, 23.1% by N, Hm, mean DBH and def_med in coniferous stands and 14.2% by N and H' in Bucegi - Piatra Craiului LTER site. Additional forest attributes and environmental and climatic factors will be further tested.

Long-Term monitoring to study the structure and function of Venezuelan tropical forests: a summary of findings and the future ahead

Emilio Vilanova^{1,2}, Hirma Ramirez-Angulo², Armando Torres-Lezama², Gerardo Aymard³, Luis Gámez⁴, Cristabel Durán⁵, Lionel Hernández⁶, Rafael Herrera^{7,8}, van der Heijden Geerjje⁹, Oliver Phillips¹⁰, Gregory Ettl¹

¹School of Environmental and Forest Sciences, University of Washington, Seattle, USA; ²Instituto de Investigaciones para el Desarrollo Forestal, Universidad de Los Andes Merida, Venezuela, Republic of Bolivarian; ³Universidad Experimental de los Llanos Ezequiel Zamora, Guanare, Venezuela, Republic of Bolivarian; ⁴Escuela de Ingeniería Forestal, Universidad de Los Andes, Merida, Venezuela, Republic of Bolivarian; ⁵University of Freiburg, Freiburg, Germany; ⁶Universidad Nacional Experimental de Guayana, Ciudad Bolívar, Venezuela, Republic of Bolivarian; ⁷Centro de Ecología, Instituto Venezolano de Investigaciones Científicas, Caracas, Venezuela, Republic of Bolivarian; ⁸Department of Geography and Regional Research, Geoecology, University of Vienna, Vienna, Austria; ⁹School of Geography, University of Nottingham, Nottingham, United Kingdom; ¹⁰School of Geography, University of Leeds, Leeds, United Kingdom (vilanova@uw.edu; rhirma@gmail.com; torres@ula.ve; cuyuni24@hotmail.com; lgamez@ula.ve; cristabelduran@gmx.de; lionelher@yahoo.com; potoy1@hotmail.com; geertje.vanderheijden@nottingham.ac.uk; o.phillips@leeds.ac.uk; ettl@uw.edu)

Permanent plots continuously measured through time are unique windows to advance forest monitoring systems from local to global scales. A team of researchers initially led by Jean Pierre Veillon and others thereafter, established in the 1960s, and late afterwards, a systematic Venezuelan forests plot monitoring network, with some of these plots being the longest running sites in Latin America and the tropics. The purpose of this study is to offer a summary of the main findings of more than three decades of research and discuss the still unlocked potential that these sites hold in terms of their value to understand the effects of climate change in tropical forests. Through this network we now know that Guiana Shield Forests are the most productive and carbon-rich systems, while the seasonal forests of the Western Plains region are characterized by a much faster dynamic with higher rates of tree mortality. Available water and length of dry season are fundamental factors driving the process of carbon accumulation and turnover. Overall, forests in wet, low elevation sites and with slow turnover stored the greatest amounts of biomass. Although faster stand dynamics are closely associated with lower carbon storage, stem-level turnover rates and woody productivity did not show any correlation, indicating that stem dynamics and carbon dynamics are largely decoupled from one another. We also highlight the risks and threats posed by the current economic and political crisis and propose a set of ideas to protect and expand this network.

B4h: NOVEL REMOTE SENSING APPROACHES TO QUANTIFY CARBON STOCKS, STRUCTURE AND FUNCTIONAL DIVERSITY OF FORESTS - 1

Automatic assessment of crown projection area on single trees and stand-level, based on terrestrial laser-scanning data

Tim Ritter¹ , Arne Nothdurft¹ 

¹University of Natural Resources and Life Sciences, Vienna (BOKU), Vienna, Austria (tim.ritter@boku.ac.at; arne.nothdurft@boku.ac.at)

Assessing Crown projection area (CPA) is crucial for estimating inter-tree competition and tree biomass volume. An approach to the fully automated assessment of CPA, using a multi-layer seeded region growing algorithm and high-resolution 3D point cloud data is presented. Data were collected via multi-scan TLS in a 4.08 ha mixed-species stand with high vertical structure, located in Lower-Austria. The new approach is tested against independently repeated manual CPA-measurements by different observers that serve as the reference. The inter-observer bias of the manual CPA-measurements is quantified, and allometric models are used to predict CPA from diameter at breast height (DBH) measurements. These predictions are then compared to the TLS-based estimates on the single tree- and stand-level. It is shown, that for single trees, there is a remarkable inter-observer bias of manual CPA measurements. The deviation between CPA measurements derived from TLS data and manual measurements is on par with the deviations between manual measurements by different observers. The inter-observer bias of the manual measurements propagates into the allometric models, resulting in a high uncertainty of the derived estimates at tree-level. At the stand level, TLS measurements reveal the high influence of crown morphology on the CPA, which only can be taken into account by the TLS measurements and not by the allometric models.

Assessing legacy effects of wildfires on tree crown structure of fire-tolerant eucalypts using airborne lidar data

Yogendra Karna¹, Mihai Tanase², Trent Penman¹, Cristina Aponte², Lauren Bennett¹

¹School of Ecosystem and Forest Sciences, The University of Melbourne, Creswick, Australia; ²School of Ecosystem and Forest Sciences, The University of Melbourne, Richmond, Australia (ykarna@student.unimelb.edu.au; mtanase@unimelb.edu.au; trent.penman@unimelb.edu.au; caponte@unimelb.edu.au; ltb@unimelb.edu.au)

Fire-tolerant eucalypt forests of South-Eastern Australia are assumed to fully recover from even the most intense fires but surprisingly very few studies have assessed that recovery. Accurate assessment of horizontal and vertical attributes of tree crowns after fire is essential to understand the fire's legacy effects on tree

growth and on forest structure. This study quantitatively assessed individual tree crowns nearly a decade after a 2009 wildfire that burnt extensive areas of temperate eucalypt forests. We used airborne lidar data validated with field measurements to estimate multiple individual tree crown metrics in 12 to 13 plots (0.05 ha) per each of four wildfire severities (unburnt, low, moderate, high). Linear mixed-effects models indicated persistent effects of both moderate- and high-severity wildfire on tree crown architecture. Trees at high-severity sites in two size classes (20 – 50 cm, > 50 cm diameter) had significantly less crown projection area and live crown width than those at unburnt and low-severity sites. Significant differences in lidar-based metrics (crown cover, evenness, leaf area density profiles) indicated that tree crowns at moderate- and high-severity sites were comparatively narrow and more evenly distributed down the tree stem. These conical-shaped crowns contrasted sharply with the rounded crowns of trees at unburnt and low-severity sites. Our data provide clear evidence that moderate- and high-severity wildfire can modify the structure of fire-tolerant eucalypts' tree for nearly a decade after the wildfire. The implications of these legacy effects on, for example, tree productivity and the accuracy of biomass allometric equations warrants further study.

Optimization of TLS based forest inventories

Christoph Gollob¹ ; Tim Ritter¹ ; Arne Nothdurft¹ 

¹University of Natural Resources and Life Science, Vienna (BOKU); Department of Forest- and Soil Sciences; Institute of Forest Growth, Vienna, Austria (christoph.gollob@boku.ac.at; tim.ritter@boku.ac.at; arne.nothdurft@boku.ac.at)

In contrast to traditional inventories, modern terrestrial laser scanning (TLS) systems are available, which became likewise easy-to-handle in survey practice. However, before TLS systems can substitute traditional measurement instruments, computer algorithms have to be developed so that the novel laser-based technology is able to fulfill very basic tasks, prominently the automatic detection of tree positions and the measurement of tree diameters. In this talk, a multi stage density-based clustering approach is presented for the automatic mapping of tree positions, and a subsequently applied algorithm is shown for the automatic measurement of tree diameters. The algorithms were tested in different settings with respect to the number and the spatial alignment of scanner positions under manifold forest conditions, covering different age classes and mixture scenarios and representing a broad gradient of structural complexity. If circular sample plots were applied with a fixed truncation distance of 20 m, the tree mapping algorithm showed a detection rate of 89.3% with seven scanner positions (hexagon vertices plus center coordinates) and achieves a detection rate of 78.2% with four scanner positions aligned in a triangle plus center. Detection rates were significantly increased with smaller truncation distances. Thus, with a truncation distance of 10 m the hexagon setting yielded a detection rate of 92% and the triangle 90.4%. Other alignments of scanner positions were also tested, but proved to be either unfavorable or too labor intensive. The commission rates were on average less than 5%. The algorithms were successfully tested by means of an international benchmark dataset.

A simple approach for bioregional assessment of forest structure types using airborne laser scanning

Syed Adnan^{1,2}, Matti Maltamo¹, David A. Coomes³, Antonio García-Abril⁴, Yadvinder Malhi⁵, José Antonio Manzanera⁴, Nathalie Butt^{6,8}, Mike Morecroft⁷, Rubén Valbuena⁸

¹University of Eastern Finland, School of Forest Sciences, PO Box 111., 80100 Joensuu, Finland; ²National University of Sciences and Technology, Institute of Geographical Information Systems 44000 Islamabad, Pakistan; ³University of Cambridge, Department of Plant Sciences, Forest Ecology and Conservation, CB2 3EA Cambridge, United Kingdom; ⁴Universidad Politécnica de Madrid, College of Forestry and Natural Environment, Research Group SILVANET, 28040 Madrid, Spain; ⁵University of Oxford, School of Geography and the Environment, Environmental Change Institute, OX1 3QY Oxford, United Kingdom; ⁶The University of Queensland, School of Biological Sciences, 4072 Queensland, Australia; ⁷Natural England, SO23 7BT Winchester, United Kingdom; ⁸Bangor University, School of Natural Sciences, LL57 2DG Gwynedd, United Kingdom (adnan@uefi; matti.maltamo@uefi; dac18@cam.ac.uk; antonio.garcia.abril@upm.es; yadvinder.malhi@ouce.ox.ac.uk; joseantonio.manzanera@upm.es; n.butt@uq.edu.au; mike.morecroft@naturalengland.org.uk; r.valbuena@bangor.ac.uk)

Forest structural types (FSTs) assessment is important for a sustainable forest management. We used field and airborne laser scanning (ALS) data from Boreal, Mediterranean and Atlantic biogeographical regions and developed a simple methodology for FSTs identification. Four forest structural variables – quadratic mean diameter (QMD), Gini coefficient (GC), basal area larger than mean (BALM) and density of stems (N) – were calculated from forest inventory data. Hierarchical clustering analysis (HCA) was applied using these four structural variables and potential clusters (FSTs) were determined in the coniferous and deciduous forests. Then, the empirical threshold values for discriminating those clusters were extracted using classification and regression tree analysis (CART). Single storey FSTs, multi-layered FSTs and exponentially decreasing size distributions (reversed J) were separated by lower, medium and high values of GC and BALM, respectively, and these two were found to be the most important variables in the identification of FSTs. We also identified young/mature and sparse/dense subtypes within each of these main FST groups using QMD and N. Furthermore, similar structural predictors derived from ALS – maximum height (Max), L-coefficient of variation (Lcv), L-skewness (Lskew), and percentage of penetration (Cover), – were used in the nearest neighbour method to predict the FSTs. The overall accuracy achieved in the deciduous forest (0.87) was higher than the coniferous forest (0.72). Our methodology proves that ALS data is useful for structural heterogeneity assessment of forests and paves the way toward transnational assessments of forest structure across bioregions.

Integrating mobile laser scanner system and unmanned aerial vehicle to measure tree characteristics

Chi-Hua Chang¹, Chaur-Tzuhn Chen², Jan-Chang Chen²

¹Institute of Tropical Agriculture and International Cooperation, Pingtung, Taiwan; ²Department of Forestry, Pingtung, Taiwan (harry199180116@gmail.com; cct@mail.npust.edu.tw; zzzjohn@mail.npust.edu.tw)

Forest resource inventories corresponded with models according to the purpose of survey equipment and management. With the advancement of science and technology, manual survey mode can be changed into a survey mode of high technology equipment. In this paper, the practical operation is used to explore the application of Handheld Mobile Laser Scanning (HMLS) and Unmanned Aerial Vehicle (UAV) in forest resource inventories. Further, we use Terrestrial Laser Scanning (TLS) as the valid data to compare the accuracy. With advantage of handheld mobile laser scanners (HMLS) and UAV, we discuss with estimating limitations and potentials of forest plot surveys. Using TLS data as ground true data, we combine the HMLS point cloud and UAV point cloud data to estimate the tree height of 43 trees. As One-way ANOVA results displayed, the tree height results between HMLS (11.8 ± 2.1 m) and TLS (15.9 ± 3.2 m) has significant differences (P < 0.01), but after we combined the UAV point cloud and HMLS point cloud, the results shows no differences (P > 0.05) with combined point cloud data (16.7 ± 3.7 m) and TLS (15.9 ± 3.2 m) point cloud data. For the TLS method, it has much more limitations for our investigation in Taiwan including time consuming and few conveniences. Combined point cloud data has more flexible procedure with high accuracy instead of time-consuming TLS method.

Mapping of forest carbon stocks and their changes using LiDAR data, high-spatial-resolution satellite data and time-series Landsat data for REDD+ implementation

Yasumasa Hirata¹, Hideki Saito¹, Chivin Leng², Sophyra Sar²

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Ministry of Environment, Phnom Penh, Cambodia (hirat09@affrc.go.jp; rslsaito@affrc.go.jp; lengchivin@gmail.com; sophyra.sar@gmail.com)

Developing countries that intend to implement the United Nations REDD-plus framework and obtain economic incentives are required to estimate changes in forest carbon stocks based on the IPCC guidelines. In this study, we developed a method to support REDD-plus implementation by estimating tropical forest aboveground biomass (AGB) by combining airborne LiDAR with high-spatial-resolution (HSR) satellite data, and by mapping forest carbon stocks and their changes at a sub-national level using time-series Landsat data. The results of AGB estimation from airborne LiDAR and HSR satellite data were used as training data for classification of forest carbon stock classes of Landsat data. We used a two-step method to estimate AGB and map it in a tropical environment in Cambodia. First, we created a multiple-regression model to estimate AGB from the LiDAR data and plotted field-surveyed AGB values against AGB values predicted by the LiDAR-based model, and calculated reflectance values in each band of the satellite data for the analyzed objects. Then, we created a multiple-regression model using AGB predicted by the LiDAR-based model as the dependent variable and the mean and standard deviation of the reflectance values in each band of the satellite data as the explanatory variables. Then, we conducted object-based classification of forest carbon stocks for time-series Landsat data using AGB derived from high-resolution satellite data as training data. Our results suggest that this approach can provide the forest carbon stock map required to support REDD-plus.

Using multispectral terrestrial lidar for early detection of tree decline: from leaf water content to fine structural details

Samuli Junttila¹, Markus Holopainen¹, Mikko Vastaranta², Riikka Linnakoski³, Päivi Lyytikäinen-Saarenmaa¹, Juha Hyyppä⁴

¹University of Helsinki, Helsinki, Finland; ²University of Eastern Finland, Joensuu, Finland; ³Natural Resources Institute Finland, Helsinki, Finland; ⁴Finnish Geodetic Institute FGI, Kirkkonummi, Finland (samuli.junttila@helsinki.fi; markus.holopainen@helsinki.fi; mikko.vastaranta@uef.fi; riikka.linnakoski@luke.fi; paivi.lyytikainen-saarenmaa@helsinki.fi; juha.coelars@gmail.com)

Climate change is causing novel stress to forests that is difficult to predict. Information on forest health has been identified as one of the key information gaps in evaluating the effects of climate change. The mapping of small-scale forest disturbance events is largely based on visual observations which is time-consuming and prone to error especially in the early stages of tree decline. Thus, new methods for objective estimation of tree decline are required. Multispectral lidar can provide highly detailed measurements of tree structure and reflectance simultaneously enabling novel approaches for the detection of tree stress. Over the last four years, we have developed a novel remote sensing method for detecting and evaluating tree decline using multispectral terrestrial lidar. The developed methods are based on utilizing lidar intensity data and the sensitivity of the used wavelengths to varying leaf water content (LWC). Thus, we have also investigated the relationship between LWC and various disturbance symptoms in different environments to determine the optimal LWC metrics for detecting tree stress. We found that multispectral lidar can detect and assess tree decline of single trees with high accuracy in our test forest that was infested by *Ips typographus* (L.) and its fungal symbionts. The developed methods showed potential in discriminating between healthy and stressed trees already in the early stages of tree decline when the foliage did not show visual symptoms. Therefore, the methods could provide new means for objective assessment of early tree decline allowing improved estimation, prediction and mitigation of forest damages.

Integration of Landsat and simulated spaceborne GEDI LiDAR data to estimate time since disturbance at the forest stand level

Nuria Sanchez-Lopez¹, Luigi Boschetti¹, Andrew Hudak²

¹University of Idaho, Department of Natural Resources and Society, College of Natural Resources, Moscow (Idaho), USA; ²Forest Service, U.S. Department of Agriculture, Rocky Mountain Research Station, Forestry Sciences Laboratory, Moscow (Idaho), USA (nsanchezlopez@uidaho.edu; luigi@uidaho.edu; ahudak@fs.fed.us)

Maps of stand-level forest disturbance history (Time Since Disturbance, TSD) are fundamental for modeling forest ecosystem processes. Recent research shows that airborne LiDAR data analysis can reconstruct the long-term (>100 years) disturbance history of a forest; this is a significantly longer time frame than what can be observed with the established methods of change detection with optical data. However, the use of airborne LiDAR is limited by its high cost compared to satellite data. These limitations could largely overcome by NASA's spaceborne LiDAR Global Ecosystem Dynamics Investigations (GEDI) instrument, launched in December 2018. The sampling configuration of GEDI (footprints separated by 600 m across-track and 60 m along-track) imposes, however, some challenges for continuous spatial analysis compared to the common discrete-return airborne LiDAR. We propose an object-oriented data fusion methodology where Landsat data are used to identify forest stands, and GEDI waveforms are used to estimate TSD. The methodology involves three main steps: (1) forest stand delineation using object-based techniques of image segmentation on Landsat derived data; (2) estimation of TSD at the GEDI footprint level using random forest analysis; (3) estimation of TSD at the stand level, by combining TSD estimated at the GEDI footprint locations with the forest stand map. The methodology is demonstrated on a 52,000 ha study area located in the Nez-Perce Clearwater National Forest (Idaho, USA), where reference maps of TSD are available for accuracy assessment. The results indicate that the GEDI-Landsat fusion has the potential of estimating TSD with accuracy comparable to airborne LiDAR data.

B4i: LONG-TERM FOREST MONITORING NETWORKS FOR EVALUATING RESPONSES TO ENVIRONMENTAL CHANGE - II

EANET monitoring in forest area under changing atmospheric environments

Hiroyuki Sase¹, Wilfredo Carandang², Naoyuki Yamashita³, Elizabeth Philip⁴, Junko Shindo⁵, Tatsuyoshi Saito⁶, Masayuki Morohashi¹, Masaaki Takahashi¹, Masamichi Takahashi³, Tsuyoshi Ohizumi¹

¹Asia Center for Air Pollution Research, Niigata, Japan; ²University of the Philippines Los Baños, Los Baños, Philippines; ³Forestry and Forest Products Research Institute, Tsukuba, Japan; ⁴Forest Research Institute Malaysia, Selangor Darul Ehsan, Malaysia; ⁵Yamanashi University, Kofu, Japan; ⁶Niigata Prefectural Institute of Public Health and Environmental Sciences, Niigata, Japan (sase@acp.asia; wmcarangand@up.edu.ph; nyamashita@ffpri.affrc.go.jp; philip@frim.gov.my; jshindoh@yamanashi.ac.jp; tsaito@a@gmail.com; morohashi@acp.asia; mtakahashi@acp.asia; masamichi_takahashi@hotmail.com; tohizumi@acp.asia)

Acid Deposition Monitoring Network in East Asia (EANET) was established as a regional cooperative initiative in 1998 and started its regular-phase activities in 2001. Currently, thirteen countries in Northeast Asia and Southeast Asia participate in the network. In the case of EANET, not only monitoring on atmospheric deposition in 62 sites but also monitoring on ecosystem components in forest area, including soil, vegetation, and inland water, have been carried out in the same network. Although the number of the regular monitoring sites is not many in forest area, 31 forest plots, 19 lakes/streams, and 2 forest catchments, the observational data have been accumulated for more than 15 years in many of the sites. According to the Third Periodic Report of State of Acid Deposition in East Asia (PRAD3) published by EANET in 2016, no clear trend was found in soil chemical properties and forest growth rates in most of the sites, while a few sites on inland water showed acidification. However, the updated data suggested recovery from acidification, which might reflect reduction of atmospheric deposition. The long-term data since the 1980s also showed that biogeochemical processes in a forest catchment in Japan sensitively responded to changing atmospheric deposition and climate. Application of isotopic analysis to the existing monitoring samples showed new views on possible mechanisms. Acknowledgements: The authors thank all the surveyors on EANET and Japanese national monitoring, the current/previous ACAP colleagues for their data compilation, and the scientists contributed to the isotopic analysis.

The Tropical managed Forests Observatory: a research network addressing the future of tropical logged forests

Plinio Sist¹ 

¹Cirad-Forests & Societies, Montpellier, France (sist@cirad.fr)

While attention to logging in the tropics has been increasing, studies on the long-term effects of silviculture on forest dynamics and ecology remain scarce and spatially limited. Indeed, most of our knowledge on tropical forests arise from studies carried out in undisturbed tropical forests. This bias is problematic given that logged and disturbed tropical forests are covering now a larger area than the so-called primary forests. The Tropical managed Forests Observatory (TmFO), a new network of permanent sample plots in logged forests, aims to fill this gap by providing unprecedented opportunities to examine long-term data on the resilience of logged tropical forests at regional and global scales. TmFO currently includes 24 experimental sites distributed across three tropical regions, with a total of 536 permanent plots and about 1200 ha of forest inventories. In this paper we will present the main results generated by the network on the impact of logging on Carbon and timber recovery, as well as biodiversity changes in the Amazon basin and South East Asia.

Long-term growth records of *Cryptomeria japonica* plantations at the University of Tokyo Forests, Japan: towards a network of experimental plots in East Asia

Toshiaki Owari¹ , Keisuke Toyama¹, Satoshi N. Suzuki¹, Takuya Hiroshima¹, Seiji Ishibashi¹

¹The University of Tokyo, Tokyo, Japan (owari@uf.a.u-tokyo.ac.jp; oyama@uf.a.u-tokyo.ac.jp; s-suzuki@uf.a.u-tokyo.ac.jp; hiroshim@uf.a.u-tokyo.ac.jp; bashi@uf.a.u-tokyo.ac.jp)

Long-term experimental plots can provide reliable and consistent tree growth data as a quantitative basis for sustainable forest management. The Europe-wide network of long-term experimental plots is currently used for quantifying and characterizing changes in forest stand growth dynamics, while Asian-wide networks of long-term experimental plots especially for plantations are still limited. *Cryptomeria japonica* D. Don is one of the important plantation species in East Asia including Japan, Taiwan, and South Korea. *C. japonica* plantations cover ca. 4.4 million ha, comprising about 44% of total plantations of Japan. It is an important plantation species covering about 41,000 ha, equivalent to 14.7% of the total plantation area of Taiwan. *C. japonica* was widely planted in the 1920s throughout the southern regions of South Korea. It is desirable to promote international collaborative research focusing on long-term *C. japonica* growth. We are aiming to create an extensive network of long-term experimental plots for *C. japonica* plantations with counterpart universities in East Asia. In Japan, the University of Tokyo Forests has established experimental forest plots in *C. japonica* plantations since the early 20th century. Long-term growth records on these plots are valuable to model forest growth and yield, to quantify the effects of silvicultural interventions (e.g., thinning), and to assess the ability to sequester carbon. We present the site and plot information, summary of long-term growth records, and previous studies in the oldest experimental forest plots at the University of Tokyo Chiba Forest (UTCBF) and Chichibu Forest (UTCF).

Popa (Peld do Oeste do Pará) Lter: reconciling long-term ecological research and communities in central Amazonia to understand effects of environmental changes in biodiversity

Leandro Lacerda Giacomini¹, Amanda Mortati¹, Rodrigo Fadini¹, Thais Almeida¹, Thiago André¹, Susan Aragón¹, Quêzia Guerreiro¹, Daniela Pauletto¹, Maria Jociléia Silva², Jorge Porto³, William Magnusson⁴, Albertina Lima⁴

¹Universidade Federal do Oeste do Pará, Santarém, Brasil; ²Instituto Chico Mendes de Conservação da Biodiversidade, Santarém, Brasil; ³Instituto Nacional de Pesquisas da Amazônia, Santarém, Brasil; ⁴Instituto Nacional de Pesquisas da Amazônia, Manaus, Brasil (giacomini.leandro@gmail.com; amortati@gmail.com; rfadini@gmail.com; blotiella@gmail.com; hiagojandre@gmail.com; saragongeo@yahoo.com; queziamoura@hotmail.com; danielapauetto@hotmail.com; leia.icmbio@gmail.com; jirporto@gmail.com; bill@inpa.gov.br; lima

The Amazon poses as containing the world's largest continuum of tropical rain forest and its rich biodiversity has captured the attention of scientists for centuries. Although it is mostly known for its astonishing forests, the domain is in fact a complex mosaic of formations and ecosystems, including savannah-like formations. This complexity is for sure associated with its rich biodiversity, but how these ecosystems interact is poorly known, as is its biota itself. Nevertheless, as population grows, large areas of the domain are rapidly transformed, especially in Brazil, being mostly converted to agricultural areas. This "against-the-odds" situation brought the idea of a long-term ecological research (LTER) in a populated area and involving the communities to light. The POPA LTER aims to monitor biodiversity along a continuum of forest and savannah-like formations in the lower Tapajós river basins close to Santarém, PA, Brazil, in protected areas of sustainable use. We maintain 64 permanent plots (RAPELD model) in pristine and disturbed formations, far and close to riverine communities, seeking a bigger picture of the natural and human-induced dynamics of the areas monitored. The riverine population is encouraged to participate in the research, seeking scientific literacy and awareness of how changes in land use can impact the availability of natural resources. Also, part of the plots structure is dedicated to fostering a scientific tourism to be maintained by the community, while short-term courses are offered, as a pilot idea of knowledge transfer and promoting conservation through a community-based ecological tourism.

Main sources of uncertainty in large-scale assessments of ozone effects on forest growth

Maxime Cailleret^{1,2}, Matthias Haeni¹, Marco Ferretti¹, Leonie Schoenbeck¹, David Simpson^{3,4}, Marcus Schaub¹

¹WSL, Birmensdorf, Switzerland; ²IRSTEA, Aix-en-Provence, France; ³Norwegian Meteorological Institute, Oslo, Norway; ⁴Chalmers University of Technology Gothenburg, Sweden (maxime.cailleret@irstea.fr; matthias.haeni@wsl.ch; marco.ferretti@wsl.ch; leonie.schoenbeck@wsl.ch; davids@met.no; marcus.schaub@wsl.ch)

Tropospheric ozone (O₃) has large impacts on plant metabolism and functions at the individual tree level. However, due to the presence of several compensatory and acclimation mechanisms, and to interactions between ozone and other environmental stressors, its long-term impacts on forest functions and dynamics at larger spatial scales is controversial (see Cailleret et al; 2018). This study aims at accurately quantifying ozone impacts on tree- and stand-scale growth across Europe and their uncertainties related to the type and quality of the data source used. We combined measured data from different national and international long-term monitoring networks (ICP Forests, LWF, Sanasilva, Swiss NFI) with modeled data (Meteoest, EMEP, ECMWF). We considered several ozone metrics such as mean ozone concentration, AOT40 and POD1 (based on the physiological process-based DO₃SE model; Emberson et al; 2000), and applied multiple statistical and re-sampling techniques to consider confounding abiotic and biotic environmental factors and for the heterogeneity in sample characteristics, respectively. We found a large uncertainty in the estimation of ozone metrics with a strong variability across sites, and that the quality of the vegetation data tends to matter more than for the meteorological variables. The estimated relationships between ozone and tree- or stand-scale growth strongly depend on the sample characteristics (e.g., size and temporal coverage of the sampling) and on the data source used (e.g., modeled vs. measured ozone concentration data). Our study provides new methodological insights into the data required to improve large-scale assessments of ozone impacts on forest ecosystems.

Long-term ecosystem research infrastructure for carbon, water and nitrogen (LTER-CWN)

Eugenio Diaz-Pines¹, Michael Bahn², Thomas Dirnböck³, Michael Englisch⁴, Stephan Glatzel⁵, Barbara Kitzler⁴, Sophie Zechmeister-Boltenstern¹

¹Institute of Soil Research, University of Natural Resources and Life Sciences, Vienna, Austria; ²Department of Ecology, University of Innsbruck, Innsbruck, Austria; ³Environment Agency Austria, Vienna, Austria; ⁴Institute of Forest Ecology and Soils, Austrian Research Centre for Forests, Vienna, Austria; ⁵Geoecology, Department of Geography and Regional Research, University of Vienna, Vienna, Austria (eugenio.diaz-pines@boku.ac.at; michael.bahn@uibk.ac.at; thomas.dirnboeck@umweltbundesamt.at; michael.englisch@bfw.gv.at; stephan.glatzel@univie.ac.at; barbara.kitzler@bfw.gv.at; sophie.zechmeister@boku.ac.at)

Long-term, coordinated monitoring networks are an extremely useful tool contributing to the better understanding of ecosystems and their response to changes in environmental conditions. Here, we present the LTER-CWN Infrastructure Network which is currently being implemented on sites belonging to the LTER-Austria network, covering major ecosystem types (forests, grasslands and wetlands). One focal point of the network is the investigation of climate extreme events and their impacts on ecosystem processes. Specifically, we aim at 1) monitoring major ecosystem processes across our sites with a top quality, comparable standard; 2) providing a research platform for ecological experiments; 3) obtaining a novel understanding of the mechanisms underlying the ecosystem responses and 4) integrating the research sites and data in the international research arena. For this purpose, harmonized instrumentation is being installed for measuring fluxes of carbon (net ecosystem exchange, ecosystem primary productivity, soil respiration, soil methane fluxes), water (water vapour, solutes in soil- and streamwater) and nitrogen (soil nitrogen, nitrous oxide emissions). Next to continuous monitoring across the sites, a mobile platform is being established involving novel isotope-laser based analyses to increase our understanding of the in-situ activities of soil microorganisms and their link to greenhouse gas fluxes. Overall, our network comprises outstanding long-term ecosystem research sites with existing long-term data, an extensive record of research studies, and a comprehensive research infrastructure

ICP Forests: long-term monitoring of the effects of anthropogenic and natural stressors on forest ecosystems under the UNECE Air Convention

Alexa Michel¹, Anne-Katrin Prescher¹, Andreas Schmitz¹, Inken Krüger¹, Till Kirchner¹, Manuel Nicolas², Marco Ferretti³

¹Thünen Institute of Forest Ecosystems, Eberswalde, Germany; ²Office National des Forêts, Fontainebleau, France; ³Swiss Federal Research Institute WSL, Birmensdorf, Switzerland (alexa.michel@thuenen.de; anne.prescher@thuenen.de; andreas.schmitz@thuenen.de; inken.krueger@thuenen.de; till.kirchner@thuenen.de; manuel.nicolas@onf.fr; marco.ferretti@wsl.ch)

The International Co-operative Programme on Assessment and Monitoring of Air Pollution Effects on Forests (ICP Forests) was established within the UNECE Air Convention in 1985 in response to wide public and political concern about the extensive forest damage observed in central Europe and North America which had been attributed to increasing air pollution and acidic deposition. Since then, ICP Forests has developed into a multifunctional long-term forest monitoring programme across the UNECE region with 42 member countries participating and produces scientific data and knowledge not only on the impact of air pollution but also on the effects of climate change and other stressors on forest ecosystems. ICP Forests works at two levels: (i) the systematic, large-scale monitoring network (Level I) provides annual data on forest condition, (ii) the intensive forest monitoring network (Level II) consists of permanent, highly-equipped plots to foster integrative studies on cause-effect relationships based on consistent long-term data series. All in all, ICP Forests collects data on ambient air quality; biodiversity and ground vegetation; crown condition and damage causes; deposition; foliage and litterfall; forest growth; meteorology, phenology and LAI; soil and soil solution. An outstanding feature of the ICP Forests monitoring programme is its high degree of standardization of data collection and quality assurance in each survey and across all member states. An overview of the ICP Forests programme and its data infrastructure, a summary of results from over 30 years of forest monitoring, latest activities as well as future challenges will be presented.

Existing long-term monitoring networks in Romanian forests

Ovidiu Badea^{1,2}, Ionel Popa¹, Stefan Leca¹, Diana Pitar¹, Ecaterina Apostol¹, Serban Chivulescu¹

¹National Institute for Research and Development in Forestry "Marin Drăcea", Voluntari, Romania; ²Transilvania University of Braşov, Braşov, Romania (obadea@icas.ro; popaicas@gmail.com; stefan.leca@icas.ro; diana.silaghi@icas.ro; cathyches@yahoo.com; serban.chivulescu@icas.ro)

In order to meet the ever-increasing needs for scientific knowledge progress about injury symptoms on forests the quality of different stressors (biotic, abiotic, pollution, fire etc.), and climate change effects on trees and forest ecosystems status and biodiversity in most European countries, several forest long-term monitoring networks have been designed and located in the forests of Romania. The first such networks (1990-1992) were created consistent with the objectives of the ICP Forests. Level I (16 x 16 km - 254 plots) and the Level II monitoring plots (12 plots). To identify and monitor the phytotoxic effects of ozone and others potential pollutants (NO₂, SO₂, NOX, and NH₃) and biodiversity in the Carpathian Mountains, in 1997, the Carpathians countries in partnership with

the USDA-Forest Service had placed a monitoring network consisting of 26 sites, 6 of which in the Romanian Carpathians. This network has contributed to initiate the International Long-Term Ecological Research (ILTER) with three Romanian sites (Retezat, Bucegi-Piatra Craiului and Rodna), and subsequently in the LTER-Europe. Furthermore, dendrochronological high potential of Romanian forest ecosystems, have been correlated with a lack of integration of Romanian research at the international level, were decisive factors in elaborating a network of dendrochronological series for the Romanian Carpathians which is integrated in European and international networks. These networks provide an integrated scientific framework, aiming for advancement in complex research projects at national and international levels, specifically relying on supporting productive capacity of socio-ecological systems in the context of climate change and air pollution effects.

Decrease of nutrients in main trees species indicated by long term monitoring across Czech and Slovak forests within the ICP Forests network

Radek Novotný¹ , Danica Krupová², Vít Šrámek¹, Pavel Pavlenda²

¹Forestry and Game Management Research Institute, Jiloviště, Czech Republic; ²NFC, Forest Research Institute, Zvolen, Slovakia (novotny@vulhm.cz; krupova@nlcsk.org; sramek@vulhm.cz; pavlenda@nlcsk.org)

The contribution evaluates the nutritional status and development of the main tree species in Central European countries - Czechia and Slovakia. Foliar nutrition data from ICP Forests monitoring network in both countries are analysed. The longest time series cover more than 20 years (1995-2017 in Czechia; 1995-2013 in Slovakia). Seven coniferous (Norway spruce and Scotch pine) and six broadleaves (European beech and Turkey oak) intensively monitored plots are evaluated. Data shows a significant decrease of main nutrients concentration, mainly P and K. Concentration of P is on roughly half of plots near or below the deficiency limit (1.2 g.kg⁻¹), concentration of K has dropped by 10 to 50 percent, especially in stands of broadleaves during the evaluated period. Temporal trends for P and K have been significantly decreasing on one third of evaluated coniferous plots and similar situation has occurred on broadleaves plots. Both countries differ in Mg trends in spruce stands – there is a decrease of Mg concentration in needles in Slovakia compared with Czech coniferous plots. On the other hand, in beech leaves there is a decrease of Mg in both countries, although only in Czechia is the trend significant. In general observed changes in nutrition level document stable or slightly increasing N concentration and decreasing tendency of phosphorus and base cations. This situation lead to nutrient imbalance, especially considering N and P ratio. Potential nutritional disorder represents a threat for forest vitality, especially in connection with drought or other abiotic or biotic risk factors.

Analysis and modelling of the wood density variability of the French forest species for the assessment of the forest biomass under climatic change

Jean-Michel Leban¹, Baptiste Kerfriden¹, Jean-Daniel Bontemps²

¹Institut National de la Recherche Agronomique, Champenoux, France; ²IGN, Nancy, France (jean-michel.leban@inra.fr; baptiste.kerfriden@inra.fr; jean-daniel.bontemps@ign.fr)

There is an increasing demand on the monitoring of the forest resources, on forests statistics, and on projections of future forest resource availability especially in terms of biomass (Leban & Bontemps, 2016). We developed a new method to enrich the forest information produced by the French National Forest Inventory by the measurement of the wood density. This technological innovation permits the fast and reliable measurement of the wood density on unprepared increments cores collected in the forests by the NFI staff. The cores are passed through a medical Xray scanner. Since 2015, about thirty thousand cores were sampled each year. At the end of this project, in November 2019 we will have a novel data base with wood density measurements on more than one hundred thousand increment cores. We will present several preliminary results that illustrate the different ways to enrich forest information, e.g. (i) the reassessment of the total standing biomass for the main forest species and (ii) the wood density models that can be used for the simulation of the forest biomass changes at the national level for different climatic hypothesis. We will present and discuss the perspective for the analysis and the sharing of this new data base that combines at the national scale level wood density and the usual forest inventory measurements such as DBH, height, age etc. Such data base pave the avenue for a better understanding of the biomass production along different climatic and trophic gradients.

Towards a better integration between National Forest Inventories and Forest Condition Monitoring – a Swiss contribution.

Marco Ferretti¹, Arthur Gessler¹, Urs-Beat Brändli¹, Esther Thürig¹, Lorenzo Fattorini², Adrian Lanz¹

¹Swiss Federal Research Institute WSL, Birmensdorf, Switzerland; ²University of Siena, Siena, Italy (marco.ferretti@wsl.ch; arthur.gessler@wsl.ch; urs-beat.braendli@wsl.ch; esther.thuerig@wsl.ch; lorenzo.fattorini@unisi.it; adrian.lanz@wsl.ch)

European forests are being monitored by means of National Forest Inventories (NFI) installed on a national basis, and the Forest Condition Monitoring (FCM), installed under the UNECE ICP Forests. FCM is further subdivided into a large-scale survey on forest health (Level I), and intensive monitoring seeking to identify relationships between stressors and forest condition (Level II). In general, NFIs, Level I and Level II occur on different networks of plots. NFIs are based on probabilistic sample surveys (p-surveys) designed at national level; Level I is also frequently based on p-based surveys, in many cases located apart from NFIs; and Level II is a series of purposively selected case studies, with no formal link to a defined statistical population. The question is therefore how to make better use of these networks, in a way that results from individual ones can be integrated for a better understanding of status and changes of forest resources, and their response to environmental changes. While a better integration between NFIs and Level I is relatively straightforward, here we present an attempt to use Level II data to improve the estimation process of the NFI in Switzerland. We concentrated on key NFI target variables measured also at Level II sites, e.g. basal area, volume and biomass increment. We investigated (i) significant predictors of increment on the basis of measurements at the Level II sites; and (ii) whether those predictors can be used as auxiliary variables in the model-assisted, design-based estimation framework of the Swiss NFI.

B4j: NOVEL REMOTE SENSING APPROACHES TO QUANTIFY CARBON STOCKS, STRUCTURE AND FUNCTIONAL DIVERSITY OF FORESTS 2

Temporal-spatial changes of wetlands in the Tarim Populus Euphratica National Nature Reserve over the past 24 years

Yiming Feng¹, Xiaoming Cao¹

¹Institute of Desertification Studies, Chinese Academy of Forestry, CAF, Beijing, China (fengym@caf.ac.cn; caoxm@caf.ac.cn)

The landscape information of wetland in the Tarim Populus Euphratica National Nature Reserve (abbreviated as the Reserve, the same as below) was extracted under the support of GIS and RS technology by using the remote sensing images obtained in 1992, 1999 and 2016, and meanwhile the temporal-spatial change characteristics of wetland was analyzed before and after the ecological water conveyance. It was found that the wetland area in the Reserve showed a trend of decreasing first and increasing later. The wetland area was decreased by 16.8% during 1992-1999 (namely before ecological water conveyance), while that was increased by 6.9% during 1999-2016 (namely after ecological water conveyance), indicating that the ecological water conveyance had positive effects on the ecological restoration and protection of wetland. During 1993-1999, the different wetlands showed a large change in the dynamic degree, and the disturbance of humans was intensified. After 17 years of ecological water conveyance, the change in the dynamic degree value of wetland slowed down, and the rapid degradation of wetland was effectively inhibited, but the restoration process was slow. The ecological water conveyance increased wetland area indeed, but which was mainly conducted along the main stream of the Tarim River, and the increased area was derived from the temporary watersheds such as permanent rivers. There was no significant increase in the swamp area with real ecological benefits. So, the increased wetland area only exerted the limited function of wetland ecosystem, and the strategy of the ecological water conveyance was not very reasonable.

Monitoring forest carbon gain and loss, and isolation of protected areas: implications to the carbon benefits of protection

Belachew Gizachew Zeleke¹, Svein Solberg¹, Stefano Puliti¹

¹Norwegian Institute of Bioeconomy Research, Ås, Norway (belachew.gizachew@nibio.no; svien.solberg@nibio.no; stefano.puliti@nibio.no)

Protected Areas (PAs) may offer great potential for carbon conservation in the context of climate change mitigation. Two Digital Elevation Model (DEM) datasets for the period 2000–2012 were used to develop a wall-to-wall map of forest carbon gain and loss for the entire Uganda. Drawing on the map, this study (1) quantified forest carbon gain and loss within 713 PAs and external buffer zones of 0.5 – 10 km surrounding each PA, and (2) evaluated the effectiveness of PAs and management regimes and detect the prevalence of local leakage in terms of forest carbon, and thus isolation of PAs in the general landscape. The net annual forest carbon gain in PAs of Uganda was 0.22 ± 1.36 t/ha, but a significant proportion (63%) of the PAs exhibited a net carbon loss. Further, carbon gain and loss varied significantly among management categories. About 37% of the PAs were “effective”, i.e., gained or at least maintained forest carbon during the period. Nevertheless, carbon losses in buffer zones of effective PAs significantly contrast with carbon gains inside of the PAs, providing strong evidence of leakage. This suggests that PAs were being threatened by deforestation and forest degradation, and thus face a significant isolation and fragmentation. For forested countries that will aim to benefit from carbon conservation through protected area management from international policies such as REDD+, there is an urgent need to look into their PA management, and design protection strategies that account for the surrounding landscapes and communities outside of the PAs.

Tropical forest and land cover monitoring using optical and SAR data

Manuela Hirschmugl¹, Mathias Schardt¹, Carina Sobe¹, Janik Deutscher¹

¹Joanneum Research Forschungsgesellschaft mbH, Graz, Austria (manuela.hirschmugl@joanneum.at; mathias.schardt@joanneum.at; carina.sobe@joanneum.at; janik.deutscher@joanneum.at)

Tropical forest monitoring is currently in a transition phase from (i) annual mapping updates to automated, near real-time applications that rely on full time-series analysis and (ii) from single sensor applications to multi-sensor monitoring systems. The research aim of the Horizon2020 project EOMonDIS is to assess the benefit of a joint use of high resolution optical and SAR time series data for cost-efficient and accurate tropical forest monitoring, specifically for REDD+ applications. We compare different methods for data combination: first, a Random Forest classification based on a combination of pre-processed SAR and optical data, and second, a result-based fusion of separate optical and SAR classification results using Bayesian combination. The final products are high resolution forest and land use maps as well as deforestation and forest disturbance maps. We present the classification results for four diverse forest monitoring test sites in Africa and Latin America that cover both humid and dry tropical forests. The accuracies of the results vary strongly among test sites and products. We analyze the influencing factors in order to better understand existing inter-dependencies. For areas with frequent cloud cover and for large deforestation plots, SAR data gives a significant added value in terms of detection timeliness and classification accuracy. However, the added value of SAR data in the processing chain for small changes (forest degradation) is only marginal. We found the use of SAR time series data in combination with a mono-temporal optical image can compensate for a full time series of optical data.

Use of SfM-constructed 3D models to estimate biomass of buttressed trees in the central Amazon

Tatsuya Otani¹, Rempei Suwa², Shinta Ohashi³, Adriano Lima⁴

¹FFPRI, Kochi, Japan; ²JIRCAS, Tsukuba, Japan; ³FFPRI, Tsukuba, Japan; ⁴INPA, Manaus, Brasil (tatsuyao@affrc.go.jp; swrmp@affrc.go.jp; shinta0084@affrc.go.jp; adriano@inpa.gov.br)

Safe and accurate measurement of stem diameter of large buttressed trees is challenging. New simple methods are required to accurately estimate tropical forest biomass to support REDD+ efforts. In the present study, we developed computations employing dimensionally-accurate 3D models created using structure from motion (SfM) to convert perimeter measurements of convex hull of a buttressed trunk to cross-sectional area at breast height; 3D models of 26 buttressed trunks in the central Amazon were constructed using free software, such as Regard3D, MeshLab, Meshmixer, and FreeCAD. Perimeter measurements of 3D model trunks were compared to field-measured values at a given height, and the results indicated that the free software created good 3D models. Regression analysis confirmed that the cross-sectional area of a buttressed trunk was estimated from 3D model perimeter of a convex hull; $\ln(\text{Area}_{1.3}) = -2.697 + 1.370 \ln(\text{Perimeter}_{1.3})$, where $\text{Area}_{1.3}$ is the cross-sectional area (m^2) and $\text{Perimeter}_{1.3}$ is the perimeter of a convex hull (m) at the standard breast height of 1.3 m ($R^2 = 0.835$, $F_{1,24} = 127.4$, $p = 4.39 \times 10^{-11}$). Further, we showed that $\text{Area}_{1.3}$ was estimated from the perimeter of a convex hull at 0.3 m height; $\ln(\text{Area}_{1.3}) = -3.538 + 1.433 \ln(\text{Perimeter}_{0.3})$, ($R^2 = 0.696$, $F_{1,24} = 58.5$, $p = 6.95 \times 10^{-8}$), demonstrating that $\text{Area}_{1.3}$ could also be estimated from buttressed tree stumps; 3D models combined with our computational equations provide a cost-effective and simplified method that can be used to calculate species-specific parameters and for estimating lost biomass in logged forests.

Comparison of estimation results of aboveground biomass using different allometric equations in a lowland Dipterocarp forest, Peninsular Malaysia

Tamotsu Sato¹, Kaoru Niiyama¹, Tsutomu Yagihashi¹, Zamah Shari Nur Hajar², Ripin Azizi³

¹Forestry and Forest Product Research Institute, Tsukuba, Japan; ²Forest Research Institute Malaysia, Selangor Darul Ehsan, Malaysia; ³Advanced Forest Resources, Selangor Darul Ehsan, Malaysia (sato@affrc.go.jp; niiya@affrc.go.jp; yagihashi@affrc.go.jp; hajar@frim.gov.my; azizi_ripin@yahoo.com)

Accurate forest carbon stock estimation is indispensable to implement a REDD+ project. To date, many allometric equations have been developed to estimate aboveground biomass (AGB) around the tropical forests. In this study, we compared estimation results of AGB between locally developed equation (Kato et al; 1978) and general equation developed by Chave et al. (2005) using a tree census data from 6-ha plot in lowland Dipterocarp forest, Peninsular Malaysia. To use the general equation, we had also calculated species specific wood densities for each tree species in the plot. The results of applying the locally developed equation, without wood density parameter, showed relatively low value (ca: 8%) than those of the general equation. Some heavy hardwood tree species (e.g. *Dipterocarpus crinitus* and *Koompassia malaccensis*) were causing differences in estimation results. On the other hand, many light hardwood tree species (e.g. *Melicope glabra* and *Endospermum diadenum*) had emerged and dominated within secondary patch where clear cutting had conducted in the early 1970s, and showed overestimated values by the locally developed equation due to lack of wood density data. Our results imply that selection of ineligible allometric equation could lead to inaccurate AGB estimation in secondary forests. Moreover, tree species identification is also important to evaluate forest carbon stocks on a regional scale using combination of remote sensing data and ground-based inventory.

Modelling the spatial variation in above ground carbon stocks in Zimbabwe's dry indigenous forests

Richard Muchena¹

¹Zimbabwe Forestry Commission, Bulawayo, Zimbabwe (richymuchena@gmail.com)

The above ground carbon pool in Zimbabwe's dry indigenous forests is often unknown and under-estimated. This is often as a result of limited resources to carry out large scale forest inventories. Moreover, most work on the estimation of forest carbon stocks have mainly focused on tropical rainforests. In that regard this study sought to close that gap by modelling the relationship between in-situ field based Above Ground-Biomass measurements and satellite data. To achieve this objective, satellite reflectance values of Bands 3, 4 and 8, the Difference Vegetation Index (DVI), Ratio Vegetation Index (RVI), Normalized Difference Vegetation Index (NDVI) and the Soil Adjusted Vegetation Index (SAVI) were computed from Sentinel satellite data of June 2018. Correlation and regression analysis were then used to relate field based carbon measurements and remotely sensed parameters. Results showed that NDVI had the most significant positive relationship with field based carbon measurements ($r^2=0.72$; $p < 0.05$) thus it can be used as a proxy for carbon estimation in Zimbabwe's dry indigenous forests. These findings underscore the potential and significance of remote sensing data in particular Sentinel in understanding and quantifying carbon stocks in Zimbabwe's dry indigenous forests.

First mission – towards a global harmonised in-situ data repository for forest biomass datasets validation

Dmitry Schepaschenko^{1,2} , Jérôme Chave³, Oliver L. Phillips⁴, Stuart J. Davies⁵, Simon L. Lewis^{4,6}, Plinio Sist⁷, Maxime Réjou-Méchain⁸, Christoph Perger⁴, Klaus Scipal⁹

Global measurements of forest height, biomass are urgently needed as essential climate and ecosystem variables, but can benefit from greater co-operation between remote sensing (RS) and forest ecological communities. The Forest Observation System – FOS (<https://forest-observation-system.net/>) is an international cooperation to establish a global in-situ forest biomass database to support earth observation and to encourage investment in relevant field-based observations and science. FOS aims to link the RS community with ecologists who measure forest biomass and estimating biodiversity in the field. The FOS aims to overcome data sharing issues and introduce a standard biomass data flow from tree-level measurement to the plot-level aggregation served in the most suitable form for the RS. Ecologists benefit from the FOS with improved access to global biomass information, data standards, gap identification and potentially improved funding opportunities to address the known gaps and deficiencies in the data. FOS closely collaborate with the CTFS-ForestGEO, the ForestPlots.net (incl. RAINFOR, AfriTRON and T-FORCES), AusCover, TmFO and the IIASA network. FOS is an open initiative with other networks and teams most welcome to join. The online database provides open access for forest plot location, canopy height and above-ground biomass. Plot size is 0.25ha or larger. Comparison of plot biomass data with available global and regional maps (incl. Kindermann et al., 2013; Thurner et al., 2013; Saatchi et al., 2011; Baccini et al., 2012; Avitabile et al., 2016; Hu et al., 2016; Santoro et al., 2018) shows wide range of uncertainties associated with biomass estimation.

Understanding the disturbance dynamics of forests using time-series remote sensing

Simon Jones¹, Mariela Soto-Berelov¹, Samuel Hislop¹, Trung Nguyen¹, Jenna Guffogg¹, Shirley Famelli¹, Andrew Haywood²

¹RMIT University, Melbourne, Australia; ²European Forestry Institute, Barcelona, Spain (simon.jones@rmit.edu.au; mariela.soto-berelov@rmit.edu.au; samuel.hislop@rmit.edu.au; trung.nguyen3@rmit.edu.au; jenna.guffogg@rmit.edu.au; shirley.famelli@rmit.edu.au; andrew.haywood@efi.int)

Time series remote sensing can be used to map trends and changes in forests over time. This research utilises long time series Landsat imagery to map and examine disturbance events, and subsequent recovery, over 8.2 million hectares of sclerophyll forest in SE Australia. All available Landsat TM imagery (1988-2017) for southern hemisphere summer months was used to create annual composites of six vegetation indices (using LandsatLinkR) across 19 WRS Landsat tiles. The spectral trajectory of each index was extracted on a per pixel basis over the 30-year period, and used to characterise the disturbance-recovery dynamics of forests. A reference dataset consisting of 8,000 training pixels and 786 permanent plots were then created to attribute disturbance events using a multiple lines of evidence approach. This was then used to prime a set classifiers (Random Forest) and map disturbance and recovery by severity/completeness of recovery and agent of change: logging (clear fell and selective logging), fire (wildfire and prescribed burning), low severity disturbance including pests, flooding, drought and

disease. Results, which achieved an 87% overall accuracy, clearly show annualised abrupt disturbance events such as logging and wildfire, as well as gradual changes such as drought and disease. About a quarter of the study area forests were impacted by medium or high severity fires during the three-decade study with a trend towards recovery times getting shorter in recent years (from a mean of 15 years to 12 years) across a range of biomes.

Tropical rainforest above ground biomass and carbon stock estimation for upper and lower canopies using terrestrial laser scanner and canopy height model from UAV imagery in Ayer-Hitam, Malaysia

Yuvenal Mtui¹, Yousif Hussin¹, Henk Kloosterman¹, Mohd Hasmadi Ismail²

¹*ITC, University of Twente, Enschede, Netherlands;* ²*University Putra Malaysia, Serdang, Selangor, Malaysia (y.p.mtui@student.utwente.nl; y.a.hussin@utwente.nl; e.h.kloosterman@utwente.nl; mhasmadi@upm.edu.my)*

To control the impact of climate change, REDD+ program and its MRV mechanism have been established under UNFCCC. There is a need for an accurate method to assess the complex multi-layered tropical rain-forest parameters for estimating above-ground biomass (AGB)/carbon stock. The emergent of Unmanned Aerial Vehicle (UAV) and Terrestrial Laser Scanner (TLS) technologies operate from air and ground respectively can provide accurate information of upper and lower canopy layers at a reasonable accuracy for monitoring of carbon stock. However, both sensors are associated with limitation of foliage coverage in the complex multi-layer tropical forest which can underestimate AGB estimation when used separately. This study aimed at establishing a reasonably accurate method for the assessment of tropical rainforest AGB/carbon estimation for REDD+ and its MRV system by complimenting UAV imagery and TLS data. The upper canopy tree height was derived from UAV imagery using SfM method, while the lower canopy height was measured using TLS. The DBH derived from TLS point clouds were used for the AGB of both upper and lower canopies. The derived AGB from the upper (using UAV data) and lower (using TLS data) canopies were combined. The accuracy of the estimated forest AGB/carbon stock on plot base using the developed method when compared to reference method achieved an R^2 of 0.98 and RMSE of 536.25 kg per plot (6.23%) for 30 plots. Also, a t-test shows no statistical significance difference between the AGB/carbon estimated by the two methods.

B4k: NOVEL REMOTE SENSING APPROACHES TO QUANTIFY CARBON STOCKS, STRUCTURE AND FUNCTIONAL DIVERSITY OF FORESTS 3

Comparison of regression techniques for LiDAR-derived aboveground biomass estimation in the Amazon

Catherine Almeida¹, Lênio Galvão¹, Luiz Eduardo Aragão¹, Jean Ometto¹, Aline Jacon¹, Francisca Pereira¹, Luciane Sato¹

¹*Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil (cathe.torres@gmail.com; lenio.galvao@inpe.br; luiz.aragao@inpe.br; jean.ometto@inpe.br; alinejacon@hotmail.com; franrsperreira@gmail.com; lucianesato@gmail.com)*

Light Detection And Ranging (LiDAR) is an active remote sensor that has been successfully applied for characterizing canopy structure, especially to estimate aboveground biomass (AGB). Parametric models, mainly the linear regression with stepwise feature selection (LMstep), are the most common approaches used for estimating AGB. However, non-parametric machine learning techniques, such as Support Vector Regression (SVR), Stochastic Gradient Boosting (SGB), and Random Forest (RF), can better address complex relationships between biomass and remote sensing variables. Therefore, it is desirable to assess the performance of different regression strategies. This study aims to compare eight regression techniques for LiDAR-based AGB estimation: LMstep, Linear Models with Regularization (LMR), Partial Least Squares (PLS), K-Nearest Neighbor (KNN), SVR, RF, SGB, and Cubist. For this purpose, 34 LiDAR metrics were regressed against AGB from 147 inventory plots across the Brazilian Amazon Biome. Models performance were evaluated by the average Root Mean Squared Error (RMSE) and R^2 from a 5-fold cross-validation strategy with 10 repetitions. The Kruskal-Wallis test was used to evaluate statistical differences among models. Results showed that LMstep presented the highest RMSE (68.85 Mg.ha⁻¹) and lowest R^2 (0.66), while SVR had the lowest RMSE (65.23 Mg.ha⁻¹) and highest R^2 (0.69). However, the differences in performance of the models were not statistically significant. Thus, we confirmed the results of previous studies that showed that simple approaches, such as linear regression models, performed just as well as advanced machine learning methods for estimating AGB based on LiDAR data.

Selection of hyperspectral variables for aboveground biomass estimation in the Brazilian Amazon

Catherine Almeida¹, Lênio Galvão¹, Luiz Eduardo Aragão¹, Jean Ometto¹, Aline Jacon¹, Francisca Pereira¹, Luciane Sato¹

¹*Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil (cathe.torres@gmail.com; lenio.galvao@inpe.br; luiz.aragao@inpe.br; jean.ometto@inpe.br; alinejacon@hotmail.com; franrsperreira@gmail.com; lucianesato@gmail.com)*

Due to the limited coverage of field Above Ground Biomass (AGB), remote sensing becomes an alternative for monitoring carbon stocks at the landscape scale. However, the most commonly used sensors have limited spectral resolution. Hyperspectral imaging (HSI) provides high-resolution information, although its high data dimensionality becomes a challenge for modeling. In this context, selection of suitable variables is a critical step for estimating AGB from HSI data. Support Vector Regression coupled with the Recursive Feature Elimination approach (SVR-RFE) can produce parsimonious models from a reduced subset of features. We applied the SVR-RFE in a 5-fold cross-validation strategy with 5 repetitions to determine which hyperspectral variables were most effective to estimate AGB. We used field AGB from 147 inventory plots across the Brazilian Amazon and 64 plot-level HSI metrics, including 14 reflectance bands, 30 vegetation indices, continuum-removal absorption features at five wavelengths (495, 670, 980, 1200, and 2100 nm), and endmember fractions (green vegetation, shade, and non-photosynthetic vegetation/soil) from Spectral Mixture Analysis. The SVR-RFE explained 67% of the AGB variation, by selecting eight HSI variables. The three most effective variables came from the shortwave infrared region (width and depth of the 2100-nm absorption band and the NDNI index), related to canopy moisture and lignin-cellulose-nitrogen absorption bands. Four metrics were retrieved from the water absorption band centered at 980 nm (depth, asymmetry, and the indices PWI and LWV11). The width of the band placed at 495 nm was also selected. SVR-RFE proved to be an efficient technique for estimating AGB from HSI data.

Correlation between distribution of emergent trees in the Brazilian Amazon and biomass maps / Correlação entre distribuição das árvores emergentes na Amazônia Brasileira e mapas de biomassa

Alline Zagnoli Villela Motta¹, Cristiano Rodrigues Reis², Luiz Carlos Estraviz Rodriguez², Eric Bastos Gorgens¹

¹Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brasil; ²Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, São Paulo, Brasil (allinezm@gmail.com; crreis28@gmail.com; lcer@usp.br; e.gorgens@gmail.com)

Quantificar a biomassa e o carbono do bioma amazônia é um desafio que vem sendo trabalhado por diversos pesquisadores. De acordo com a literatura, os mapas existentes de biomassa disponíveis para a região possuem diferenças significativas. Ainda que, o estoque de carbono estimado pelas metodologias apresentem um padrão espacial coerente, a incerteza associada aos valores encontrados são elevados. Pensando em tecnologias que possam contribuir na redução dessas incertezas, o escaneamento a laser aerotransportado (ALS, Airborne Laser Scanning) tem ganhado destaque. Para contribuir com as iniciativas de quantificação dos estoques de biomassa da Amazônia, o Projeto Monitoramento Ambiental da Amazônia, apoiado com recursos do Fundo Amazônia, realizou o levantamento de mais de 800 transectos distribuídos aleatoriamente na região. As nuvens de pontos obtidos pelo levantamento ALS foram filtradas e normalizadas. As árvores emergentes foram localizadas utilizando um algoritmo de busca por máximos locais com janela fixa. Cada máximo local identificado representou uma árvore emergente. O centróide do transecto foi associado ao valor médio da altura obtida com base no modelo digital de altura de dossel das 3750 árvores mais altas (10 árvores por hectare). Os valores obtidos para cada transecto serão correlacionados com os valores de biomassa estimados pelos diferentes mapas de biomassa disponíveis. Espera-se apresentar o grau de aderência dos atuais mapas de biomassa aos valores de altura obtidos das árvores emergentes.

Assessing the association between surfaces derived from LiDAR cloud in an Amazon Tropical Forest

Eric Gorgens¹, Cristiano Reis², Mariana Andrade³, Luiz Carlos Rodriguez²

¹Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brasil; ²Universidade de São Paulo, Piracicaba, Brasil; ³European Forestry Erasmus Mundus, Joensuu, Finland; (e.gorgens@gmail.com; cristiano.reis@usp.br; mandrade0305@gmail.com; lcer@usp.br)

Association is a general relationship implicating that one variable brings information about another. Currently, a large number of layers of information can be extracted from an airborne laser scanning (ALS) cloud. Directly from the LiDAR cloud, three main surfaces were usually created: the digital terrain model (DTM), the canopy height model (CHM) and the relative density model (RDM). Especially from DTM and CHM, many other layers can be derived. From those surfaces, many other surfaces can be extracted, adding information from different aspects of the study area. From DTM, we analyzed 4 layers related to hydrologic information, 2 related to operational restrictions, and 1 related to topographic information. From the CHM, one extra layer was derived bringing information about the vegetation. Any new layer was created from the RDM. To investigate the association between those layers we used the hierarchical clustering based on the Euclidean distance and Ward's minimum variance criterion for grouping. We suggest that five groups can capture the most important information to planning. The representatives of each group were: DTM, slope model (SLM), CHP, RDM, and topographic wetness model (TWM). Usually, the hierarchical cluster grouped layers from similar parent surface, or a parental surface and its subproduct. The exception was the group formed by RDM and vertical distance to the drainage. SLM and TWN are both derived from the DTM, but they were not grouped together, either with the DTM. This indicates that those layers are adding different information that holding by DTM.

Detecting forest management impacts over the canopy

Cristiano Rodrigues Reis¹, Luiz Carlos Estraviz Rodriguez¹, Eric Bastos Gorgens²

¹Universidade de São Paulo, Piracicaba, Brasil; ²Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brasil (cristiano.reis@usp.br; lcer@usp.br; eric.gorgens@ufvjm.edu.br)

Selective logging comprises on harvesting a few trees of interest in large forested areas without compromise the ecosystem function. Remote sensing has already been applied for monitoring deforestation. However, most of the traditional techniques are not able to deal properly with degradation. Usually, degradation occurred in the layers below the canopy, which is a limitation for monitoring using aerial or satellite images. LiDAR sensors coupled in aircraft was able to provide information about forest vertical structure for large areas, including the understory layer. Modeling the vertical profile of the understory using airborne laser scanning through probability density functions identified the impact of selective logging activities over the forest structure. Overall, the values for scale and shape Weibull coefficients decrease in stands where roads and skid trails were opened, damaging the forest canopy. The curve format for the distribution of Weibull coefficients revealed different patterns for recently exploited and not exploited areas. Clustering the scale coefficients allowed us to classify the study area in low, medium-low, medium-high and high impacted areas. Recently managed areas showed a proportion of high impacted areas. Instead, conservation areas presented much more areas classified as low impact. These results showed that the impact classification by the scale coefficient clearly matched selective logging activities incidence. Further, our results showed that modeling understory profile through Weibull function can be used to monitor the effects of forest management under dense vegetation for large areas.

Comparing dendrometric variables obtained from conventional forest inventory and from land-platform LiDAR / Comparação entre variáveis dendrométricas obtidas pelo inventário florestal convencional e pelo sistema LiDAR de plataforma terrestre

Lucas Timo¹, Aguida Viana¹, Carlos Torres¹, Cibele Amaral¹, Elpidio Fernandes¹, Felipe Santana¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (lucas.timo@ufv.br; aguida.viana@ufv.br; carlos.eleto@yahoo.com.br; cibeleha@gmail.com; elpidio@ufv.br; fsantana90@gmail.com)

A utilização dos sistemas de varredura a laser (LiDAR – Light Detection and Ranging) tem se tornado uma prática recorrente e eficaz no que diz respeito à análise das variáveis dendrométricas em um inventário florestal. Desta forma, objetivou-se comparar as estimativas de variáveis dendrométricas coletadas por meio do inventário florestal convencional e com o auxílio de um laserscanner terrestre (TLS – Terrestrial Laser Scanning) em um fragmento de Floresta Estacional Semidecidual. A coleta dos dados foi realizada em 30 indivíduos arbóreos de 9 espécies distintas presentes em uma parcela permanente do fragmento. Desses, coletaram-se o CAP (circunferência a altura do peito) (cm) e altura total (m) com o auxílio de uma fita métrica e um hipsômetro Vertex, para avaliar o método de inventário florestal convencional. Para a estimação utilizando o TLS, o equipamento foi posicionado em 12 pontos diferentes dentro da parcela. A nuvem de pontos obtida foi processada nos softwares Riscan-Pro e 3D Forest, no qual foi coletado o DAP e altura total dos indivíduos. A espécie *Trichilia pallida* foi a que apresentou menor diferença para DAP médio, 0.14 cm (± 0.10). Já a espécie *Rollinia laurifolia*, apresentou a maior diferença, 1.34 cm (± 0.95). Para altura total média, a espécie que se destacou foi *Siparuna guianensis*, com diferença igual a 0.28 m (± 0.20). A espécie *Albizia polycephala* obteve a maior diferença, -7.18 m (± 5.08). Os valores encontrados demonstram que o uso do LiDAR obtém resultados significativos para o DAP, entretanto, as alturas totais demonstraram uma tendência a superestimação.

Obtaining information to subsidize annual production units definition in forest management plans through the combination of ground plots, LiDAR data and satellite images

Marcus d'Oliveira¹, Evandro Figueiredo¹, Daniel Papa¹, Nara Pantoja²

¹Embrapa Acre, Rio Branco, Brasil; ²MMA, Brasilia, Brasil (marcus.oliveira@embrapa.br; evandro.figueiredo@embrapa.br; daniel.papa@embrapa.br; narapantoja@gmail.com)

The objective of this work was to optimize the design of the Annual Production Units (APU) in forest management plans, through the combination of field and remote sensing data. The study was carried out in the Antimary State Forest (ASF) located in Acre State, Southwestern Brazilian Amazon. As this area already have a forest management plan our study was limited to the identification of the UPA forest structure and relief. A high resolution biomass map was elaborated through the upscaling of biomass models from ground plots (permanent sample plots) to LiDAR data and from LiDAR to Landsat-OLI and ALOS-PALSAR images. To the identification of the watersheds, restrict access areas (RAA) and permanent preservation areas (PPA) a digital terrain model (DTM) was elaborated through the use of ground information (GPS), LiDAR and ALOS-PALSAR images. The biomass map was used to the forest stratification in three forest typologies, used to identify the forest areas timber production potential. For each APU we determine: i. the APP and watershed areas and location; ii. restricted access; areas iii. forest stratum and dried above ground biomass stocks. The APU shape, size and distribution must be defined in a way to promote similar annual costs and timber production, minimizing environmental damages. This procedure can be used as a method to define APU in forest management plans in the Amazon.

An overview on the use of active and passive remote sensors to estimate carbon stocks, structure and diversity in forests

Luiz Carlos Estraviz Rodriguez¹, Thais Hudari Abib¹, Juliana Vicentini¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (lcer@usp.br; thais.abib@usp.br; ju_vicentini@yahoo.com.br)

Remote sensing techniques used to quantify forest biomass or to assess the structural diversity of forests have become ubiquitous. Based on a collection of scientific papers published over the last twenty years, we categorize the use of active and/or passive remote sensors to provide some sort of estimate about forest biomass and forest structural diversity. The method used to categorize these historical contributions consists on classifying the estimate according to the type of sensor used to collect data (for instance, optical, radar, lidar, multispectral, hyperspectral etc.); the type of platform used to fasten the sensor (fixed, mobile, terrestrial, aerial, orbital etc.); the scale of the estimate (local, regional, global), the methodological approach and type of algorithms used to process the estimates (empirical, model based etc.); the type of estimate (biomass allocation, carbon stock, etc.) and allocation (total, above or below ground, per vegetation type etc.). The assessment tries to identify the set of essential questions and hypothesis proposed by the many authors and the seminal contributions and technological breakthroughs observed in the period. The review presents a table with some open questions still not sufficiently explored that might offer interesting opportunities for researchers. The fast pace evolution of new technologies and data analysis make projections difficult, but we prospectively comment on some new approaches that will make the future monitoring of our forests very promising.

B4I: CLIMATE SMART FORESTRY OR HOW TO INTEGRATE ADAPTATION, MITIGATION AND SUSTAINABLE FOREST MANAGEMENT

Varying effects of tree composition, diversity and structure on the microclimate of European forests

Radim Matula^{1,2}, Martin Svátek², Roman Gebauer², Roman Plichta²

¹Czech University of Life Sciences, Prague, Czech Republic; ²Mendel University in Brno, Brno, Czech Republic (radimmatula@gmail.com; msvatek@centrum.cz; gebo@email.cz; plichta.roman@gmail.com)

Due to climate change, European forests face rising temperatures and increasing severity and frequency of droughts. However, forests itself may potentially buffer a great part of the negative climate-change effects. These buffering effects likely depend on forest structure, composition and diversity, which in most European forests can be manipulated by forest management to support these climate-change mitigation functions. Here, we present results of the project in which we measured soil moisture, temperature and air temperature in 200 research plots with varying species composition and species mixtures spanning from boreal to Mediterranean forests. The most pronounced difference was found between coniferous and broadleaved trees species, which, in comparison with conifers, had greater summer maximum and winter minimum air and soil temperatures but conserved better soil moisture, especially in late summer and the autumn. Mixed stands had an intermediate microclimate. Increasing tree density reduced temperature extremes but decreases soil moisture. These results suggest that by varying tree composition and structure, foresters may influence forest microclimate but the species that mediate temperature extremes may be different from species the best conserve soil moisture. The great microclimate variation observed in our study also indicates that the typical use of one climate dataset from the nearest climatic station (usually located outside forest) for all study site may be inaccurate. This also means that the quantification of the effects of droughts for forest on the small and medium spatial scale may be significantly biased without local data.

Consistent carbon equivalents for pricing the warming power of surface albedo according to its social cost

Jussi Lintunen¹, Aapo Rautiainen¹

¹Natural Resources Institute Finland, Helsinki, Finland (jussi.lintunen@luke.fi; aapo.rautiainen@luke.fi)

Optimizing forest management for timber and climate benefits means choosing a management schedule that jointly maximizes the net present value of both ecosystem services. Forests affect the climate through various channels. Here, we focus on carbon storage and surface albedo which tend to force the climate in opposite directions. The accumulation of biomass in boreal coniferous forests increases carbon storage (cooling effect) but also reduces Earth's surface albedo (warming effect). Taking carbon and albedo optimally into account in forest management requires pricing them according to their social value. Management choices are affected by the assigned prices, as well as the strength of the climatic impacts caused through these channels. The socially optimal price for CO₂ is the Social Cost of Carbon (SCC). Albedo can be priced in two ways: directly, based on the transient warming power of a given surface and the Social Cost of Forcing (SCF), or indirectly, by converting its warming impact into carbon equivalents and then applying the carbon price. Potential inconsistencies between the methods lead to different albedo prices and affect inferences made about optimal forest management. We present a consistent way to calculate carbon equivalents and compare it with a common but inconsistent method. We show that the latter method can (coincidentally) produce roughly correct albedo prices but is sensitive to arbitrary parameter choices and is unable to capture temporal changes in the albedo-to-carbon price ratio. Our results improve the transparency of comparisons between studies in which different albedo pricing methods are applied.

Economic and environmental impacts of European conservation and bioenergy forest management strategies

Alexander Moiseyev¹, Birger Solberg¹, Annikki Mäkelä², Sanna Härkönen²

¹Norwegian University of Life Sciences, Ås, Norway; ²University of Helsinki, Helsinki, Finland (alexander.moiseyev@nmbu.no; birger.solberg@nmbu.no; annikki.makela@helsinki.fi; sanharko@gmail.com)

Forest conservation and use of wood for energy can be alternative forest management strategies to mitigate climate change. The global partial equilibrium forest sector model and the FORMIT forest simulation model are applied together to study the market impacts of the Business as Usual (BAU) and two alternative forest management scenarios – Maximum Bioenergy and Biodiversity scenarios. The Biodiversity scenario is similar to BAU on the demand side, but differs on the biomass supply side as it assumes 20% of the EU forest growing stock is set aside in 2010, longer rotation periods, selection of species better adapted for climate change and no logging residues removals in the EU region. The Bioenergy scenario differs by higher energy wood demand in Europe and globally, and on the wood supply side by shorter rotation periods, selection of the faster growing species and high share of residues removals. The quantified results show that the Bioenergy scenario will substantially increase EU forest owner's gross income from selling wood, forest industries gross sales and value added, and in addition substantial energy substitution effect will benefit climate change mitigation. The Biodiversity scenario will benefit climate adaptation and biodiversity conservation policies in Europe, but will negatively affect EU forest owner's gross income from timber sales and forest industries gross sales, value added and employment. However, neither the reduced growing stock in forests under the Bioenergy scenario nor the increased harvest leakage under Biodiversity scenario give clear benefits for climate change mitigation policy.

Adapting current forest management for multiple ecosystem services to climate change in the Austrian Alps

Florian Irauschek¹, Werner Rammer¹, Manfred J. Lexer¹

¹University of Natural Resources and Life Sciences, Vienna, Austria (florian.irauschek@boku.ac.at; werner.rammer@boku.ac.at; mj.lexer@boku.ac.at)

Traditional forest planning tools focus on sustainable timber yield by utilizing classical volume-based indicators. Services beyond timber provision are not explicitly included and largely depend on the knowledge and experience of local foresters. State-of-the-art forest simulation models can predict multiple ecosystem services and impacts of changing climates to inform forest planning processes. However, so far just a few applications at sufficient operational detail levels are available. In this contribution we assess the multifunctionality of the currently practiced management regime for a management unit of 4500 hectare in an Alpine valley in Austria. We initialize the simulation model PICUSv1.5 with data from standard inventory and remote sensing sources. Forest management routines are prescribed at compartment level and disturbances are included via submodules for spruce bark beetle, windthrow and browsing by ungulates. Ecosystem service indicators are evaluated using tree-level model output in a spatially explicit landscape. First we assessed multifunctionality and resilience of the current management strategy for a period of 90 years under 5 climate scenarios. Subsequently we designed a targeted management alternative including altered species composition, retention trees and sanitary concepts. Results show interacting effects of management, forest dynamics and disturbance regimes driven by temperature, precipitation and disturbance events. Particularly storm damages disrupted ecosystem service provisioning. Impacts of less intensive climate change were partly compensated by increasing growth rates. Adaptive management moderated negative effects and caused positive impacts for some ecosystem services. Results showed the potential of landscape scale ecosystem service analysis and its integration in long term management planning.

Agroforestry systems and soil remineralizers: effects on CO₂ capture / Sistemas agroflorestais e remineralizadores de solos: efeitos na captura de CO₂

Gustavo Soares¹, Suzi Theodoro¹

¹Universidade de Brasília, Brasília, Brasil (suzihuff@hotmail.com; suzitheodoro@unb.br)

Os Sistemas Agroflorestais (SAFs) são uma opção viável para garantir a produção de alimentos de forma sustentável. O uso de remineralizadores de solo (derivados de rochas moídas) aplicados ao solo amplia a oferta de nutrientes e facilita o desenvolvimento das espécies vegetais inseridas nesses sistemas. Este trabalho tem como objetivo demonstrar que o uso de remineralizadores assegura o crescimento das espécies vegetais e potencializa a captura de CO₂. Partiu-se da hipótese de que ao se combinar o uso de insumos minerais em sistemas biodiversos está se favorecendo o crescimento das espécies vegetais, o que resulta em maior captura e retenção de CO₂. A pesquisa comparou as práticas de manejo e o uso (ou não) dos remineralizadores em quatro SAFs (localizados no Distrito Federal) e de que forma eles contribuíram para a melhoria físico-química do solo e para o incremento na retenção de CO₂, averiguado por meio do crescimento de indivíduos arbóreos previamente selecionados e acompanhados durante um ano. Os dados obtidos nas diferentes fases da pesquisa foram tabulados e submetidos a análises não-paramétrica "ANOVA on Ranks". Adicionalmente, uma análise multivariada (sem atribuição de pesos ou limites para os parâmetros) foi realizada para os parâmetros que apresentaram diferenças significativas isoladamente. As médias foram comparadas entre si pelo teste "Tukey on Ranks". Os resultados mostraram que as áreas onde os remineralizadores foram inseridos apresentaram níveis de fertilidade superiores aquela área sem o acréscimo desse insumo, o que possivelmente influenciou no desenvolvimento das espécies analisadas e no potencial de captura de CO₂.

Estimating the climate services value for forest management: the case of drought for maritime Pine plantations in South-West France

Sylvain Caurila¹, Antonello Lobianco²

¹Institut National de la Recherche Agronomique, Nancy, France; ²AgroParisTech, Nancy, France (sylvain.caurila@inra.fr; antonello.lobianco@agroparistech.fr)

In Western Europe, climate changes are likely to come with increasing risk of droughts and heat waves during summer. For forest ecosystems, a drought may result both in an increase of trees mortality and a reduction of tree growth. These impacts are delayed in time, which makes it possible to adjust forest management practices and, in particular, to harvest the impacted stand prematurely and replant a new stand if it is economically profitable to do so. We define here the Climate Services (CS) as the information which supports forest owners in their decision to harvest prematurely or not after a drought. Our paper aims at developing a method to estimate the economic value of these CS in the case of a maritime Pine stand in South-West of France. Using a comparison of Land Expected Values over an infinite period of forest rotations, our analysis suggests that the Climate Services Value (CSV) is highly dependent on three characteristics: (1) the age of the forest facing the drought; (2) the intensity of the drought both in terms of mortality and growth impacts; and (3) the value of discount rate used. Overall, for a 2% discount rate, for a young stand (below 15-20 years old), CSV is rather low and ranges from 0 to 50 €/ha depending on the intensity of the drought. However, for a mature stand, CSV increases rapidly, up to a maximum the year before the optimal harvest date. In this latter case, for intense droughts, CSV reach 4,900 €/ha.

Empirical evidences on the potential adaptive performance of alternative species under current and future climate: first results of the REINFFORCE arboreta network

António Henrique Correia¹, Christophe Orazio², Hernán Serrano-León², Maria Helena Almeida¹

¹CEF, Instituto Superior de Agronomia, Universidade de Lisboa, Lisboa, Portugal; ²European Federation for Immunogenetics, Bordeaux, France (ahcorreia@isa.ulisboa.pt; christophe.orazio@efi.int; hernan.serrano@efi.int; nica@isa.ulisboa.pt)

The forestry sector is strongly dependent on a very limited number of tree species whose long-term performance is increasingly threaten by climate change impacts. In order to sustain their productivity and mitigation capacity, the adaptation potential of our productive forests needs to be increased by diversifying the number of available species with better-adapted provenances. It is therefore crucial to provide forest owners and managers with empirical evidences on the potential performance of alternative species/provenances under a future climate. However, most of the current available information is originated from models that do not account for species/provenance plasticity, nor climatic conditions outside their current distribution. With the aim of reducing the uncertainty in the selection of adapted material, the REINFFORCE arboreta network was established along the European Atlantic arc (between latitudes 37°-58° N) to test current and alternative species/provenances under contemporary and future climates. We present the field performance results of 33 different tree species under the wide gradient of climatic conditions covered by the 38 innovative network sites. We identified the climate drivers which better explain growth and survival performance, and the best and worst performing species under different climatic conditions. We also present a risk analysis for predicted performance for RCP 4.5 and 8.5 climate change scenarios. Our results will improve the knowledge about the site - climate matching of alternative planting species and the prediction of its behaviour in response to future climate, providing evidences for recommended plantation material with real adaptive capacity to climate change.

Forestry policies and practices for climate adaptation and mitigation in China

Youjun He¹, Ye Bing¹

¹Chinese Academy of Forestry, Beijing, China (hyjun163@163.com; yb70@caf.ac.cn)

In recent decades, changes in climate have caused impacts on natural and human systems on all continents and across the oceans. Mitigation and adaptation are complementary strategies for reducing and managing the risks of climate change. Forestry has multiple benefits which is the best and economic way for adaptation and mitigation to climate change in the future. In the past decades, China has always regarded forestry as a strategic choice to deal with climate change, and has implemented a series of major measures, which have made important contributions to the adaptation and mitigation of climate change. Intended Nationally Determined Contributions on forestry in China stated that by 2030 is to increase the forest stock volume by around 4.5 billion cubic meters on the 2005 level. In this paper, the forestry Policies and practices on climate change in China were summarized, the achievements and problems were analyzed, and the opportunities and challenges for forestry to cope with climate change were discussed, forestry carbon project and markets in China was also introduced. Finally, priorities for forestry response to climate change in the future were proposed, which include how to increase forestry carbon sink by large-scale territory greening activities and improve forest management, reduce forestry carbon emission by resources management and forest degradation prevention, strengthen wetland and grassland protection, develop green and prosperous industries, strengthen carbon accounting and monitoring, promote forestry carbon sink trading and enhance international cooperation.

Contribution of indigenous knowledge by local communities to forest management and climate change mitigation and adaptation: case study of Offinso Municipality in Ghana

Margaret Sraku-Lartey¹, Ernest Foli¹

¹CSIR-Forestry Research Institute of Ghana, Kumasi, Ghana (msrakulartey@gmail.com; efoli@hotmail.com)

Goal 13 of the Sustainable Development Goals (SDG) stipulates that all countries should take urgent action to combat climate change and reduce its impact because it is considered to be a significant threat that faces mankind in this century. Climate change impacts all sectors of the global economy, but Africa is one of the most vulnerable continents. It is therefore important to develop and implement policies to help curb the effects of climate change. These policies must be based on local people's perception and knowledge of climate change, the adaptation strategies they adopt, and the perceived barriers to adaptation. The main objective of this study was to assess the contribution of indigenous knowledge to climate change adaptation strategies by local people in the Offinso District of Ghana, and to determine management protocols needed to document the knowledge. A mixed methods approach was used to collect primary data on local people's perception and knowledge on climate change from five communities in the Offinso Municipality. The results indicated that local people in the study area perceive climate change in terms of low rainfall, high temperatures and prolonged drought, indicators that are in consonance with scientific literature. Managing, processing and storing this indigenous knowledge on climate change will contribute greatly to policy guidance on forest management and climate change mitigation efforts in Ghana. It is recommended that indigenous knowledge should be documented and backed with scientific information to contribute meaningfully to policy on climate change mitigation and adaptation in Ghana.

The epistemology of models in relation to the border between science and policy: public policies for land use and occupation in mitigating and adapting to climate change in Minas Gerais, Brazil / A epistemologia dos modelos na relação de fronteira entre ciência e política: políticas públicas de uso-ocupação do solo em face à mitigação e adaptação às mudanças climáticas em MG

Maxwel Ferreira da Silva^{1,2}

¹Centro Federal de Educação Tecnológica de Minas Gerais, Belo Horizonte, Brasil; ²Escola de Engenharia da Universidade Federal de Minas Gerais, Belo Horizonte, Brasil (max.wel.ferreira@hotmail.com)

Esta proposta de discussão gira em torno da utilização de cenários de referência, ou simulações computacionais que incorporam os efeitos das mudanças climáticas globais (MCG), para a avaliação dos impactos climatológicos sobre o território do Estado de Minas Gerais e, na perspectiva regional de mitigação e adaptação às MCG, como instrumentos para a elaboração e prática de políticas públicas de uso e ocupação do solo na produtividade agrícola, levando-se em conta os efeitos das MCG sobre as áreas de lavoura, pasto e floresta. Nossa perspectiva é de que tais modelos ou cenários apenas se tornam instrumentos efetivos para políticas públicas quando ressignificados no espaço de fronteira em que ciência, política e sociedade precisam se articular para a produção de sentidos, de acordos e de um comum horizonte de expectativa. A partir de uma abordagem epistemológica dos modelos e da produção discursiva que se realiza sobre eles, buscamos analisar como uma simulação pode se transformar num norteamento para as ações e práticas governamentais e quais os limites de sua performatividade. Em outros termos, como poderia ser possível inserir a produção científica na arena social e política, levando-se em conta a competição entre os imperativos de ordem econômica, social e ambiental e, é claro, os diferentes jogos de linguagem que permeiam esse espaço. Esperamos explicitar, por vias

teóricas, que existe um real problema de teoria e prática no que diz respeito aos modelos ambientais (enfoque aos que se ocupam do uso do solo) que se configura como um problema de ordem política.

B4m: FOREST TREE AND STAND GROWTH PROCESSES UNDER DIFFERING ENVIRONMENTS: CONCEPTS, METHODS AND EVIDENCE - 2

Spatial fine root distribution in pure and mixed stands of European beech, Norway spruce, and Douglas-fir under different site conditions

Amani Saul Lwila¹, Christian Ammer¹, Martina Mund¹

¹Burckhardt-Institut - Georg-August-Universität Göttingen, Göttingen, Germany (amani.lwila@uni-goettingen.de; christian.ammer@forst.uni-goettingen.de; martina.mund@forst.uni-goettingen.de)

Inter and intraspecific competition play an important role on below ground functional traits and resulting ecosystem functioning. Root biomass production is not the only determinant for below ground success but also rapid vertical and horizontal roots capability to explore the additional soil space along the limited resources. We investigated the impact of inter-intraspecific competition on spatial fine root distribution, and how the effects differ with site conditions and species identity. By pulling together the effect of site condition and different in competitions effects on ecosystem functioning, helped us to understand the existing complementarity between the species in water usage as strategies to reduce drought water stress. We studied the spatial fine root distribution in four quintets comprising in total 20 mature stands aged over 60 years of pure beech, pure spruce, pure Douglas-fir, mixed beech-spruce, and mixed beech-Douglas fir in Northwestern Germany. We considered the site quality by analyzing site nutrient and intra- and interannual variation in weather conditions, and soil moisture our findings show that, beech and Douglas-fir have high plasticity by changing with site conditions and competition while spruce shows to be more conservative in changing, e.g. the mixed stands of Douglas-fir and beech shows higher interspecific root diversity, specific root lengths and biomass of fine root than pure stands and mixed stands of spruce and beech, this difference was more pronounced with changes in site quality. Our finding will help to understand the below ground complex interaction in responses to species identity, site quality and inter and intraspecific competition.

Multi-layered Scots pine forests in boreal Sweden result from mass regeneration and size stratification

Lars Lundqvist¹, Martin Ahlström¹, Petter Axelsson², Tommy Mörling¹, Erik Valinger¹

¹Dept of forest ecology and management, SLU, Umeå, Sweden; ²Dept of wildlife, fish and environmental studies, SLU, Umeå, Sweden (lars.lundqvist@slu.se; martin.ahlstrom@slu.se; petter.axelsson@slu.se; tommy.morling@slu.se; erik.valinger@slu.se)

Understanding historic development of multi-layered Scots pine (*Pinus sylvestris* L.) stands and how they became multi-layered is essential for assessing the feasibility of other management practices than rotation-forestry and clear cutting. To address this we measured trees (DBH \geq 4 cm) and saplings (height > 0.5 m DBH < 4 cm) and used increment cores from 244 sample trees to reconstruct stand structure development, ingrowth and basal area increment in four multi-layered Scots pine stands in Sweden. Three of the four stands had age distributions that were dominated by one or two 20 year age classes, suggesting that the irregular diameter distributions displayed in 2013 had developed from more homogeneous distributions. Analyses of the historical ingrowth of Scots pine into the tree layer suggested that the multi-layered structure was created by mass regeneration followed by size stratification caused by differences in growth rates within even-aged cohorts of regeneration. Large basal area reductions in the past resulted in abundant regeneration and ingrowth of Scots pine. When the over-story increased in basal area over time, there was a growth differentiation among the saplings and small trees, gradually creating a multi-layered stand structure as some of the trees grew into the larger size classes while others remained in the smaller size classes. When the stands reached a basal area of 13-14 m²ha⁻¹ the ingrowth of saplings past 1.3 m height essentially stopped but the size stratification among the small trees continued, further enhancing the multi-layered structure.

Estimating aboveground net biomass change in tropical and subtropical forests: refinement of IPCC default values using forest plot data

As countries advance in greenhouse gas (GHG) accounting for climate change mitigation, consistent estimates of aboveground biomass (AGB) net change are needed for the tropics and subtropics. Countries with limited forest monitoring capabilities rely on 2006 IPCC default AGB net change values, which are averages per ecological zone, per continent. These previous defaults come from single studies, provide no uncertainty indications, and aggregate old secondary forests and old-growth forests. In this study, we update these default values using forest plot data. In comparison with previous estimates, new values include data published from 2006 onwards, are derived from multiple sites per global ecological zone, provide measures of variation, and divide forests >20 years old into older secondary forests and old-growth forests. We compiled 176 AGB chronosequences in secondary forests and AGB net change rates from 536 permanent plots in old-growth and managed or logged forests. In this dataset, across all continents and ecozones, AGB net change rates in younger secondary forests (≤ 20 years) are higher than rates in older secondary (>20 years and ≤ 100 years) forests and managed or logged forests, which in turn are higher than rates in old-growth forests (>100 years). Data availability is highest for North and South America, followed by Asia then Africa. We provide a rigorous and traceable refinement of the IPCC 2006 AGB net change default rates, identify which areas in the tropics and subtropics require more research on AGB change, and reflect on possibilities for improvement as more data becomes available.

The significance of temporal and spatial variation in forest growth for climate change impact modelling

Hans-Peter Kahle¹ , Chaofang Yue²

¹Chair of Forest Growth, Institute of Forest Sciences, Albert-Ludwigs-University Freiburg, Freiburg, Germany; ²Forest Research Station Baden-Württemberg, Freiburg, Germany (hans-peter.kahle@iww.uni-freiburg.de; chaofang.yue@forst.bwl.de)

The factors that control forest growth vary across spatial and temporal scales. Modificative adaptation allows trees to cope with short-term fluctuations and long-term trends in environmental conditions that occur during their lifetime, as well as enables species growing on diverse sites to adjust to spatial environmental heterogeneity. Whereas it is difficult to determine to which extent such changes in growth response are genetically determined or the result of phenotypic plasticity, it is evident, that individuals with a greater adaptive plasticity will be more likely to survive under environmental change. Models predicting climate change impacts on forest growth often draw upon the space-for-time substitution (SFTS) approach, thus relying on the assumption that the growth response across spatial environmental gradients is analogue to the dynamic growth response over time. Forest inventory-based models typically rely on the SFTS approach. In contrast, longitudinal studies combining time series of forest growth with forest growth variation across space are scarce. In this presentation, we revisit application of the SFTS approach to predict forest production under climate change in light of longitudinal growth data. Based on measurement data from long-term forest research plots we found that site index changes of Norway spruce across spatial climatic gradients largely differ from dynamic changes in site index under climate change. Thus, application of SFTS would produce largely misleading results. Finally, an updated concept is provided to assess the potentials and limitations of the SFTS approach in a systematic way.

Do increasing respiratory costs explain the decline with age in forest growth rate?

P.W. West¹ 

¹Forest Research Centre, Southern Cross University, Lismore, NSW ²⁴⁸⁰, Australia (pwest@nor.com.au)

Once forests have achieved a full canopy, their growth rate declines progressively with age. This work analysed a global data set with estimates from a wide range of forest types, aged 20-795 yr, of their annual photosynthetic production (gross primary production, GPP) and subsequent biomass production (net primary production, NPP). Both GPP and NPP increased with increasing mean annual temperature and precipitation. GPP was then unaffected by forest age whilst NPP declined progressively with age, meaning that autotrophic respiration increased with age. It has been proposed that GPP should decline in response to increasing water stress in leaves as water is raised to greater heights as trees grow taller with age. However, trees may make substantial plastic adjustment in morphology and anatomy of newly developing leaves, xylem and fine roots to compensate for this stress and maintain GPP with age. This work suggests NPP declines with age as respiratory costs increase progressively in, any or all of, the construction and maintenance of more complex tissues, the maintenance of increasing amounts of live tissue within the sapwood of stems and coarse roots, the conversion of sapwood to heartwood, the increasing distance of phloem transport, increased turnover rates of fine roots, maintaining alive competitively unsuccessful small trees or supporting very tall trees that are unable to compensate fully for increased water stress in their canopies.

B4p: MONITORING FOREST DYNAMICS AND BIOMASS

Forest and biomass dynamics in the Andean forests of Southern Ecuador / Dinâmica florestal e biomassa nas florestas andinas do Sul do Equador

Celso Yaguana¹, Deicy Lozano¹, Ney Quezada², Jhoana Muñoz², Giselda Durigan³

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil; ²Universidad Nacional de Loja, Loja, Ecuador; ³Instituto Florestal do Estado de São Paulo, Assis, Brasil (anibalya09@gmail.com; caroladeicylo@hotmail.com; quezadaney@gmail.com; joana.munoz@unl.edu.ec; giselda.durigan@gmail.com)

As florestas montanhosas andinas são consideradas prioridade global de conservação, especialmente pela elevada biodiversidade e grau de endemismo. No entanto, são ecossistemas fortemente ameaçados por perturbações antrópicas, mas ainda pouco estudados e mal compreendidos. O objetivo deste estudo foi caracterizar a dinâmica da floresta em parcela permanente com área de 1 hectare, na Reserva Natural Tapichalaca, localizada na cordilheira do sudeste dos Andes equatorianos, para quantificar seu papel no armazenamento e, possivelmente, como sumidouro de carbono. Realizamos a amostragem da comunidade arbórea com diâmetro mínimo de 10 cm, em duas ocasiões (2008 e 2018), utilizando o método padronizado pela Rede Amazônica de Inventários Florestais - RAINFOR. A biomassa foi estimada pela equação alométrica para florestas úmidas tropicais de Chave et al. (2005). A biomassa aérea registrada em 2018 foi de 255,63 Mg ha⁻¹, correspondendo a um estoque de carbono aproximado de 128 Mg ha⁻¹. A taxa anual de mortalidade (1,99%) foi similar à taxa anual de recrutamento (1,57%). O incremento diamétrico médio anual foi de 1,94 mm, valores similares aos observados na Amazônia brasileira (1,4–2 mm por ano). A dinâmica da biomassa correspondeu a um incremento de 26,62 Mg ha⁻¹ em dez anos, com aumento de 2,82 m² ha⁻¹ na área basal. A floresta estudada, portanto,

apresentou balanço positivo de biomassa no período 2008-2018, exercendo o papel de sumidouro de carbono e, assim, contribuindo para mitigação dos efeitos das mudanças climáticas globais.

Tree community dynamics over ten years in an Andean forest in Southern Ecuador / Dinâmica da comunidade arbórea ao longo de dez anos em uma Floresta Andina do sul do Equador

Celso Yaguana¹, Deicy Lozano¹, Ney Quezada², Jhoana Muñoz², Giselda Durigan³

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Universidad Nacional de Loja, Loja, Ecuador; ³Instituto Florestal do Estado de São Paulo, Assis, Brasil (aniba09@gmail.com; caroladeicylo@hotmail.com; quezadaney@gmail.com; joana.munoz@unl.edu.ec; giselda.durigan@gmail.com)

As florestas montanhosas dos Andes tropicais, incluídas entre os hotspots globais para conservação da biodiversidade, são pouco conhecidas em sua estrutura, composição e mudanças temporais. Em parcela permanente de 01 ha na Reserva Natural de Tapichalaca, cordilheira oriental do sul do Equador, amostramos a comunidade arbórea (DAP \geq 10 cm) em duas ocasiões (2008 e 2018), com o objetivo de compreender as mudanças na comunidade nesse período. Em 10 anos, constatamos mudança na composição florística do dossel, com a perda de 5 espécies (morte) e o ingresso de 6 espécies (recrutamento), de modo que o nível de riqueza permaneceu praticamente constante (74 espécies em 2008 e 80 espécies em 2018). Por outro lado, as mudanças ocorridas na abundância relativa das espécies resultaram em aumento do índice de diversidade de Shannon de 3,81 para 3,90, especialmente porque espécies dominantes na comunidade, como *Nectandra laurel* Klotzsch ex Nees e *Hieronyma asperifolia* Pax & K. Hoffm. sofreram redução populacional de 12,8% e 12,3%, respectivamente. Algumas espécies apresentaram incremento em área basal, destacando-se *Ficus insipida* Willd. (5,98 m²ha⁻¹), *Nectandra laurel* Ness. (1,99 m²ha⁻¹) e *Guarea kunthiana* A. Juss. (1,81 m²ha⁻¹), sendo que os maiores incrementos diamétricos foram observados na classe entre 23 a 36 cm. As mudanças observadas podem ser consideradas positivas do ponto de vista da conservação, uma vez que houve ligeiro aumento de diversidade, devido ao aumento da equabilidade no trecho amostrado da floresta.

Periodic increment in seed-based plantations of *Khaya ivorensis* A. Chev. in Bonfinópolis, Goiás, Brazil Incremento periódico em um plantio seminal de *Khaya ivorensis* A.Chev. no município de Bonfinópolis, GO

Marco Antônio Marcelino Bahia¹, Matheus Zampetrik Caetano¹, Sybelle Barreira¹

¹Universidade Federal de Goiás, Goiânia, Brasil (eng.marcobahia@gmail.com; matheuszampetrik@gmail.com; sybelle.barreira@gmail.com)

A resistência apresentada pela *Khaya ivorensis* contra a Broca-do-ponteiro (*Hypsipyla grandella*), e a sua adaptabilidade ao clima brasileiro são motivos pelos quais os plantios florestais de mogno exóticos têm sido amplamente recomendados. Objetivando aumentar o conhecimento a respeito do crescimento e desenvolvimento da espécie na região, esse estudo tem por objetivo apresentar o incremento em diâmetro a 1,3 m (DAP) e altura total de um plantio seminal de mogno africano referente ao período de março a setembro de 2018. O plantio está localizado no município de Bonfinópolis-GO e tem idade de 6 anos. O clima da região segundo a classificação de Köppen é Aw, sendo que o período de avaliação coincidiu com o período seco do ano. O DAP foi obtido através da medição com a suta, e a altura estimada com o uso de um clinômetro digital. Na primeira medição realizada em março de 2018 as árvores apresentaram uma média de 11,1 cm de DAP e 8,4 m de altura, já em setembro as médias subiram para 12,4 cm e 8,6 m respectivamente. Dessa forma, o incremento periódico para os meses de março a setembro de 2018 foi de 1,3cm para o DAP e 0,2 m para a altura. O baixo incremento em ambas variáveis pode ser explicado pela alta densidade do plantio e pelo período da amostragem. A expectativa é que o incremento periódico para os meses complementares do ano seja consideravelmente maior, e que após os primeiros desbastes a média dos incrementos também se eleve.

Aerial woody biomass in savanna and forest formations in the Cerrado biome associated with cambissols in the Rio Vermelho Watershed in Goiás, Brazil / Biomassa aérea lenhosa em formações savânica e florestal de Cerrado associadas a Cambissolos na Bacia Hidrográfica do Rio Vermelho, GO

Sabrina Miranda¹, Plauto De-Carvalho¹, Cássio Cezare², Weuler Vasconcelos³, Laerte Ferreira²

¹Universidade Estadual de Goiás, Palmeiras de Goiás, Brasil; ²Universidade Estadual de Goiás, Palmeiras de Goiás, Brasil; ³Universidade Federal de Goiás, Goiânia, Brasil; ⁴Universidade Federal do Tocantins, Gurupi, Brasil (sabrinas.miranda@gmail.com; plauto.decarvalho@gmail.com; cassio_cezere@hotmail.com; weulervasconcelos@hotmail.com; lapig.ufg@gmail.com)

Este trabalho analisou a contribuição de remanescentes de vegetação nativa de Cerrado, em áreas de Reserva Legal (RL), em termos de estoque de carbono na biomassa aérea da vegetação lenhosa (BAVL). Foram amostrados cerrado típico (formação savânica) na base da Serra Dourada e cerradão (formação florestal) em Itapirapuã, GO, ambos na Bacia Hidrográfica do Rio Vermelho sobre Cambissolos (textura franco-arenosa com cascalho). Em cada área foram instaladas 10 parcelas (1.000 m² cada) e amostrados os indivíduos com diâmetro da base \geq 5 cm. Nas estimativas foram utilizadas equações alométricas específicas. O cerrado típico apresentou densidade de 879 ind/ha, com BAVL e estoque de carbono 15,83 Mg/ha e 7,44 Mg/ha. A densidade total no cerradão foi 1.699 ind/ha. Para os indivíduos com DAP \geq 5 cm o valor foi 1.259 ind/haestes somam 157,30 Mg/ha de BAVL e estoque de carbono 73,93 Mg/ha. O cerrado típico é constituído por indivíduos de pequeno porte, altura entre 2,0 e 5,9 m (81,1% do total), que contribuem com 64,6% da BAVL. Apenas dois indivíduos apresentaram altura \geq 10 m. No cerradão a maioria dos indivíduos possuem altura entre 4,0 e 7,9 m (70% do total) estes somam 36,3% da BAVL. Em contrapartida 65 indivíduos apresentaram altura \geq 10 m que representam 42,4% da BAVL. As formações estudadas são estruturalmente distintas, o cerradão é mais denso e com indivíduos mais altos. Estes resultados destacam a importância das áreas de RL além da conservação da biodiversidade, são também relevantes para armazenamento de carbono e emissões evitadas.

Frost risk zoning at the local scale to optimize *Eucalyptus* plantations / Zoneamento de risco de geadas em escala local para otimização de plantios de eucalipto

Alexandre Simões Lorenzon¹, Cibele Hummel do Amaral¹, Rosane Barbosa Lopes Cavalcante², Gustavo Eduardo Marcatti³, Nero Lemos Martins de Castro⁴, Rafael Tassinari Resende¹, Lucas Arthur de Almeida Telles¹, Brenner de Almeida Oliveira¹, Rodrigo Vieira Leite¹

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²CMPC Celulose Rio Grandense, Guaíba, Brasil; ³Universidade Federal de São João del-Rei, Sete Lagoas, Brasil; ⁴Universidade Federal de Viçosa, Viçosa, Brasil (alexandre.lorenzon@ufv.br; chamaraal@ufv.br; rosanecavalcante@gmail.com; gustavomarcatti@ufsj.edu.br; nerolmcastro@gmail.com; rafael.tassinari@gmail.com; lucasarthur36@gmail.com; b.oliveira@ufv.br; rvieira@ufv.br)

Nas últimas décadas, os eventos de geada afetaram consideravelmente as atividades florestais, causando enormes prejuízos para o setor. A frequência e a intensidade das geadas têm alta variabilidade temporal e espacial e podem ser causadas por diversos fatores ambientais. Em escala local, as geadas ocorrem com

maior frequência nas partes mais baixas do terreno. Diante disso, este trabalho objetiva realizar o zoneamento da probabilidade do risco de geadas em plantios florestais de eucalipto na região sul do Brasil. O classificador utilizado para prever a ocorrência de geadas foi o Random Forest. O algoritmo foi treinado a partir de dados históricos de ocorrência de geadas. Parte destes dados (30%) foram separados e utilizados para a validação do modelo. As variáveis preditoras do modelo foram: longitude, latitude, altitude, altitude relativa, distância euclidiana da hidrografia e orientação do relevo. Todo o processo foi realizado nos softwares R e ArcGIS. As variáveis mais importantes para o modelo foram a longitude e a altitude relativa. A longitude reflete o efeito da continentalidade. Já a altitude relativa reflete os efeitos locais de cada unidade de manejo, sugerindo que as regiões mais baixas do terreno possuem maior probabilidade de ocorrência de geadas. O resultado da validação gerou uma exatidão global de 91%. O modelo permitiu determinar a aptidão climática para as unidades de manejo. Desta forma, os clones mais produtivos, porém sem resistência a geadas, poderão ser implantados de forma otimizada em áreas de baixo risco de ocorrência desse evento climático.

Linear models for predicting tree biomass in an area of Atlantic Forest undergoing ecological restoration / Modelos lineares para predição de biomassa arbórea em área de Mata Atlântica em processo de restauração ecológica

Susane Raser¹, Flávio Gandara¹, Edgar Vismara²

Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo; ²Universidade Tecnológica Federal do Paraná, ITFPR/DV Campus Dois Vizinhos, Dois Vizinhos, Brasil (susanerasera@yahoo.com; fgandara@usp.br; edgarvismara@gmail.com)

Frente às mudanças climáticas, foi estabelecido via Acordo de Paris o compromisso brasileiro em reduzir as emissões de gases do efeito estufa em 37% até 2025 e 43% até 2030. Sendo a restauração de 12 milhões de hectares de florestas uma das formas apresentadas para atingir essas metas, entender o real potencial das florestas plantadas em sequestrar carbono, obtido via quantificação da biomassa, torna-se de grande importância e oportunidade. O objetivo do trabalho foi desenvolver modelos de predição de biomassa do estrato arbóreo para uma área restaurada com 12 anos de idade, localizada na Estação Experimental de Ciências Florestais de Anhembi (ESALQ/USP). Para desenvolvimento das equações foi realizado o abate de 100 indivíduos arbóreos das 20 espécies presentes na área. Todas as árvores foram divididas e pesadas separadamente em quatro compartimentos: raízes, tronco, galhos grossos e copa. De cada compartimento foram retiradas amostras para determinação do teor de umidade e densidade básica dos discos. Foram desenvolvidas quatro equações para predição de biomassa: Biomassa total acima do solo (Btas), Biomassa de tronco (Btr), Biomassa de copa (Bcp) e Biomassa de raiz (Brz). Para ajuste dos modelos foram testadas duas equações lineares, comumente utilizadas no meio florestal para cálculo de volume, e variações dessas equações com a inclusão de cinco variáveis preditoras: DAP, Altura, Altura do tronco, Comprimento de Copa e Densidade básica da madeira do tronco. As melhores equações incluíram pelo menos o DAP e densidade básica da madeira, sendo esta essencial para melhoria nos critérios de seleção de modelos.

Diversity and dynamics of the tree community in four natural forests in southeastern Brazil / Diversidade e dinâmica da comunidade arbórea em quatro florestas naturais do Sudeste do Brasil

Natalia Ivanaukas¹, Renato Lima², Debora Rother³, Juliana Vendrami², Jefferson Polize⁴, Geraldo Franco¹, Vinicius Souza⁴, Alexandre Oliveira², Ricardo Rodrigues⁴

¹Instituto Florestal, São Paulo, Brasil; ²Universidade de São Paulo, São Paulo, Brasil; ³Universidade Estadual de Campinas, Campinas, Brasil;

⁴Universidade de São Paulo, Piracicaba, Brasil (nivanaukas@yahoo.com.br; raflima@usp.br; deborarother@gmail.com; juliana.lv@gmail.com; jlpolize@usp.br; gadefranco@gmail.com; vcsouza@usp.br; adalardo@usp.br; rresalq@usp.br)

Na região Sudeste do Brasil existem poucas áreas extensas de florestas naturais, grande parte protegidas em unidades de conservação, mas imersas numa paisagem bastante modificada pela ação humana. O conhecimento da composição, estrutura e dinâmica dessas florestas é essencial para o entendimento dos padrões e processos relacionados à resiliência dessas comunidades, consideradas ecossistemas de referência para a restauração de áreas degradadas no entorno. No Estado de São Paulo, numa estreita faixa latitudinal (entre 22 e 25 °S) a partir do litoral e em direção ao interior do continente, encontram-se quatro formações florestais distintas: Floresta Ombrófila Densa de Terras Baixas (floresta alta de restinga), Floresta Ombrófila Densa Submontana (floresta atlântica de encosta), Floresta Estacional Semidecidual Montana (floresta de planalto) e Savana Florestada (cerradão). Em cada fitofisionomia foi instalada uma parcela de 320 x 320 m (10,24 ha), na qual foi realizado o mapeamento pedológico ultradetalhado. Todas as árvores com circunferência na altura do peito (CAP a 1,30 m) maior ou igual a 15 cm foram mapeadas e tiveram o seu perímetro registrado periodicamente (censos de 2002, 2005, 2011, 2018), para cálculo posterior de descritores demográficos (taxas de mortalidade e recrutamento, tempo de estabilidade e rotatividade). Listas florísticas e guias de identificação foram produzidos para cada fitofisionomia, a fim de facilitar o reconhecimento das espécies no campo. Ao término da última avaliação, as quatro parcelas totalizavam cerca de 61.000 indivíduos e 487 espécies, figurando entre um dos inventários mais extensos já realizados em São Paulo, e, para algumas dessas formações, no Brasil.

Factors associated with uncertainties in estimating biomass stocks in native Atlantic Forest / Fatores associados às incertezas nas estimativas de estoque de biomassa em floresta nativa da Mata Atlântica

Eduardo Gusson¹, Edgar Vismara²

¹Biodendro Consultoria Florestal Ltda, Piracicaba, Brasil; ²Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (eduardogusson@gmail.com; edgarvismara@utfpr.edu.br)

O estudo analisa alguns fatores relacionados aos erros de predição e de estimação de estoque de biomassa em floresta nativa da Mata Atlântica, localizada no município de Registro-SP. Para isso, inicialmente avaliou-se o ajuste de equações de predição de biomassa a partir de dados de uma amostra estratificada contendo 80 árvores de 10 espécies distintas, considerando diferentes combinações de preditores, incluindo diâmetro, altura total e informação relativa à densidade da madeira. Juntamente com outras equações disponíveis em literatura, verificou-se o desempenho de aplicação desses, utilizando-as na predição da biomassa de um conjunto de 146 árvores presentes em nove parcelas destrutivas instaladas em diferentes estágios sucessionais da floresta. Posteriormente estas foram aplicadas aos dados de inventário florestal previamente realizado na área do estudo com o objetivo de se verificar as discrepâncias nas estimativas e incertezas associadas às quantificações de biomassa devido ao uso das diferentes equações de predição. O estudo confirma a natureza empírica dessas equações, expondo alguns fatores relacionados à sua construção e ajuste que podem gerar vieses preditivos, atentando também para a necessidade de prévia avaliação do desempenho de predição das equações antes de sua aplicação e, em especial, das ajustadas com amostras de outras florestas. Por fim, o estudo demonstra as discrepâncias nas estimativas de estoques de biomassa em florestas nativas devido ao uso de diferentes modelos de predição.

B4q: FOREST MODELS

Modeling stand-level mortality of mongolian oak (*Quercus mongolica*) using stand, climate, and site type based on mixed effect model and zero-inflated model methods

Chunming Li¹

¹Chinese Academy of Forestry, Beijing, China (lichunm@jfrt.ac.cn)

Accurate prediction of mortality is an important component of forest growth yield systems, yet mortality remains one of the least understood components of the system. The permanent sample plot was established across the natural range of mongolian oak in the JiLin province in 1995. The main objective of this study was to develop models for predicting stand-level mortality of mongolian oak natural forest using stand characteristics, climate and site type variables. Models were constructed using a two-step modeling strategy. In the first step, a model predicting the probability of tree death occurring in a stand over a measurement period was developed based on bernoulli distribution and logistic function; in the second step, a function that estimates the reduction in tree number was fitted, and the function including the Poisson, negative binomial (NB), and generalized Poisson (GP). Also considered are zero-inflated and hurdle modifications of these basic models. Data used in modelling are from nested samples, with the highest level referred to as plots. Each plot contains many trees with repeated measurements. Analyses performed on stand-level mortality data has recently begun to account for the structured nature and non-independence by using generalized linear mixed-effects models. Performance of all the approaches was compared using leave-one-cluster-out cross-validation. When climate and site type variables, the generalized linear mixed-effects models and the ZINB model were used in the model simultaneously, the prediction approach performed the best.

Aboveground biomass and expansion factors of a riparian forest in the Brazilian Savanna

Luanna Elis Guimarães¹, Gabriel Mendes Santana², Indiara Nunes Mesquita Ferreira¹, Fernanda Gomes Ferreira¹, Joberto Veloso de Freitas³, Iris Roitman⁴, Fábio Venturoli⁵

¹Programa de Pós Graduação em Agronomia, Produção Vegetal, Universidade Federal de Goiás, Goiânia, Brasil; ²Programa de Pós Graduação em Engenharia Florestal, Universidade Federal do Paraná, Curitiba, Brasil; ³Serviço Florestal Brasileiro, Brasília, Brasil; ⁴Radis Project, Faculdade UnB Planaltina, Universidade de Brasília, Brasília, Brasil; ⁵Universidade Federal de Goiás, Goiânia, Brasil (luanna.meioambiente@gmail.com; gabrielmendes_santana@hotmail.com; indiaranunes22@gmail.com; gomesfernanda@hotmail.com; joberto.freitas@florestal.gov.br; irisroitman01@gmail.com; fabioventuroli@gmail.com)

We estimated biomass for different aboveground compartments of a riparian forest in Niquelândia, Goiás, Brazil, and determined expansion factors for necromass, litter, herbaceous layer, tree poles and undergrowth. The tree sample comprised 20 (10 x 10 m) plots of trees with diameter at breast height (dbh) \geq 5 cm, distributed in four transects (five plots per transect). In each transect, plots were equidistant (50 m apart). For each plot, we sampled the following compartments in five (1 x 1 m) subplots: tree poles (dbh < 5 cm and height (h) \geq 1.5 m), undergrowth (trees, shrubs and herbs with h < 1.5 m), necromass, and litter. The herbaceous layer sample consisted of one (0.4 x 0.6 m) subplot per plot. Tree biomass was estimated with the equation: $\ln(\text{AGB}) = -10.4398 + 2.1183 * \ln(\text{dbh}) + 0.8339 * \ln(\text{h})$, where AGB, dbh and h are in Mg, cm, and m, respectively. Dry weight of all other compartments was determined in the laboratory. Tree aboveground biomass was 92.74 Mg ha⁻¹ (\pm 36.93 Mg ha⁻¹), necromass was 1.2292 Mg ha⁻¹ (\pm 0.3063 Mg ha⁻¹), litter biomass 2.5675 Mg ha⁻¹ (\pm 0.2365 Mg ha⁻¹), herbaceous layer biomass was 0.3996 Mg ha⁻¹ (\pm 0.2288 Mg ha⁻¹), tree-pole biomass was 0.4600 Mg ha⁻¹ (\pm 0.1761 Mg ha⁻¹), undergrowth biomass was 0.2230 Mg ha⁻¹ (\pm 0.0925 Mg ha⁻¹). Necromass, litter, herbaceous layer, tree-pole, and undergrowth biomass comprised 0.33%, 0.26%, 0.25%, 0.19%, and 0.10% of tree aboveground biomass, respectively.

Retrieving diameters from trees using increment cores: a need for shelterbelt trees in Saskatchewan, Canada

Rafaella Mayrinck¹, Colin Laroque¹

¹University of Saskatchewan, Saskatoon, Canada (rcm786@mail.usask.ca; cpl585@mail.usask.ca)

Tons of carbon have been locked in shelterbelt trees in Saskatchewan. However, it is hard to quantify their carbon stocks, since data on tree growth is lacking due to no standard inventories ever having been made on shelterbelt trees. A carbon tax was recently implemented in Canada, but before the carbon sequestration conducted by these trees can receive a monetary value, shelterbelt tree carbon balance needs to be precisely quantified on a site specific basis through time. To do so, information on past tree attributes are needed, such as the change in tree diameter from year-to-year. The goal of this study was to retrieve information on tree diameter using increment cores by testing three methods: A) using the average growth from two increment cores subtracted by the last diameter; B) using the average growth from three increment cores subtracted by the last diameter; C) using a Steiner ellipse formula to calculate diameter from the increment cores. An analysis of variance was done and contrasts were applied. The methods differ significantly from each other and the best method was the number two, since it yielded the smallest error and standard deviation.

Allometric equations for *Pinus leiophylla* and *Pinus pringlei* in Sao Paulo

Rafaella Mayrinck¹, Vinicius Roque², Anani Zanini³

¹University of Saskatchewan, Saskatoon, Canada; ²Resinas Brasil, Itapeva, Brasil; ³Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (rcm786@mail.usask.ca; vinicius.gontijo@resinasbrasil.com.br; ananizanini@hotmail.com)

Forest inventories are expensive and time demanding. Hence, having accurate allometric equations to estimate difficult-to-measure variables is helpful, especially for species that are not commercially established such as *Pinus leiophylla* and *Pinus pringlei*. These species, although native of Central America, have not had their commercial potential and commercial capacity fully exploited in Brazil. This study's goal is to fit volume equations for these species, and to present stand attribute values for two-level spacing plantations owned by Resinas Brasil in Guarei, São Paulo. Models were evaluated for fit by the adjusted coefficient of determination, mean square error, and residual plots. The best model for estimating volume was the Logarithmized Spurr for both species. The mean form factor for all species was 0.53. The mean annual increment ranged from 9.6 to 17.4 m³ha⁻¹ (*Pinus leiophylla* at 3 x 3 and 3 x 1.5, respectively), which is very good, considering that the trees have no genetic improvement and or fertilization level, further enforcing the silvicultural potential for these species.

Towards a global network of tree-ring based information on tree mortality

Maxime Cailleret^{1,2}, Christof Bigler³, Harald Bugmann³, Vasilis Dakos⁴, Lucia de Soto^{5,6}, Arthur Gessler², Steven Jansen⁷, Elisabeth Robert⁸, Jordi Martínez-Vilalta^{8,9}
¹IRSTEA, Aix-en-Provence, France; ²WSL, Birmensdorf, Switzerland; ³ETH Zürich, Zürich, Switzerland; ⁴ISEM, CNRS, Montpellier, France; ⁵EEZA-CSIC, Almería, Spain; ⁶University of Coimbra, Coimbra, Portugal; ⁷Ulm University, Ulm, Germany; ⁸CREAF, Cerdanyola del Vallès, Spain; ⁹Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain (maxime.cailleret@irstea.fr; christof.bigler@env.ethz.ch; harald.bugmann@env.ethz.ch; vasilis.dakos@umontpellier.fr; luciaadesoto@gmail.com; arthur.gessler@wsl.ch; steven.jansen@uni-ulm.de; e.robert@creaf.uab.cat; jordi.martinez.vilalta@uab.cat)

Tree mortality is a key driver of forest dynamics and its occurrence is projected to increase in the future due to climate change. Despite our better understanding of carbon and water dynamics associated with mortality, our ability to predict individual tree mortality is still limited. Most studies thus far have focused on saplings and on few stress factors only such as drought. Consequently, their outputs are not necessarily valid for the multifactorial and long-term processes that usually occur in old-growth forests. Instead, focusing on the temporal changes in tree-ring properties is pertinent as tree-ring data are available for numerous individuals, sites, and species, and for almost the entire life span of a tree at an annual resolution. In this presentation, we will show how tree rings can be used as an indicator of individual tree mortality, and contribute to our understanding of the physiological and ecological drivers of the actual mortality process. Based on a pan-continental tree ring-width database from sites where both dead and living trees were sampled (more than 8000 trees from 198 sites; 36 species), we will show that growth patterns (growth rate, trend, resilience to extreme events, inter-annual variability, lag⁻¹ temporal autocorrelation, and synchrony) differ between trees that died and those that survived a given mortality event. On a subset of sites, we will also highlight the value of combining ring-based $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ information to indicate the various physiological pathways that may occur prior to drought-induced mortality.

Top-down tree growth modelling: a case study for silver fir at its Southernmost European distribution limit

Pasquale Antonio Marziliano¹, Roberto Tognetti², Fabio Lombardi¹
¹Mediterranean University of Reggio Calabria, Department of Agraria, Reggio Calabria, Italy; ²University of Molise, Campobasso, Italy (pasquale.marziliano@unirc.it; tognetti@unimol.it; fabio.lombardi@unirc.it)

Global climate change will modify forest productivity. As a consequence, the analysis of forest growth and yield during the transition period of climate change is essential for supporting forest management activities in relation to the most widespread forest tree species. In Europe, silver-fir forests are one of the most important sources of timber and CO₂ storage. The sustainable management of these stands requires adequate growth models. In this context, we here present the fundamentals of a top-down growth model for silver-fir forests occurring in Italy at their southernmost European distribution limit. Top-down modelling begins when bottom-up process modelling ends. In the top-down approaches, the most common predictable parameters are the standing volume, aboveground biomass and basal area; they are usually disaggregated into size-classes, but also into individual-tree information. The basic element of the proposed model is the stand basal area growth equation. Stand age, current stand basal area and site index are considered as predictors. If the current diameter at breast height distribution is also known, a second function estimates the size-class distribution of the overall stand growth, projecting the dbh distribution to the end of the considered growth period. The parameter estimated by the model were significant, describing most of the variations of the basal area growth. No systematic bias for all the observed age classes and diameter classes were observed. The proposed prototype predicts the tree growth at least as accurately as the empirical equations, and this prediction can be easily based on the available forest inventory data.

Performance of Douglas-fir provenances on the crossroads of Central and Southeast Europe – growth, historical aspect, contemporary silviculture and adaptation possibilities

Martina Dodan¹, Sanja Perić¹
¹Croatian Forest Research Institute, Jastrebarsko, Croatia (martinat@sumins.hr; sanjap@sumins.hr)

Douglas-fir is a species of increased importance in reforestation activities in Europe due to its higher potential for coping with predicting climate change in respect to declining Norway spruce. It has become important non native tree species in European forests. Provenance selection is essential for climate change adaptation of newly planted forests, both including afforestation and reforestation activities. In this respect, we stress the importance of long-term studies concerning introduced tree species since those are expensive and sensitive to ever changing managerial decisions. We discuss advantages and disadvantages of the use of 26 Douglas-fir provenances in continental and coastal area placed on the crossroads of Central and Southeast Europe (case studies from Croatia), both from historical aspect and contemporary silvicultural aspect. Study provides review on the research activities, which include 26 Douglas-fir provenances tested in the last 60 years. The intent of this review is to provide a synthesis of what is known about Douglas-fir provenances on the study area, to facilitate decision making on which provenance to use in afforestation and forest restoration programs. It tracks the performance of different provenances, providing insight into provenances with best and lowest survival and wood production. Review includes management and legislative legacy as well as state of the art of contemporary silviculture. Since present legislative restrictions may omit the successful use of this tree species in Southeast Europe, special consideration is given to forest and nature conservation acts.

Litter and soil organic carbon stocks under different land uses in Bangladesh

Md. Akhter Hossain^{1,2}, Mondal Falgoonee Kumar¹, Kristofer Johnson¹, Matieu Henry¹, Rashed Jalal¹, Rajib Mahamud¹
¹Food and Agriculture Organization of the United Nations, Dhaka, Bangladesh; ²Institute of Forestry and Environmental Sciences, University of Chittagong, Chittagong, Bangladesh (akhter.hossain@cu.ac.bd; falgoonee_kumar@hotmail.com; kristofer.johnson@fao.org; matieu.henry@fao.org; rashed.jalal@fao.org; rajib.mahamud@fao.org)

Estimation of litter and soil organic carbon is crucial for improving sustainable forest management and understanding the global carbon cycle affected by deforestation, forest degradation, and land-use changes. This research aims to quantify C stored in the litter and mineral soils of major land cover classes of Bangladesh. Soil and litter samples were collected inside nested plots of 0.57 ha each. The stratified random sampling method was followed for laying the plots across the country. According to the national land cover classification system, the survey identified 25 land cover classes taking account of the locations of soil sampling points. Results indicate that total soil organic carbon up to 30 cm is about 1120 times greater than the litter carbon. The litter carbon ranged from 0.001 (Herb Dominated Area) to 0.448 (Plain Land Forest (Sal Forest)) Mg C ha⁻¹ whereas soil organic carbon ranged from 14.3 (Sand) to 153.6 (Bamboo forest) Mg C ha⁻¹ up to 30 cm soil depth. The highest soil and litter carbon density were found in the natural forests and plantations respectively, especially bamboo

forest and forest plantations, and they are lowest in built-up areas. In terms of total soil organic carbon, cultivated areas have the highest carbon stocks followed by rural settlements and hill forests. The study also explored the importance of these pools for supporting biomass and tree diversity. The results are relevant for understanding greenhouse gas emissions and the role of soils in the country's ecosystems.

B4r: ASSESSING CLIMATE CHANGE IMPACTS ON FORESTS

High-resolution bias corrected EURO-CORDEX climate data for historical and future periods for Europe

Debojyoti Chakraborty¹, Laura Dobor², Lea Henning³, Tomáš Hlásny², Silvio Schueler¹

¹Austrian Research Centre for Forests, Vienna, Austria; ²Czech University of Life Sciences Prague, Prague, Czech Republic; ³Johann Heinrich von Thünen Institute Federal Research Institute for Rural Areas, Forestry and Fisheries, Eberswalde, Germany (debojyoti.chakraborty@bfgw.gv.at; dobor.laura@gmail.com; lea.henning@thuenen.de; tomas.hlasny@gmail.com; silvio.schueler@bfgw.gv.at)

Climate projections are in immediate demand by scientists, governments and nongovernmental organizations. In climate-sensitive sectors such as forestry and agriculture, the biological relevance of the climate data is of equal importance as its resolution and accuracy. In the last decades, continental scale high-resolution climate projections have become globally available. Majority of these climate surfaces are empirically downscaled directly from Global climate models. Downscaling is a general concept that embraces various methods for increasing spatial resolution and reduces some of the biases in order to improve the usability of climate scenarios. Two major approaches to downscaling climate data are, statistical and dynamic. For robust predictions, a dynamic approach is often recommended because it is based on the dynamical and physical processes that govern the weather and thus the climate. EURO-CORDEX is an initiative of the World Climate Research Program for coordinating dynamic regional downscaling of the global climate projections from the CMIP5 (Coupled Model Intercomparison Project Phase 5). We used five bias-corrected regional climate model (RCM) projections of daily temperature and precipitation from the EURO-CORDEX database and downscaled them from 10 km resolution to 1 km with the delta-algorithm of spatial downscaling. Using this approach we calculated 83 biologically relevant climate variables for both historic periods (mean of 1961-90) and future periods (2041-2060, 2061-2080, 2081-2100) under RCP4.5 and RCP8.5 scenarios. An evaluation with independent data from approximately 3000 weather stations across Europe showed promising results with high correlations between observed and predicted data. The dataset is available for free public use.

Growth rate and carbon storage in South African plantation forests for the period July 2001 to June 2017

Iain Kerr^{1,2} , Oswald Olempong²

¹University of KwaZulu-Natal, Durban, South Africa; ²The Paper Manufacturers Association of South Africa, Johannesburg, South Africa (kerr@ukzn.ac.za; oswald.olempong@gmail.com)

Measuring the carbon stored by forests is an obligation of signatories to The United Nations Framework Convention on Climate Change (UNFCCC) and Kyoto Protocol. South Africa is a signatory to the Paris Agreement and is required to submit a national greenhouse gas inventory to the UNFCCC biennially. Storing carbon in fast-growing forests is a climate change mitigation option for South Africa. We developed a model to determine the amount of carbon sequestered in the living biomass of plantation forests in South Africa. These forests are managed to produce either industrial roundwood or pulpwood. The model was used to determine carbon stocks for the years 2001 to 2017 using publically available data. The model was re-run using average yield tables for the new Eucalypt hybrids reported as "other gum" and updated yield tables for softwood species. This resulted in an increase in estimated carbon stocks of 46.6 and 4.3 % for hardwoods and softwoods respectively. Although the area under plantations is decreasing temporally, the stocks are relatively constant taking into account the growth rates of new hybrids. Local demand for roundwood is being met from local resources as a result. The model requires further refinement and discrepancies in the various government forest inventory reports need to be investigated. Collection of data by the government requires more detail including the extent of the area planted to new hybrids and number of survey forms not returned versus the number of registered growers and extent of the area permitted for afforestation.

Plurifor: transnational plans for the management of forest risks

Sarah Yoga¹, Christophe Orazio¹, Eduard Mauri¹

¹European Forest Institute, Cestas, France (sarah.yoga@efi.int; christophe.orazio@efi.int; eduard.mauri@efi.int)

Forest ecosystems play an important role in South West Europe. They occupy more than 30% of the land area in France, Spain, and Portugal. These ecosystems are subject to increasing multiple biotic (e.g. insects and fungi) and abiotic (e.g. storms, fires) hazards. Although European forests are managed at a local level, forest damages often have effects beyond administrative borders. PLURIFOR is a three-year project that aimed to facilitate cross-border collaboration in South-west Europe and to improve local or transnational risk management plans for forest areas susceptible to forest hazards. The project focused on five biotic (eucalyptus weevil, pinewood nematode, chestnut gall wasp, pine pitch canker, emerging pests, and diseases) and three abiotic (storm, wildfire, soil degradation) hazards currently prevailing in southwestern forests. Research institutes, universities, forest-related organisations, and governments at local, regional and national levels exchanged their expertise through survey questionnaires and during technical workshops to build innovative risk tools and up to date risk management plans. Field inventory and laboratory analyses were conducted to test new methodologies for forest risk prevention. Remote sensing tools (lidar, UAV) were also used to characterize tree mortality. Altogether, PLURIFOR contributed to the development of 27 risk management tools and 13 risk management plans. A panel of forest risk management experts has been implemented to ensure an on-going collaboration on forest hazards at a European level.

Phenologically contrasting silver fir (*Abies alba* Mill.) groups and belowground root-associated fungal communities in Slovenia

Tina Unuk^{1,2}, Tijana Martinović², Domen Finžgar¹, Rok Damjanec¹, Nataša Šibanc¹, Tine Grebenc¹, Hojka Kraigher¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Institute of Microbiology of the CAS, Prague, Czech Republic (tina.unuk@gozdis.si; tijana.martinovic@gozdis.si; domen.finžgar@gozdis.si; rok.damjanec@gozdis.si; natasa.sibanc@gozdis.si; tine.grebenc@gozdis.si; hojka.kraigher@gozdis.si)

Leaf phenology is one of the most important characteristics for tree growth and survival and tend to be crucial in controlling ecosystem processes. In forest ecosystems, tree roots are colonized by various ecto- or endo-mycorrhizal and endophytic fungi, which impact plant growth and vigour, as drives nutrient mobilization processes of their host plants. Linking plant phenological characteristics with belowground ectomycorrhiza community composition was rarely questioned, thus we aimed to (1) analyse fungal communities of four phenologically distinct groups of silver fir trees, by using Illumina MiSeq platform, and to (2) link analysed communities and community differences with phenological characteristics of sampled groups. Based on phenological data of silver fir

trees (project LIFEENMON), individual trees with extreme phenologies were combined into two phenologically contrasting groups, and further separated based on silver fir tree age. Changes in fungal community composition were evaluated with PerMANOVA on Bray-Curtis distances, meanwhile for alpha diversity estimation Shannon-Wiener and Simpson indexes were used. Significant differences in beta diversity and mean alpha diversity were confirmed for overall community of ectomycorrhizal root-associated fungi of young silver fir trees, but not also for ectomycorrhizal community of adult silver fir trees. Meanwhile for non-ectomycorrhizal root-associated fungi only significant differences in beta diversity were observed. At genus level root-associated fungal genera abundances differed significantly between early and late flushing young and adult silver fir trees. The presentation contributes to the aims and means of the project LIFEENMON (LIFE13 ENV/SI/000148).

Growth response of the main Carpathian forest tree species to climate extremes between 1997 and 2017

Zuzana Sitková¹, Jozef Pajtik¹, Roman Sitko², Katarína Merganičová^{2,3}, Pavel Pavlenda¹, Ján Merganič², Peter Fleischer²

¹National Forest Centre, Forest Research Institute, Zvolen, Slovakia; ²Technical University in Zvolen, Faculty of Forestry, Zvolen, Slovakia; ³Czech University of Life Sciences Prague, Faculty of Forestry and Wood Sciences, Prague, Czech Republic (sitkova@nlcsk.org; pajtik@nlcsk.org; sitko@tuzvo.sk; k.merganicoval@forim.sk; pavlenda@nlcsk.org; merganic@tuzvo.sk; p.fleischerjr@gmail.com)

Recent knowledge indicates that climate-induced changes affect productivity of temperate forests in Central Europe. Systematic measurements conducted within the framework of the unique forest monitoring networks enable an evaluation of tree responses to unprecedented long-term environmental changes at a large spatial scale. The primary objective of this study is to analyse recent growth changes in key tree species of the West Carpathians in relation to climate extremes. We focused on economically most significant forest tree species in Central Europe: European beech (*Fagus sylvatica* L.), Norway spruce (*Picea abies* L. Karst.), Sessile oak (*Quercus petraea* Liebl.) and Downy oak (*Quercus pubescens* Willd.). Growth analysis is based on 20 years of periodic measurements of a large number of individual trees growing on eight ICP-Forests plots (Level II) distributed across Slovakia at an altitudinal range from 225 m to 1,250 m a.s.l. In the study, we analysed annual increments of the following growth parameters: diameter at breast height, tree height, tree volume and tree basal area. The series of bioclimatological indicators and various climate indices quantifying particularly drought and extreme air temperatures were derived from the data of meteorological stations situated in the surrounding of the research plots for individual years between 1997 and 2017. Key questions answered by this contribution are: Do tree species exhibit recent climate-driven growth changes? How do species growth reactions to climate extremes differ? Which environmental indicators affecting tree growth were most significant? How does the changing climate affect the inter-annual variability in forest productivity of study sites?

Use of the normalized difference vegetation index to estimate biomass and carbon stocks of restored areas in the Atlantic Forest

Eduardo Gusson¹, Edgar de Souza Vismara², Frederico Tomas de Souza e Miranda¹, Paulo Guilherme Molin³

¹Biodendro Consultoria Florestal Ltda, Piracicaba, Brasil; ²Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil; ³Universidade de São Carlos, Buri, Brasil (eduardogusson@gmail.com; edgarvismara@utfpr.edu.br; fredtsmiranda@gmail.com; pgmolin@gmail.com)

This study aims to evaluate the applicability of the vegetation index NDVI to assist in inventory of biomass stocks in natural forests. For this, we used the information obtained in the study of case project, entitled "Forest Restoration and Carbon Credits AES Tietê S/A". Different sampling procedures commonly used in forest inventories were applied, looking to compare them in terms of accuracy and conservativeness of the estimates of biomass and carbon. The vegetation index NDVI show good correlation with the measured biomass in the field inventory plots. As result, this index can be applied as support decision tool to define the strata in the stratified random sampling as well as a predictor variable of the regression estimator in the double sampling procedure. This latter procedure was able to minimize the uncertainty of estimates, using a reduced sampling effort. It makes the approach very interesting in the context of biomass and carbon surveys applied to natural and restored Atlantic forests. It is because those studies are often applied in large areas, where the field works are time consuming and very expensive.

Growth of pau-marfim (*Balfourodendron ridelianum*) for introduction into urban forestry programs in Brazil / Crescimento de Pau-marfim (*Balfourodendron ridelianum*) para fins de introdução em planos de arborização em áreas urbanas no Brasil

Isis Manzano¹, Flavia Brun¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (manzano@alunos.utfpr.edu.br; flaviagbrun@gmail.com)

O objetivo do presente estudo foi avaliar o desenvolvimento do Pau-marfim (*Balfourodendron ridelianum*) em área urbana, a fim de avaliar seu potencial para a utilização em arborização viária. Estudaram-se quarto indivíduos, implantados em 2013 no campus da UTFPR Dois Vizinhos. As mudas, quando implantadas, apresentavam altura média (Ht) 1,65 m e diâmetro médio (DAP) 0,71 cm, plantados em covas formato bacia (1,5 m x 0,6 m), recebendo adubação orgânica (5 L de cama de aviário) e química (300 g de NPK 06-30-06 incorporados ao solo da cova+150 g da mesma fórmula, como cobertura, em coveta lateral, aos 12 meses de idade), em área livre de 1m². Foram mensuradas Ht (m) com o uso do hipsômetro Vertex IV, Diâmetro a altura do peito (DAP cm), obtido pela medição da circunferência à altura do peito (CAP) com fita métrica e cálculo do DAP pela relação CAP/π e a Área de Copa (m²), calculada com base na medição de 4 raios equidistantes a partir do tronco até a extensão dos galhos. Os resultados encontrados estão de acordo com o previsto na literatura científica sobre o tema, com um incremento médio em Ht de 1,7 m/ano, DAP de 2,8 cm/ano e área de copa de 5,1 m²/ano, sendo assim, os resultados encontrados nesse estudo foram satisfatórios ao se tratar de árvores nativas com 6 anos de idade, expostas e submetidas ao estresse cotidiano urbano, de acordo com os resultados encontrados, o Pau-marfim mostra-se como espécie potencial para a utilização na arborização urbana devido ao seu bom desenvolvimento no ambiente urbano.

B4s: CLIMATE SMART FORESTRY OR HOW TO INTEGRATE ADAPTATION, MITIGATION AND SUSTAINABLE FOREST MANAGEMENT

Modeling changes in the distribution of agro-climatological zones of Kenya for incorporation of area-specific mitigation and adaptation measures in integrated land use plans and forest management at Sub-county level

Richard Muita¹, Phesto Osano², Mercy Gichora², Kasina Muo³

¹Kenya Meteorological Department, Institute For Meteorological Training and Research, Nairobi, Kenya; ²Kenya Forestry Research Institute, Nairobi, Kenya; ³Kenya Agricultural and Livestock Research Organization, Nairobi, Kenya (muita.richard@gmail.com; phesto@kefri.org; mgichora@kefri.org; muo.kasina@kalro.org)

Kenya's seven agroclimatic zones were first published in 1983 and upscaled to 12 homogenous climatic zones in 2000. As climate change became more evident over time, a need was identified to once again review and update the distribution of existing climatic zones at a finer scale for use in Sub-counties, the lowest

administrative units of the country. For the study, daily rainfall from 300 locations for the period 1960 to 2015 and daily temperature from 30 locations for the period 1974 to 2015 were obtained from the Kenya Meteorological Department. Combined approaches to missing data-imputation were used. The Statistical Downscaling Model was applied to reconstruct the daily data sets using NCEP predictors while satellite-derived values obtained from NOAA were used to calibrate the observed station records for improved accuracy on estimating the missing observations. A Generalized Additive Model (GAM) in R environment was applied to derive the relationships and trends of rainfall and temperature over the period and to test the capability of GAM to predict the spatial distribution of the historical climatic data across all the Sub-counties in Kenya. This model is expected to become a valuable tool for operational forecasters and decision makers in the natural resource-based economic sector of Kenya. It can generate more accurate and area-specific climatic information and provide information required by policy makers to initiate effective adaptation and mitigation measures against impacts of climate change. It has application in County integrated land use planning and management of forests and agriculture, among other sectors.

Harvesting of old-growth Boreal Forest decrease soil carbon stock

Jenny Dahl¹, Tomas Lundmark¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden (jenny.dahl@slu.se; tomas.lundmark@slu.se)

The Boreal Forest is a vast region, consisting of diverse ecosystem types with different carbon dynamics and vulnerability to climate change, exposed to various intensities of forest management. There are large uncertainties among scientists on the contribution of boreal forest management to climate change mitigation, and disagreements among stakeholders whether bio-economy or conservation is the winning concept. The most appropriate mitigation actions will be decided by current forest conditions and climate change impacts, socio-economic state and regional policy for mitigation actions. Therefore, mitigation strategies need to be adapted to regional conditions to meet objectives regarding carbon as well as other forest management objectives. This study focus on the effects on soil carbon in old-growth boreal forests in northern Sweden after a first regeneration cut. This was done by empirically quantifying soil carbon stock in the humus layer and down to 20 cm in the mineral soil at 14 paired sites of adjacent old-growth and younger stands. The younger stands had been established after clear cutting of old-growth forests similar to the one at the adjacent site 15-55 years ago. Results indicate a reduction of soil carbon after a final harvest. This temporary or permanent carbon debt needs to be considered when assessing the climate benefit of turning old growth forests into managed forests.

Changes in the rate of shrub coverage in native forests within the Mesopotamian Espinal Region of Argentina: using remote sensing for analysis / Evolución del nivel arbustización en bosques nativos del espinal mesopotámico: utilización de sensores remotos para su análisis

Monitorear la evolución de los cambios ocurridos sobre los recursos naturales es una prioridad a nivel mundial. Los modelos de cambio y cobertura de la tierra, y su facilidad en la predicción, son una herramienta potente de análisis espacial. El objetivo del trabajo consistió en determinar y explicar los cambios sobre el nivel de arbustización en bosques nativos del Espinal Mesopotámico, con la finalidad de predecir el nivel de degradación y ajustar la carga animal. El estudio se realizó en el Área Natural Protegida "El Carayá" ubicada en Entre Ríos (Argentina). El estado del bosque nativo se determinó en los años 2012 y 2018, a través puntos georreferenciados con GPS. Se cuantificó el nivel de arbustización en cinco clases, y utilizaron dos imágenes satelitales Landsat. El modelo Markov fue utilizado para determinar las predicciones. El 36% (3.775 ha) del "El Carayá" se mantuvo estable en relación con el nivel de arbustización durante el período evaluado. El porcentaje restante, presentó cambios notables debido a la dinámica sucesional característica de estos ecosistemas. En el año 2027 se espera que la superficie sin cambios sea del 33%. La dinámica sucesional en la cobertura de arbustivas propia de los bosques nativos, estuvo influenciada por la variación estacional del clima, la intervención antrópica a través de la limpieza química y la implementación de un sistema de pastoreo rotativo intensivo. Este trabajo permitió definir y ajustar la capacidad de carga de los diferentes ambientes teniendo en cuenta los potenciales cambios sobre la arbustización de los bosques nativos.

Calculations of socio-economic efficiency of environmental forestry measures including reforestation activities considering climate change and forests disasters in the Czech Republic

Ludek Sisak¹, Vilem Jarsky¹, Roman Dudik¹, Roman Sloup¹, Marcel Riedl¹

¹Czech University of Life Sciences Prague, Prague, Czech Republic (sisak@fld.czu.cz; jarsky@fld.czu.cz; dudik@fld.czu.cz; sloup@fld.czu.cz; riedl@fld.czu.cz)

The first experimental socio-economic efficiency evaluation of environmental forestry operations in the landscape under the Rural Development Programme (RDP) in the Czech Republic is presented. The efficiency evaluation is based on environmental operations costs provided by the Ministry of Agriculture for all the Czech Republic in years 2015-2017, considering the future socio-economic improvements of the respective environmental landscape ecosystem services' socio-economic values (both market and non-market) expressed by their differences. The socio-economic efficiency represents a relationship between public financial inputs into the forestry environmental measures on one hand, and enhancement of respective landscape ecosystems services' socio-economic values on the other hand. The main landscape ecosystems such as forestland, grassland, arable land, and solid soil cover were included, and valued by the methodology created by the research team, and certified in the Czech Republic in 2018. The following main services were included: production service (both market and non-market), game management and hunting, hydrological services, soil protection services, air protection – CO₂ sequestration services, health-hygienic (recreational services), cultural-educational services (based on nature-protection service closely related to biodiversity, important in educational, scientific and institutional points of view). The results show that the selected forestry measures within the RDP significantly improve the given landscape services' socio-economic values within the Czech Republic and that all measures' value benefits are higher than the public funds invested.

Dicyandiamide as an alternative for mitigating nitrous oxide emissions from nitrogen fertilizer used on eucalyptus / Uso da dicianodiamida como alternativa para a mitigação da emissão de óxido nitroso proveniente da adubação nitrogenada do eucalipto

Mariana Ibarra¹, Ricardo Ribeiro¹, Josiléia Acordi Zanatta², Marcos Fernando Gluck Rachwal², Jeferson Dieckow¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil (marianaibarr@gmail.com; kico_ribeiro@hotmail.com; josileia.zanatta@embrapa.br; marcos.rachwal@embrapa.br; jefersondieckow@ufpr.br)

O uso de inibidor de nitrificação (IN) concomitantemente à adubação nitrogenada constitui uma alternativa para a mitigação da emissão de óxido nitroso (N₂O) do solo. O objetivo do estudo foi avaliar o potencial do IN dicianodiamida (DCD) em reduzir a emissão de N₂O do solo proveniente da adubação nitrogenada do

eucalipto. O experimento foi conduzido em povoamento de *Eucalyptus urograndis* cultivado em Latossolo Vermelho argiloso. Os tratamentos foram: controle (C), ureia (U) e ureia com DCD (U-DCD), aplicados 10 e 120 dias após plantio (DAP), correspondendo à adubação de base (13 kg N ha⁻¹) e cobertura (33 kg N ha⁻¹), respectivamente. O fluxo de N₂O foi avaliado durante 247 dias pelo método da câmara estática fechada. O fluxo de N₂O do solo variou de 1,5 a 1030,8 µg N m⁻² h⁻¹, com picos concentrados entre 15 e 65 DAP, seguidos de valores basais até o final do período de avaliação. A emissão acumulada (EA) de N₂O do solo do tratamento C, U e U-DCD foi de 2,93, 5,53 e 3,29 kg N ha⁻¹, respectivamente. No entanto, embora a U apresente EA duas vezes maior que o controle e que a U-DCD tenha reduzido a emissão de N₂O do solo fertilizado com U em 40,5%, os tratamentos não apresentaram diferença significativa entre si, possivelmente devido ao elevado coeficiente de variação entre as repetições (3). Neste sentido, conclui-se que o inibidor de nitrificação dicianodiamida não foi eficiente em reduzir a emissão de N₂O do solo nas condições edafoclimáticas deste estudo.

Nitrous oxide emissions in an area of mixed eucalyptus and acacia plantations in Northern Mato Grosso, Brazil / Emissões de óxido nitroso em área de plantio misto de eucalipto e acácia no norte Mato-grossense

Júlia Graziela da Silveira¹, Renato de Aragão Ribeiro Rodrigues², Maurel Behling³, Diego Camargo⁴, Leticia Helena Campos de Souza⁵, Jacqueline Jesus Nogueira da Silva⁶, Natassia Magalhães Armacolo⁷, Antonio de Arruda Tsukamoto Filho⁵

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Embrapa Solos, Rio de Janeiro, Brasil; ³Embrapa Agrossilvipastoril, Sinop, Brasil; ⁴Universidade Federal de Mato Grosso, Sinop, Brasil; ⁵Universidade Federal de Mato Grosso, Cuiabá, Brasil; ⁶Universidade Federal Fluminense, Niterói, Brasil; ⁷Universidade Estadual de Londrina, Londrina, Brasil (juliagrazielasilveira@gmail.com; renato.rodrigues@embrapa.br; maurel.behling@embrapa.br; camargo.die@gmail.com; leticiahelena_cs@hotmail.com; jacqueufmt@gmail.com; nmarmacolo@gmail.com; tsukamoto@ufmt.br)

O eucalipto é a espécie florestal mais plantada no Brasil e para explorar seu máximo potencial produtivo, é necessária a reposição de nutrientes, sobretudo nitrogênio (N), principal fonte de emissão de óxido nitroso (N₂O). Plantios mistos de eucalipto com leguminosas arbóreas fixadoras de nitrogênio, surge como uma alternativa sustentável de fornecer N e reduzir as emissões de N₂O. O objetivo do estudo foi avaliar o efeito do plantio misto de *Eucalyptus urograndis* (*E. urophylla* x *E. grandis*) e *Acacia mangium* na redução das emissões de N₂O. Foi realizado na Embrapa Agrossilvipastoril, Sinop-MT e foram avaliados cinco tratamentos: monocultivo de eucalipto com fertilização nitrogenada (E+N), sendo aplicado 190 kg ha⁻¹ de ureia; monocultivo de eucalipto sem fertilização nitrogenada (E); monocultivo de acácia (A); plantio misto com 67% eucalipto e 33% acácia (67E:33A); plantio misto com 50% eucalipto e 50% acácia (50E:50A). O delineamento experimental foi blocos casualizados, com três repetições. As coletas foram realizadas em 2016 e 2017, em período de seca e chuva. Foram instaladas câmaras estáticas para coleta de gases e as amostras foram analisadas por cromatografo gasoso. No período seco, os maiores valores de emissões de N₂O foram 5,44 µg N m⁻² h⁻¹, não apresentando diferença significativa entre os tratamentos. No período de chuva, a emissão foi superior à seca e os maiores valores foram no E+N, com emissões de 189,49 µg N m⁻² h⁻¹, sendo superior aos demais tratamentos. Plantio misto de eucalipto com acácia tem potencial de mitigação de emissões de N₂O, comparado a monocultivos fertilizados com N.

B4t: ESTIMATION OF STATUS AND CHANGE IN FOREST CARBON POOLS BASED ON INVENTORY DATA: GOING BEYOND TREE CARBON

Combretum-Terminalia vegetation accumulates more carbon stocks in the soil than the biomass along the elevation ranges of dryland ecosystem in Southern Ethiopia

Musse Tesfaye¹, Mesele Negash²

¹Ethiopian Environment and Forest Research Institute, Addis Abeba, Ethiopia; ²Wondo Genet College of Forestry and Natural Resources, Hawassa University, Hawassa, Ethiopia (mussetesfaye36@gmail.com; kelemuamelese@yahoo.com)

Dryland ecosystems including Combretum-Terminalia vegetation cover a wider area in the tropics. These resources are believed to greatly contribute to climate change mitigation in dryland ecosystems. Therefore, the objective of this study was to investigate biomass and soil carbon stocks of Combretum-Terminalia vegetation along the elevation ranges. A total of 60 nested sample plots of 20 m × 20 m were laid systematically along lower, middle and higher elevation ranges, representing 20 plots for each elevation. Within each nested sample plot of woody species, litter and soil samples (0-15, 15-30 cm layers) were collected. The total carbon stocks (biomass plus soil) significantly (p < 0.05) differed among the three studied elevation ranges. The biomass carbon stocks were significantly different between middle and higher elevations but both of them significantly (p < 0.05) differed from lower elevation, and also showed a decreasing trend from lower to higher elevations. However, inconsistency trends were observed for organic carbon and litter along the elevation ranges. It was concluded that the woodland ecosystem has a potential to accumulate higher carbon stocks in the soil than the biomass and significantly vary along elevations.

Quantification of soil organic and inorganic carbon stocks in Gambari Forest Reserve, Nigeria

Oladele F. Falade¹, Ayobami A. Adeagbo¹

¹Department of Forest Production and Products, University of Ibadan, Ibadan, Nigeria (faladedele@yahoo.com; aydeagbo@yahoo.com)

Soil carbon is the largest carbon pool in the terrestrial biosphere and contains organic carbon and inorganic carbon components. Inorganic carbon has not been considered in estimation of soil carbon stock. Assessment of both carbon components is required to understand the effects of land use on soil carbon stock. Therefore, this study was conducted to quantify organic and inorganic carbon among soil aggregates of selected land use types in Gambari Forest Reserve. Four (30m x 30m) plots were randomly demarcated on each land use; Natural Forest, Plantation Forest and Cultivated Land. Soil core samples were collected to depths of 0-15, 15-30 and 30-45cm in the sub-plots of 8m x 8m established at four corners and centre of each plot. Soil core samples were oven dried at 1050C to constant weight and 100g of soil sample was sieved into five aggregate sizes (> 2, 2-1, 1-0.5, 0.5-0.05, <0.05mm) and total carbon content was determined by Loss-in-Ignition method at 5000C for 4 hours. Walkley Black method was used to determine soil organic carbon and inorganic carbon was computed from each aggregate fractions. Data collected were analyzed using descriptive statistics. Aggregates > 2.0 mm had the highest total carbon content at three depths in Plantation Forest and Cultivated Land while 1.0 mm had the highest carbon content at three depth in Natural Forest. Soil organic and inorganic carbon decreased with increase in soil depths in the three land use type. Land use and aggregates determined the distribution pattern of soil organic and inorganic carbon.

Soil organic carbon stock under poplar based plantation in relation to tree age and soil depth

Gurveen Arora¹, Rajesh Kaushal²

¹Indian Council of Forestry Research and Education, Dehradun, India; ²Indian Institute of Soil and Water Conservation, Dehradun, India (gargi_one@yahoo.com; kaushalrajsh1@rediffmail.com)

Poplar based agroforestry system improves aggregation of soil through huge amounts of organic matter in the form of leaf biomass. The extent of improvement however is largely governed by the age of the poplar trees and the soil type. Keeping above in view, a study was conducted in “Tarai” region of Central Himalayas to quantify the soil carbon stock along age series “*Populus deltoides*” plantation at different soil depth. Soil samples were collected from 1 to 11 years from 3 depths i.e. 0-30 cm, 31-60 cm and 61-90 cm respectively. The results showed that organic carbon per cent increased significantly with age ranging from 1.59-2.20 in 0-30 cm, 1.39-1.43 in 31-60 cm and 1.25-1.31 in 61-90 cm depth. Similar trend was observed in bulk density varying from 1.27-1.34, 1.38-1.44 and 1.47-1.52 g/cm³ in 0-30 cm, 31-60 cm and 61-90 cm respectively. Both the factors decreased with increasing soil depth. Soil carbon stock also increased significantly with increasing tree age and showed reverse trend with soil depth at 5 per cent probability level. Soil carbon stock in different ages of plantations varied from 63.9 to 83.8 Mg/ha at 0-30 cm depth, 57.5 to 60.1 Mg/ha at 30-60 cm depth, and 55.5 to 59.7 Mg/ha at 60-90 cm depth. The carbon sequestration rate of the soil varied from 1.18 to 1.81 Mg/ha/yr from 7 to 11 years. Based on the study, it can be recommended that poplar based plantation helps in retention of soil organic matter.

Forest ecosystem carbon fluxes after stand-replacing disturbance

Sille Rebane¹, Kalev Jõgiste¹, Andres Kiviste¹, John Stanturf¹, Marek Metslaid^{1,2}

¹Estonian University of Life Science, Tartu, Estonia; ²Norwegian Institute of Bioeconomy Research, Ås, Norway (rebane.sille@gmail.com; kalev.jogiste@emu.ee; andres.kiviste@emu.ee; drdirt@gmail.com; marek.metslaid@emu.ee)

A large area of Estonian hemiboreal forest is recovering from clear-cut harvesting and reflecting carbon (C) balance with the stand. Net ecosystem total CO₂ exchange (NEE) was measured by eddy covariance (EC) technique between two different stages of stand development. The one study site, which is divided into two stands are located in south-east Estonia, Europe. Growing trees and the harvest stands is moderated into a C source immediately after harvesting. Stands which already were 6 and 8 years old, were acting as a light C sinks. They had similar patterns of carbon exchange and results showed clear correlation between C fluxes and ecosystem responses to environmental conditions. Eddy fluxes were based on high quality data being most accurate and reliable. Mean summertime (May-September) measured NEE for 2014 was -1.4281 μmol m⁻² s⁻¹. Seasonally, NEE peaked in July with -96.793 μmol m⁻² s⁻¹. In June, August and September was the highest -78.110, -96.618 and -73.785, respectively. However measured mean CO₂ concentration was 343 ppm and mean temperature was 15 degrees. Weather conditions played a key role in the rapid rise in NEE results. NEE result was driven primarily by early-growing-season temperature and length. Meteorological data confirm ecosystem depends on climate variability and water vapor. Results indicates strong relationship between carbon fluxes, stand age and climate conditions.

Investigating wood density as a proxy for biomass production of economically relevant tree species in the temperate zone of China

Lars Sprengel¹, Sandra-Maria Hipler¹, Wu Shuirong², Heinrich Spiecker¹

¹University of Freiburg, Freiburg, Germany; ²Chinese Academy of Forestry, Beijing, China (lars.sprengel@iww.uni-freiburg.de; sandra.hipler@iww.uni-freiburg.de; shuirongwu@126.com; instww@iww.uni-freiburg.de)

Recent trends in climate change and future predictions of increasing carbon emissions and rising temperature have drawn a general focus towards the topic of carbon storage and the enlargement of carbon sinks. However, some forest ecosystems and tree species have not been investigated in terms of their biomass production and the closely linked carbon storage potential in much detail. Here, we investigate biomass production of *Larix gmelinii* (Rupr.) Kuzen, *Pinus tabulaeformis* Carr. and *Quercus mongolica* Fisch. ex Ledeb. in the temperate zone of China by analyzing gravimetric wood density as a proxy. As gravimetric wood density varies within a tree we use high-frequency densitometry on radial cuts of stem discs to analyze the inter-annual density variations at 1.3 m and 10 m stem height, respectively, by applying linear mixed-effects models and pairwise comparisons of estimated marginal means. Results show an overall lower gravimetric wood density for *P. tabulaeformis* compared to *L. gmelinii* and *Q. mongolica*. For all three tree species mean annual gravimetric density develops in a curvy-linear pattern and decreases to lower values than the initial values after leveling off at different cambial ages. Results will help to quantify stored carbon in the aboveground merchantable timber compartment of the investigated tree species and during different developmental stages of a tree.

Quantification of the effect of agriculture on forest carbon stock: case study of a Nigerian Forest Reserve

Temitope Elizabeth Ogana¹, Friday Nwabueze Ogana¹

¹University of Ibadan, Ibadan, Nigeria (topeadeniyi2005@gmail.com; fn.ogana@ui.edu.ng)

The competition for land between forest and agriculture has been a long-time issue. The tropical forest has been greatly reducing due to agricultural activities. There are few studies on the quantification of forest carbon loss stock caused by encroaching agricultural activities. Therefore, this study compared the biomass in the areas encroached by farming activities and forested areas; and also analyze the forest cover change in Cross River South Forest Reserve, Nigeria. Data were obtained through forest inventory and satellite imageries. Eight sample plots of 0.25 ha were used (plots were laid in the forested and the encroached parts of the reserve). Established allometric equation was used to estimate the biomass. Satellite images from Landsat between 2002 and 2017 were used for the forest cover change. The results showed that there is a significant difference in the mean aboveground carbon density of the forested part (108.6571 tC/ha) and the encroached part (44.1567 tC/ha) of the reserve. The forest cover change of Forest Reserve showed that about 6,750 ha was deforested within the period with an annual rate of forest cover loss of 0.54%. It was concluded that the farming activities have negatively impacted the quantity of carbon stock of the Forest Reserve.

Forest management certification for sustainable negative emissions

Florian Kraxner¹, Dmitry Schepaschenko^{1,2}, Piera Patrizio¹, Sylvain Leduc¹, Sabine Fuss^{1,3}, Linda See¹, Ping Yowargana¹, Bintang Yuwono¹, Kaspas Spokas¹, Anders Lunnan³, Anatoly Shvidenko¹

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²Bauman Moscow State Technical University, Mytishi, Moscow, Russian Federation; ³Mercator Research Institute on Global Commons and Climate Change, Berlin, Germany; ⁴Princeton, University, Princeton, USA; ⁵Norwegian University of Life Sciences, Ås, Norway (kraxner@iiasa.ac.at; scheidp@iiasa.ac.at; patrizip@iiasa.ac.at; leduc@iiasa.ac.at; fuss@mcc-berlin.net; see@iiasa.ac.at; yowargan@iiasa.ac.at; yuwono@iiasa.ac.at; kspokas@princeton.edu; anders.lunnan@nmbu.no; shvidenk@iiasa.ac.at)

Land-based negative emission technologies (NETs), in particular bioenergy with carbon capture and storage (BECCS), are often criticized by science and policy with respect to their land demand and potentially negative environmental effects. However, the ambitious climate mitigation targets under the Paris Agreement and with some of the most relevant SDGs might become unattainable without NETs, says the latest IPCC special report on 1.5 deg C. This study presents a new methodology for identifying sustainable forest biomass feedstock for BECCS applications. A new global forest certification map at one-kilometer resolution (Geo-Wiki) together with a biophysical forest model (G4M) and an engineering model (BeWhere) to optimize the feedstock supply chain are applied to map a realizable and sustainable potential for BECCS in the US. It is shown that BECCS potentials strongly vary under different sustainability scenarios developed for the US. Rather conservative assumptions with respect to biomass availability indicate that BECCS potentials are reduced by up to two thirds if strict sustainability criteria are being applied. However, the study also reveals that sustainable feedstock supply chains for BECCS can be developed with the help of this new integrated approach. Furthermore, forest certification appears to be an appropriate tool for identifying sustainable bioenergy feedstock - i.e. for the generation of negative emissions for climate mitigation. Certifying multiple ecosystem services including energy provision and carbon sequestration seems to be a promising way forward for present and future certification schemes. Finally, a near-term ramping up of bioenergy systems with highest sustainability safeguards is strongly recommended.

Blue carbon and biodiversity within Suriname's mangrove forests using a multipurpose NFI

Gianni Wip¹, Verginia Wortel², Gunovaino Marjanom³, Jasper Feyen¹, Sarah Crabbe¹, Joey Zalman¹, Dorothy Traag³, Gwen Landburg⁴

¹Foundation for Forest Management and Production Control, Paramaribo, Suriname; ²Center for Agricultural Research and Development Suriname, Paramaribo, Suriname; ³The National Herbarium of Suriname, Paramaribo, Suriname; ⁴National Zoological Collection Suriname, Paramaribo, Suriname (gianniw@sbb.sr; wortelv@gmail.com; gunovaino.marjanom@gmail.com; jasperfeyen@hotmail.com; crabbes@sbb.sr; zalmanj@sbb.sr; dorothea.traag@uvs.edu; gwendolyn.landburg@uvs.edu)

Mangrove forests provide important ecosystem services as habitat, feeding, aery grounds for fish, molluscs, crustaceans, as well as coastline protection. The biomass, dead organic material and the soil are significant sinks of blue carbon (McLeod, E; 2011) and represent an important economic resource pool for adjacent communities. These mangrove forests are currently threatened by urban and rural development. While we are well aware of its importance, insufficient statistically sound data is available on the extent of the mangrove forests, the blue carbon and the biodiversity it fosters. To better inform policy makers, Suriname has initiated its efforts towards a National Forest Inventory (NFI) within the mangrove forest in a collaborative process between governmental and academic institutions. The methodology implemented can be easily harmonized with the NFI-methodology used in its neighbouring country Brazil. Data is collected on the blue carbon stored in mangrove forests, but also on its floristic and fauna biodiversity. The NFI is a component of the National Forest Monitoring System (NFMS) developed within the framework of REDD+ and thus provides data for reporting to the UNFCCC, but also to the Convention of Biological Diversity (CBD) and the Forest Resource Assessment (FRA). According to the previous mangrove plot data collected in Suriname, a carbon stock of 57.93 Mg/ha was found, but the inclusion of soil organic carbon in this study and a more extensive sampling intensity could prove that the carbon storage potential of mangroves is much higher, supporting the case for intensifying mangrove forest conservation efforts.

B4u: ESTIMATION OF STATUS AND CHANGE IN FOREST CARBON POOLS BASED ON INVENTORY DATA: GOING BEYOND TREE CARBON

Detecting and evaluating degraded forests by combining remote sensors and data and information from the Chilean national forest inventory / *Detección y evaluación de bosques degradados mediante la combinación de sensores remotos y datos e información del inventario forestal nacional en Chile*

Carlos Bahamondez¹, Yasna Rojas Ponce¹, Rodrigo Sagardia¹, Marjorie Martin¹, Müller-Using Sabine¹

¹Instituto Forestal, Valdivia, Chile (cbhamon@infor.cl; yrojas@infor.cl; rsagardia@infor.cl; mmartin@infor.cl; smuller@infor.cl)

Los bosques degradados en Chile constituyen la principal causa de pérdida del potencial de remoción de carbono desde la atmósfera. Avanzar en la detección de estos bosques permite determinar en qué áreas concentrar los esfuerzos en el marco de REDD+ y mejorar el rol mitigador de los bosques. En este contexto, INFOR ha desarrollado una metodología espacialmente explícita para la detección de bosques degradados, que permite evaluar en el tiempo las pérdidas y ganancias de carbono en un período de evaluación. Esta metodología se ha utilizado para establecer el nivel de referencia de emisiones forestales/nivel de referencia forestal de los bosques templados de Chile. La metodología consiste en la combinación de material satelital Landsat con unidades de muestreo generadas por el Inventario Forestal Nacional de INFOR. Se recurre a herramientas biométricas respecto del bosque, que permiten establecer los valores umbrales que determinan en forma operacional, cuando un rodal está en estado de degradación, y necesita de recuperación activa. Se utilizan los diagramas de densidad de los bosques que establecen la relación de número de árboles y área basal por hectárea. Los resultados muestran para el período 2001-2010 una superficie total de degradación de 461.231 hectáreas con emisiones anuales de 4,9 millones de toneladas de CO₂e y de 677.669 hectáreas que se recuperaron con una absorción neta anual de 9,1 millones de toneladas de CO₂. La metodología ha demostrado resultados aceptables y es suficientemente flexible para ser parte relevante de un sistema medición, reporte y verificación en el contexto de REDD+.

Influence of methodologies for forest restoration in fine-root carbon stocks / *Influência de metodologias de restauração florestal no estoque de carbono da raiz fina*

Anani Morilha Zanini¹, Simone Aparecida Vieira², Ricardo Ribeiro Rodrigues¹

¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Piracicaba, Brasil; ²Universidade Estadual de Campinas, Campinas, Brasil (ananizanini@hotmail.com; savieira08@gmail.com; rrrresalq@usp.br)

Estimativas de biomassa são importantes nos estudos de mudanças climáticas, sendo as raízes finas potenciais fontes de carbono. Assim, o objetivo do trabalho foi quantificar o estoque de carbono da raiz fina de áreas com diferentes metodologias de restauração florestal. O presente estudo foi realizado no município de Itu, SP, em parcelas de 30 x 30 m (900 m²) distribuídas de forma sistemáticas na área, sendo elas: restauração passiva (apenas isolamento da área dos fatores de perturbação), restauração assistida (condução da regeneração natural, adensamento e enriquecimento de espécies), restauração ativa (plantio total escalonado), pasto limpo em uso e fragmento nativo remanescente de floresta estacional semidecidual. Para coleta, foram utilizados 2 pontos sorteados por parcela. Em cada ponto, foram retiradas porções de solo correspondentes às profundidades de 0-10, 10-20 e 20-30 cm. Para a quantificação da biomassa foi utilizado a metodologia do ponto-a-ponto, que consiste em remover concomitantemente das três profundidades de solo, todas as raízes com diâmetro igual ou menor a

2 mm em 4 intervalos de tempo de 2 minutos, para ajuste de uma curva de tendência logarítmica que estima a produção total. Posteriormente as raízes foram submetidas a análise de teor de carbono. A partir de ANOVA e teste de Tukey, observamos que entre os tratamentos a estocagem no fragmento e nas áreas com maior quantidade de gramíneas foi superior, e que entre profundidade cerca de 58% foi estocado na primeira camada. Podendo concluir que a produção de raízes finas é um indicador de conservação, principalmente do solo.

Quantification of carbon and diversity at the Atlantic Rainforest in the South central region of the State of São Paulo, Brazil

Deicy Carolina Lozano Sivasaca¹, Jaqueline Pinheiro da Silva¹, Celso Anibal Yaguana Puglla¹, Felipe Góes de Moraes¹, Renata Cristina Batista Fonseca¹, Maria Tereza Umbelino², Carlos Alexandre Costa Crusciol¹, Iraê Amaral Guerrini¹

¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Botucatu, Brasil; ²Brasil Mata Viva Program, Goiânia, Brasil (caroladeicylo@hotmail.com; jaqueline.pinheiros@hotmail.com; anibalya@hotmail.com; felipe.goes.de.moraes@gmail.com; rfonseca@fca.unesp.br; maria.tereza@brasilmataviva.com.br; carlos.crusciol@unesp.br; irae.guerrini@unesp.br)

The aims of this work were to estimate the total accumulation of elemental carbon (Celem) and equivalent (CO₂), and the species diversity in three physiognomies of the Atlantic Rainforest: Semideciduous Seasonal Forest (SSF), Riparian Forest (RF) and "Cerradão" (CE). All five carbon sinks proposed by the IPCC were measured: tree biomass (DBH ≥ 5 cm), dead wood, root biomass, litter and soil (every 20 cm up to 1 m depth). An analysis of variance (ANOVA) was performed to compare Celem and CO₂ accumulation in the vegetations and the diversity index of Shannon (H') was calculated. ANOVA indicated that Celem and CO₂ in the Riparian Forest and Cerradão present a significant difference. Celem average in RF was 385.89 ± 50.59 Mg ha⁻¹, in SSF it was 350.97 ± 27.71 Mg ha⁻¹ and 212.79 ± 39.19 Mg ha⁻¹ in CE. The CO₂ average reached 1416.22 ± 185.67 Mg ha⁻¹ in RF, in SSF it ranked 1288.07 ± 101.69 Mg ha⁻¹ and 780.95 ± 143.82 Mg ha⁻¹ in CE. In all three physiognomies the Celem and CO₂ distribution in the sinks was on average 40% in trees, 52% in the soil, 5% in roots, 1% in the litter and 2% in dead wood. The species diversity was the like in the three vegetation formations: RF (H' = 3.42), SSF (H' = 3.66) and CE (H' = 3.70). Forests can have different amounts of carbon and equal species diversity, and therefore, carbon and diversity require explicit considerations in environmental policies.

Carbon storage potential of selected mangrove Forests in Padre Burgos, Quezon, Philippines

Lourdes Breva¹

¹Ecosystems Research and Development Bureau- Department of Environment and Natural Resources, Los Baños, Philippines (alcala_breva99@yahoo.com)

One of the most-talked about issues of global concerns today is climate change. Tropical forests play an important role in the climate change as sources and sink of carbon. Thus, mangrove forests have significant role in mitigating the climate change problem. The study aimed to measure the amount of accumulated biomass in a mangrove forest; determine the amount of carbon storage in the above-ground biomass and belowground of the area; and assess the potential contribution of mangrove forest to the mitigation of climate change. Results of the study showed that the mangrove area has a mean biomass carbon density of 189.53 Mg/ha where the entire amount is contributed only by tree biomass. Soil however, accounted to 51.92 Mg/ha of carbon density. Total carbon density of the area including aboveground (tree) biomass and belowground (soil) has amounted to 241.45 Mg/ha. Highest amount was accounted by the aboveground which is 78 percent and the remaining 22 percent was in belowground. Using the results obtained in this study, Philippine mangrove forest can store 28 M tons of carbon. This implies that mangrove can offer a great potential carbon sink.

Field-based performance of macropropagated and seedlings of Narra (*Pterocarpus indicus* willd.) in the experimental plantation, Digos, Davao del Sur, Philippines

Lourdes Breva¹, Ma. Lourdes Reyes¹, Marilou Avanzado¹

¹Ecosystem Research and Development Bureau, Los Baños, Philippines (alcala_breva99@yahoo.com; ludcreyes@yahoo.com; malu_rene@yahoo.com)

In the absence of quality seeds for massive and restoration of degraded forest lands, the use of vegetative parts of plant like stem as planting material, is a feasible alternative. However, there are reports indicating the morphological differences between cuttings and seedlings, hence, gauging the extent of how such differences could affect the growth and performance in the field. This study compares the growth (height and diameter) and survival of the macropropagated and seedlings of Narra (*Pterocarpus indicus* Willd.) in the established field trail plantation in Davao Region of Mindanao. Three hundred seedling materials were evaluated. After 2 years, survival in the stock-type trials was 96% for rooted cuttings, and 98% for seedlings. Mean diameter and height ratios revealed that rooted cuttings are better than seedlings with 14.42 mm and 121.51 cm; 13.98 mm and 119.81 cm, respectively. Despite the differences of cloned and seedling results, differences in size and relative growth rates had no significant differences between treatments.

Woody plant waste in a commercially managed plantation and undisturbed forest in Central Amazonia / *Necromassa lenhosa em floresta sob manejo comercial e floresta não perturbada na Amazônia Central*

Filipe Campos de Freitas¹, Celso Paulo de Azevedo^{2,3}, Cintia Rodrigues de Souza², Natalino Calegario⁴

¹Universidade Federal de Lavras, Programa de Pós-Graduação, Lavras, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil; ³Universidade Estadual do Amazonas, Manaus, Brasil; ⁴Universidade Federal de Lavras, Lavras, Brasil (felipecamposdefreitas@hotmail.com; celso.azevedo@embrapa.br; cintia.souza@embrapa.br; calegari@dcf.ufla.br)

O estoque de necromassa em florestas tropicais tem mostrado grande relevância à dinâmica de carbono, não quantificá-lo pode gerar uma subestimativa de até 45% do carbono disponível nesses ecossistemas. O objetivo deste estudo foi avaliar o estoque de necromassa em duas florestas na Amazônia Central, uma sob manejo florestal comercial, outra sem distúrbios antrópicos. A coleta de dados foi realizada nos municípios de Itacoatiara e Rio Preto da Eva, estado do Amazonas, Brasil. Coletou-se dados de árvores mortas em pé e troncos caídos com diâmetro mínimo de 10 cm. Foram feitas estimativas de volume, massa e carbono para a necromassa medida em campo e a estimativa de carbono em indivíduos mortos identificados em inventário florestal contínuo. Na floresta manejada observou-se volume médio de 72,46 ± 10,93 m³ ha⁻¹, massa de 66,19 ± 9,56 Mg ha⁻¹ e 32,09 ± 4,64 Mg ha⁻¹ de carbono. A floresta não manejada apresentou volume médio de 44,41 ± 16,19 m³ ha⁻¹, massa igual a 40,80 ± 11,17 Mg ha⁻¹ e 20,67 ± 8,20 Mg ha⁻¹ para o carbono. Não houve diferença estatística significativa entre as médias das duas áreas. Não foi observada diferença entre as estimativas de carbono feitas com a taxa de mortalidade e as obtidas em campo. A exploração florestal proporcionou maior estoque de necromassa. Por outro lado, a intensidade de exploração não exerceu influência significativa. Considerando apenas troncos caídos e árvores mortas em pé, a taxa de mortalidade é suficiente para gerar estimativas do estoque de necromassa.

Carbon dynamics in a seasonal semideciduous forest in Brazil / Dinâmica de carbono em floresta estacional semidecidual no Brasil

Samuel José Silva Soares da Rocha¹, Carlos Moreira Miquelino Eieto Torres¹,IVALDO DA SILVA TAVARES JÚNIOR¹, Paulo Henrique Villanova¹, Bruno Leão Said Schettini¹, Rodrigo Vieira Leite¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (samueljoserocha@gmail.com; cmmet23@gmail.com; ivaldojr8@hotmail.com; villa.floresta09@gmail.com; blsschettini@gmail.com; r.vieiraite@gmail.com)

Entender a dinâmica do estoque de carbono em florestas secundárias da Mata Atlântica fornece subsídios para projetos de gestão que visem a conservação e recuperação dos serviços ecossistêmicos nesses ambientes. Desta forma, objetivou-se avaliar o estoque e a dinâmica de carbono no fuste, por 22 anos, de uma Floresta Estacional Semidecidual, em Viçosa, MG, Brasil. O estudo foi realizado em um fragmento de Mata Atlântica, com 17 ha. Os dados de 10 parcelas permanentes, com 0,1 ha (20 x 50 m) cada, foram utilizados. Nos anos de monitoramento (1994, 1997, 2000, 2004, 2008, 2010, 2013 e 2016), todos os indivíduos com DAP (Diâmetro à Altura do Peito; à 1,3 m do solo) maior ou igual 5,0 cm foram inventariados e identificados. Para verificar diferenças estatísticas entre as estimativas dos anos aplicou-se o teste “t” pareado. O incremento periódico foi calculado com dos dados de crescimento, mortalidade e ingresso. Em relação ao estoque de carbono, observou-se uma tendência de acréscimo com o passar dos anos, de 50,36 Mg ha⁻¹, em 1994, para 75,87 Mg ha⁻¹, em 2016, um aumento de 25,51 Mg ha⁻¹. Não foram observadas diferenças significativas pelo teste t “pareado” para os períodos de 2000-2004 (p-valor = 0,2155), 2008-2010 (p-valor = 0,8491) e 2013-2016 (p-valor = 0,4945). O incremento periódico líquido anual em carbono para a comunidade foi de 1,16 Mg ha⁻¹ ano⁻¹. O fragmento avaliado apresenta um alto potencial de estocagem de carbono e contribui efetivamente para remoção do carbono atmosférico e consequente mitigação dos impactos no clima.

Carbon stocks in planted forest in Brazil / Estoque de carbono de florestas plantadas no Brasil

¹Embrapa Florestas, Colombo, Brasil (josileia.zanatta@embrapa.br; marcos.rachwal@embrapa.br; wilson.holler@embrapa.br; bruno.bordron@gmail.com; marcelo.rossi@embrapa.br; rosana.higa@embrapa.br)

A estimativa do carbono (C) contido nas florestas plantadas é feita com base na produtividade média nacional, que não reflete as variações devido ao clima, solo e material genético. O objetivo deste estudo foi estimar o estoque de C das florestas plantadas no Brasil seguindo procedimentos do IPCC, e produtividades regionalizadas por tipo climático, para 2017. A produção de eucalipto foi identificada em 9 tipos climáticos, sendo as maiores áreas no Aw (31%), Cfa (22%), Cwa (12%), Cfb (10%), Am (10%) e Cwb (7%). O pinus está presente no clima Cfb predominantemente (81%), enquanto acácia negra fica restrita ao Cfa. Baseado em levantamento bibliográfico foi identificado a produtividade de biomassa da parte aérea, do sistema radicular e da necromassa para cada região climática. Para o eucalipto o incremento médio anual de C (IncRef) variou de 5,9 t C/ha/ano no clima Am até 16,1 t C/ha/ano no clima Cfb. O pinus teve IncRef de 7,3 e 5,6 t C/ha/ano para os climas Cfa e Cfb, respectivamente. Na acácia negra, o IncRef foi de 6,5 t C/ha/ano. A razão parte aérea raiz foi estimada em 0,21 para pinus e eucalipto e 0,12 para acácia negra. O fator de expansão para necromassa foi de 14% para pinus e 13% para eucalipto e acácia. O estoque de C total do reflorestamento no Brasil em 2017 foi de 508 milhões de toneladas de C, dos quais eucalipto respondeu por 76%, pinus por 23% e acácia negra 1%.

B4v: LEGACIES OF DISTURBANCES ON FOREST FUNCTIONS**Dynamics of pioneer tree species in dense ombrophilous forests affected by fire in western Pará, in the Amazon region of Brazil / Dinâmica de espécies arbóreas pioneiras em floresta ombrófila densa atingida por fogo no oeste do estado do Pará, Amazônia, Brasil**

Dárlison Fernandes Carvalho de Andrade^{1,1}, João Ricardo Vasconcellos Gama¹, Ademir Roberto Ruschel³

¹Universidade Federal do Oeste do Pará, Santarém, Brasil; ²Instituto Chico Mendes de Conservação da Biodiversidade - ICMBio Santarém Brasil;

³Embrapa Amazônia Oriental, Belém, Brasil (darlisonicmbio@gmail.com; jrvagama@gmail.com; ademir.ruschel@embrapa.br)

Os incêndios em florestas úmidas na Amazônia têm potencial para alterar taxas de recrutamento e mortalidade de árvores, composição florística e aumentar a densidade de espécies pioneiras. Neste estudo, a dinâmica de recrutamento de espécies arbóreas pioneiras foi monitorada, por meio de dados de inventário em 12 parcelas permanentes de 0,25 hectares, ao longo de 29 anos (1983 - 2012), sendo 5 (cinco) parcelas atingidas por incêndio (T1-fogo), em 1997, e 7 (sete) parcelas controle (T0-semfogo), em área de floresta ombrófila densa, sem histórico de distúrbios antrópicos, na Floresta Nacional do Tapajós. O estudo buscou responder: qual o efeito do fogo no aumento das taxas de recrutamento de espécies pioneiras em uma floresta ombrófila densa na Amazônia Central? Para isto calculamos o tamanho da população de espécies arbóreas pioneiras em períodos anterior (1983-1995) e posterior ao fogo (1995-2012), analisamos as mudanças nas taxas de recrutamento ao longo do tempo e avaliamos quais espécies se beneficiaram com o ambiente pós-fogo. Antes do fogo, as taxas de recrutamento para as pioneiras variaram entre 0,31 árvores ha⁻¹ ano⁻¹ (1987-1989) a 0,94 árvores ha⁻¹ ano⁻¹ (1983-1987) e, após o fogo aumentou para 6,05 árvores ha⁻¹ ano⁻¹ (1995-2008) e 5,11 árvores ha⁻¹ ano⁻¹ (2008 e 2012). Em T0-fogo, a maior taxa de recrutamento registrada para as pioneiras foi de 1,33 árvores ha⁻¹ ano⁻¹ (1987 e 1989). As condições pós-fogo da floresta foram favoráveis ao aumento das taxas de recrutamento de espécies pioneiras, principalmente *Cecropia sciadophylla* e *Aparasthmium cordatum* que se destacaram no ambiente pós-fogo.

Changed land-use and increased deer browsing reduce the oak regeneration niche at a landscape-scale

Linda Petersson¹, Per Milberg², Johan Bergstedt², Jonas Dahlgren³, Annika Felton¹, Frank Götmark¹, Carl Salk¹, Magnus Löf¹

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²Linköping University, Linköping, Sweden; ³Swedish University of Agricultural Sciences, Umeå, Sweden; ⁴University of Gothenburg, Gothenburg, Sweden (linda.petersson@slu.se; per.milberg@liu.se; johan.bergstedt@gmail.com;

jonas.dahlgren@slu.se; annika.felton@slu.se; frank.gotmark@bioenv.gu.se; carlsalk@gmail.com; magnus.lof@slu.se)

Rapidly changing land-use and disturbance regimes may reduce tree regeneration niches and thereby affect the forest ecosystem services. However, it is difficult to disentangle complex effects influencing regeneration processes on long-lived tree species at large scales. We use Swedish National Forest Inventory data (1953-2015) combined with ungulate hunting data (1960-2015) to reveal experimentally-intractable processes impeding oak (*Quercus* spp.) regeneration in southern Sweden. Oak-dominated ecosystems are widespread in northern temperate regions, where they provide multiple ecosystem services and harbor biodiversity. Our study reveals that during the six decades, oak tree numbers increased continuously, while natural oak regeneration declined steeply after the early 1980s. We connect this decline to denser and darker forests, combined with an overabundance of deer. Land-use changes during the six decades (e.g. abandonment of forest grazing and large-scale introduction of forest management oriented towards high volume production) led to continuously denser forests and thereby reduced the oak regeneration niche. Moreover, the negative effect of changed game management was evident. This was particularly clear from a

natural experiment on Gotland, a large island that lacked wild ungulates until roe deer were introduced in the late 20th century, resulting in a steep decline of oak regeneration on the island. Active management that resemble previous disturbance regimes and restore forest habitats with more light and less browsing pressure therefore seem essential. The latter includes developing strategies that manage both ungulate populations and their available food across landscapes.

Mapping burned forest recovery using time-series satellite images

Xianlin Qin^{1,2}, Xiaotong Li¹, Qian Liu¹, Guifen Sun¹, Shuchao Liu¹

¹Institute of Forest Resources Information Technique, Chinese Academy of Forestry, Beijing, China; ²Forestry Remote Sensing and Information Technology Laboratory of State Forestry Administration, Beijing, China (noaags@ifrit.ac.cn; girl19950388@qq.com; olivia250864095@163.com; sunguifen12@163.com; 83453418@qq.com)

To satisfy the monitoring technology needs for the long-term effect on forest growth and restoration by forest fires, the burned forest area formed in May 6, 1987 in the Great Xing'an Mountain of China has been selected as the experimental area. Based on the selected time-series of Landsat TM/ETM+ images, the stand regrowth index (SRI) and the relative regrowth index (RRI) have been used to study annual changes of vegetation regeneration in different disturbance intensity during 30 years after the fire. The SRI showed that the vegetation could recover to the pre-fire vegetation state in the third year after the fire for the light burned area, 6 years for the moderate burned area, and 14 years for the severe fire area. However, according to the RRI, it took 8 years to restore to the same state as the post-fire normal vegetation for the light burned area, 13 years for the moderate burned area, and 14 years for the severe fire area.

Ecological modelling of hawk moths (Insecta: Lepidoptera) of kerala part of Western ghats using climatic variables

Sheik Mohammed Shamsudeen¹, Wah Wah Linn²

¹Sir Syed College, Kannur University, Taliparamba, Kannur-670142, Kannur, India; ²Forest Protection Sub Section, Forest Reserach Institute, Yezin, Nay Pyi Taw, Myanmar (rsmshamsudeen@gmail.com; wahwahlinn48@gmail.com)

Like butterflies being so diverse and ecologically important, Hawk Moths are affected by disturbances to their habitat and climatic change. The moths which are being conspicuous insects like butterflies and dragonflies are therefore particularly valuable in monitoring ecological changes and serve to warn us of today's deteriorating environment. They have a significant and beneficial role as the pollinators. Distribution range and status of Sphingidae are often a prerequisite information for developing appropriate conservation strategies. However, most often several surveys failed to collect such data largely because of time, financial, labour and in accessible terrain conditions. Considering these facts, we predicted the geographic distribution of Ecologically important Hawk Moths Kerala part of Western Ghats using ecological niche modelling paradigm (Maxent algorithm) with a set of eco-geographical variables (Bioclimatic and topographic variables). The geo-coordinates of occurrence localities of the Sphingidae were recorded during the long term study on Lepidoptera in the Southern Western Ghats. The result revealed that high probability sites were found in the low and mid elevation forests of Kerala. Among the eco-geographical variables, MODIS Tree cover had the highest gain when used in isolation, which therefore appears to have the most useful information by itself. The environmental variable that decreases the gain the most, when it is omitted, is altitude, which therefore appears to have the most information that isn't present in the other variables. Hence, conservation of low and mid elevations forest patches is required for the long term conservation of Hawk Moths in Kerala part of Western Ghats.

Recover of boreal forest functions after fire and clear-cutting

Frank Berninger¹, Narasinha Shurpali², Ville Kasurien², Marjo Palviainen³, Kajar Köster³, Xuan Zhou³, Heidi Aaltonen³, Anatoly Prokushkin⁴, Jukka Pumpanen²

¹University of Eastern Finland, Joensuu, Finland; ²University of Eastern Finland, Kuopio, Finland; ³University of Helsinki, Helsinki, Finland; ⁴Sukachev Forest Institute, Krasnoyarsk, Russian Federation (frank.berninger@uef.fi; narasinha.shurpali@uef.fi; ville.kasurinen@helsinki.fi; marjo.palviainen@helsinki.fi; kajar.koster@helsinki.fi; xuan.zhou@helsinki.fi; heidi.m.aaltonen@helsinki.fi; prokushkin@ksc.krasn.ru; jukka.pumpanen@uef.fi)

Fire has been the dominant disturbance in boreal forests. However, larger and larger boreal areas are regenerated by clearcutting. Clearcutting and fire differ since fire removes a large part of the organic layer and the ground vegetation. However, clearcutting removes tree stems and often also tree foliage. Here we use various published data sources to compare carbon and nitrogen balances of boreal forests over several decades after disturbance. The results indicate that carbon stocks of southern more productive ecosystems recover more rapidly from disturbances and that the carbon stocks of older stands in these are higher than in northern less productive forests. Stands, after a stand-replacing fire, recover less rapidly than stands after clearcutting. Fire, also, leads to a substantial reduction of nitrogen stocks which has to be replaced gradually over time. It was not easy to estimate the recovery of soil carbon stocks after the disturbance since there was quite a lot of scatter in the data. Besides, we analysed patterns in vascular diversity as well as wood volume for fire chronosequences only. Diversity was highest in middle-aged stands. Wood volume started to decrease in northernmost stands due to paludification.

Influences of agricultural and forestry land uses on the microclimate of natural forests / Influencia de los usos del suelo pecuarios y forestales sobre el microclima de bosques naturales

Maria Constanza Meza Elizalde^{1,2}, Dolors Armenteras Pascual³

¹Maestría en Manejo, Uso y Conservación del Bosque. Universidad Distrital Francisco José de Caldas., Bogotá, Colombia; ²Grupo de Investigación en Ecología del Paisaje y Modelación de Ecosistemas. Universidad Nacional de Colombia. Bogotá Colombia; ³Universidad Nacional de Colombia, Bogotá, Colombia (mmezae@unal.edu.co; darmenterasp@unal.edu.co)

Los bordes generan cambios en la humedad de los bosques que influyen en las respuestas de las especies. Para evaluar esta influencia en fragmentos amazónicos colombianos, se cuantificó el alcance y magnitud de la pérdida de humedad desde bordes de pastos y plantaciones de caucho hacia el interior del bosque, a partir de análisis multitemporales y multiescalares de los cambios en la estructura del paisaje, variables climáticas, la vegetación y la desecación del dosel en el periodo 1989–2016. Se emplearon imágenes satelitales, transectos de vegetación y sensores de temperatura y humedad atmosférica. Se evidenció una expansión de las áreas de pastos y una reducción del 56,34% de las áreas de bosque, los índices NDMI y SIWSI reflejan pérdidas de humedad y aumento del estrés hídrico de la vegetación que se extienden hacia el interior de los relictos boscosos. La respuesta de la humedad difiere según la cobertura adyacente, las plantaciones de caucho proporcionan un buffer que mantiene la humedad del bosque, mientras que hay una pérdida significativa de la humedad cuando los bosques limitan con pastos, en las zonas de mayor estrés hídrico hay menor diversidad y dominan especies forestales características de ambientes perturbados. Los resultados encontrados señalan que para aumentar la tolerancia a la sequía de los bosques se deben considerar los contrastes entre la matriz y los relictos, y definir estrategias orientadas a la reducción de bordes abruptos y el impulso de usos de la tierra que proporcionen condiciones para la protección del microclima de los bosques.

Academic contribution to formulating policies on the topic of forest fires and forest governance / *Aporte de la academia a la formulación de políticas en torno al tema de incendios forestales y gobernanza forestal*

Maria Constanza Meza Elizalde¹, Tania Marisol Gonzalez¹, Dolors Armenteras Pascual¹

¹Grupo de Investigación en Ecología del Paisaje y Modelación de Ecosistemas, Universidad Nacional de Colombia, Bogotá, Colombia (mmezae@unal.edu.co; tmgonzalezd@unal.edu.co; darmenterasp@unal.edu.co)

Los incendios de la vegetación han sido un proceso ecológico natural presente en los trópicos, influyendo en la estructura del paisaje, en la composición de especies y en la diversidad biológica. Sin embargo, también han estado presentes como una perturbación antropogénica en prácticas de gestión del suelo y son un motor de degradación de los bosques. Considerando la dinámica de los incendios forestales en Colombia y los efectos negativos que tienen sobre los bosques, se propone cerrar las brechas entre la ciencia y la política, respaldando con las investigaciones realizadas la formulación de legislación que atienda la problemática de Incendios Forestales y Degradación de Bosques por esta causa. Se recopiló la investigación científica de más de 10 años en incendios forestales, se realizó la revisión documental de la propuesta normativa para identificar los vacíos en torno al tema en la legislación nacional, se realizaron talleres con diferentes actores (parques nacionales, entes territoriales, autoridades ambientales, empresas forestales, acueductos comunitarios, tomadores de decisiones y comunidades) para identificar su percepción sobre el tema, se crearon espacios de coordinación para aunar esfuerzos y visibilizar el tema en los instrumentos de planificación territorial, y se diseñaron estrategias de comunicación incluyentes. Con la información cuantitativa y cualitativa recopilada, se ha respaldado la formulación de política pública de forma conjunta con el Congreso de la República, se han establecido acuerdos de voluntades entre diferentes actores y se ha aterrizado el tema a instrumentos de planeación como los Planes de Ordenación de Cuencas Hidrográficas.

Carbon capture in Andean forests within private nature reserves in Zapatoca (Santander, Colombia) / *Captura de carbono en bosques andinos de dos reservas naturales de la sociedad civil en Zapatoca (Santander, Colombia)*

Carolina Serna¹, Jaime Polanía¹

¹Universidad Nacional de Colombia sede Medellín, Medellín, Colombia (csernac@unal.edu.co; jhpolaniav@unal.edu.co)

El carbono capturado por un bosque es crucial para estimar sus servicios ecosistémicos. Este estudio estimó la biomasa aérea y el carbono almacenado en dos reservas naturales de la sociedad civil (en adelante RNSC), en Zapatoca (Santander, Colombia). Una de ellas (RNSC-PF) fue creada hace aproximadamente 10 años, y otra (RNSC-MM) hace cinco y comparten zona de vida bh-PM. En los predios de las RNSC se desarrollaron previamente tala indiscriminada y ganadería extensiva, pero aún conservan relictos de *Quercus humboldtii* ('roble'), amenazados. También cuentan con otras formas de sucesión vegetal y especies emblemáticas (e.g. *Ceroxylon quindiuense* y *Tremarctos ornatus*). El protocolo IDEAM permitió estimar C capturado y biomasa a partir del diámetro de individuos DAP ≥ 10 cm en 58 parcelas permanentes de 400 m², así como en subparcelas de 25 m² (allí se midieron los individuos $5 \leq \text{DAP} < 10$ cm). Hubo diferencias entre parcelas más conservadas y aquellas en recuperación. RNSC-PF presentó mayor acumulación de C (64,67 mg/ha en promedio, versus RNSC-MM: 44,64 mg/ha); así como máximos y mínimos (v.gr. bosque denso: 224,70 mg/ha y vegetación secundaria: 0,92 mg/ha). Comparativamente, bosques secundarios de otras cordilleras andinas colombianas capturaron en promedio 20,9 mg/ha (en Antioquia), y bosques de 'roble' 197,8 mg/ha (en Huila), equivalente al bosque denso de Zapatoca. El C fijado por ecosistemas forestales puede mitigar efectos del cambio climático y, por lo tanto, confirma la importancia de formas alternativas de áreas protegidas.

B4w: LEGACIES OF DISTURBANCES ON FOREST FUNCTIONS

Complex disturbance histories in seasonal tropical forests from western Thailand: evidence and implications

Patrick Baker¹, Sarayudh Bunyavejchewin^{2,3}

¹University of Melbourne, Richmond, Australia; ²Department of Forest Biology, Faculty of Forestry, Kasetsart University, Bangkok, Thailand; ³Department of National Parks, Wildlife, and Plant Conservation, Bangkok, Thailand (patrick.baker@unimelb.edu.au; sarayudh_b@yahoo.com)

The legacy of disturbance on tropical forest functioning is poorly understood due to the lack of annual growth rings in most tropical tree species. Recent advances in tree-ring research in seasonal tropical forests have begun to address this issue. Here we describe the historical legacy of disturbance in an area of Thailand's Western Forest Complex based on dendrochronology and long-term, large-scale forest dynamics plots. Over the past 200 years these forests have been impacted by disturbances that vary in intensity, spatial scale, and return interval. We found that evergreen and deciduous forest types within the broader landscape mosaic had all experienced complex disturbance histories, with landscape-scale disturbances impacting all forests and forest types at the decadal to centennial scale, and more stochastic, small-scale disturbances impacting different forest types at the annual to decadal scale. Extreme climate events, particularly ENSO-driven droughts, appear to drive landscape-scale fires, which generate a synchronous pulse of treefall gaps across hundreds of square kilometres. Interactions between regional climate variability, disturbances, and reproductive phenology may lead to a wide range of potential stand development trajectories in these forested landscapes complicating strategies for restoration and management.

Increasing end-user participation in the management of forest risk through integrated open-access tools

Barry Gardiner¹, Christophe Orazio¹, Sarah Yoga¹, Tommaso Locatelli², Duncan Heathfield³

¹EFI Planted Forests Facility, Cestas, France; ²Forest Research, Roslin, United Kingdom; ³World in a Box Finland OY, Karkkila, Finland (barry.gardiner@efi.int; christophe.orazio@efi.int; sarah.yoga@efi.int; tom.locatelli@forestry.gsi.gov.uk; duncan.heathfield@worldinabox.eu)

In order to develop resilient forests it is necessary to understand the factors affecting the level of risk from different hazards. In addition it is critical to know how these risks change with management choices and with the changing climate in order to develop adaptive management strategies. In this paper we discuss the creation of an open-access system for calculating the risk of wind damage to forests. The system combines the predictions of the Forest GALES wind risk model and the industry standard airflow model WAsP within the open-access QGIS software. The combined system allows calculation of wind risk within a forested landscape and the impacts of tree growth and forest management choices. Because the models are incorporated within GIS software the models can be integrated with standard forest management plans and environmental data sets, such as LiDAR measurements of tree and terrain heights, in order to calculate the level of risk at all scales from individual trees to the landscape. To make the system useful and applicable within the forestry sector a series of workshops has been organised in south-west France, the Spanish Basque country and Scotland to train foresters and forest owners in the software and to receive feedback on how it can be improved. In addition, there has been close liaison with the regional authorities in these regions in the incorporation of the software in the forest risk management process as part of regional crisis management plans.

The assessment of forest disturbance and vulnerability from 2000-2015 year in Kao Ping River Basin of Taiwan

Ya-Li Huang¹, Chaur-Tzuhn Chen¹, Jan-Chang Chen¹

¹Forestry department, National Pingtung University of Science and Technology, Pingtung, Taiwan (goodrinoa93@gmail.com; goodrinoa93@gmail.com; goodrinoa93@gmail.com)

Taiwan is located on the Pacific seismic belt where the geological structure is more complex, and cause frequent landslides, debris flows and other sediment disasters. Chishan and Lennon river working circle lays in the national forest land of Kaoping river basin, and was greatly damaged by 2009 Morakot typhoon, thus, the understanding of land cover change before and after typhoon were important tasks in watershed management. In this study, the variation of forest disturbance index (DI) from 2000-2015 was obtained through Tasseled Cap Transformation. Moreover, estimating the distribution of environmental vulnerability through Principal Components Analysis, reduces the number of environmental variables and determines the weight of principal components. The results shows that Landslides has indeed disturbed Chishan and Lennon river working circle. The Integrated of Disturbance Index (IDI) of Chishan were 2.128, 2.751 and 2.670, respectively, which represents that some areas were damaged by Morakot typhoon were partially recovered after 2015. There were no significant change in the annual IDI of Lennon river working circle; however, differences between each DI level of sample plot was found. The environment vulnerability in Chishan and Lennon River were classified as heavy and extreme level of environmental vulnerability accounts for 38% and 31% of the area, mostly are located in relatively high altitude and steep terrain, where vegetation renewal and restoration is unlikely to happen. Facing extreme climate challenges, the forest watershed management must be based on the principle of ecological management and forest structure, in order to maintain the balance of the ecosystem.

The Weakest Link: assessing vulnerabilities, risks, and tree adaptive capacity of temperate forests to global changes

Rita Sousa-Silva¹, Frédéric Doyon², Philippe Nolet²

¹UQAM, Montreal, Canada; ²ISFORT, Ripon, Canada (anarita.silva@kuleuven.be; frederik.doyon@uqo.ca; philippe.nolet@uqo.ca)

Forests are shaped by disturbances – for better or worse. Disturbances can be analysed individually, but it is their interactions that are likely to lead to megadisturbances regimes – such as hotter droughts and more extensive and severe wildfires – challenging the main objectives of forest management, which are to provide ecosystem services sustainably to society and to restore or maintain its resilience. Applying resilience concepts in forest management is especially relevant in a context of climate variability because the stochastic nature of disturbances often makes them difficult to predict. The resistance of a forest to disturbance depends largely on the species composition of the canopy trees that currently dominate the forest; yet its adaptive capacity may reside primarily in future canopy replacement by trees of the same or other species. Therefore, we focused on (i) the effect of disturbances on a subset of biological characteristics (e.g., dispersal, shade tolerance) of 30 tree species of temperate forests; and (ii) their tolerance to a wide range of disturbances (e.g., drought, insects) for both the overstory and regeneration strata. While recognizing that ecosystem collapse will likely manifest itself differently depending on landscape context, we provide a systematic approach that can be applied to any forest to evaluate the risk of collapsing, as a result of loss of ecosystem resistance and resilience. We argue that, given the complexities and uncertainties related to increasingly frequent and severe disturbances, management should aim at increasing diversity thus keeping more options open for the future if conditions or responses change.

Changes in land use and ground coverage from 1985 to 2017 in the production of sediments in the Taquari River Basin / *Varição das mudanças no uso e cobertura da terra entre 1985 e 2017 na produção de sedimentos da Bacia do Rio Taquari*

Rafael Mingoti¹, Isabelle Caroline Ribeiro Sais², Carlos Roberto Padovani², Marcia Divina Oliveira³, Debora Fernandes Calheiros³

¹Embrapa Territorial, Campinas, Brasil; ²Universidade Estadual de Campinas, Campinas, SP, Brasil; ³Embrapa Pantanal, Corumbá, Brasil (rafael.mingoti@embrapa.br; isabellersais@gmail.com; carlos.padovani@embrapa.br; marcia.divina@embrapa.br; debora.calheiros@embrapa.br)

O objetivo desse trabalho é comparar o efeito da alteração do uso e cobertura da terra, entre os anos de 1985 e 2017, na produção de sedimentos da sub-bacia do Rio Taquari. Essa bacia possui área de drenagem de 26.924 km² e está localizada na Bacia do Alto Paraguai, na região do Planalto do Pantanal brasileiro. Foram utilizados mapeamentos de uso e cobertura da terra, elaborados com imagens do satélite Landsat, por meio dos quais verificou-se a supressão de 48,4% na vegetação nativa no período analisado, sendo substituída predominantemente por pastagem. Em 1985 a cobertura vegetal nativa ocupava 18.000 km² da área da sub-bacia e em 2017 passou a ocupar 9.280 km². A estimativa da produção de sedimentos foi realizada por meio do modelo hidrológico SWAT, aplicativo ArcGIS, mapa pedológico, dados de atributos de solos e de uso da terra e dados meteorológicos diários. Verificou-se que as alterações de uso e cobertura da terra promoveram aumento médio de 30,5% na produção de sedimentos, sendo que em algumas microbacias o aumento na produção de sedimentos foi de 157%. As regiões em que a mudança no uso e ocupação acarretou maior aumento na produção de sedimentos estão localizadas nos municípios de Alcinópolis/MS, Camapuã/MS, São Gabriel do Oeste/MS, Figueirão/MS, Coxim/MS e Alto Araguaia/MS. Os resultados gerados poderão subsidiar os diferentes órgãos públicos na tomada de decisão para o planejamento de ações prioritárias de conservação do solo.

Economic value of ecosystem service losses due to disturbances in Western United States forests

Jose J. Sanchez¹, Lorie Srivastava², Raymundo Marcos-Martinez³

¹USDA Forest Service, Pacific Southwest Research Station, Riverside, USA; ²University of California, Davis, Davis, USA; ³National Research Collections Australia Canberra, Australia (jsanchez@fs.fed.us; lsrivastava@ucdavis.edu; raymundo.marcosmartinez@csiro.au)

The increasing severity and frequency of environmental climate-driven forest disturbances challenge the sustainable management and protection of forests in the United States (U.S.), and the benefits they provide to individuals and communities. Between 1985 and 2015, about 9 million acres of U.S. forest land was disturbed annually across the country. In the western U.S., wildfires, droughts, timber harvesting, and bark beetle outbreaks are the main drivers of tree mortality, loss of recreation opportunities, and water quantity. An understanding of the environmental and socioeconomic consequences of forest disturbances could improve the management and protection of public lands. This study provides monetised estimates of forest disturbances for two key areas of value: recreation and carbon storage. We estimate the monetary value of these ecosystem services and how they are affected by fire, drought or disease due to climate change. We employ benefit function transfer to estimate the economic value of forest ecosystem services – both market and non-market values. This information may improve stakeholders' understanding of how heterogeneous forests disturbances affect economic and environmental processes at different temporal and spatial scales. The results could also inform the design of spatially targeted forest conservation, pest control, or fire suppression strategies to generate greater benefits to society.

Prioritization of forest patches for conservation through geotechnologies

Ana Paola Di Toro¹, Roberta Valente¹, Eliana Cardoso-Leite¹

¹Universidade Federal de São Carlos, Sorocaba, Brasil (anapaolagomes@hotmail.com; roavalen@ufscar.br; cardosoleite@yahoo.com.br)

Forest patches in rural and urban landscapes have been the main responsible for their biodiversity maintenance. Despite of that, they are suffering constant both cropland and urbanization pressure. So, aiming at the forest conservation, strategies of environmental planning are needed, which should be supported by the knowledge of forest patches dynamic. In this context, we aimed to show the Patches Prioritization Index (IPP) application for biodiversity conservation planning, at the municipality of Boituva - São Paulo, Brazil. Firstly, we identified the forest remnants (bigger than 5 ha), that represents either Atlantic forest and Cerrado type, basing in the remote sensing image (5 m resolution) and, using a supervised classification (MaxLike algorithm). The Normalized Difference Vegetation Index (NDVI) was calculated to separate the forest types. Basing in the Atlantic forest patches map, we calculated the IPP value, that is composed by the metrics "AREA", "SHAPE" and "CONNECTIVITY", including weights, which reflect their importance to forest conservation. It were mapped 155 fragments of native vegetation, occupying 9.62% of the area of the municipality. All of them were classified into three priority classes (high - 9,03%, medium - 82,6% and low - 8,38%) for biodiversity conservation. We concluded that IPP is accurate to determine priority forest remnants for biodiversity conservation, due to the techniques and metrics used, which were precise to support environmental planning with focus on biodiversity conservation, and these data can be used by decision markers in landscape management.

B4x: NOVEL REMOTE SENSING APPROACHES TO QUANTIFY CARBON STOCKS, STRUCTURE AND FUNCTIONAL DIVERSITY OF FORESTS - 1

Evaluation of persian oak forests die-back using Spot 6

Mohammadreza Negahdarsaber¹, Mehrdad Zarafshar¹

¹Agricultural Research, Education and Extension Organization (AREEO) Research institute of forest and range land - Forest Department, Shiraz, Iran, Islamic Republic of (sabersiamak@gmail.com; mehrdadzarafshar@gmail.com)

Iranian oak has been affected by oak canopy level dieback in recent years. This phenomenon has led to damage a vast part of the oak forests in the Zagros arena. As to the suitable temporal and special resolution of the recent satellite images, it seems promising to detect the forest dieback by remote sensing. The spatial capabilities of Spot 6 images with pan and spectral resolution of 1.5 and 5 m, respectively in detecting the drying of oak trees was investigated. The forest area was located on Kuhmareh district of Shiraz in Fars province. The results showed that by using standard deviation values, the NDVI value of each tree base can be estimated for the stocks with more than 30% of dieback using the obtained equation as $y = 19.96(x - 0.04) - 0.21$ with an $R^2 = 79$. Monitoring forest areas to understand the decline or recovery of trees will be of great help to the forest management community. Therefore, using the results of this study can be a proof to compare the current situation with future periods.

Mapping of potential carbon storage in kalimantan (Indonesia) forests, using the high carbon stock approach (HCSA) criteria by airborne LiDAR

Olivier Matte¹

¹Université Laval, Québec, Canada (olivier.matte.5@ulaval.ca)

Forests in Southeast Asia are under heavy pressure from extensive land-use activities, including oil palm plantations. The desire to protect and manage habitats with high carbon storage potential has increased the need for preserving the unique ecosystems of local forests. To preserve tropical forest ecosystems from agricultural expansion, a methodology for classifying forests with high carbon storage potential, known as the High Carbon Stock Approach (HCSA) was developed. Our research objective is to evaluate the efficiency of using airborne LiDAR for HCSA classification. To do this, we will examine the above-ground biomass using the equation developed by Asner (2018) and Jucker (2017), established in the Sabah territory, as well as LiDAR metrics such as canopy height, canopy cover, and the forest basal area. LiDAR metrics of forest structure will also be used to try to differentiate HCS classes. LiDAR data and field surveys were collected from the Jet Propulsion Laboratory (JPL - NASA). The area of interest for this study covers part of the Kalimantan territory (Indonesian part of Borneo). The data collected has been part of the ongoing Carbon Monitoring System (CMS) project. The results will develop a forest classification methodology based on the airborne LiDAR HCS approach within Southeast Asian forests.

Testing four models to estimate eucalyptus volumes using airborne LIDAR / Teste de quatro modelos para estimativa de volume de eucalipto utilizando LiDAR aerotransportado

Rodrigo Leite¹, Cibele Amaral¹, Hélio Leite¹, Renata Macedo¹, Brenner Oliveira¹, Lucas Arthur de Almeida Telles¹, Antonilmar Silva²

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Cenibra - Celulose Nipo-brasileira S.A, Belo Oriente, Brasil (rvieiraleite@gmail.com; cibelega@gmail.com; hgleite@gmail.com; renata.macedoufv@gmail.com; b.oliveiraefl@gmail.com; lucasarthur36@gmail.com; antonilmar.silva@cenibra.com.br)

Sensores LiDAR aerotransportados podem ser utilizados para estimativas de densidade, altura, biomassa e volume de florestas, com exatidão similar a métodos convencionais com a vantagem de possibilitar a espacialização dos dados. Uma das abordagens mais comuns para se obter essas estimativas é a partir da relação entre as métricas LiDAR (estatísticas referentes às nuvens de pontos) e a variável dendrométrica de interesse. Esse estudo teve por objetivo estimar o volume de um plantio de eucalipto a partir de métricas geradas de dados LiDAR. Para isso, utilizou-se dados de 17 talhões de eucalipto somando aproximadamente 470 ha. Para cada talhão foram calculados: volume, através de dados de inventário, e 93 métricas, utilizando uma nuvem de pontos gerada a partir de LiDAR aerotransportado. O número de métricas a serem utilizadas nos modelos foi reduzido a cinco, utilizando o método Recursive Feature Elimination. Quatro modelos foram testados: Random Forest (RF), Máquina de Suporte de Vetor (MSV), Cubist e Linear. Utilizou-se como variável de entrada as métricas e volume como variável de saída. Os dados foram separados em 70% para ajuste e 30% para validação dos modelos e foram avaliados utilizando as estatísticas R^2 e RMSE. Os valores de R^2 e RMSE dos modelos variaram entre 0,82 a 0,97 e 21,2 a 69,75 m³/ha, respectivamente. Os resultados mostram um bom desempenho dos algoritmos testados para estimativa de volume, utilizando cinco métricas LiDAR. Futuros estudos podem ser feitos variando-se o número de métricas para verificar o desempenho dos modelos.

Use of low-density LiDAR to characterize structural attributes of restored areas in the Atlantic Forest

Frederico Tomas de Souza e Miranda¹, Girlei Costa Cunha¹, Susane Raseira², Eduardo Gusson¹, Flávio Bertin Gandara Mendes², Raquel Aparecida Passaretti³
¹Biodendro Forest Consulting, Piracicaba, Brasil; ²Luiz de Queiroz College of Agriculture, Piracicaba, Brasil; ³AES Tietê, Bauru, Brasil
 (fredsmiranda@gmail.com; girlei.cunha@gmail.com; susaneraseira@yahoo.com; eduardogusson@gmail.com; fgandara@usp.br; raquel.passaretti@aes.com)

Restored areas monitoring is a current subject of study due to the growing demand for large scale degraded ecosystems restoration. Remote sensing has been used for evaluating restored areas, and among new geotechnologies, the Light Detection and Ranging (LiDAR) has a wide advantage by enabling a three-dimensional analysis of forest structure. However, the high cost of scanning, mainly when there are high densities of points per square meter, limits a more detailed study of plant structure. Through the metrics extracted from the low-density points LiDAR (3 pts/m²), our first aim was to estimate the biomass (t/ha) of an experimental restored area at 10 years, with different spatial arrangements (3 x 1 m and 3 x 2 m), managements (usual and maximum) and species proportions of pioneers and non-pioneers. We also aimed to try to discriminate the plots with different spatial arrangements and proportions of ecological groups using the metrics extracted from the LiDAR. The results showed that the number of returns up to the average height, the percentiles of return between 25% and 99%, and the canopy relief ratio, obtained larger correlations with the biomass per plot, all with R² above 0.75, especially the average height (R² = 0.81; p-value < 0.001). We were able to discriminate the plots with the 3 x 1 m arrangement from the 3 x 2 m using the return percentiles between 20% and 35%. The 3 x 2 m plots had more returns in the lower parts of the vertical stratum and smaller biomass. In conclusion, low-density points clouds were able to characterize important restored areas vegetation attributes.

Resilient future forests development platform

Palle Madsen¹, John Stanturf², Ahto Kangur², Marek Metslaid²

¹InNovaSilva, Vejle, Denmark; ²Estonian Univ. of Life Sciences, Tartu, Estonia (palle.madsen47@gmail.com; drdirt48@gmail.com; ahto.kangur@emu.ee; marek.metslaid@emu.ee)

Forest growth is the main driver of climate change mitigation; additional mitigation will be proportional to the area managed and restored into highly-productive forests. The Sustainable Intensification Principle has become an important driver of climate change mitigation. The intensively managed and highly-productive planted forests component of the global forest resource and as part of FLR efforts can contribute to the implementation of this principle, which may be applied to other land-uses as well, including agriculture, agroforestry, horticulture and nature conservation. Such mosaic forests can serve a range of important functions and ecosystem services in addition to carbon sequestration. To validate this approach, field experiments and modeling are needed to provide evidence for managers and decision makers. Field experiments generate experimental data to develop, document, demonstrate and support implementation of new or alternative cost-efficient silvicultural and restoration methods that result in high CC-mitigation capacity of the forests. Installation and management of long-term field experiments, however, is constantly under pressure because they are seen as expensive science infrastructure to establish and maintain. Nevertheless, new and rapidly developing technology based on remote sensing and terrestrial LiDAR offer lower cost measurement and inventory methods that may pave the road for a new generation of field experiments. We explore the content and structure of a global scientific platform for shared data to provide site-adapted and goal-oriented solutions for adaptive silvicultural practices for sustainable forest management and restoration and globally.

Use of LANDSAT 8 satellite imagery to apply vegetation indexes in characterizing vegetation cover in the Raimundo Irineu Serra environmental preservation area, 2013–2018 / Utilização de imagens do Satélite LANDSAT 8 para aplicação dos índices de vegetação na caracterização da cobertura vegetal da APA Raimundo Irineu Serra no período de 2013 à 2018

Julio Roberto da Rocha Almeida¹, Karla da Silva Rocha¹

¹Universidade Federal do Acre, Rio Branco, Brasil (julio.151094@gmail.com; rocha.karla3@gmail.com)

A demanda por estudos e metodologias que quantifiquem o estoque de CO₂ em ambientes florestais vem crescendo exponencialmente nas últimas décadas, tanto em florestas plantadas quanto em florestas tropicais. Neste sentido, o presente trabalho teve como objetivo contribuir com esta literatura no sentido de avaliar os índices de vegetação (NDVI, PRI e CO₂ Flux), visando caracterizar a cobertura vegetal, assim como estimar relações de sequestro e estoque de carbono em uma área de proteção ambiental no município de Rio Branco, AC, dentro de um período de 5 anos (2013 – 2018). Para as análises, foram utilizadas duas cenas do sensor OLI do satélite Landsat 8, a escolha das cenas tiveram como critério o período de menor cobertura de nuvens, para o processamento das imagens foram utilizados os softwares Envi 4.5 e Arcgis 10.6, onde foi realizada a correção atmosférica nas duas cenas. Os resultados encontrados apresentaram pouca diferença em relação ao estoque de carbono na APA para as duas datas em estudo, de modo a ser possível concluir que a APA vem contribuindo para a manutenção e equilíbrio do ecossistema em estudo.

Spatio-temporal evaluation of forest cover and relationship with socioeconomic data in landscapes of the Caatinga biome in the Sertão region of Pernambuco, Brazil / Avaliação espaço-temporal da cobertura florestal e a relação com dados socioeconômicos em paisagens do Bioma Caatinga no sertão de Pernambuco

Emanuel Araújo da Silva¹, Elisiane Alba², José Jorge Monteiro Júnior¹, João Pedro Mesquita Souza Santos¹, Gabriela Salami¹, Mayara Maria de Lima Pessoa¹, Rinaldo Luiz Caraciolo Ferreira¹

¹Universidade Federal Rural de Pernambuco, Recife, Brasil; ²Universidade Federal de Santa Maria, Santa Maria, Brasil (emanuel.ufrpe@gmail.com; elisianealba@gmail.com; josejorgemonteirojunior@gmail.com; joao_mesquita01@outlook.com; gabriela.salami@ufersa.edu.br; mayapessoa@gmail.com; rinaldo.ferreira@ufrpe.br)

Modelos de simulação espacial visam auxiliar o entendimento dos mecanismos causais e processos de desenvolvimento de sistemas ambientais, e assim determinar como eles evoluem frente diferentes cenários traduzindo em quadros socioeconômicos, políticos e ambientais. Esse estudo objetivou uma avaliação espaço-temporal da degradação de paisagens do bioma Caatinga, no sertão do Estado de Pernambuco, BR, por meio de imagens provenientes do sensor OLI do satélite LANDSAT-8, correlacionando com dados socioeconômicos da região, esta que sofre com a supressão de vegetação nativa devido ao mercado energético e das atividades agropecuárias e silvipastoris. Foi realizado o mosaico com as imagens adquiridas para obtenção do recobrimento total da área e criadas novas classes temáticas que correspondessem ao cruzamento das classes de uso e cobertura da terra do período estudado, obtendo assim um mapa de dinâmica da cobertura florestal e as seguintes classes: cobertura florestal consolidada, cobertura florestal regenerante, supressão da cobertura florestal e outros usos. Portanto, após avaliação, foi constatado que as variáveis provenientes do cruzamento do mapa temático com os dados socioeconômicos influenciaram

na alteração da cobertura vegetal da região. As classes temáticas regeneração e manutenção apresentaram a maior quantidade de áreas quando os fatores PIB, IDH e índice populacional estiveram altos. Constatou-se também que a densidade de caprinos é inversamente proporcional a quantidade de áreas regeneradas. A classe desmatamento se torna mais presente em áreas menos populosas e com o PIB e IDH considerados baixos, bem como em regiões onde a densidade de caprinos e bovinos é considerada alta.

Identifying heat islands in a dry forest in the Sertão region of Pernambuco, Brazil / Identificação de ilhas de calor em Floresta Seca no Sertão de Pernambuco

Emanuel Araújo da Silva¹, Fernanda Vanilly de Lira Paulo¹, Carolina Rovira Pereira Fernandes¹, José Jorge Monteiro Júnior¹, Gabriela Salami¹, Elisiane Alba², Mayara Maria de Lima Pessoa¹, Rinaldo Luiz Caraciolo Ferreira¹

¹Universidade Federal Rural de Pernambuco, Recife, Brasil; ²Universidade Federal de Santa Maria, Santa Maria, Brasil (emanuel.ufrpe@gmail.com; fernandavanilly@hotmail.com; fernandes.rovira@gmail.com; josejorgemonteirojunior@gmail.com; gabriela.salami@ufersa.edu.br; elisianealba@gmail.com; mayapessoa@gmail.com; rinaldo.ferreira@ufrpe.br)

O objetivo do estudo foi relacionar o uso da terra com o aumento da temperatura em áreas da Caatinga no sertão Pernambucano por meio de imagens do satélite LANDSAT-8 sensor TIRS e OLI, com resolução de 30 m em dezembro de 2017. Foi elaborado o mapa de uso e ocupação do solo desta região classificadas em: água, solo exposto, agropecuária e floresta. Utilizou-se o algoritmo da Máxima Verossimilhança e o ajuste atmosférico pela radiação no topo da atmosfera e o delineamento de classificação do solo foi realizado por meio de software a partir do coeficiente NDVI dos usos em questão. Calculou-se assim a emissividade do ambiente, temperatura de brilho e superfície. Para verificar a correlação realizou-se um cruzamento entre o Mapa de Temperatura e de Uso do Solo. A área de estudo apresentou 1.742.828,22 ha, os municípios de Floresta e Ibimirim apresentaram maior presença de muito solo exposto e consequentemente as áreas com maior elevação de temperatura; em contrapartida, os municípios com maior área de floresta são os municípios de maior altitude ao leste: Buique e Arcoverde. As áreas de agropecuária apresentaram temperatura moderada causada pela constante irrigação existente em algumas culturas e também à similaridade de emitância na agropecuária e Caatinga de baixo porte, que, por ser uma floresta, mantém a temperatura. É possível perceber que as ilhas de calor se formam, principalmente, em áreas de solo exposto e longe de grandes cursos d'água; refletindo a importância da vegetação da Caatinga para a manutenção das temperaturas.

B5a: CLIMATE CHANGE, ENVIRONMENT AND CONSERVATION: CHALLENGES FROM THE ANALYSIS OF TREE RINGS

Effects of competitions on the relationships between tree-ring width and climate

Biing Guan¹, Bo-Yin Chen¹

¹National Taiwan University, Taipei, Taiwan (btguan@ntu.edu.tw; b04613026@ntu.edu.tw)

One of the goals of dendrochronology is to clarify the effects of interactions between tree growth and environmental conditions across space and time, e.g. the influences of competition and climate. The main objective of this study is to understand the differences in climate signal expressions among trees grew under different initial spacings in a sugi (*Cryptomeria japonica*) plantation in central Taiwan. This study used ensemble empirical mode decomposition to develop chronologies. Correlations were calculated between the detrended tree-ring width chronologies and local monthly climatic records, including the monthly average of daily maximum temperature, the monthly average of daily mean temperature, the monthly average of daily minimum temperature, and monthly precipitation amount. Results showed that the high-frequency variations of sugi ring widths, regardless of the initial spacings, were negatively correlated with temperature, especially the temperature from the previous summer to early current winter. Except for trees grew in the narrowest initial spacing, high-frequency variations of sugi ring widths were also negatively correlated with the amount of precipitation of the previous growing season in general. Trees grew in the wider initial spacings showed stronger relationships with the local climatic factors. Only ring widths after the initial 15 to 20 years of growth had significant correlations with large-scale atmospheric-ocean circulations. In summary, sugi trees in the study area were more sensitive to local climatic variations when they grew under a weaker competition situation.

Photometric method for tree rings determination

Sergij Striamets¹, Nataliya Stryamets²

¹Lviv Politechnic National University, Lviv, Ukraine; ²Ca'Foscari University of Venice, Venice, Italy (sergijstr@gmail.com; natastr@gmail.com)

The tree rings determination is crucial for the climate change research. The photometric method of the determination of the tree rings growth on the cross-cut are proposed in this study. This method helps determinate the year trees growth on the photos of the trees cross-cut using the software. Precise determination of tree age and annual growth is done by developed and patented software by counting annual rings and measuring the distance between adjacent annual rings on the trees crosscut photos. Aim of our study was to develop and patent the photometric method and analyse the pros and cons of developed software to determinate and calculate automatically the tree rings from the tree crosscut photo. This method was patented, based on a patent the computer software was developed and tested. The pros and cons of the method and software were demonstrated. The advantages of this method are that automatic measurement of annual tree rings and are improving the accuracy, avoiding in the process of measuring the human factor influence, speed of the research and the software provides for the applicability of the linear filtering image slices, which allows to eliminate random noise in the image. The disadvantages of the method is need of places the scale ruler on the trees crosscut before taking photo. We discussed the importance of development and improvement of this method and software in order to get more precise results for tree rings determination.

Climate sensitivity of tropical tree growth: a global meta-analysis based on tree rings

Peter Groenendijk¹, Valerie Trouet², Flurin Babst^{3,4}, Pieter A. Zuidema⁵

¹Department of Plant Biology, Institute of Biology, University of Campinas – UNICAMP, Campinas, Brasil; ²Laboratory of Tree-Ring Research, University of Arizona, Tucson, USA; ³Swiss Federal Research Institute for Forest, Snow and Landscape Research (WSL), Birmensdorf, Switzerland; ⁴Department of Ecology, W. Szafer Institute of Botany, Polish Academy of Sciences Krakow Poland; ⁵Forest Ecology and Forest Management Group, Wageningen University, Wageningen, Netherlands (peterg@unicamp.br; trouet@email.arizona.edu; flurinbabst@gmail.com; pieter.zuidema@wur.nl)

Tropical forests are crucial components of the global carbon cycle. Yet, we poorly understand climatic drivers of tropical tree growth and their responses to climatic shifts. Tree-ring based global analyses of climate sensitivity typically exclude tropical regions due to a perceived lack of data. Here, we help filling

this knowledge gap with a meta-analysis of published tropical tree-ring width chronologies. We compiled > 400 tropical chronologies from various climate zones across the tropics between 30°N - 30°S. We explore i) the main climatic drivers of tropical tree growth and their clustering, ii) how tropical tree-growth variability and climate sensitivity change along temperature and precipitation gradients, and iii) how common are autocorrelation and lag effects of previous-year climate on tree growth. The main drivers of tropical tree growth are mean annual precipitation (MAP) and temperature (MAT) and we identified several climate-response clusters. The strength of the growth-precipitation correlation, the inter-series correlations and growth variability decrease with increasing MAP, but MAP does not affect autocorrelation. The strength of the growth-temperature correlation increases with increasing elevation (i.e., decreasing MAT). Increasing MAT leads to lower inter-series correlations and autocorrelation, while leading to increased growth variability. We discuss how the strength of MAP and MAT as drivers of tree-growth variability changes across tropical climate zones. We show that tree-ring studies have a strong potential to improve our understanding of global tropical forest climate-growth patterns. Our results can be used to benchmark global vegetation modelling and to understand responses of tropical tree species to climate change.

Intensifying the development of tropical tree-ring research using multi proxy measurements across temporal and spatial scales

Aster Gebrekirstos¹, Mulugeta Mokria¹, Abraham Abiyu², Achim Braeuning³

¹World Agroforestry Centre, Nairobi, Kenya; ²World Agroforestry Centre, Addis Ababa, Ethiopia; ³Institute of Geography, University Erlangen-Nuremberg, Erlangen, Germany (a.gebrekirstos@cgiar.org; m.mokria@cgiar.org; abraham.abiyu@gmail.com; achim.braeuning@fau.de)

Global climate change is modifying the patterns of rainfall variability and the composition of vegetation, with many consequences on the use and management of trees and forests. Recent advances in tropical dendrochronology shows a high number of tree species form datable annual tree rings and may reach multi century age. Tree-ring based climate reconstructions provided potentials to fill the severe lack of instrumental climate data, to understand the drivers and impact of climate, their interactions and impacts in the tropics. In turn, the gap on fundamental knowledge concerning how tropical species grow in response to climate variability, and therefore how they might react to future climatic change is substantial and can be addressed using tree-ring based data and novel quantitative wood anatomy measurements. This presentation will be highlighting on the prospects and applications of dendrochronological techniques in the tropics. We will present results from case studies in East and West Africa and South America using multi proxy measurements (ring width, carbon and oxygen isotopes, and wood anatomical techniques) to exemplify reconstructions of climate variability, trends and atmospheric circulation patterns and long-term impacts of climate variations at the species and landscape levels and their implications in forest restoration and management. In addition, we will discuss on the need to advance dendrochronology research and the development of tree-ring based networks, especially in Africa, where large scale tree ring based data is still lacking compared to other continents.

Recent advances in isotope dendroclimatology at Forestry and Forest Products Research Institute/FFPRI, Tsukuba, Japan

Akira Kagawa¹

¹Wood Anatomy and Quality Laboratory, Forestry and Forest Products Research Institute, Tsukuba, Japan (akagawa@ffpri.affrc.go.jp)

This talk reviews advances of isotope dendroclimatological research at FFPRI. Recent methodological breakthroughs in both tree-ring core sampling and cellulose extraction enabled rapid development of tree-ring oxygen isotope network in Japan, which currently dates back to 4500 yBP. In order to facilitate production of tree-ring isotope data, we have made breakthroughs in the two bottle-neck processes, i.e. core sampling and cellulose extraction. Firstly, we developed a light-weight rechargeable increment borer (Kagawa & Fujiwara 2018, Journal of Wood Science, www.smartborer.com [http://www.smartborer.com]) to facilitate collection of increment cores. Secondly, we have developed new method for rapidly processing tree-ring samples to cellulose, which makes the extraction process 10-100 times more efficient compared to the conventional methods (Kagawa et al; 2015, Chemical Geology). These methodological breakthroughs expanded the application of stable isotope analysis to various fields in Forestry research, such as estimating the geographic origins of wood for detecting illegally-sourced wood (Kagawa & Leavitt 2010, Journal of Wood Science), detecting “invisible oxygen isotope rings” of trees from Amazon (Ohashi et al 2016, Oecologia), visualizing the effects of the 2011 Tsunami on the pacific coast in Japan via tree-ring carbon isotopes of pines (Kubota et al 2017, Ecological Research), and the effects of mass fruiting on tree-ring carbon isotopes of beech (Han et al; 2016, Tree Physiology). Application of tree-ring oxygen isotopes, are currently spreading across various fields of forestry research in Japan and future applications of tree-ring isotopes into the new frontier, such as into tropical dendroclimatology, is expected.

The responses of dominant tree species to climate warming at the treeline on the eastern edge of the Tibetan Plateau

Mingming Guo¹, Yuandong Zhang²

¹International Centre for Bamboo and Rattan, Beijing, China; ²Chinese Academy of Forestry, Beijing, China (736011705@qq.com; zyd@caf.ac.cn)

Tree growth at boreal/alpine treelines is generally expected to be stimulated by climate warming. However, tree growth has been shown to have changed insignificantly or reduced in numerous studies. Tree response to climate warming also varies among species in the same eco-region. The Tibetan Plateau has experienced rapid warming in the past several decades. It remains unknown how the dominant species in this region have responded to this warming, which is expected to significantly influence treeline dynamics. We obtained 288 tree cores from fir (*Abies faxoniana* and *Abies squamata*) and spruce (*Picea purpurea* and *Picea baijfouriana*) at six treeline sites on the eastern edge of the Tibetan Plateau to detect their growth trends and climate responses. The results showed that the growth of fir did not change significantly at any site, whereas spruce growth increased, especially at the Songpan and Luhuo sites. The strong negative temperature or positive moisture controls of April on fir growth indicated spring drought stress. The radial growth of spruce was positively related to June and July temperature; at the Songpan and Luhuo sites, it was also positively related to the temperature from February to April. The results indicated that both pre-growing season temperature and growing season temperature accelerate spruce growth, whereas pre-growing season temperature causes drought stress to fir. The tree species composition at the alpine treeline on the eastern edge of the Tibetan Plateau will change as warming continues.

Influence of climate change on tree ring characteristics of *Cunninghamia lanceolata* provenances in South Subtropical China

Aiguo Duan¹, Anming Zhu¹, Jianguo Zhang¹, Xiongqing Zhang¹

¹Research Institute of Forestry, Beijing, China (duanag@163.com; 844239445@qq.com; zhangjg@caf.ac.cn; xqzhang85@caf.ac.cn)

To select the provenances adaptive to future's climate change. The different responses of tree ring width of fifty-two provenances to climate were studied by the method of dendroclimatology. It indicated that the response of the whole tree ring width, early wood width and late wood width to mean annual temperature was obvious, the maximum correlation coefficients are -0.515, -0.590 and -0.491 respectively. The response of the whole tree ring width, early wood width and

late wood width to the maximum annual temperature was also obvious, and the maximum correlation coefficients are -0.482, -0.624 and -0.499 respectively. In recent years, there is an increasing trend of mean annual temperature of test plot, which will be unfavorable to tree growth to a certain extent. It will be an effective way to solve this problem to select appropriate provenances which are not sensitive to the mean or maximum annual temperature and have relatively high growth. The provenances from Jianghua in Hunan Province, Bobai and Ziyuan in Guangxi Province may be the adaptable provenances for the afforestation at Liuzhou in Guangxi Province.

Wildfire regime shifts and fire feedbacks in Andean Araucaria forests: climate and anthropogenic influences

Mauro Gonzalez^{1,2}, Jason Sibold³, Ariel Muñoz⁴, Ana Abarzúa¹, Timothy Assal⁵

¹Universidad Austral de Chile, Valdivia, Chile; ²Center for Climate and Resilience Research, Santiago, Chile; ³Colorado State University, Fort Collins, USA; ⁴Pontificia Universidad Católica De Valparaíso, Valparaíso, Chile; ⁵U.S. Geological Survey, Fort (maurogonzalez@uach.cl; jason.sibold@colostate.edu; ariel.munoz@pucv.cl; anaabarzua@uach.cl; assalt@usgs.gov)

Wildfire activity of many forests around the world has increased as a consequence of climate change, increasing the likelihood that recently burned areas will reburn in a subsequent fire. In this study we examine the fire history of Araucaria forests, fire-climate relationships, and the causes and consequences of the recent increased wildfire activity. Fire is the most important disturbance influencing the Andean Araucaria – Nothofagus forested landscape. Across the Andean distribution, these forests have been shaped by a mixed-severity fire regime, including low-severity surface fires to stand-replacing fires. Over the last ~ 500 years, climate variability and changes in land-use practices have had a strong influence on the fire regime. The Euro-Chilean settlers (1883-1960) significantly increased fire activity compared to the Modern Fire Exclusion period (1961-2005) and the Native American period (pre-1882). Even though human land use plays a central role in shaping multi-decadal trends in fire activity, the occurrence of wildfire is still strongly controlled by weather. Specifically, regional-scale drought drives fire occurrence and large fire events. Since 2000 fire activity has increased in Araucaria forests. During the summer 2001-2002 a significant area of Andean Araucaria forests burned at different severities, which provided differential opportunities for tree seedling and understory species recruitment. In 2015 a subsequent severe fire reburned c. > 60% of area that burned in 2001-2002. Using long-term monitoring plots, we examine the vegetation response following two high severity fires in a relatively short time period, and evaluate the likely increased susceptibility of the post-fire vegetation to subsequent fires.

Amazon trees exposed to edge effects are more susceptible to Atlantic Ocean warming and Intertropical Convergence Zone North displacement from 1980

Recent researches observed an Atlantic Ocean temperature increase since 1980, probably influenced by anthropic actions, inducing rainfall intensification mainly during the rainy season and slight reductions during the dry period in the Amazon. Here we demonstrate through a dendrochronological approach using non-destructive samples of *Scleroneima micranthum* growth rings located in Terra Firme forest at the Biological Dynamics of Forest Fragments Project in the Brazilian central Amazon and spatial correlations, using the data available from the Climate Explorer Website, how trees, exposed and not exposed to edge effects are influenced by these changes previously (1941 to 1982) and after the forest fragmentation (1983 to 2013) in three moments: previously the dry period (March to June) during the dry period (July to October) and after the dry period (November to February). Through the spatial correlations, we can verify the strong action of the Atlantic sea surface temperature in the growth dynamics of the trees, and we highlight here the space-time transition of the influence of the South Atlantic sea surface temperature before the forest fragmentation and the North Atlantic sea surface temperature after fragmentation, and proved that trees growth dynamics responded to the Intertropical Convergence Zone displacement to the north, due to the increase in Atlantic sea surface temperature from 1980, mainly during the dry period. Consequently, if we consider the future scenarios of global warming, significant increases in sea surface temperature will modify rainfall patterns in the Amazon, influencing the performance of trees, especially in fragmented forest as edge areas.

Linking climate and wood properties with the use of carbon and oxygen stable isotopes as proxies

Mariana Hassegawa¹, Lisa Wingate², Alexis Achim¹

¹Laval University, Quebec, Canada; ²French National Institute for Agricultural Research, Bordeaux, France (mariana.hassegawa@sbf.ulaval.ca; lisa.wingate@bordeaux.inra.fr; alexis.achim@sbf.ulaval.ca)

Black spruce (*Picea mariana*), one of the main tree species in the North American boreal forests, has great economic importance in Canada. To improve the resilience of the boreal forest and ensure the future supply of high-quality wood, it is critical to understand the factors that affect wood formation. The difference in temporal resolution between climate variables and annual growth data, as well as the high collinearity between climate variables, can contribute to the low predictive power of current models relating climatic conditions to tree growth or wood properties. One solution for linking climate events and wood formation is to use high-resolution assessments of $\delta^{13}\text{C}$ cellulose (ratio of carbon-13 and carbon-12 isotopes in α -cellulose) and $\delta^{18}\text{O}$ cellulose (ratio of oxygen-18 to oxygen-16 isotopes in α -cellulose) as indicator variables for environmental factors. This work aimed to study the effects of climate on wood density of black spruce, using $\delta^{13}\text{C}$ cellulose and $\delta^{18}\text{O}$ cellulose as proxies. Our results suggested that higher water availability during wood formation was related to lower values for $\delta^{13}\text{C}$ cellulose, a behavior identified through the standardized precipitation-evapotranspiration index. Good correlations were observed between $\delta^{18}\text{O}$ cellulose and climate variables. The average temperature during the growing season and the total amount of rain in July were responsible for about 70% of the variation in $\delta^{18}\text{O}$ cellulose. These results may contribute to the improvement of predictions of the boreal forest's growth and ability to act as a carbon sink in a changing climate.

B5b: INNOVATIVE WOOD PROTECTION AND DURABILITY STRATEGIES TO MITIGATE CLIMATE CHANGE IN THE TROPICS AND WARM TEMPERATE CLIMES

From fungal detoxification systems to wood durability

Eric Gelhaye¹, Melanie Rouhier², Rodnay Sormani², Thomas Perrot²

¹Institut National de la Recherche Agronomique, Nancy, France; ²Université de Lorraine, Nancy, France (eric.gelhaye@univ-lorraine.fr; melanie.morel@univ-lorraine.fr; rodnay.sormani@univ-lorraine.fr; thomas.perrot@univ-lorraine.fr)

Organisms and in particular static (no-motile) organisms have to be adapted to their environment to cope with biotic and abiotic stresses. In the case of wood-decaying fungi, these latter have developed an efficient detoxification system with expended multigenic families, such as cytochrome P450 monooxygenases and glutathione transferases (GSTs), involved in the catabolism/detoxification of wood extractives. Concerning GSTs, their activity or even their expression are widely used to evaluate physiological and environmental stress of diverse organisms. In this context, we postulated that fungal GSTs could be used as tools to identify wood extracts that possess interesting biological properties and could also give some clues on the ecological traits of the corresponding trees. We have therefore developed biochemical tests quantifying the interactions between fungal GSTs and wood extracts from subtropical and temperate forests. The obtained results that validate the initial hypothesis and demonstrate a correlation between these interactions and the natural durability of the tested woods as well as the growth strategy (heliophilic/sciaphilic continuum) of the considered species, will be discussed. Exemplary kempas hardwood protection with two proprietary microemulsion termiticides based on permethrin and cypermethrin against *Coptotermes termite* attack under tropical aboveground indoor and weathered conditions

Daouia Messaoudi¹, Andrew H. H. Wong², Carlson A. D. Tawi², Nebil Bourguiba³, Olivier Fahy³

¹Adkalis, Blanquefort, France; ²Universiti Malaysia Sarawak, Kota Samarahan, Malaysia; ³Adkalis, Blanquefort, France (daouia.messaoudi@berkem.com; awong.unimas@gmail.com; carlson.tawi@gmail.com; nebil.bourguiba@berkem.com; olivier.fahy@berkem.com)

Patented proprietary SARPECO® and AXIL® environmentally acceptable microemulsion wood-protecting chemicals are water-based wood preservatives approved for dipping and pressure treatment providing 25 years of termite protection for solid wood and wood-based products in Europe and for more than 10 years in Indonesia. Field trials conducted in Malaysia confirmed the efficacy of SARPECO® and AXIL® solutions at three product concentrations on short dip-treated kempas (*Koompassia malaccensis*) heartwood, a major hardwood species used in Malaysian wood construction, against the Southeast Asian subterranean termite *Coptotermes curvignathus* exposed to aboveground H2 (indoor, non-wetting conditions) hazard class targeting termites compared to CCA-treated kempas and radiata pine (*Pinus radiata*) sapwood. Prior to the H2 hazard class termite field test exposure, treated wood blocks were conditioned to either a non-leaching volatilization (H2 hazard class weathered wood) or to a leaching with volatilization (aboveground H3 hazard class weathered wood) as well as non-leaching/non-volatilization and leaching/non-volatilization reference treatments. After 6 months field exposure, untreated kempas was severely (AWPA termite ratings: 0, mean mass loss: 97.4%) or moderately attacked (mean ratings: 7.7, mean mass loss: 17.5%), while none of the leached-volatilized (H3 hazard class) or non-leached-volatilized (H2 hazard class) test blocks treated with SARPECO® and AXIL® at both target retentions were regarded as attacked (mean ratings: 9.7-10, negligible mean mass loss) at low applied termiticide concentrations, leached or non-leached wood, volatilized or non-volatilized wood treatments. Concluding, due to their unique compositions, both patented formulations conferred excellent protection against *Coptotermes curvignathus*, at far lower termiticide concentrations where conventional agro-insecticides will fail, for tropical aboveground indoor-outdoor wood construction.

Tropical indoor wood floorings and outdoor deckings are in dire need of wood protection

Andrew H. H. Wong¹, Malcolm Farmer²

¹Universiti Malaysia Sarawak, Kota Samarahan, Malaysia; ²Koppers Performance Chemicals, Manila, Philippines (awong.unimas@gmail.com; farmerm@koppers.eu)

In many tropical regions indoor timber floorings and sometimes outdoor deckings have become popular features of buildings and parks, which when installed without naturally durable woods, are readily predisposed to the biological hazards of termites and rot fungi that are destructive to wood materials. Such premature failure of unprotected structural materials incurs considerable monetary losses as well as carbon loss from wood biodeterioration that is detrimental to climate change mitigation plans. Brief illustrations of wood being climate-friendly material, that wood must be treated in the tropics, variable natural durability of Malaysian woods, their tropical wood degraders, options for biocidal and non-biocidal wood protection strategies of wood floorings and deckings, and case studies of biocidal wood protection of tropical woods in aboveground conditions, are presented.

Evaluation of furfural/urea complexes to improve properties of commercial birch wood (*Betula* sp.)

Davood Efhamsisi¹, Marie-France Thevenon^{2,3}, Marzieh Sharifat¹, Asghar Taromian¹, Mehdi Jonoobi¹

¹Department of Wood and Paper Sciences and Technology, Faculty of Natural Resources, University of Tehran, Tehran, Islamic Republic of Iran; ²Wood Preservation Laboratory, CIRAD, UR BIOWooEB, Montpellier, France; ³BIOWooEB, Univ. Montpellier, CIRAD Mont (efhami@ut.ac.ir; marie-france.thevenon@cirad.fr; marzieh.sharifat@ut.ac.ir; asghar.taromian@ut.ac.ir; mehdi.jonoobi@ut.ac.ir)

Due to recent national forestry policy banning logging from the Northern parts of the country, Iranian wood industry must mostly rely on wood importation. Birch (*Betula* sp.) from Russia is a commonly imported wood, but has a low durability and therefore must be protected for long-term uses. Protection systems based on wood impregnation with different monomers and their conversion to un-leachable reacted polymers were developed to create new wooden products with improved properties. Furan compounds such as Furfuryl Alcohol (FA) can be commercially used for wood modification. Wood is impregnated with FA, which is converted to polyFA by heating. Furfural is, in fact, the primary raw material in the production of FA, and is extensively manufactured in Iran from residues of sugar cane. Furfural can not be easily polymerized alone like FA; however it is an aldehyde able to react with urea to make polymer network. In this study, the possibility of creating furfural/urea polymer along with acidic catalyzer (maleic anhydride) was evaluated for the improvement of physico-mechanical properties, as well as the durability of birch wood.

Valorization of pyrolysis by-products from sugar cane bagasse for the protection of biomaterials

Febrina Dellarose Boer^{1,2}, Marie France Thevenon^{1,2}, Jean-Michel Commandré^{1,2}, Mériem Fournier³

¹CIRAD, UR BIOwooEB, Montpellier, France; ²BIOwooEB, Univ. Montpellier, CIRAD Montpellier France; ³LERFOB, AgroParisTech, INRA, Nancy, France (febrina.boer@cirad.fr; marie-france.thevenon@cirad.fr; jean-michel.commandre@cirad.fr; meriem.fournier@agroparistech.fr)

This research focused on the “Energy valorization of lignocellulosic products and their by-products for the protection of bio-materials”, is dedicated to the valorization of the sugar cane bagasse from Réunion Island (Oversea territory, France), a region where the sugar industry plays an important role in the agricultural sector. The objectives of this research were to: (i) characterize the biochar and the bio-oil according to the pyrolysis process parameter and the biomass used, and to (ii) evaluate the potential of said bio-oil as wood preservatives. Pyrolysis of bagasse was conducted using an experimental set up of fixed bed reactor. Various temperatures (T = 400 °C, 500 °C) and holding time th (30 and 60 minutes), and a heating rate of 10 °C/minutes were applied. Pyrolysis products, consisting of biochar and bio-oil, were recovered for further analysis. The biochars were characterized for their proximate and ultimate analysis for energy valorization. For evaluating the antifungal efficacy of the recovered bio-oil, we conducted fungal growth inhibition tests against two types of wood-decaying fungi: *Coriolus versicolor* (white-rot) and *Coniophora puteana* (brown-rot) on Petri dishes, as well as decay tests on treated wood samples.

Engineered Wood Products (EWPs) in mass timber construction and their durability

Tripti Singh¹

¹Scion, Rotorua, New Zealand (tripti.singh@scionresearch.com)

With proven improved performance in fire and seismic characteristic, the projected market potential for softwood Engineered Wood Products such as CLT (Cross Laminated Timber) and LVL (Laminated Veneer Lumber) for multi-story buildings are very positive. However, potential prolonged rain leakage or moisture exposure during construction and in-service could pose considerable concern for its durability and reputation. This research was conducted to assess the decay resistance of LVL, OSB (Oriented Strand Board) and CLT produced from radiata pine in an accelerated trial. This testing method is used in establishing the effectiveness of wood products in framing subject to intermittent wetting. The results showed untreated OSB and CLT were very susceptible to decay. In comparison, LVL was less susceptible. Testing conducted on CLT using surface application of boron preservative prevented decay. Further work is needed to understand the full extent of moisture ingress in wooden panels during construction and service of the multi-story buildings and improving the durability of panel products.

Improvement of the dimensional stability and weathering resistency of wood treated with an hydrorepellent product for exterior use

Claudia Ibañez¹, Damian Ghersovic²

¹Universidad de la Republica, Tacuarembó, Uruguay; ²INTI, Buenos Aires, Argentina (cmibanes@gmail.com; damianghe@hotmail.com)

Wood is a common construction material used in all environments. However its sensibility to abiotic agents, in particular its dimensional instability limit its durability and decrease its properties. In this work, the efficiency of a paraffine-emulsion-based product as a wood protector was tested for its use on both interiors and exteriors- mainly decks and utility poles. *Eucalyptus grandis* and *Pinus taeda* sapwood were treated with the Bethel method at two retention levels, and later compared with untreated wood. The dimensional stability of the treated samples was studied through determining the swelling percentage and the water repellency level. Test samples were also exposed to accelerated weathering processes of 100 and 300 h, and later analyzed by FTIR and SEM microscopy. Results showed a significative improvement of the dimensional stability of treated wood when compared to untreated samples. Despite the weathering process slightly affected the surface of the wood, the product is suitable for exterior use.

Protection of wood from fungi and termite with liquefied wood polyols

Anil Kumar¹, Asieleavio John¹, TaraSingh Mehra¹, B.N. Hazarika¹

¹College of Horticulture and Forestry, Central Agricultural University, Pasighat, Arunachal Pradesh, India, Pasighat, India (anil19wst@gmail.com; asieleavio@gmail.com; mehra_chf@hotmail.com; chfdeanpsg@gmail.com)

Liquefaction of wood is one of the promising approaches to utilize woody waste wherein wood meal is converted into chemically active liquid with the help of a liquefying agent like polyhydric alcohols, phenol, cresol, etc. The potential of liquefied wood as a wood preservative has not been studied. In this study, wood meal was liquefied in phenol, glycerol and polyethylene glycol as the liquefying media and the efficacy of liquefied wood was tested as a wood preservative against termite and fungi. Wood samples were impregnated with liquefied wood diluted with methanol and were subjected to accelerated termite graveyard test and fungal resistance test. The level of impregnation of liquefied wood in wood was estimated by determining the weight percent gain. In the graveyard test, samples were periodically observed for 18 months. Samples treated with phenol-assisted liquefied wood exhibited promising results both in visual observation and percentage weight loss as compare to initial condition and untreated control samples. The percentage weight loss of phenolated wood treated wood sample was ranging from only 5 - 20% of its initial weight; whereas treatment with glycerol and PEG based liquefied wood did not exhibit any improved resistance against termite as compared to the untreated samples. The treated samples were also exposed to fungus for 16 weeks. The fungicidal traits of phenolated wood showed higher antifungal efficacy against both white rot and brown rot of wood whereas liquefied wood in glycerol and polyethylene glycol shows insignificant effects on growth of fungus and was similar to control samples.

B5p: CLIMATE CHANGE AND FOREST PRODUCTS

The contributions of rate and duration of stem radial increment to annual increments of *Picea meyeri* in a sub-alpine habitat, North-Central China

Yuan Jiang¹, Mingchang Wang¹

¹Beijing Normal University, Faculty of Geographical Science, School of Natural Resources, Beijing, China (jiangy@bnu.edu.cn; wmch123@yeah.net)

Stem radial increment rate and duration are the most important parameters in determining the width of annual tree rings. To identify the contributions of rate and duration to annual radial increments and their relationships with environmental factors, we analyzed intra-annual stem increments of five *Picea meyeri* trees

in a sub-alpine habitat of North-Central China over 7 years (2008–2015, except for the year 2012) with point dendrometers in this study. The results showed the following. (1) We estimated that approximately 53% of the variability in the annual radial increments is attributable to the rate of radial increment and approximately 47% to its duration. (2) The contribution of cessation time to the annual increments was more than three times that of the initiation time. (3) The initiation of radial increment was primarily controlled by soil temperature and warmer soil temperature could advance the initiation time. The cessation and rate of radial increment were mainly influenced by thermal and light-related environmental factors. During growing seasons, low temperatures and insufficient light caused by many rainy and cloudy days at the high altitudes of the Luya Mountains may result in earlier cessations and lower rates of radial increment. Overall, our results may have further applications in modeling the responses of tree stem growth to climate change in a sub-alpine habitat of North-Central China.

Dendrochronology applied to urban afforestation management

Cláudia Fontana^{1,2} 

¹Instituto Federal Catarinense, Luzerna, Brasil; ²Claretino, Blumenau, Brasil (claudiafontanabio@gmail.com)

Trees in urban area present their own responses to environmental pressures when compared to those in native forests. Monitoring these trees is essential for urban planning and security. Jacaranda mimosifolia D. Don is an exotic species in Brazil but widely used in urban afforestation. Tree falls of this species in urban area have been related to fungal infection. In this work, a dendrochronological study of a wood disc of *J. mimosifolia* that fell in an urban square (Joaçaba, Santa Catarina state) was carried out. The tree was flowering and apparently healthy. A disk with a diameter of 58 cm was collected one meter above the ground. It was polished (sands from 80 to 2000 grains) and five radii were dated, photographed with a reference scale and the growth rings measured in image software. Dating was checked in Cofecha and dendrochronological parameters were generated in Arstan. The estimated age was 37 years, and the correlation between the radii was $r = 0.563$ and the sensitivity of 0.255 (Cofecha), with $r_{bar} = 0.451$ (standard chronology). The average width-rings was 7.96 mm (0.74 to 16.89 mm). Areas with rot caused by fungi and routes caused by termites were observed. One hypothesis is that the fungal infection occurred for some injury between the tree's 17 and 20 ages (years 1998 to 2001) facilitating insects entry. The rot compromised about 2/3 of the disk, causing tree weakening and probably its fall.

Dendroecology and wood anatomy of a rare species *Dinizia jueirana-facao* (Fabaceae), “Tabuleiros” Atlantic Forest, Brazil

Cláudia Fontana¹ , Luiz Santini-Junior² , Caroline Américo da Silva² , Juliano Moraes Oliveira³ , Mario Tomazello-Filho² , Paulo Cesar Botosso⁴ 

¹Instituto Federal Catarinense, Luzerna, Brasil; ²Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Piracicaba, Brasil;

³Unisinos, São Leopoldo, Brasil; ⁴Embrapa Florestas, Colombo, Brasil (claudiafontanabio@gmail.com; luizsantini82@gmail.com; caroline.americo.silva@usp.br; julianooliveira@unisinos.br)

The great diversity of tree species present in the tropics results from the high quantity of rare species. Therefore, understanding their ecology is critical to the conservation of these complex tropical ecosystems. Dendrochronology can retrieve valuable information from tree rings analysis. We characterize the wood anatomy of *Dinizia jueirana-facao*, a rare tree species recently described, occurring only in semi-deciduous Atlantic rain forest in Espírito Santo State, Southeastern Brazil. Preliminary results of dendrochronological studies are also presented. For microscopic analysis of growth-ring boundaries and dendrochronology, we prepared samples of five adult trees by standard techniques in each area. *Dinizia jueirana-facao* has growth rings visible to the naked eye, but sometimes with difficulty, demarcated by thin marginal parenchyma bands. It shows fiber wall thickness variation sometimes resulting in distinct tangential fiber zones in the latewood. Confluent parenchyma bands are especially frequent sometimes masking the tree-ring boundaries. Despite difficulties in some samples, we crossdating five trees (10 rays). The correlations within the trees were 0.40 up to 0.80, among trees of $r = 0.538$, $r_{bar} = 0.277$, $EPS = 0.81$ and mean sensitivity of 0.551. Although preliminary, the results obtained so far demonstrate the dendrochronological potential of the species can already be verified. The high synchronicity and sensitivity of the growth rings in the investigated population shows that this rare tree species is affected by recurrent variations in the environment. After completing crossdating, we will test the chronology with local and global climate data.

Dendroanatomy of *Copaifera pubiflora* and the prospect of oleoresin production

Patricia da Costa¹ , Mateus Natan Lee Cardoso², Tomaz Longhi-Santos² , Renata Cristina Bovi³

¹Embrapa Roraima, Boa Vista, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil; ³Universidade Estadual Paulista “Júlio de Mesquita Filho”, Instituto de Geociências e Ciências Exatas, Rio Claro, Brasil (patricia.da-costa@embrapa.br; zoso2622@gmail.com; longhi@ufpr.br; bovir@gmail.com)

Copaifera pubiflora Benth. (Fabaceae) is a medium-sized tree species recorded in Brazil, only in Roraima state, on river Branco Savannas, where it is observed in forest islands and gallery forests. It can also be found in small patches of tropical rainforests at its Southern boundary, in a transition area between the savanna formation and tropical rainforests. The word copaiba comes from the Tupi “kupa ‘iwa” and means “tank tree”, referring to the fact that the species produces and stores an oleoresin in its trunks. This oil is collected solely from native forests, mainly in Amazon. In spite a large number of studies conducted on copaiba oleoresin chemical composition and pharmacological activities, aiming the definition of potential applications, there are still gaps in species ecological aspects that must be filled to define its productive potential, contributing to the establishment of management plans and practices. In this work, preliminarily, we used a dendroecological approach to characterize *C. pubiflora*'s growth rings and its annual formation from non-destructive samples collected in two phyto-ecological units, in Roraima. With ring dating and data synchronization, we hope to quantify the secretory structures occurrence and density in *C. pubiflora*'s timber over time, relating them to oleoresin production (liters) and trees functional and structural attributes (age, diameter at breast height, total height, commercial height, crown area), from a dendroanatomic analysis. Funding: This work was supported by Embrapa through Kamukaia III Project – “Appreciation of non-timber forest products in the Amazon” [grant number SEG 12.13.07.007.00.00].

Prediction of tree-ring widths using climate data time-series modeling approach

Dejan Stojanovic¹, Milena Kresoja², Tom Levanič³, Bratislav Matovic¹, Vladimir Djurdjevic⁴, Sasa Orlovic^{1,5}, Srdjan Stojnic¹, Mirjana Stevanov^{1,6}

¹University of Novi Sad, Institute of lowland forestry and environment, Novi Sad, Serbia; ²University of Novi Sad, Faculty of Sciences, Department of Mathematics and Informatics, Novi Sad, Serbia; ³Slovenian Forestry Institute, Ljubljana, Slovenia; ⁴University of Belgrade, Faculty of Physics, Institute of Meteorology, Belgrade, Serbia; ⁵University of Novi Sad, Faculty of Agriculture, Novi Sad, Serbia; ⁶University of Goettingen, Faculty of forest sciences and forest ecology, Chair of forest and nature conservation policy Goettingen Germany (dejan.stojanovic@uns.ac.rs; milena.kresoja@dmi.uns.ac.rs; tom.levanic@gozdis.si; bratslav.matovic@gmail.com; vdj@ff.bg.ac.rs; sasao@uns.ac.rs; srdjan.stojnic@uns.ac.rs; mzavodj@gwdg.de)

Dendrochronology is a scientific discipline that performs dating of historical events allowing better understanding of environmental processes and human induced changes including past weather, forest fires, landslides, insect outbreaks, etc. Tree-rings, central paradigm of Dendrochronology, may be well used also

for climate-growth studies. Impact of extreme climate events on forests in Europe are well documented (forests mortality, frequency of forest fires, intensive and frequent pest attacks, etc.). Numerous climate impact studies were published regarding potential forest survival and growth in the 21st century. What was missing are prediction regarding near future. We analyzed tree-ring data from oak trees from southeast Europe together with temperature and precipitation data from CARPATCLIM database using time-series model. Autoregressive Integrated Moving Average Model joined with mean temperature and precipitation for the period April-August was used. Model parameters were obtained for the period 1961-2000 and then tested on the last 10 years of climate data (20 % of sample, period 2001-2010). Calculated mean absolute error and mean square error between modeled and measured data were below 5%. Developed modeling approach may provide firm base for near real-time prediction of tree-ring widths and consequentially forest growth and their response to extreme weather events.

Dendroecology applied to the sustainability of *Hevea spruceana* management in central Amazon

Claudio Roberto Anholetto Junior^{1,2} , Mario Tomazello-Filho² 

¹Mamirauá Institute for Sustainable Development, Tefé, Brasil; ²Universidade de São Paulo, Piracicaba, Brasil (anholettoj@usp.br; mtomazel@usp.br)

Among the Amazon forest environments, the várzea stands out because it occupies a large part of the territory. They are floodplains with high productivity that occur along white water rivers with high concentration of nutrients and sediments. The effects of climate change in Amazon are mainly felt in the influence on the hydrological cycle, with recent and recurring events of climate extremes, and várzea is known as one of the most vulnerable environments to these events. In order to verify the effect of the climate change over growth dynamics of tree species in the Amazonian floodplain, samples of *Hevea spruceana* trees secondary xylem were obtained for tree rings analysis. Permanent plots were installed in the Mamirauá Sustainable Development Reserve, in Amazonas state, in areas that were later submitted to community forest management, and 20 trees were sampled from there. From the macro/microscopic anatomical analysis we verified the formation of growth limits by thickening of secondary cell walls. The delimitation of the annual rings allowed the definition of the diametric increment pattern, followed by the date synchronization between the samples and time series of growth rings. The correlation between the growth series presented values of $r = 480$, notably influenced by the presence of false growth rings throughout the series. The sensitivity of the master series was $r = 425$. The analysis of the growth series will allow the definition of the minimum cutting diameter and cutting cycle to which species should be submitted, contributing to the sustainability of the activity.

Dendrogeomorphological approach to evaluate soil degradation process in the tropics

Renata Cristina Bovi¹, Marcelo Pablo Chartier², Fidel Alejandro Roig³, Mario Tomazello-Filho⁴ , Miguel Cooper⁵

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Instituto de Geociências e Ciências Exatas, Rio Claro, Brasil; ²Instituto de Investigaciones Biológicas y Tecnológicas, Centro de Ecología y Recursos Naturales Renovables, Córdoba, Argentina; ³Instituto Argentino de Nivología, Glaciología y Ciencias Ambientales, Mendoza, Argentina; ⁴Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ⁵Universidade de São Paulo, Departamento de Solos e Nutrição de Plantas, Piracicaba, Brasil (bovir@gmail.com; mpchartier@gmail.com; froig@mendoza-conicet.gov.ar; mtomazel@usp.br; mcooper@usp.br)

Soil erosion is a degradation process that has caused significant impacts in the environment and does not glimpse changes in the 21st century, especially in developing countries in the tropics and subtropics. The basis of the dendrogeomorphology method is the determination of the influence of geomorphological processes that affect the tree species healthy growth, verified by changes in the growth patterns and tree-rings anatomical features. In this study, we describe the anatomical responses and changes in the pattern of root growth subject to the natural exposure by erosive processes of a Brazil native hardwood species (*Esenbeckia leiocarpa*, Rutaceae), to estimate the first year of root exposure. Changes in the growth and anatomy of the tree-ring after the root exposure was identified, such as changes in eccentricity index, tree-ring width, vessel frequency and scars, which enabled dating the first year of root exposure. Based on the dates of exposure of each root, we reconstructed the dynamics of the erosive process and inferred the soil loss rate. The present study represents one of the firsts applications of the dendrogeomorphology in a tropical climate arboreal species once almost all studies were carried out in temperate species. This analysis allowed quantifying and evaluate the erosive process dynamics of complex systems in tropical regions, in a time and space form, and to infer soil erosion rates. The results can be relevant to warn about the dangers of soil loss in forests and agricultural areas that sustain large economies in the neotropics.

Measuring growth rings in cedar trees (*Cedrela odorata* L.) from the Tapajós National Forest in Pará, Brazil using X-ray absorptiometry for environmental studies / Caracterização dos anéis de crescimento das árvores de cedro (*Cedrela odorata* L.), da Flona, Tapajós, PA, Brasil, pela densitometria de raios x para estudos ambientais

Arielle Martinelli Bondioli¹, Luciana Karla Valéria dos Santos Souza¹, Bruna Hornink¹, Daigard Ricardo Ortega Rodriguez¹, Mario Tomazello-Filho¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo Piracicaba, Brasil (arielle.bondioli@usp.br; lucianasousaufopa@gmail.com; bruna.hornink@usp.br; dai.ricardo.or@gmail.com; mtomazel@usp.br)

No Brasil, os estudos dendroclimatológicos têm significativa e estratégica importância na floresta tropical da Amazônia, a qual colabora com o regime de chuva do país e vem sofrendo contínuo desmatamento. Assim, este projeto tem o objetivo, no contexto de mudanças do clima, de caracterização da microdensidade dos anéis de crescimento do lenho das árvores de *Cedrela odorata*, a fim de subsidiar estudos climatológicos. Foram coletadas 15 discos do lenho da base de árvores de *Cedrela odorata* na Floresta Nacional do Tapajós, Belterraém, PA. Foi utilizado um raio por amostra. As amostras foram polidas e um raio por disco cortado obtido na uma seção transversal para análise por microdensitometria de raios X. Verifica-se, através do perfil de densidade, que a espécie delimita seus anéis por parênquima marginal, podendo apresentar anéis falsos ou descontínuos. Os anéis de crescimento apresentam densidade aparente de 0,377 g/cm³ no cerne e no alburno de 0,434 g/cm³. Na região do lenho inicial, a densidade média é de 0,311 g/cm³ e no lenho tardio, 0,403 g/cm³. Em anéis estreitos, a densidade é de 0,308 g/cm³, no lenho inicial e 0,398 g/cm³, no lenho tardio, ocorrendo redução aproximada de 8% e de 1% respectivamente. Esses resultados auxiliarão na determinação acurada dos anéis de crescimento para a construção do incremento anual e dos perfis de microdensidade dos anéis de crescimento da espécie, para estudos dendroclimatológicos.

Growth response to extreme drought of endemic Mediterranean forests in central Chile

Alejandro Venegas-González¹, Tania Gipoulou¹, Ariel Muñoz², Isabella Aguilera²

¹Universidad Mayor, Santiago, Chile; ²Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile (alejandro.venegas@umayor.cl; taniagipoulou@gmail.com; ariel.munoz@pucv.cl; isabella.aguilera@pucv.cl)

The forest ecosystems of central Chile (30°–35° S) are the only Mediterranean forests in South America. These forests contain a high diversity of endemic plants, so they have been declared a biodiversity hotspot, that is, a biogeographic area of great biological richness with need of conservation. The increase in drought conditions experienced in central Chile during the last century has been little studied, mainly the extremes droughts. For this reason, it is essential to study the influence of climate change and extreme drought on the forest dynamics of the two most important forest-types in central Chile, sclerophyllous forests (evergreen trees, <1000 m a.s.l.) in valleys and hillsides; and Nothofagus forests (deciduous trees, >1000 m a.s.l.) on the mountain peaks of central Chile. Here, we use a dendroecological approach to assess the resistance, resilience and recovery of sclerophyllous and Nothofagus forest to exceptional droughts in 1968 and 1998. We selected five chronologies per forest type in a latitudinal gradient (32°–34° S). Preliminary results showed that southern populations (sites with higher rainfall) are more resistant to drought than northern sites, but they have lower recover. Relative resilience to drought increased with dry sites but decreased with increasing winter precipitation in southern sites. Similar results have found in forests from Western Mediterranean basin. The results will provide valuable information to understand the ecological resilience of the Mediterranean ecosystems of South America, and thus be useful for future conservation and restoration programs for the effects of climate change.

B6a: ACHIEVING REDD+: FROM LOCAL ACTIONS TO NATIONAL COMMITMENTS

Saying no to ITMO: implications for REDD+ finance from Indonesia's rejection of internationally transferred mitigation outcomes

Ellyn Kathalina Damayanti^{1,2}, Andi Fadly Yahya², Nicholas John Berry³

¹Faculty of Forestry, Bogor Agricultural University, Bogor, Indonesia; ²Rafflesia Research Network, Bogor, Indonesia; ³The Landscapes and Livelihoods Group, Edinburgh, United Kingdom (ellyn.kdamayanti@gmail.com; andifyahya@gmail.com; nick@landscapesandlivelihoods.com)

Indonesia was one of the first countries to finalize its National REDD+ strategy and has made good progress with other REDD+ instruments development. The Funding Instruments for REDD+ have only recently been clarified, however, and the implications of Indonesia's decisions in UNFCCC negotiations are not yet fully understood. In 2016, Indonesia ratified the Paris Agreement, but excluded Article 6 that allow voluntary international transfers of mitigation outcomes (ITMO). Indonesia intends to use all emission reductions achieved within the country, including those from REDD+, to the targets in its Nationally Determined Contribution (NDC), reducing the potential for REDD+ projects and sub-national programs to directly access international finance for emission reductions. This research aims to clarify the current state of REDD+ funding instrument development in Indonesia and identify the funding opportunities can now be accessed by the REDD+ proponents. The study highlights that through the funding instrument system being developed, REDD+ proponents must be registered in a National Registry System. Emission reductions achieved within Performance Measurement Areas delineated by the Ministry of Environment and Forestry, may receive funding for implementing REDD+ activities and result-based payments through the Environment Fund Management Agency. This Agency will manage funds from various sources for restoration of environmental destruction and pollution, including REDD+. Indonesia's decision on Article 6 of the Paris Agreement therefore affects proponents who have been engaging international cooperation and transfer of mitigation outcomes, who must now comply with this decision and adjust any cooperation agreements to exclude ITMO by 31 December 2019.

Identifying entry points among competing forest conservation and land development priorities in subnational implementation of REDD+ in Indonesia's agricultural frontiers

Anna Sanders¹, Rebecca Ford¹, Rodney Keenan¹, Anne Larson²

¹University of Melbourne, Parkville, Australia; ²Center for International Forestry Research, Lima, Peru (annaps@student.unimelb.edu.au; ford@unimelb.edu.au; rkeen@unimelb.edu.au; a.larson@cgiar.org)

Limitations of top-down approaches are often identified in the design and implementation of international forest conservation and climate change objectives. Reducing Emissions from Degradation and Forest Degradation (REDD+) is a prominent environmental scheme focusing in carbon-rich forested landscapes in developing countries. This research addresses gaps in understanding of subnational implementation of REDD+ relating to competing forest conservation and land development priorities in resource frontiers. The case study in the southern peatlands of Central Kalimantan province in Indonesia, an agricultural resource frontier, combined an ethnographic approach with document analysis. The findings are based on approximately 10 months of field research conducted at time intervals between 2013 and 2015. Features of actor-network theory (ANT) were used to explore negotiations over land relating to large REDD+ projects, forest conservation, such as national parks, and large-scale land development, principally commercial oil palm concessions. The concept of an entry point was identified to describe how different actors, including oil palm and REDD+ investors, entered the existing systems of forest and land allocation in contested legal arrangements, and how interactions among land use changes affect local villagers. This concept is relevant to approaches to forest conservation and environmental governance to identify impediments to achieving global objectives and provide space for local inputs into planning processes at higher levels. It is also relevant to land development in resource frontiers generally, where there is a need to identify strategic, political entry points to target environmental reform.

Jurisdictional REDD+ in Brazil: transnational pathways of influence and domestic strategies of policy entrepreneurship in subnational policy processes

Carolina Gueiros¹

¹University of Oxford, Oxford, United Kingdom (carolina.gueiros@ouce.ox.ac.uk)

As part of the world's efforts to combat climate change, many tropical states and provinces are developing subnational 'jurisdictional' REDD+ policy programs that seek to transform the way forests and related sectors are governed. While these initiatives are largely 'bottom-up', they are also guided and supported through the rules, norms, funding, and assistance provided by a wide array of multilateral and bilateral initiatives. Whether REDD+ efforts will be able to deliver transformative change in environmental governance or reproduce the policy status quo remains an outstanding question. More research is needed to understand whether and how domestic policy actors may harness the transnational pathways of influence opened by REDD+. This paper examines the pursuit of subnational jurisdictional REDD+ in Brazil. While debates have been ongoing at the federal level, three states in the Brazilian Amazon have developed state-level REDD+ policies. This paper seeks to understand progress made by the Brazilian states of Amazonas, Acre, and Mato Grosso in enacting subnational

jurisdictional policies. Through exploring the interplay between the transnational pathways of influence generated by REDD+ and strategies of domestic policy entrepreneurship in each state, this paper draws on 50 interviews with key policy makers in Brazil, documental analysis, and participant-observation to process-trace how domestic policy actors in those states have harnessed or not the pathways of influence provided by the transnational REDD+ movement. This paper aims to generate important lessons about the pursuit of REDD+ within a federal system, and about the cross-scale dynamics of policy innovation more broadly.

Designing the market for environmental reserve quotas: property-level analysis of environmental compliance strategies in Mato Grosso, Brazil

Ruben Lubowski^{1,2}, Breno Pietracci¹, Diego Herrera¹, Gabriela Leslie¹

¹*Environmental Defense Fund, New York, USA; ²School of International and Public Affairs, Columbia University, New York, USA (rlubowski@edf.org; bpietracci@edf.org; dherrera@edf.org; gleslie@edf.org)*

The 2012 Brazilian Forest Code establishes native vegetation preservation requirements within private rural properties. It introduced a marketable instrument, Environmental Reserve Quotas (Cota de Reserva Ambiental; CRA) that enables landowners to compensate for deficits by paying for the conservation of surplus forest areas on other properties. The recent promulgation of federal regulations for CRAs in December 2018 can be a major opportunity for landowners to monetize environmental assets and reduce costs of Forest Code compliance, but impacts hinge critically on appropriate market designs. We provide a microeconomic analysis of the economic and environmental impacts of alternative potential designs for the CRA market using a novel property-level database for the leading agricultural state of Mato Grosso where private properties have to bring to compliance a deficit of 8.7 million hectares. Using econometrically-derived estimates of opportunity costs of avoided deforestation, property data on native vegetation surpluses and deficits, and land values and reforestation cost information, we build supply and demand curves for CRAs for each property and model alternative market equilibria. A large potential supply of CRAs with zero opportunity costs can drive the market equilibrium price to zero, while the price is about 500 reais/hectare/year with supply only from medium-large properties with native vegetation surplus. We evaluate alternatives to restrict supply, interactions with potential carbon and other ecosystem service incentives programs, role of penalties for noncompliance, and transaction costs, and show that a well-designed market can drive important environmental benefits and costs savings.

Evaluating the impacts of different types of REDD+ interventions on forests and people

Amy Duchelle¹, Astrid Bos², Claudio de Sassi^{1,3}, Erin Sills^{1,4}, Mella Komalasari¹, Sven Wunder⁵

¹*Center for International Forestry Research (CIFOR), Bogor Barat, Indonesia; ²Wageningen University, Wageningen, Netherlands; ³Swiss Federal Office for the Environment, Bern, Switzerland; ⁴North Carolina State University, Raleigh, USA; ⁵European Forest Institute (EFI), Barcelona, Spain (a.duchelle@cgiar.org; astrid.bos@wur.nl; cdesassi@gmail.com; sills@ncsu.edu; m.komalasari@cgiar.org; s.wunder@cgiar.org)*

Since its inception over ten years ago, REDD+ (Reducing Emissions from Deforestation and forest Degradation plus enhancing carbon stocks) has been piloted through more than 300 subnational initiatives across the tropics. Initiative implementers are applying REDD+ intervention packages that in customized ways combine disincentives (e.g. restrictions on forest access or conversion) and incentives (conditional or non-conditional) to allegedly achieve better protection of forests. Through CIFOR's Global Comparative Study on REDD+, we evaluated the forest conservation and community well-being impacts of 22 subnational REDD+ initiatives in Brazil, Peru, Cameroon, Tanzania, Indonesia and Vietnam. We combined socioeconomic surveys in 150 communities and nearly 4,000 households (including control groups) in 2010-2012 (pre-intervention) and 2013-2014 (post-intervention), with an analysis of Global Forest Change data (2000-2015), to assess how different interventions affected changes in income, assets, perceived well-being and forest cover at the community level. We found a reduction in forest cover loss at half of the REDD+ sites, with better conservation outcomes in places where there was higher treatment intensity of disincentives. Both intervention types had neutral impacts on income and assets, but higher exposure to disincentives led to decreases in overall perceived well-being, except when balanced out by incentives. Although disincentives may be an effective REDD+ instrument for conserving forests, other measures are clearly needed to safeguard and enhance community well-being. This critically needed empirical evidence on REDD+ performance on the grounds relevant to policy makers and practitioners interested in developing REDD+ strategies that can provide both conservation and livelihood benefits.

Can REDD+ provide local as well as global forest benefits? A process and impact evaluation of the Katingan Mentaya Project, Central Kalimantan, Indonesia

Vivi Selviana¹, Stibniati Atmadja², Erin Sills¹

¹*North Carolina State University, Raleigh, USA; ²Center for International Forestry Research, Addis Ababa, Ethiopia (vselviana@ncsu.edu; s.atmadja@cgiar.org; sills@ncsu.edu)*

The traditional rural population of Indonesia is highly dependent on forests for their livelihoods, including both products and services for both market and subsistence. Thus, their livelihoods are threatened by economic development activities that lead to deforestation. In this context, REDD+ can potentially be a win-win for local and global populations, protecting livelihoods while it mitigates climate change. However, there is significant controversy over whether REDD+ can achieve this potential. The controversy partly reflects highly varied understandings about what REDD+ really is and how it will be implemented on the ground. To shed light on this debate, we present a detailed explanation of how one REDD+ project has been implemented and counterfactual-based evidence on its livelihood impacts. The Katingan Mentaya Project was launched in 2009 and issued its first carbon credits in 2017. To accomplish this, it implemented a bundle of interventions, which we categorize as restrictions on forest access and/or conversion, forest enhancement, non-conditional livelihood enhancements, conditional livelihood enhancement, environmental education, and tenure clarification. Based on detailed income data collected at three points in time (2011, 2014, and 2018) in communities both inside and outside the intervention area, we estimate a difference-in-difference model in a matched sample to test the effects of these interventions on household income from the forest.

Evaluating the impacts of integrated conservation as a REDD+ strategy in Mato Grosso (Brazilian Amazon)

Adriana Molina Garzon¹, Amy E. Duchelle², Sven Wunder^{2,3}

¹*University of Colorado at Boulder, Boulder, USA; ²Center for International Forestry Research (CIFOR), Bogor, Indonesia; ³European Forest Institute (EFI), Barcelona, Spain (adriana.molinagarzon@colorado.edu; a.duchelle@cgiar.org; s.wunder@cgiar.org)*

For decades, integrated conservation and development projects (ICDP) have attempted to simultaneously reduce deforestation and improve livelihoods, by creating alternative employment options, introducing land-sparing agricultural technologies, and reducing rural poverty. ICDP-like strategies also prove to

be at the core of many subnational REDD+ programmes to mitigate climate change. Here we examine one such programme, implemented in northwestern Mato Grosso, in the so-called Arc of Deforestation of the Brazilian Amazon. Interventions have aimed to improve agricultural productivity and livelihoods of beneficiary communities, without establishing direct conditions of conservation outcomes in exchange (non-performance-based incentives). Based on before-after control-intervention (BACI) surveys of 240 households (53% intervention, 47% control group), we first identify household-level drivers of forest clearing, and then examine early conservation impacts after four years of programme implementation. Our preliminary findings stress the importance of male adult labour for households' self-reported forest clearing: female-dominated and elderly households clear significantly less forest, as do more educated households that likely have higher opportunity costs of labour. In principle, the ICDP focus on household use of labour thus the main goal would be to redirect male adult labour into more sustainable activities. Nevertheless, the intervention has so far not mitigated forest clearing: the difference-in-difference (DID) impacts between intervention and control groups are insignificant, both for the entire programme as for selected subcomponents: either its conservation impacts need more time to pan out, or the ICDP approach was locally inadequate, compared for instance to performance-based alternative forms of intervention.

Evaluating the forest conservation impacts of local REDD+ initiatives: insights from Madre de Dios, Peru

Javier Montoya^{1,3}, Sven Wunder^{2,3}, Amy Duchelle³

¹Australian National University, Canberra, Australia; ²European Forest Institute (EFI), Barcelona, Spain; ³Center for International Forestry Research (CIFOR), Bogor, Indonesia (jmontoya.iq@gmail.com; s.wunder@cgiar.org; a.duchelle@cgiar.org)

Initiatives to Reduce Emissions from Deforestation and forest Degradation and enhance carbon stocks (REDD+) have been implemented tropics-wide over the last decade, yet so far surprisingly little is known about their forest conservation impacts. REDD+ policy mixes are often highly complex, combining incentives, forest law enforcement, and investments in productive alternatives, which also makes their attributive impact evaluation methodologically challenging. Here we analyze one such REDD+ initiative, involving Brazil nut concessionaries in the Peruvian Amazon (Department of Madre de Dios), close to Peru's trilateral border with Bolivia and Brazil. This initiative is emblematic in that it seeks to conserve a portion of the largest remaining tract of Brazil nut rich-forests through private funds. Combining longitudinal data from remote sensing (2000-2018) and surveys with 240 households from 2010, 2014, and 2018, we evaluate the project's impacts vis-à-vis the intended goal of mitigating forest degradation and conversion. To do so, we use a before-after control-intervention (BACI) approach, combined with matching techniques and multivariate regressions, so as to minimize any participation selection bias. As for results, we find that forest conservation impacts so far have been curtailed by low treatment intensities, caused particularly by interrupted funding and consequent project delays. This highlights the importance of REDD+ financial sustainability. We discuss the relevance of our findings for national policies that seek to mitigate Peru's forest-based emissions, such as the Programa Bosques that is currently being upscaled from its pilot stage.

B6p: ACHIEVING REDD+: FROM LOCAL ACTIONS TO NATIONAL COMMITMENTS

Quantifying emissions and their uncertainties in a forest transition landscape: the case of the Southern Cameroon forest plateau

Johannes Pirker^{1,2}, Aline Mosnier^{1,3}, Tatiana Nana⁴, Matthias Dees^{5,6}, Achille Momo⁴, René Siwe⁷

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²KU Leuven, Catholic University of Leuven, Leuven, Belgium; ³Sustainable Development Solutions Network, Paris, France; ⁴Technical REDD+ Secretariat, Ministry of the Environment, Yaoundé, Cameroon; ⁵University of Freiburg, Freiburg, Germany; ⁶UNIQUE forestry and land use GmbH, Freiburg, Germany; ⁷US Forest Service, Brazzaville, Congo (pirker@iiasa.ac.at; mosnier@iiasa.ac.at; andytatiana@gmail.com; matthias.dees@i-online.de; machibe2003@yahoo.fr; rene.siwe@gmail.com)

Cameroon is a HFLD country characterized by high remaining forest cover and relatively low but steadily rising deforestation rates (i.e. > 50% forest cover and a deforestation rate < 0.22% per year). The driving forces of forest conversion are expected to even accelerate in the next decades due to population growth, infrastructure development and agriculture expansion. These factors have to be taken into account when predicting future forest loss and resulting emissions for the establishment of forest reference (emission) levels. However, the consideration of these likely future developments contributes an additional degree of uncertainty to the overall uncertainty of future GHG emission estimates. Greenhouse gas accountings should follow the TCCCA principles (Data underlying any emissions reporting need to be Transparent, Complete, Consistent, Comparable and Accurate according to the UNFCCC), which many countries often find difficult to live up to in their national GHG reportings, specifically when addressing projections into the future. The objective of this paper is to introduce a new and flexible methodology in us in Cameroon to account for likely future development trajectories in projections of greenhouse while also quantifying the sources of uncertainty underlying these calculations. Accounting for the future demand for agricultural commodities, the approach takes quantitative account of emerging mega-trends in Cameroon such as population growth and urbanization; both are considered to have substantial impact on land use in the country. Furthermore, the contribution will place specific focus on quantifying the uncertainty associated with the calculation of emissions, in particular when accounting for likely future development trajectories.

The contribution of the Austrian forest-based sector to climate change mitigation with regard to climate change impacts and adaptation measures in Austrian forests

Martin Braun¹, Peter Schwarzbauer^{1,2}, Franziska Hesser², Thomas Ledermann³, Thomas Gschwantner³, Georg Kindermann³, Klemens Schadauer³, Robert Jandl⁴, Alice Ludvig⁴, Gerhard Weiss⁴, David Fritz⁵, Werner Pölz⁵, Carmen Schmid⁶, Peter Weiss⁶

¹Institute of Marketing & Innovation, Dept. of Economics and Social Sciences, University of Natural Resources and Life Sciences, Vienna, Austria; ²Team for Market Analysis and Innovation Research, Wood K plus - Kompetenzzentrum Holz GmbH, Linz, Austria; ³Federal Research and Training Centre for Forests, Natural Hazards and Landscape, Vienna, Austria; ⁴Institute of Forest, Environmental, and Natural Resource Policy, Dept. of Economics and Social Sciences, University of Natural Resources and Life Sciences, Vienna, Austria; ⁵Environment Agency Austria, Vienna, Austria (martin.braun@boku.ac.at; peter.schwarzbauer@boku.ac.at; franziska.hesser@wood-kplus.at; thomas.ledermann@bfw.gv.at; thomas.gschwantner@bfw.gv.at; georg.kindermann@bfw.gv.at; klemens.schadauer@bfw.gv.at; robert.jandl@bfw.gv.at; alice.ludvig@boku.ac.at; gerhard.weiss@boku.ac.at; david.fritz@umweltbundesamt.at; werner.poelz@umweltbundesamt.at; carmen.schmid@umweltbundesamt.at; peter.weiss@umweltbundesamt.at)

Forests and harvested wood products (HWP) can significantly contribute to meet nationally determined contributions (NDC) arising from the Paris Agreement. The global forest-based sector (FBS) and its contribution to climate change mitigation is not only affected by climate change impacts and expected forest adaptation measures affecting harvest rates and wood delivery but is also facing structural changes through global shifts in production centres and changes in production and consumption patterns. The presented project analysed mid- to long-term developments in the Austrian wood-based value chain using a partial equilibrium dynamic forest sector model for different climate change impacts and related adaptation measures in the forests including six scenarios: - two

business-as-usual scenarios (for RCP 4.5 and 8.5), a scenario assuming tree species shift through adaptive management, a catastrophe scenario with rising impacts from storm, bark beetle infestation, and dry spells, a scenario implementing a reduction of the rotation period and a scenario aiming at the increase of the growing stock in forests. Simulations were conducted for the time period 2010-2150 including long-term forecasts for economic framework conditions until 2050 and assumptions for constant market conditions after 2050. Results help contribute to the understanding of carbon dynamics through a cascade of models comprising forest management, harvested wood products and life cycle assessments (considering material & energy substitution). Identification of critical factors helps to assess the potential contribution of the FBS to NDC. Furthermore, associated impacts on forest product markets as well as interdependencies within the FBS can be identified.

Forestry sector engagement in climate change action: the role of public and private sector in Zimbabwe

Lizzie Mujuru¹ , Vincent Oeba², Mahamane Larwanou²

¹Bindura University of Science Education, Bindura, Zimbabwe; ²African Forest Forum (AFF), Nairobi, Kenya (lzmjmr2009@gmail.com; v.oeba@cgiar.org; m.larwanou@cgiar.org)

Forests and forest products industries are a source of economic growth and employment in both developed and developing nations. A study was done to examine the role of Zimbabwean forestry sector in responding to climate change with the aim of generating knowledge to facilitate development of public-private sector partnerships. Questionnaires and face to face interviews were used to collect data from public, private and non-governmental organisations (NGOs) working in forestry. Results suggest that there was some response to climate change by public and private forest organizations and NGOs. There was however, realization of climate change and some effort to change management practices (e.g. using planting gel and species selection) although, there was uncertainty about how to adapt. Level of adaptation was low and somehow difficult to measure among key actors as existing adaptive actions were not normally documented as climate change actions. Climate change related actions were mostly limited to ways of reducing emissions in industrial operations. Forestry activities were not really focused on addressing climate change but on survival given national economic crisis. All private sector actors were not involved and had no plans for marketing and trade in forest carbon but efforts were made by NGOs to make communities aware of climate change. Main challenges to forest productivity included the poor national economy, wild fires and invasion of forests by illegal settlers. More work is needed to encourage forestry sector to focus on climate change mitigation and adaptation and promote resilience.

Carbon sequestration as a new objective in fast growing plantations' tactical management

Carlos Romero¹, Luis Diaz-Baltero¹

¹Universidad Politécnica de Madrid, Madrid, Spain (inv.florestal@gmail.com; carlos.romero@upm.es; luis.diaz.balteiro@upm.es)

Forest plantations can play an important role in the CO₂ removals considering this new ecosystem service in the forest management planning issues. This goal might contribute to the mitigation of climate change, considering the reduction of the greenhouse gases emissions from the harvesting operations and transportation in spatially explicit tactical planning problems. This research aims to integrate the carbon balance as a new objective for solving a tactical forest planning integrating other production criteria by resorting to multiple criteria decision making tools. The case study corresponds to an industrial forest company located in Brazil. The results reveal the marked difficulty in obtaining from an economic and forestry viewpoint good harvest schedules compatible with high levels of carbon captured.

A large-scale restoration strategy for small landowners in Brazil

Aline Soterroni^{1,2}, Fernando Ramos¹, Marluce Scarabello¹, Hugo Valin², Aline Mosnier², Vagna Pereira³, Marcia Zilli¹, Wanderson Costa¹, Pedro Andrade¹, Marina Pena⁴, Heloisa Ruivo¹, Rolf Simões¹, Alexandre Carvalho⁴, Gilberto Câmara¹, Michael Obersteiner²

¹Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil; ²International Institute for Applied Systems Analysis, Laxenburg, Austria; ³Universidade Federal de Viçosa, Viçosa, Brasil; ⁴Instituto de Pesquisa Econômica Aplicada, Brasília, Brasil; ⁵UN Environment World Conservation Monitoring Centre, Cambridge, United Kingdom (soterr@iiasa.ac.at; fernando.ramos@inpe.br; mascarabello@gmail.com; valin@iiasa.ac.at; mosnier@iiasa.ac.at; vagna.jp@gmail.com; marciatz@gmail.com; wcosta.comp@gmail.com; pedro.andrade@inpe.br; marina.pena@ipea.gov.br; helo_mr@hotmail.com; rolfsimoes@gmail.com; alexandre.ywata@ipea.gov.br; gilberto.camara@inpe.br; oberstei@iiasa.ac.at; pirker@iiasa.ac.at; havlikpi@iiasa.ac.at; val.kapos@unep-wcmc.org; will.simonson@unep-wcmc.org; shena.garciarangel@unep-wcmc.org; kraxner@iiasa.ac.at)

Brazil's new Forest Code grants amnesty of environmental debts for small landowners that illegally cleared their forests before 22 July 2008. Based on the Rural Environmental Registry (Portuguese acronym: CAR) from December 2016, this exemption applies to 19 million deforested hectares across country, mainly located in Atlantic Forest and Amazon biomes. We investigated the implications of this amnesty for the potential for forest restoration and associated changes to land use and emissions using the global economic partial equilibrium model GLOBIOM-Brazil. We modeled scenarios on the future enforcement of the Forest Code and its restoration requirements, with and without the small farms amnesty, and found that the area of forest restoration ranged from 12 to 31 million hectares. The different scenarios investigated included different governance in relation to the degree of control of illegal deforestation and compliance with forest restoration obligations. We estimated future negative emissions from each of these scenarios along with positive emissions from land use conversions. We assess the potential for emissions reduction of forest restoration within the land for which amnesty was granted, as well as the trade-offs with the production sector. Our results emphasize the need to design large-scale restoration policies or incentives for small landowners that could be key to enabling Brazil to fulfill its Nationally Determined Contributions of emissions reductions under the Paris Agreement.

Assessment of per capita CO₂ emission from households' fuel wood consumption in and around the forest areas of Bangladesh

Md Nazmus Sadath^{1,2}, Md Wasiul Islam¹

¹Forestry and Wood Technology Discipline, Khulna University, Khulna, Bangladesh; ²Georg August University, Goettingen Forest and Nature Conservation Policy and Forest History, Georg-August University, Goettingen, Germany (mnsadath@yahoo.com; wasiulislam7@yahoo.com)

Forest emission reference level determination is first step in successful implementation of UN- REDD program. Fuel-wood is the most important energy source for rural households in and around the forest areas of Bangladesh, hence fuel-wood consumption is one of the major contributor to the CO₂ emission source, which needs to be accounted. However, very little to no study has been done in Bangladesh to estimate CO₂ emission from household fuel-wood consumption. This research has been conducted to determine the per-capita household CO₂ emission from fuel-wood consumption in and around the forest areas of Bangladesh. Household survey using a semi-structured questionnaire was the applied method for data collection; 500 households were surveyed in five

differ regions; Southwest zone near the Sundarbans forest, Southeast zone near the hill forest, Northeast zone near hill and swamp forest of Sylhet, Northwest zone near Birol Sal forest and Central zone near Inland Sal forest. The study reveals that the average per capita household carbon emission from fuel-wood consumption is 9.923 tons CO₂ per year however the amount varies on the household size and household income. Out of these amount 4.45 ton CO₂ per capita household emission is coming from natural forest sources and 5.47 ton CO₂ per capita household emission is coming from non-forest sources like home garden and plantations. The study also indicate a possible increasing trends of CO₂ emission from household fuel-wood consumption and hence an alternative renewable energy source is warranted for reduction of carbon emission from forest sources.

The potential of tree-based management systems in optimizing the outcomes of REDD+ strategies

Caroline Souza¹

¹Instituto de Pesquisas Tecnológicas, São Paulo, Brasil (casouza@uol.com.br)

This study highlights the potential of commercial tree-based management systems in optimizing the outcomes of REDD+ strategies. Five smallholder tree-based management systems were compared regarding both GHG emissions reductions and generation of environmental and socio-economic co-benefits. The systems analyzed were: oil palm plantation, rubber plantation, rubber agroforestry and forest plantation for pulp wood and natural forest management for wood fuel production. A questionnaire with key questions on environmental and socioeconomic aspects of the system was used in semi-structured interviews with 70 producers. The performance of each system considered three indexes: carbon benefit index (I-carbon), environmental conservation benefit index (I-env) and local quality of life benefit index (I-qual life). The average of the three indexes generated the REDD+ index (I-REDD) – representing the potential of the system in contributing to REDD+ strategies. The best performance for I-REDD (0,8114) was achieved by natural forest management for wood fuel production, followed by rubber agroforestry (0,6167), rubber plantation (0,5204), oil palm plantation (0,4054) and forest plantation for pulpwood (0,2758). The final classification on each system's potential in contributing to REDD+ strategies was as follows: very high for natural forest management for wood fuel production; high for rubber agroforestry; medium for both rubber plantation and oil palm plantation; low for forest plantation for pulpwood. The methodology proposed can help decision-makers to design REDD+ strategies considering the potential of tree-based management systems to complement conservation activities in composing the strategy.

Forest governance challenges and opportunities in Bangladesh: institutionalization of co-management as the local level solution under UN-REDD regime

Md Nazmus Sadath^{1,2}, Abdus Subhan Mollick¹, Md Wasiul Islam¹

¹Forestry and Wood Technology Discipline, Khulna University, Khulna, Bangladesh; ²Forest and Nature Conservation Policy and Forest History, Gerog August University, Goettingen, Germany (mnsadath@yahoo.com; amsubhan@hotmail.com; wasiulislam7@yahoo.com)

For successful implementation of UN-REDD+ program, good forest governance and equity-based benefit sharing is imperative, which is the challenge in Bangladesh forest sector. The newly adopted Co-management of forest resources has been perceived as the solution for the forest governance issue particularly in light of UN-REDD+ Bangladesh National Program. Despite the establishment of legal and institutional frameworks for developing a meaningful authority of local people, Co-management in Bangladesh has been facing many governance challenges. Therefore meaningful involvement of multilevel stakeholders in forest governance needs to be evaluated. A quantitative and qualitative research method has been applied to investigate a forest governance framework for evaluating the Co-management of forest resources in Bangladesh. A category based content analysis of relevant policy documents and 80 key personal in-depth interview were applied to obtain the data for analysis. A proposed modified framework for evaluation of good governance in terms of participation, transparency, accountability and capacity are adopted. Analysis of data revealed the institutional and legal arrangement of co-management program can provide the local level institution for REDD+ program implementation in Bangladesh. Analysis also indicate that participation received the highest score (3.90/5) followed by capacity (3.70/5), transparency in decision-making (2.42/5) and accountability has the lowest score (2.3/5). Initiation of UN-REDD+ program enhanced the capacity of the stakeholders and forest administration in terms of forest governance. Findings indicate that poor governance still exists in Co-management program but emergence of REDD+ initiative has provided opportunities for achieving good forest governance.

B6q: ACHIEVING REDD+: FROM LOCAL ACTIONS TO NATIONAL COMMITMENTS

Generating green energy and reducing greenhouse gas emissions / Geração energia verde e redução de emissões de GEE

Fábio de Paula¹

¹Eldorado Brasil Celulose SA, Três Lagoas, Brasil (fabio.paula@eldoradobrasil.com.br)

A Eldorado Brasil já nasceu comprometida com as práticas responsáveis, realizando as atividades de forma ambientalmente adequado, socialmente benéfico e economicamente viável. O que reforça esta diretriz são as certificações que conquistamos: FSC® e CERFLOR, que atestam o emprego das melhores práticas de manejo florestal e o compromisso da Companhia no cumprimento do Código Florestal e legislações pertinentes. A fábrica é autossuficiente em energia renovável e ainda disponibiliza mais de 45 MW/h de sua geração para o sistema elétrico nacional, contribuindo com ganhos de eficiência no setor elétrico. Também, estamos em fase de construção uma UTE - Usina Termoeletrica, que terá capacidade para produzir 50 MW/h a partir de 2021, cuja matéria prima é a biomassa vinda do aproveitamento de tocos e galhos da produção florestal de eucalipto, fazendo um maior aproveitamento da árvore. A companhia possui diversos programas e estudos que visam reduzir e gerenciar as emissões de GEE para atmosfera. Desde 2013 a empresa faz parte do Programa Brasileiro GHG Protocol, programa que possui método mais usado mundialmente pelas empresas e governos para a realização de inventários de GEE - Gases de Efeito Estufa. Para monitorar cerca de 30% das áreas destinadas à conservação ambiental e mais de 230 mil hectares de reflorestamento, a Eldorado utiliza sistema de monitoramento com câmeras de última geração e com qualidade de imagem em Full HD que captam ocorrências de focos de incêndios em tempo real. Esta tecnologia possibilitou redução de 70% dos incêndios florestais reduzindo assim as emissões involuntárias de GEE, demonstrando o compromisso com a conservação das florestas e a qualidade do ar. Nossas florestas em contante crescimento, sequestram o CO₂ da atmosfera, acumulando um estoque atual de carbono suficiente para neutralizar mais de 11 anos de todas nossas operações. Na indústria, substituímos a matriz energética de uma das nossas três principais fontes de emissões na fábrica, substituindo no forno de cal o óleo combustível por gás natural, além disso a eficiência operacional da fábrica é de 96%, isso permite operarmos em média 30% abaixo dos limites legais de emissões atmosféricas, contribuindo assim para a redução dos gases de efeito estufa, contribuindo assim para a melhoria da qualidade do ar e da vida.

Locking carbon in wooden school furniture - a case study of Haryana State, India

Subhash Chander¹, Vivek Saxena¹, Amarinder Kaur²

¹Haryana Forest Development Corporation, Gurugram, India; ²Haryana Forest Development Corporation, Panchkula, India (syadavhfs02@gmail.com; viveksax1@gmail.com; md@hfdc.gov.in)

Locking carbon in wooden furniture has been discussed at many platforms in relation to one of strategy under climate change adaptation and mitigation. The wooden furniture in schools can play an important role in locking carbon. The dual desks and furniture used in schools were mainly of iron or plastic in past. But a big initiative was taken by State Government to use wooden dual desks or furniture for government schools to be supplied by State Forest Department or State Forest Development Corporation. Forest Department or State Forest Development Corporation used to do logging activities in the state. The harvested forest produce used to be auctioned to contractors. The contractors used to utilize some of the lesser timber value species for fuelwood after sawing on their saw mills. A big initiative was taken and school furniture of wood was supplied in government schools during 2015-16 and 2016-17 from furniture workshops of the Forest Department and State Forest Development Corporation. The various types furniture supplied and estimated carbon locked in the school furniture will be discussed in the paper and will be presented during the Congress.

Application of REDD+ scheme for blue carbon ecosystem management: potentials and challenges

Ryo Kohsaka¹, Yuta Uchiyama¹, Kaoru Kakinuma², Jay Mar D. Quevedo³, Kevin Muhamad Lukman³

¹Graduate School of Environmental Studies, Nagoya University, Nagoya, Japan; ²Asian Demographic Research Institute, Shanghai University, Shanghai, China; ³Graduate School of Environmental Studies, Tohoku University, Sendai, Japan (yutau4@gmail.com; yutau4@yahoo.co.jp; k.kakinuma0214@gmail.com; quevedojaymar@gmail.com; kevin.muhamad.lukman@gmail.com)

Sustainable management of blue carbon ecosystems is an urgent task especially in the so called “coral triangle area” as emerging frontier for REDD+ related discussions. Blue carbon ecosystems provide multi ecosystem services from their main components including (mangroves, seagrass meadows and salt marshes). They are gaining salience as globally major carbon stocks. Despite its great potentials to enhance the local and global sustainability, blue carbon ecosystems have serious challenges in their managements to acknowledge their multi services. Particularly, implementation of schemes of benefit sharing including REDD+ for their sustainable managements involve issues related to their monitoring and evaluation methods and collaboration of stakeholders including consensus building among them. For example, accurate assessment of carbon stock in blue carbon ecosystem is remained as a challenging task. The remote sensing technic applied for terrestrial forests to identify their carbon stocks cannot be used, because the carbon stocks of blue carbon ecosystem mainly exist underground and simple correlation between the carbon stocks of the aboveground parts of the ecosystem and those of the underground parts is not methodologically solved. Furthermore, the managements of blue carbon ecosystems require collaboration of various stakeholders, and the industrial sectors related to the managements from local and comprehensive perspectives, because of the geographical location of blue carbon ecosystems located in between marine and terrestrial areas.

Socio-economic monitoring in the La Amistad community within the REDD+ Paraguay forest conservation project, Alto Paraná Atlantic Forest component (BAAPA) / Monitoreo socioeconómico en la comunidad La Amistad en el marco del Proyecto de Conservación de Bosques del Paraguay REDD+ componente Bosque Atlántico del Alto Paraná (BAAPA)

Carmen Monges¹, Elizabeth Monges¹, Cecilia Pizzurno²

¹Universidad Nacional de Asunción, Asunción, Paraguay; ²Guyra Paraguay, Asunción, Paraguay (aracelymonges@gmail.com; lizamonges@gmail.com; ccipizzu2@gmail.com)

El proyecto de Conservación de Bosques del Paraguay en su componente REDD+ BAAPA, busca fortalecer las capacidades y los medios de vida a los beneficiarios de la comunidad La Amistad, integrada por pequeños productores agrícolas que se asentaron dentro de los límites de la reserva para Parque Nacional San Rafael en el distrito de Alto Vera, Departamento de Itapúa, Paraguay. Es la primera experiencia exitosa de mercado voluntario de carbono en Paraguay con certificación internacional bajo los estándares de Verifield Carbon Standard (VCS) y Climate, Community and Biodiversity Standards (CCB). Las actividades establecidas por el proyecto incluyen; el pago por servicios ambientales correspondiente a un ingreso fijo anual de 170USD por superficie de bosque comprometida con REDD+ servicios de extensión, apoyo técnico para la gestión sostenible de sus bosques y el mejoramiento de su producción agrícola. El objetivo general del trabajo fue monitorear los capitales de la comunidad mediante el análisis de indicadores socioeconómicos, la cuantificación de la evolución de los mismos desde el inicio del proyecto hasta el año 2015 y la identificación de los impactos sociales netos, la recolección de datos se realizó mediante una encuesta. Se observó que el contexto de vulnerabilidad está dado por la debilidad en la gestión y organización de la comunidad así como también en la infraestructura vial limitada que impide el acceso a mercados y otros servicios. El aislamiento territorial y la falta de oportunidades de desarrollo generan una mayor tendencia a utilizar el capital natural para la generación de ingresos económicos.

History and current panorama of payment for environmental services in the state of São Paulo: a potential vision for Brazil / Histórico e panorama atual do Pagamento de Serviços Ambientais no Estado de São Paulo: uma visão prospectiva para o Brasil

Luiz César Ribas¹, Rafaela Prosdocini Parmeggiani¹, Miguel Ángel Sarmiento²

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Universidad Nacional de Santiago del Estero, Santiago del Estero, Argentina (luiz.c.ribas@unesp.br; rafaela.prosdocini@gmail.com; migui@unse.edu.ar)

Pagamento de Serviços Ambientais (PSA) é um instrumento de política florestal que remunera, pecuniariamente ou não, prestadores de serviços ecossistêmicos que propiciem suporte para atividades econômicas. Serviços ecossistêmicos (de provisão, suporte, regulação e culturais) são benefícios que as pessoas obtêm dos ecossistemas. Serviços ambientais são os serviços ecossistêmicos obtidos por iniciativas antrópicas que impactam positivamente os ecossistemas. O PSA é um instrumento econômico, mas integra-se também aos de comando e controle, de mercado e voluntários. Em São Paulo, o PSA está originariamente atrelado à Convenção-Quadro das Nações Unidas sobre Mudança do Clima (UNFCCC-Rio 92), à Lei n. 12.187/2009 (Política Nacional sobre Mudança do Clima), à Lei n. 13.798/2009 (Política Estadual de Mudanças Climáticas) e ao Decreto n. 55.947/2010 (regulamento paulista). O PSA paulista tem origem na mitigação das mudanças climáticas globais e no Programa de Remanescentes Florestais, sendo pautado na restauração da vegetação nativa e no reflorestamento visando a absorção e fixação de carbono e na biodiversidade. À estratégia paulista (e mesmo nacional) do PSA devem ser fortemente agregados, conforme previsão legal, mecanismos financeiros de liquidez para antecipar o retorno dos investimentos para plantio de essências florestais nativas com potencial de exploração econômica. Para tanto, deve-se também consolidar: i) exploração de produtos madeireiros e não madeireiros; ii) exploração econômica de florestas nativas implantadas; iii) SAF's e sistemas de iLPF, e; iv) manejo de culturas e plantações florestais que favoreçam o desenvolvimento de vegetação nativa em sub-bosque, sem prejuízo da colheita da produção ou do corte da floresta plantada.

Forestry potential, under the REDD + mechanism in Tocantins State, threatened by agricultural and livestock expansion

Yara Ferreira¹, Jacqueline Gerage Marques¹, Luciana S. Soler¹, Jean Pierre Ometto¹

¹Instituto de Pesquisas Espaciais, São José dos Campos, Brasil (ycf1690@hotmail.com; jacqueline.marques@inpe.br; lusoler@gmail.com; jean.ometto@inpe.br)

Cerrado conservation is essential to the maintenance a number of species and ecosystem services (ESS), as it holds 30% of national biodiversity. Considering REDD+ mechanisms facilitate forest conservation and prevent climate change, these mechanisms contribute to the maintenance of ESS. The Tocantins state is into nowadays area of expansion agriculture and livestock in Brazil, however, the total of production is not completely destinate to population consumption. The objective of this work was to relate areas with potential for REDD + and their use for the generation of calory for human consumption through agricultural production. Based on SICAR data of limits of properties and land use/cover of MapBiomias we performed spatial analyses to retrieve relationships between agricultural and forested areas. Agricultural Census data (IBGE) will allow the estimation of available calory from regional agricultural production. The analysis resulted in approximately 484,16 Mha of forested areas prone for REDD+ at the property level in Tocantins. Despite agricultural expansion in the Cerrado it's based on high technological improvements, part of this production is not consumed directly by the population, where almost 20% of soybean production goes to national livestock feeding linked to increasing meat consumption by population. That is food habits of Brazilian population is also contributing to land pressure over forests, but not improving nutrients intake. So REDD+ mechanisms policies must be considered together with more sustainable food education habits.

B7a: MONITORING AND MODELLING OF FOREST HEALTH IN A CHANGING WORLD

How accurate are the predictions made by ecological modelling? A case study of the eucalypt pest *Glycaspis brimblecombei* (Hemiptera) around the world

Dalva Queiroz¹ , Marilice Cordeiro Garrastazu¹ , Marcos Silveira Wrege¹ , Daniel Burckhardt² 

¹Embrapa Florestas, Colombo, Brasil; ²Naturhistorisches Museum Basel, Basel, Switzerland (dalva.queiroz@embrapa.br; marilice.garrastazu@embrapa.br; marcos.wrege@embrapa.br daniel.burckhardt@unibas.ch)

The red gum lerp psyllid *Glycaspis brimblecombei* Moore (Psylloidea: Aphalaridae), originating from Southeast Australia, is a major pest in eucalypt plantations around the world. In a study published in 2012 the potential distribution was estimated using ecological modelling based on the occurrence of the species in Australia, the Americas (eight countries), Mauritius, Italy, Portugal and Spain. The study predicted that temperate areas are more favourable for the occurrence of *Glycaspis brimblecombei* than tropical ones. Since the publication of the study, the red gum lerp psyllid spread all around the Mediterranean Basin (Africa: three countries; Asia: two countries; Europe: five countries) and invaded southern Africa (four countries). The envelope score model that seemed very pessimistic at the time turned out to be quite realistic. According to the canonical analysis, the pest *G. brimblecombei* is very plastic, adapting easily to newly colonised areas. We conclude that ecological modelling provides reliable predictions and, hence, is a useful tool for managing eucalypt plantations.

Ecological niche modeling of *Araucaria angustifolia*

Giulliana Baggio Bernardinis¹, Victor Pereira Zwiener², Fernanda Thiesen Brum¹, Marcos Bergmann Carlucci¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade Federal do Paraná, Palotina, Brasil (giulli_bag@hotmail.com; vzwiener@gmail.com; fibrum@gmail.com; marcos.carlucci@gmail.com)

Ecological niche modeling (ENM) has been used to estimate current, past, and future geographic distributions, based on the correlation of observed species occurrences and environmental variables. Such estimates can be used in ecology to predict geographic changes in species occurrences, and give support to decisions towards conservation of biodiversity. Species of the genus *Araucaria* are mostly endemic and restricted to areas with temperate climate. In Brazil *Araucaria angustifolia* is the only representative of the genus, with great ecological importance in the Atlantic forest, characterizing an entire forest ecosystem. Currently the species is in danger of extinction, yet only few attempts have been made to estimate potential effects climate change to its distribution. In this study we aim to assess spatio-temporal changes in the distribution of *Araucaria angustifolia* with regard to current, past and future climatic scenarios. We obtained occurrences and climatic layers for different scenarios on digital databases and used Maxent to calibrate models and project to different scenarios. Our results indicate that the overall trend for future climate change scenarios is retraction of the geographic distribution, however the intensity of changes depends on the future scenario. The species may experience expansion to some areas, indicating the variability of local responses. Conservation and restoration actions need to consider potential effects of climate change for effective use of limited resources, ENM has been shown to give support to decision making with regard to estimating geographical distribution of endemic and endangered species such as *Araucaria angustifolia*.

Do ozone and drought change the parameters of photosynthesis-stomatal model? The analysis by the optimal stomatal conductance model

Yasutomo Hoshika¹, Elena Paoletti¹

¹CNR, Sesto Fiorentino (FI), Italy (yasutomo.hoshika@cnr.it; elena.paoletti@cnr.it)

The exchange of gases, as well as water vapor, between interior of leaves and the atmosphere are regulated by stomatal pores, termed stomatal conductance (gs). Semi-empirical photosynthesis-stomatal models (e.g., Ball-Woodrow-Berry model) are widely used in many land-surface schemes in climate model. These model need two important parameters, 1) the slope of the conductance-photosynthesis relationship, 2) the y-intercept of this relationship (gmin, minimum conductance). In Mediterranean region, trees are often suffered from ozone (O3) and drought stress in summer. Both O3 and drought are known to affect gs. Therefore we investigated whether O3 would change the parameters of the photosynthesis-stomatal model in Mediterranean trees (*Phillyrea angustifolia*, *Quercus ilex*, *Q. pubescens*, *Q. robur*) grown under O3 FACE (Free-Air Controlled Exposure) experiment. To discuss the effect of O3 on gs, we applied the optimal photosynthesis-stomatal model involving water, CO₂ and O3 flux using gas exchange data. This analytical model was proposed based on the optimization theory of gs for maximizing carbon gain while minimizing accompanying water loss and O3 influx. The optimization theory suggests that O3-induced stomatal closure in early summer may reduce O3 influx, and allow maximum photosynthetic capacity to be reached. However, in late summer, the theory did not explain the effects of O3 on gs in *Q. robur*, showing an increase of gmin under elevated O3. This may relate to the loss of closing response of stomata by O3 (i.e., stomatal sluggishness).

Climate change and air pollution effects on forest ecosystems status in representative Romanian Level II monitoring plots

Ovidiu Badea^{1,2}, Ionel Popa¹, Diana Pitar¹, Stefan Leca¹, Ecaterina Apostol¹, Albert Ciceu¹, Serban Chivulescu¹

¹National Institute for Research and Development in Forestry "Marin Drăcea", Voluntari, Romania; ²Transilvania University of Braşov, Braşov, Romania (obadea@icas.ro; popaicas@gmail.com; diana.silaghi@icas.ro; stefan.leca@icas.ro; cathythes@yahoo.com; albert.ciceu@yahoo.ro; serban.chivulescu@icas.ro)

This research refers to monitoring and evaluation of forests ecosystems status in four representative Level II monitoring sites under air pollution and climate change effects. During the last period 2011–2017, trees from these plots have been slightly affected by excessive drought, high temperatures or air pollution. The pedunculate oak registered the lowest mean crown defoliation percentage in Stefanesti – stejar plot, ranging between 5.4% (2011) and 10.9% (2016). Sessile oak and beech proved to be more sensitive to stress factors, the highest mean crown defoliation percentage being registered in 2014 (20%). For spruce the health status maintained relatively constant due to optimal site condition from Predeal – molid plot. The years 2014 and 2016 proved to be the most stressful ones being characterized by high temperatures and low precipitations. Volume growth of forests is correlated with mean defoliation percentage recording decreasing values while crown defoliation increase, also the influence of climate change on growth season was emphasized. Phytotoxic pollutants (O₃, NO₂, NH₃) recorded low concentrations. In Ştefăneşti-stejar site, ozone recorded the lowest values of the studied plots. At mean levels (>40 ppb), in Predeal-molid site, ozone positively correlates (r = 0.43) with mean defoliation percentage, indicating a possible negative effect on forests health status. Although NO₂ and NH₃ concentrations show a positive/negative correlation with crown mean defoliation percentage (r = -0.25; r = 0.49), they have no real influence on forest health status. Positive values of net throughfall, especially for Sulphur anions, show the important filtering role of the forest ecosystems

Tree and microclimate measurements using low-cost automated devices: the reliable approach for quantifying climate effects on woody vegetation across ecosystems

Radim Matula^{1,2}, Josef Urban^{2,3}, Roman Gebauer², Roman Plichta², Martin Svátek²

¹Czech University of Life Sciences, Prague, Czech Republic; ²Mendel University in Brno, Brno, Czech Republic; ³Siberian Federal University, Krasnoyarsk, Russian Federation (radimmatula@gmail.com; josef.urban@email.cz; gebo@email.cz; plichta.roman@gmail.com; msvatek@centrum.cz)

Alteration of climate patterns under climate change affects productivity and stability of forests. However, current data on tree growth have too low precision and remeasurement frequency for a mechanistic understanding of how trees respond to climate variation and particularly drought. In addition, available climate and soil moisture data usually do not represent local microclimate of the study sites because they come either from climate stations located outside forest or from climate databases, which have a low spatial resolution. To tackle these issues, we developed low-cost but high precision and resistant automatic point dendrometers that continuously measure tree diameter changes. In combination with inexpensive automatic microclimate dataloggers they represent a powerful tool for measuring tree responses to climate on a very fine scale. These devices have been used in ecophysiology for a long time, but their high costs have limited their use to a low number of trees and sites, not allowing for broader ecological inference. By testing these devices in various forest ecosystems, we demonstrated, that they provide high precision and directly comparable data on diurnal and daily tree diameter changes, on soil moisture, soil and air temperature from boreal to tropical forests. Due to low-cost, they can be used on a great number of trees and sites even within a limited budget. The low-cost automatic dendrometers in combination with microclimate dataloggers are a reliable and cost-effective way to quantify climate effects on tree vitality, growth and carbon allocation across forest ecosystems.

Simulating the response of mixed broadleaved forests to changes in climate conditions: disentangling the relative importance of various abiotic factors

Louis de Wergifosse¹, Frédéric André¹, Nicolas Beudez², François de Coligny², Hugues Goosse¹, Mathieu Jonard¹

¹UCLouvain, Louvain-la-Neuve, Belgium; ²Institut National de la Recherche Agronomique, Montpellier, France (louis.dewergifosse@uclouvain.be; frederic.andre@uclouvain.be; nicolas.beudez@inra.fr; francois.decoligny@inra.fr; hugues.goosse@uclouvain.be; mathieu.jonard@uclouvain.be)

Forests will face in the future unprecedented climatic conditions that are expected to impact them in various and sometimes opposite ways. The fertilizing effect of rising atmospheric CO₂ concentrations and nitrogen deposits added to the lengthening of the vegetation period due to warmer temperatures are likely to increase forest productivity. These effects could be offset or even reversed by the increase of drought frequency and severity that trigger stomatal closure and can even lead to tree death. Due to the complex interactions between these factors, their spatial variability and the uniqueness of their combinations, the future forest response to climate change cannot be deducted only from observational studies or environmental manipulation experiments. Here, we use HETEROFOR, an individual and mechanistic tree growth model recently developed and evaluated to simulate the gross primary production of diverse mixed broadleaved forest according to different climatic scenarios. Among the model outputs, a drought index accounting for both the length and the magnitude of the stand hydric deficit is calculated. First, these simulations are conducted with atmospheric CO₂ concentration values maintained constant, then with those from the IPCC scenarios. The results of these simulations are finally used to assess the impact of the various abiotic stressors and their interactions on forest productivity. In a second step, a second set of simulations is launched to assess the impact of the soil properties and of the stand composition, structure and density on tree growth by interchanging soil and forest structures subjected or not to different thinning intensity.

HETEROFOR: an individual-based and spatially-explicit model for exploring the response of structurally-complex forests to uncertain future conditions

Mathieu Jonard¹, Frédéric André¹, Nicolas Beudez², François de Coligny³, Louis de Wergifosse¹, Quentin Ponette¹, Caroline Vincke¹

¹Université catholique de Louvain, Louvain-la-Neuve, Belgium; ²Institut National de la Recherche Agronomique, Montpellier, France; ³CIRAD, Montpellier, France (mathieu.jonard@uclouvain.be; frederic.andre@uclouvain.be; nicolas.beudez@inra.fr; coligny@cirad.fr; louis.dewergifosse@uclouvain.be; quentin.ponette@uclouvain.be; caroline.vincke@uclouvain.be)

Given the multiple abiotic and biotic stressors resulting from the global changes, management systems and practices must be adapted in order to maintain and reinforce the resilience of the forests. Among others, the transformation of monocultures into uneven-aged and mixed stands is an avenue to improve forest resilience. To explore the forest response to these new silvicultural practices and to the changing environment, one needs models combining a process-based approach with a detailed spatial organisation, which is very rare. We therefore decided to develop our own model (HETEROFOR) according to a spatially-explicit approach describing individual tree growth based on resource sharing (light, water and nutrients). HETEROFOR was progressively elaborated through the integration of various modules (light interception, phenology, water cycling, photosynthesis and respiration, carbon allocation, mineral nutrition and nutrient

cycling) within the modelling platform CAPSIS devoted to tree growth and stand dynamics. The advantage of using such a collaborative platform is to use a common development environment, model execution system, user-interface and visualization tools and to share data structures, objects, methods and libraries. The objectives of this presentation are to describe the functioning of HETEROFOR, to show its ability to estimate resource availability and to reconstruct tree growth in mixed oak and beech stands in Wallonia (Belgium). The growth dynamics in these stands was simulated according to four climate scenarios of IPCC to illustrate how the model can be used to predict climate change impacts on forest ecosystems.

Impact of climate change and land use and land cover change on forest biodiversity

Saroj Panthi¹

¹Ministry of Industry, Tourism, Forest, and Environment, Pokhara, Nepal (mountsaroj@gmail.com)

Impact of environmental change may affect the biodiversity. Due to lack of scientific information about effect of future environmental change on biodiversity, long-term conservation plans can be incomplete and inaccurate. Here, we identified the impact of climate change and land use and land cover change on red panda based on red panda occurrence data and environmental variables: climatic, topographic and anthropogenic variables. The model suggested that the future suitable habitat for red pandas in Nepal will be increased by 6.5% under the future climate change scenario. However, the suitable habitat will be reduced by 0.5% due to the combined effects of future climate change and land use and land cover changes. The study recommends that conservationists should pay more attention to the land use planning in the future in order to mitigate the potential economic impact on red panda as well as other endangered species.

B7b: PHYSIOLOGICAL AND BIOGEOCHEMICAL RESPONSE OF FOREST ECOSYSTEMS TO CLIMATE CHANGE AND AIR POLLUTION

Dynamics of sulfur in forest ecosystems under changing atmospheric environment in Japan and Thailand

Hiroyuki Sase¹, Naoyuki Yamashita², Tatsuyoshi Saito³, Bopit Kietvuttinon⁴, Hathairatana Garivait⁵, Masayuki Morohashi¹, Masaaki Takahashi¹, Yayoi Inomata⁶, Makoto Nakata⁷, Kazuhide Matsuda⁸, Tsuyoshi Ohizumi¹

Atmospheric environment in Northeast Asia and Southeast Asia is dynamically changing. In particular, gaseous air pollutants, such as SO₂ and NO_x, which were largely emitted from developing countries in the 1990s/2000s, have started declining recently. Since effects of these air pollutants may remain for a while even after reduction of the emissions, their dynamics in forest ecosystems should carefully be investigated. In particular, SO₄²⁻ is retained in the soil-plant system and its retention/release processes may be changed with air pollution and climate. In this study, monitoring on atmospheric deposition and stream water (SW) chemistry has been conducted in forested catchments in different climatic zones, namely in Kajikawa site (KJK) under the humid subtropical climate in Japan since 2002 and in Sakaerat site (SKT) under the tropical savanna climate in Thailand since 2005. In both countries, atmospheric S deposition has been declining, reflecting national and/or regional SO₂ emission trends. The SO₄²⁻ concentration in SW declined with increase in pH and alkalinity in KJK, however it increased with decline of pH in SKT. The different climatic conditions appear to cause the different reactions. Reactions of forested catchments to declining S deposition should carefully be monitored in the region, where atmospheric environment is dynamically changing. The possible mechanisms in both sites will be discussed with sulfur isotopic data in the presentation.

Measuring and mapping the effectiveness of the European air quality directive in reducing N and S deposition at the ecosystem level

Cristina Branquinho¹, Helena Cristina Serrano¹, Maria Alexandra Oliveira¹, Pedro Pinho¹

¹Centre for Ecology, Evolution and Environmental Changes (cE³c), Faculdade de Ciências, Universidade de Lisboa, Lisboa, Portugal (cbranquinho@fc.ul.pt; hcserano@fc.ul.pt; alexandra.oliv@gmail.com; paplopes@fc.ul.pt)

To protect human health and the environment, the 2001 EU Air Quality Directive imposed national emission ceilings for atmospheric pollutants (Directive 2001/81/EC), including the reduction of sulfur (S) and nitrogen (N) emissions, by 2010. The evaluation of the results of this emission reduction at the ecosystem level has not been thoroughly done. Our aim was to measure and map the consequences of the emission's reduction at the ecosystem level. This was done in a region with multiple industrial activities using ecological indicators, comparing data at the onset of the Directive implementation (2002) and nine years after (2011). The reduction of S emissions was a success at the ecosystem level, emphasizing that most S deposited to the ecosystem had an industrial origin. Overall, the ecosystem within the region experienced a reduction of S deposition (up to -72%), coincident with reductions of SO₂ in emissions (-76%) and air concentration (ca. -59%). However, for N that was not the case. Although a reduction of emissions was achieved for industrial facilities (ca. -37%), for NO₂ and NO₃⁻, ca. -24% reduction was noticed, but on the other hand, there was a 47% increase in NH₃. The results highlight the critical importance of going beyond emissions and air concentrations to verify the success of the implementation of the air quality directive. N pollution remains a challenge for air quality mainly because deposition to ecosystems did not reflect those reductions. Acknowledgements: NitroPortugal EU H2020 research and innovation programme, n.69233 and "Towards INMS", implemented by UN Environment.

N and S deposition across Europe and the impact on tree nutrition

Anne-Katrin Prescher¹, Andreas Schmitz¹, Inken Krüger¹, Tanja Sanders¹, Alexa Michel¹, Pasi Rautio²

¹Thünen Institute of Forest Ecosystems, Eberswalde, Germany; ²Natural Resources Institute Finland (Luke), Helsinki, Finland (anne.prescher@thuenen.de; andreas.schmitz@thuenen.de; inken.krueger@thuenen.de; tanja.sanders@thuenen.de; alexa.michel@thuenen.de; pasi.rautio@luke.fi)

Anthropogenic emissions of nitrogen and sulphur are affecting tree nutrition and nutrient cycling of forest ecosystems across Europe. While nitrogen deposition is still on a high level, the legacy of historic sulphur inputs still takes effect on forest soils. Here we use the extensive data provided by the monitoring framework of UNECE/ICP Forests (International Co-operative Programme on Assessment and Monitoring of Air Pollution Effects on Forests). Across Europe and beyond, this programme is monitoring deposition, foliar concentrations and other variables in forest ecosystems. This study reports on trends in nitrogen

and sulphur deposition and the influence on foliar nitrogen, phosphorus and sulphur concentrations in European beech (*Fagus sylvatica*), Norway spruce (*Picea abies*) and Scots pine (*Pinus sylvestris*) in Europe. The measurements in nitrogen and sulphur deposition over the period 2000 - 2015 revealed reductions, however, most ICP Forests plots are still at risk of eutrophication effects since nitrogen deposition levels are above critical values. Variable trends in foliar nitrogen, phosphorus and sulphur concentration were found depending on tree species and location. Similarly, the comparison of foliar nitrogen and phosphorus concentrations between the periods 2000 - 2005 and 2010 - 2015 indicated heterogeneous developments following the critical ranges for foliar element ratios defined in the literature. It was found that depending on site conditions and tree species, deposition can have an increasing or decreasing effect on foliar nutrient concentrations. Thus, reductions in air pollution can have diverse implications for tree nutrition status.

Interactive effects of ozone, nitrogen deposition and climate in terrestrial ecosystems of Spanish mountain areas

Rocío Alonso¹, Ignacio González-Fernández¹, Héctor García-Gómez¹, Raquel Ruiz-Checa¹, Susana Elvira¹, Isaura Rábago¹, Javier Sanz¹, Victoria Bermejo¹
¹Ecotoxicology of Air Pollution, CIEMAT, Madrid, Spain (rocio.alonso@ciemat.es; ignacio.gonzalez@ciemat.es; hector.garcia@externos.ciemat.es; r.ruizcheca@gmail.com; susana.elvira@ciemat.es; isaura.rabago@ciemat.es; j.sanz@ciemat.es; victoria.bermejo@ciemat.es)

The Mediterranean Basin is one of the Biodiversity Hotspots for conservation priorities. Particularly, the Mediterranean mountains concentrate some of the most valuable areas, due to the high biodiversity and to the provision of many environmental, cultural and economic services. Many of these areas have been recognized and protected under different conservation plans. While conservation plans can implement management strategies to reduce the impact of human activities, those ecosystems can still be affected by air quality and climate change. Tropospheric ozone (O₃) and atmospheric nitrogen (N) deposition are two of the main air pollutants affecting natural and semi-natural ecosystems of the Mediterranean Basin. Unfortunately, most of the air quality networks do not include monitoring stations at high elevation. Ozone, atmospheric N deposition and meteorology have been monitored at different elevations in the Guadarrama mountain range (Madrid, Spain) from 500 up to 2200 m.a.s.l. for several years. At some plots, soil water content data are also available. New flux-based O₃ critical levels proposed for the protection of the Mediterranean vegetation and new methodologies for estimating N deposition in water-limited environments have been used for risk assessment of effects of air pollution in different ecosystems along the elevation gradient. Air pollutants, meteorological variables and plant physiological activity data of different plant communities will be presented. Possible interactions between O₃, N deposition and soil water availability on plant physiology, growth and stomatal uptake of air pollutants will be discussed.

The influence of water and nutrition on productivity of *Pinus taeda* / Influência dos fatores hídricos e nutricionais na produtividade do *Pinus taeda*

Isabel Deliberali¹, Mauro Valdir Schumacher², James Stahl³, Marco Aurélio Figura³, Rodrigo Toledo Coutinho⁴, Reinaldo Hoinacki da Costa⁵, Rildo Moreira e Moreira⁶

¹Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ²Universidade Federal de Santa Maria, Santa Maria, Brasil; ³Klabin S.A., Telêmaco Borba, Brasil; ⁴Arauco do Brasil, Curitiba, Brasil; ⁵Juliana Florestal Ltda, Caçador, Brasil; ⁶Escola Supe (isabel@ipef.br; mauro.schumacher@ufsm.br; jstahl@klabin.com.br; mafigura@klabin.com.br; rcoutinho@arauco.com.br; reinaldo@frameport.com.br; rmoreira@usp.br)

O *Pinus taeda* é a espécie florestal de maior expressão econômica plantada no sul do Brasil e possui uma das maiores produtividades do mundo. Entretanto, devido ao seu bom crescimento (média nacional de 31 m³ ha⁻¹ ano⁻¹) até mesmo em solos de baixa fertilidade e ausência de sintomas visuais de deficiência nutricional, não é comum realizarem-se fertilizações nos plantios comerciais. Além do fator nutricional, a disponibilidade de água e luz é essencial para produção e madeira. Dessa forma, este estudo buscou avaliar o efeito hídrico (irrigação ou redução de 30% da chuva) e nutricional (duas fertilizações de cobertura com 1 e 9 anos de idade) no crescimento do *Pinus taeda* em Itatinga-SP e Telêmaco Borba-PR, até os 11 anos de idade, em Latossolos Vermelhos de textura média. Em Itatinga, o incremento médio anual em volume (IMA) do tratamento irrigado (1,5 x ETP) foi 7% maior que o controle (sem irrigação e sem fertilização), passando de 21,2 para 22,6 m³ ha⁻¹ ano⁻¹ e quando combinado com a fertilização, o aumento foi de 14%. Já em Telêmaco Borba-PR, região com excedente hídrico o ano todo, a redução de 30% da chuva não diminuiu o crescimento das árvores, porém a fertilização aumentou a produtividade em 28% (de 26,5 para 33,8 m³ ha⁻¹ ano⁻¹). Portanto, em Telêmaco Borba o fator nutricional se mostrou limitante ao crescimento do *P. taeda*, enquanto em Itatinga o fator hídrico teve maior resposta. Esses resultados de manipulação hídrica são importantes no desenvolvimento de modelos processuais que simulam mudanças climáticas.

Soil respiration under elevated CO₂ at a temperate mature forest

Angeliki Kourmouli^{1,2}, Liz Hamilton³, Rebecca Bartlett¹, Iain Hartley⁴, Zongbo Shi¹

¹University of Birmingham, Birmingham, United Kingdom; ²Birmingham's Institute of Forest Research, Birmingham, United Kingdom; ³University of Gloucestershire, Cheltenham, United Kingdom; ⁴University of Exeter, Exeter, United Kingdom (axk661@bham.ac.uk; lhamilton3@glos.ac.uk; r.bartlett@bham.ac.uk; i.hartley@exeter.ac.uk; z.shi@bham.ac.uk)

Forest ecosystems are of high importance in the global carbon cycle since they currently stock 861± 66 Pg C, and represent one of the most important carbon sinks, absorbing approximately 2.4 ± 0.4 PgC⁻¹ 1. With the atmospheric CO₂ continuously rising, forests might be able to uptake more carbon. Hence, trees may invest more carbon in their belowground systems to increase their access to soil nutrients, prompting a soil respiration (Rs) increase. However, there is limited understanding of how nutrient dynamics interact with Rs under elevated CO₂. Thus, Rs regulates significantly the carbon dynamics, and even small changes may impact significantly atmospheric CO₂ and global climate. This study assesses the impact of elevated CO₂ on soil respiration at the BIFoR FACE research facility. BIFoR FACE is a second generation FACE experiment, and is the first, globally, set in a mature, temperate woodland. The site comprises of control and elevated CO₂ rings, with CO₂ concentrations matching the 2050 atmospheric CO₂ scenario. Experimental blocks were established in every ring, in order to investigate the contribution of heterotrophic and autotrophic respiration. Measurements were made continuously since December 2016. Results from 2016-2018 show higher soil respiration in eCO₂ rings, post fumigation. Further analysis on the heterotrophic respiration data will help us identify the mechanisms of this increase.

Carbon flux from decomposing wood and its dependency on temperature, wood N₂ fixation rate, moisture and fungal composition in a Norway spruce forest

Katja Rinne-Garmston¹, Krista Peltoniemi¹, Janet Chen¹, Mikko Peltoniemi¹, Hannu Fritze¹, Raisa Mäkipää¹

¹Natural Resources Institute Finland, Helsinki, Finland (katja.rinne-garmston@luke.fi; krista.peltoniemi@luke.fi; janetchen613@gmail.com; mikko.peltoniemi@luke.fi; hannu.fritze@luke.fi; raisa.makipaa@luke.fi)

Globally 40-70 Pg of C are stored in coarse woody debris on forest floor. Climate change may reduce the function of this stock as a C sink in the future due to increasing temperature. However, current knowledge on the drivers of wood decomposition is inadequate for detailed predictions. To define the factors that control wood respiration rate of Norway spruce and to produce a model that adequately describes the decomposition process of this species as a function of time, we used an unprecedentedly diverse analytical approach, which included measurements of e.g. respiration, fungal community sequencing and N₂ fixation rate. Our results suggest that climate change will accelerate C flux from deadwood in boreal conditions, due to the observed strong temperature dependency of deadwood respiration. At the research site, the annual C flux from deadwood would increase by 27% with the projected climate warming. The second most important control on respiration rate was the stage of wood decomposition. Wood decomposition process was best described by a Sigmoidal model, where after 116 years of wood decomposition mass loss of 95% was reached. Our results on deadwood decomposition are important for C budget calculations in ecosystem and climate change models. We observed for the first time that the temperature dependency of N₂ fixation, which has a major role at providing N for wood-inhabiting fungi, was not constant but varied between wood density classes due to source supply and wood quality. This has significant consequences on projecting N₂ fixation rates for deadwood in changing climate.

Wood degradation by white rot basidiomycetes and production of simple phenolic compounds

White rot fungi degrade and mineralize lignin through secretion of strong oxidative ligninolytic enzymes, preventing accumulation of deadwood organic matter. Due to the specific structures, different lignolytic enzymes has different mechanism in lignin degradation/oxidation, producing many natural secondary metabolites, including phenolic compounds (PC). PC in soil may regulate nutrient cycling in forest ecosystems by controlling the pool and form of nutrients available for trees. This work explores the PC produced at different times by nine main decay fungal species, belonging to *Heterobasidion* and *Armillaria* genera, before and after their inoculation and growth on silver fir (*Abies alba* Mill.) sawdust, as axenic culture system, under controlled conditions. A total of 81 samples (three replicates for each fungal species and other three replicates kept as a control) were analysed using high-performance liquid chromatography coupled to a hybrid quadrupole-orbitrap mass spectrometer. Eighteen PC, including simple phenols, alkylphenyl alcohols, hydroxybenzoketones, hydroxycinnamaldehydes, hydroxybenzaldehydes, hydroxyphenylacetic acids, hydroxycinnamic acids, hydroxybenzoic acids and hydroxycoumarins were detected. In particular, coniferyl alcohol, ferulic acid, p-coumaric acid, acetovanillone, vanillic acid, etc. showed a decreasing trend during degradation process, by contrast an accumulation trend was observed for protocatechuic acid, syringic acid and scopoletin. These results suggested different strategies of silver fir lignin degradation by selected fungal species. PCA revealed a good differentiation between PC and the activity of nine fungal species along the three times of silver fir sawdust degradation. The nine fungal species have different climate requirements which imply different PC production under different global warming scenarios.

B7p: PHYSIOLOGICAL AND BIOGEOCHEMICAL RESPONSE OF FOREST ECOSYSTEMS TO CLIMATE CHANGE AND AIR POLLUTION

The effect of elevated carbon dioxide on leaf-level physiology in a mature temperate woodland

Anna Gardner^{1,2}, Jeremy Pritchard^{1,2}, Rob Mackenzie^{1,2}

¹University of Birmingham, Birmingham, United Kingdom; ²Birmingham Institute of Forest Research, Birmingham, United Kingdom (axg042@student.bham.ac.uk; j.pritchard@bham.ac.uk; a.r.mackenzie@bham.ac.uk)

Anthropogenic carbon dioxide (CO₂) is the main greenhouse gas driving change in the Earth's climate. Rising CO₂ is expected to stimulate photosynthesis, but limited studies have been conducted on mature or temperate forests. It is uncertain how mature temperate forest ecosystems may respond to the future CO₂ emissions and what interacting environmental factors may influence this. This experiment has been conducted at the Birmingham Institute of Forest Research Free Air Carbon Enrichment Experiment (BIFoR-FACE). BIFoR-FACE is set in a mature oak (*Quercus robur* L.) woodland and provides additional CO₂, to 30 m diameter experimental plots, to simulate the future atmospheric conditions in 50 years' time (+150 ppm). Instantaneous gas exchange measurements have been conducted in the second year of CO₂ fumigation (2018) in the upper canopy of *Q. robur* trees, from bud burst (June) to leaf fall (October). This study used a paired plot design (n = 3) of elevated CO₂ (eCO₂) (550 ppm) and ambient control plots (aCO₂) (400 ppm). Measurements were taken using a Li-6800 portable photosynthesis machine (LICOR) to calculate leaf-level rates of photosynthesis (A), stomatal conductance (gsw) and intrinsic water use efficiency (iWUE) across the growing season. The results suggest an average of +24% increase in photosynthesis, seasonally variable decrease in gsw and increase in iWUE under eCO₂ conditions. The effect of eCO₂ varied depending on the prevailing seasonal and diurnal fluctuations in environmental variables, such as light and water availability. This data will help understand, and contribute, to the accurate modelling of canopy physiological responses to eCO₂ for mature temperate forest ecosystems.

Projected global tropospheric ozone impacts on vegetation under different emission and climate scenarios

Pierre Sicard¹, Alessandro Anav², Alessandra De Marco³, Elena Paoletti²

¹ARGANS, Biot, France; ²Consiglio Nazionale delle Ricerche, Sesto Fiorentino, Italy; ³ENEA, Rome, Italy (psicard@argans.eu; alessandro.anav@ipspp.cnr.it; alessandra.demarco@enea.it; elena.paoletti@cnr.it)

The impact of ground-level ozone on vegetation is largely under-investigated at global scale despite worldwide large areas are exposed to high surface ozone levels and concentrations are expected to increase in the next future. To explore future potential impacts of ozone on vegetation, we compared historical and projected ozone concentrations simulated by six global atmospheric chemistry transport models on the basis of three representative concentration pathways emission scenarios (i.e. RCP 2.6, 4.5, 8.5). To assess changes in the potential ozone threat to vegetation, we used the AOT40 metric. Results point out a significant overrun of AOT40 in comparison with the recommendations of UNECE for the protection of vegetation. In fact, many areas of the northern hemisphere show that AOT40-based critical levels will be exceeded by a factor of at least 10 under RCP 8.5. Changes in surface ozone by 2100 range from about + 4-5 ppb worldwide in RCP 8.5 scenario to reductions of about 2-10 ppb in the RCP 2.6 scenario. The risk of ozone injury for vegetation decreased by 61% and 47% under RCP 2.6 and RCP 4.5, respectively and increased by 70% under RCP 8.5. Key biodiversity areas in South and North Asia, Central Africa and Northern America were identified as being at risk from high ozone concentrations. To better evaluate the regional exposure of ecosystems to ozone pollution, we recommend the use of improved chemistry-climate modelling system, fully coupled with dynamic vegetation models. We thank the project MOTTLES "Monitoring ozone injury for setting new critical levels" (LIFE15 ENV/IT/000183) for financial support.

Nutritional availability changes ozone risk-assessment for poplars: results by the Ozone FACE study

Yasutomo Hoshika¹, Lu Zhang², Elisa Carrari¹, Lorenzo Cotrozzi³, Elisa Pellegrini³, Ovidiu Badea⁴, Elena Paoletti¹

¹CNR, Sesto Fiorentino (FI), Italy; ²Northeast Agricultural University, Harbin, China; ³University of Pisa, Pisa, Italy; ⁴INCDS, Bucarest, Romania (yasutomo.hoshika@cnr.it; caszhanglu@hotmail.com; eli.carrari@gmail.com; lorenzo.cotrozzi@for.unipi.it; elisa.pellegrini@unipi.it; obadea@icas.ro; elena.paoletti@cnr.it)

Assessing ozone (O₃) risk to vegetation is crucial for informing policy making. The availability of nitrogen (N) and phosphorus (P) could influence photosynthesis and growth. However, our knowledge of plant responses to O₃ under various nutritional conditions is still limited. In this study, a sensitive poplar clone (Oxford) was subject to two N levels (N0, 0 kg N ha⁻¹; N80, 80 kg N ha⁻¹), three P levels (P0, 0 kg P ha⁻¹; P40, 40 kg P ha⁻¹; P80, 80 kg P ha⁻¹) and three levels of O₃ exposure (ambient concentration, AA; 1.5×AA; 2.0×AA) for a whole growing season in an O₃ free air controlled exposure (FACE) facility in Florence, Italy (43° 48' 59" N, 11° 12' 01" E, 55 m a.s.l.), which is the first O₃ FACE facility in Mediterranean Europe. Ozone-induced biomass decline was greater at high N supply, while P alleviated such biomass losses, but not under high N supply. Ozone-induced loss of net photosynthetic rate was mitigated by N in medium O₃ exposure (1.5×AA). However, such a mitigation effect was not observed in the higher O₃ level (2.0×AA). Nitrogen addition exacerbated O₃-induced increase of dark respiration rate suggesting an increased respiratory carbon loss in the presence of O₃ and N. This may result in a further reduction of the net carbon gain for poplars exposed to O₃.

Leaf micromorphological traits of trees for improvement of urban air quality: air pollution abatement potential

Myeongja Kwak¹, Jongkyu Lee¹, Sanghee Park¹, Handong Kim¹, Yeaji Lim¹, Suyoung Woo¹

¹University of Seoul, Seoul, Republic of Korea (016na8349@hanmail.net; gpl90@naver.com; parksanghee0930@gmail.com; blasterkhd92@gmail.com; oxlpl@naver.com; wsy@uos.ac.kr)

Plants have functional advantages for reducing ambient air pollution including particulate matter (PM) on human health in urban areas, and this is one of the recognized ecosystem services of urban vegetation. Especially, trees within urban life zones are considered to be one of the key elements to mitigate and reform atmospheric environmental issues, however, in fact that it does not take into account tree potential in urban policy and strategy. Tree species efficiency for capturing PM is influenced by plant ecophysiology and environmental factors including altitude, wind direction, precipitation, and seasons. Leaf micromorphology (e.g., groove, trichomes, and wax crystals) showed a strong correlation for trapping and retention of PM rather than macromorphology in the broadleaved tree species, thus serving as effective indicators for evaluating PM adsorption. Coniferous pine needles had a higher efficiency of potential PM retention after rainfall than broadleaved species. Regarding needle traits of an evergreen, conifers may be effective for PM reduction, especially during winter and early spring than other seasons. Urban tree diversity with different phenologies can maximize the trapping effects of PM by a prolonged leaf expansion period for urban areas in temperate climates. Because of the limited open space for green infrastructure planning in urban areas, it is necessary to study various planting techniques that maximize the adsorption and absorption of PM. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (N° 2018R1A6A3A11050628).

Effects of elevated Ozone (O₃) on photosynthetic apparatus of *Chionanthus retusus*

Sanghee Park¹, Sungeun Yoon¹, Myeongja Kwak¹, Jongkyu Lee¹, Jieun Kim¹, Yeaji Lim¹, Handong Kim¹, Suyoung Woo¹

¹University of Seoul, Seoul, Republic of Korea (parksanghee0930@gmail.com; sanghui4629@naver.com; 016na8349@hanmail.net; gpl90@naver.com; quhweii@gmail.com; oxlpl@naver.com; blasterkhd92@gmail.com; wsy@uos.ac.kr)

Increasing ground-level O₃ concentrations is one of the main environmental issues in forest ecosystems. This study was conducted to examine the potential non-stomatal limitations induced by elevated O₃ on photosynthesis of leaves in *Chionanthus retusus* which is native species in East Asia. Two years old seedlings of *C. retusus* were exposed to elevated O₃ concentration (100 nmol mol⁻¹, 8h d⁻¹) in growth chamber. To investigate the effect of elevated ozone on the photosynthetic apparatus of *C. retusus*, net photosynthetic rate and the curves of photosynthesis rate (A) against intercellular CO₂ concentration (Ci) were investigated after 6 weeks exposure to O₃. The maximum rate of carboxylation by RuBisCO (Ribulose-1,5-bisphosphate carboxylase/oxygenase) (V_{max}), the maximum rate of photosynthetic electron transport based on NADPH requirement (J_{max}) and the rate of triose-phosphate use (T_p) were calculated by analyzing the A/Ci curves. While T_p had no significant difference between two groups, V_{max} and J_{max} of treatment group were decreased 42% and 24%, respectively, compared to the control. Also, there was significant difference in net photosynthetic rate between two groups. O₃ exposure had a negative impact on non-stomatal responses; reduction in the activity of RuBisCO and rate of photosynthetic electron transport chain and it induced decrease of carbon assimilation capacity of *C. retusus*. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (No 2018R1D1A1A02044683).

Multiple environmental stresses, future climate and germination of Caatinga endemic *Cenostigma* sp. seeds

Barbara França Dantas¹, Samara Elizabeth Vieira Gomes², Janete Rodrigues Matias³

¹Embrapa Semiárido, Petrolina, Brasil; ²Universidade do Estado da Bahia, Juazeiro, Brasil; ³Universidade Federal Rural do Semi-Árido, Mossoró, Brasil (barbara.dantas@embrapa.br; samaraelizabethvg@yahoo.com.br; janete07@hotmail.com)

The Caatinga is predicted to be the most vulnerable Brazilian biome in a future climate scenario of global warming and decreased rainfall. Climate projections for the region in 2100 indicate significantly hotter conditions and a decrease of almost 50% in rainfall, thus worsening the water deficit in the region. *Cenostigma pyramidale* (Tul.) Gagnon & G.P. Lewis and *C. microphyllum* (Mart. ex G. Don) E. Gagnon & G. P. Lewis are endemic Fabaceae from the Brazilian Caatinga. The objective of this study was to evaluate the influence of combined environmental stresses (temperature x water restriction or temperature x salinity) on the germination of seeds of *C. pyramidale* and *C. microphyllum*. Seeds were germinated at constant temperatures between 10 to 40 °C combined with osmotic potentials from 0 to -1.0 MPa (in polyethylene glycol 6000 or NaCl solutions). Germination data were then analysed using thermal, hydro and halo time models, and future germination responses projected according to climate change scenarios predicted by IPCC (International Panel for Climate Change) and PBMC (Brazilian Panel for Climate Change). The germination thermal thresholds ranged from 5 to 55 °C. The germination base osmotic threshold (using polyethylene glycol or NaCl) were decreased in higher temperatures. According to the predictions for future climate (RCP 8.5), the reduced rainfall volume and increased temperature by 2100 will directly affect seed germination and seedling development of *C. pyramidale* and *C. microphyllum*.

Stomatal uptake to improve air pollution mitigation in urban tree species

Myeongja Kwak¹, Jongkyu Lee¹, Suyoung Woo¹, Sanghee Park¹, Yeaji Lim¹, Handong Kim¹

¹University of Seoul, Seoul, Republic of Korea (myeongja8349@hanmail.net; gpl90@naver.com; wsy@uos.ac.kr; parksanghee0930@gmail.com; oxll1@naver.com; blasterkhd92@gmail.com)

Urban forests interact directly with air pollution abatement, local microclimate changes, pollen dispersal, and volatile organic compounds (VOCs) emissions. Therefore, it is necessary to understand the interactions of trees and air pollutants to improve air quality. The aim of the present study was to investigate the stomatal uptake, photosynthetic carbon assimilation, and stomatal physiological control in major tree species response to urban air pollution such as ozone (O₃) and sulfur dioxide (SO₂). Trees exposed to air pollution generally showed excellent ability to absorb O₃ and SO₂ due to their abilities to improve air pollution tolerance through the positive regulation of stomatal movement. Among the main tree species used in this study, it is resistant to atmospheric pollutants (O₃ and SO₂) by maintaining photosynthetic ability and stomatal conductance in treatment compared to control, even though it has high ability to absorb air pollutants. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (No; 2018R1D1A1A02044683).

B7q: PHYSIOLOGICAL AND BIOGEOCHEMICAL RESPONSE OF FOREST ECOSYSTEMS TO CLIMATE CHANGE AND AIR POLLUTION

Nitrogen (NO₃) input from rainfall in *Eucalyptus saligna* plantations / Input de nitrogênio (NO₃) via precipitação pluviométrica em plantação de *Eucalyptus saligna*

Grasiele Dick¹, Mauro Valdir Schumacher¹, Monique Pimentel Lagemann¹, Claudinei Garlet¹

¹Universidade Federal de Santa Maria, Santa Maria, Brasil (grasiedick@hotmail.com; mauro.schumacher@ufsm.br; moniquelagemann@gmail.com; claudineigarlet@gmail.com)

A precipitação pluviométrica é uma importante via de aporte dos nutrientes em plantações florestais. Por meio da água que incide sobre as árvores, lava o dossel e escoo pelo tronco, muitos nutrientes são carregados até o solo, ou são absorvidos diretamente pelas folhas. Neste estudo avaliamos a entrada de nitrogênio via precipitação pluviométrica incidente e precipitação interna em uma plantação de *Eucalyptus saligna*, cultivada na região central do bioma Pampa, Rio Grande do Sul, Brasil. O monitoramento ocorreu durante o ano de 2012, onde o volume de precipitação médio foi de 1.224,7 mm. Através da precipitação pluviométrica houve a entrada de 2,25 kg ha⁻¹ ano⁻¹ de nitrogênio (NO₃⁻) e, após a água passar pelo dossel, a quantidade foi de 3,98 kg ha⁻¹ ano⁻¹. Ou seja, com a lavagem das copas das árvores houve aumento de 76,8% na quantidade de nitrogênio depositada no interior da plantação. Considerando este valor anual, para um ciclo de corte das árvores após sete anos de cultivo, a precipitação interna representa mais de 25 kg ha⁻¹ nitrogênio (NO₃⁻). Visando a redução de impactos ambientais decorrentes da contaminação hídrica e edáfica, causada pelo excesso de nitrogênio, além de economia de recursos financeiros, esta quantidade deverá ser reduzida da aplicação via fertilizante mineral. O nitrato é preferencialmente absorvido pelas árvores e, este estudo evidencia a importante contribuição da precipitação pluviométrica na nutrição florestal. Ressaltamos que, além do fornecimento deste elemento às plantações florestais, também há possibilidade de redução de custos e impactos ambientais.

Adaptation of Agro-IBIS model for *Eucalyptus* carbon budget estimation at regional level – a case study in São Paulo State, Brazil

Highly productive fast-growing *Eucalyptus* plantations cover more than 5 million hectares in Brazil and exhibit very dynamic carbon fluxes throughout their 6-7 year rotations. These plantations quickly shift from C sources at the beginning of the rotation to large C sinks until harvest. In order to get a model simulating carbon pool and fluxes for both *Eucalyptus* plantations and other crops, we integrated several sub-models of the *Eucalyptus*-dedicated Generic Decomposition And Yield Model (G'DAY) into the large scale and multi-cover model Agro-IBIS (Integrated Biosphere Simulator). The G'DAY model was

previously parametrized and validated using large experimental datasets obtained in commercial eucalypt plantations in the state of São Paulo. Implementing an *Eucalyptus* plantation cover type within AgroIBIS, which had no Plant Functional Type dedicated to fast-growing forest plantations, required important changes in the carbon allocation turnover sub-models. This study included three phases: (1) the computational modification of AgroIBIS; (2) the model parametrization, calibration and validation using data from intensively monitored sites or inventories datasets; and (3) model application at regional scale using sets of parameters which were considered to be constant in space and/or time based on data from the local experiments, and other sets of parameters which could vary spatially. Carbon fluxes of *Eucalyptus* plantations were simulated at the regional scale, and their inter-annual and spatial variabilities were analysed. Such spatial and multiannual quantification of carbon fluxes at large scales brings a better understanding of these forest ecosystems on global carbon cycling, which is a prerequisite to support policy decisions.

Shoot water potential of saxaul trees *Haloxylon ammodendron* (C.A.Mey.) Bunge from two distinctive populations of Mongolia

Enkhchimeg Tsedensodnom^{1,2}, Batkhuu Nyam-Osor²

¹Institute of Geography and Geoecology, Mongolian Academy of Sciences, Ulaanbaatar, Mongolia; ²Laboratory of Forest Genetics and Ecophysiology, Department of Environment and Forest Engineering, National University of Mongolia, Ulaanbaatar, Mongolia (enkhii_smile@yahoo.com; nbatkhuu@gmail.com)

Haloxylon ammodendron (C.A. Mey) Bunge, Amaranthaceae (saxaul) grows in the desert and semi-desert regions of Mongolia forming southern Saxaul forests. This species is of great ecological and economic importance, not only because it can survive in harsh environmental conditions but also because it can reduce wind erosion and sand movement. The objectives of this study were to determine the water potential of assimilation shoot of Saxaul trees of natural stands. This study was conducted in the two distinctive population differing geographical location, vegetation and climate condition. The BZ population, Bayanzag (103°42' E, 44°05' N, 1,100 m, asl) is situated in the southern part of Mongolia, Umnugobi province and DU population, Dulaan uul (44°12' N, 110°01' E, 700-1,000 m, asl) is located in the southeastern part of Mongolia, Dornogobi province. Shoot water potential were measured using a Pressure Chamber (Model 1505DPMS Instrument Company, U.S.A.) following the method of Scholander. The assimilation shoot water potential was measured in trees differing in their age classes, mature tree (200 ≤ cm), young tree (80 - 200 cm) and juvenile (≤ 80 cm) according to their stem height classes. Generally, trees BZ population trend to have higher water potential at predawn, while DU population had higher in midday. According to measurement of water potential the young and juvenile trees are more subjected water stress than that of mature trees, which shows their adaptation performance in drought conditions.

Nitrogen and sulfur deposition by rainfall and throughfall in *Pinus taeda* L. in Southern Brazil

Mauro Valdir Schumacher¹, Grasielle Dick¹

¹Universidade Federal de Santa Maria, Santa Maria, Brasil (mauro.schumacher@ufsm.br; grasedick@hotmail.com)

Soil fertility in areas planted with *Pinus taeda* is closely associated with nutrient input by atmospheric deposition, mainly with rainfall and throughfall. The objective of the present study is to quantify the input of nitrogen-NO₃⁻ and sulfur-SO₄²⁻ in *Pinus taeda* stand, in Camará do Sul, Southern Brazil. For the quantification and sampling of water from rainfall, three funnels surrounded by a bird ring were installed. In order to evaluate the throughfall, nine funnels were installed. Sampling was biweekly for a period of four years. After the samples were filtered and analyzed for N-NO₃⁻ and S-SO₄²⁻. The average total annual rainfall and throughfall was 2081.5 mm and 1280 mm, respectively. Rainfall added 2.70 kg ha⁻¹ year⁻¹ and 4.97 kg ha⁻¹ year⁻¹ of N-NO₃⁻ and S-SO₄²⁻, respectively. The amounts added by throughfall were 2.81 kg ha⁻¹ year⁻¹ of N-NO₃⁻ and 6.53 kg ha⁻¹ year⁻¹ of S-SO₄²⁻. The S-SO₄²⁻ presented an increase of 28% in the value of its quantity, after the interaction with the canopy of the trees.

Nitrogen return to soil by litterfall in Semideciduous Seasonal Forest and *Pinus taeda* L.

Mauro Valdir Schumacher¹, Grasielle Dick¹, Monique Lagemann¹, Claudinei Garlet¹

¹Universidade Federal de Santa Maria, Santa Maria, Brasil (mauro.schumacher@ufsm.br; grasedick@hotmail.com; moniquelagemann@gmail.com; claudineigarlet@gmail.com)

The dynamics of litter and nutrients is essential to maintaining the productive capacity of native forests and commercial plantations with tree species. The objective of the present study is to characterize the return of total nitrogen, via litterfall, in a semideciduous seasonal forest and a *Pinus taeda* stands, in Quedas do Iguaçu, Paraná, Brazil. In each ecosystem three plots of 21 m x 20 m were demarcated, in which four traps with 1 m² of area were systematically distributed to quantify the litterfall. The amount of litterfall in native forest and pinus stands is 7.76 and 7.15 mg ha⁻¹ year⁻¹, respectively. In the native forest the amount of N was 147.19 kg ha⁻¹ year⁻¹, about 191.3% higher than the value found in pinus, which presents 50.53 kg ha⁻¹ year⁻¹. This difference in the values obtained is explained by the presence of legume species in the native forest, which by symbiosis with bacteria of the genus *Rhizobium*, can fix the atmospheric nitrogen and increase the values of this element in its biomass. Litterfall is the most important source of nitrogen return to the soil.

Using process-based modelling to better understand the impact of mineral (N, P, K) cycles and climate change on stand growth and resource-use in Eucalypt plantations

Ivan Cornut¹, Nicolas Delpierre¹, Otávio Campoe^{2,3}, Joannès Guillemot^{4,5,6}, Jean-Paul Laclau^{4,5}, Louis Mareschal^{4,5}, Yann Nouvellon^{4,5}, José-Luiz Stape^{2,7}, Guerric le Maire^{4,5,8}

¹Ecologie Systématique Evolution, Université Paris-Sud, CNRS, AgroParisTech, Université Paris-Saclay, Orsay, France; ²Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil; ³Universidade Federal de Santa Catarina, Curitiba, Brasil; ⁴UMR Eco&Sols, CIRAD, Montpellier, France; ⁵Eco&Sols, Univ Montpellier, CIRAD, INRA, IRD, Montpellier, France; ⁶Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ⁷Suzano Pulp and Paper, Suzano, Brasil; ⁸Universidade Estadual de Campinas, Campinas, Brasil (ivan.cornut@u-psud.fr; nicolas.delpierre@u-psud.fr; otavio.campoe@ufsc.br; joannes.guillemot@cirad.fr; laclau@cirad.fr; louis.mareschal@cirad.fr; yann.nouvellon@cirad.fr; stape@suzano.com.br; guerric.le_maire@cirad.fr)

In addition to wood production services, forest ecosystems play an important role in the mitigation of anthropogenic climate change. However the role of forests as future C sinks is being discussed since there is increasing evidence of a progressive shift from carbon-limited growth to nutrient-limited growth as demonstrated in FACE experiments. The development of mechanistic models, including the main nutrient balance and their relationship with the carbon and water balances, is necessary to evaluate the future response of forests to climate change. In this contribution, we present the first joint evaluation of a coupled C-water-N-P-K model on a large number of biogeochemical measurements collected in fast-growing eucalyptus plantations in Brazil along entire rotations, including trials with variable levels of fertilisation and water availability. We have first adapted the CASTANEA ecophysiological model, primarily designed for

temperate and boreal forests, to the simulation of carbon and water fluxes in tropical Eucalypt. Then, the N, P, K fluxes and stocks within the plant were modelled based on process from the literature and calibrated on specific measurements, including the interaction between nutrient content of organs and carbon and water related processes. The final objective is to quantify the relative importance of single nutrients and water limitation on stand growth and carbon productivity, and evaluate the impact of climate change on these different cycles through a change in mean temperature, CO₂ concentration and precipitation regime.

Monitoring populations of *Picea mexicana* Martínez and conservation activities in Mexico / Monitoreo de poblaciones de *Picea mexicana* Martínez y acciones de conservación en México

Celestino Flores-López¹, Loreto Edelmira Chaparro-Gómez¹, Salvador Valencia-Manzo¹, Adrián Hernández-Ramos²

¹Universidad Autónoma Agraria Antonio Narro, Saltillo, Mexico; ²Instituto Nacional de Investigaciones Forestales, Agrícolas y Pecuarias, Saltillo, Mexico (cele64@gmail.com; edel_188@hotmail.com; svalenciam2016@gmail.com; hernandez.adrian@inifap.gob.mx)

Picea mexicana es una especie de clima subalpino con distribución natural superior a los 2800 m de altitud, endémica, en riesgo y sensible al cambio climático del Norte de México. Se evaluaron sitios permanentes en las tres únicas poblaciones conocidas: La Marta, Nuevo León, El Coahuilón, Coahuila y El Mohinora, Chihuahua. Durante el periodo 2006-2018 se realizaron dos inventarios, se desarrolló una tabla de proyección de volumen, se evaluaron indicadores reproductivos de conos, semillas y germinación. Las especies dominantes en las poblaciones son *Pseudotsuga menziesii*, *Pinus rudis*, *Abies vejari*, *Abies duranguensis* y *Picea mexicana*, ésta última sobresale de las especies asociadas en incremento en volumen anual con un rango de 0.5 a 3.4 m³/ha, sin embargo, del 49 al 85% del arbolado no hay cambio de categoría diamétrica, concentrándose la mortalidad en la población el Coahuilón para las especies *Picea mexicana* y *Pinus rudis*. El coeficiente plántulas/árboles en las poblaciones menor de 6es bajo con respecto a las especies del género *Picea*. La baja eficiencia en la producción de semillas y los tamaños de la semilla reflejan valores mayores de 0.7 en índice de endogamia, con mayor efecto en las poblaciones El Mohinora y El Coahuilón. La sequía crítica de un año con presencia de incendios ha sido la causa principal de mortalidad. Las acciones de los ejidatarios y particulares, así como el desarrollo de proyectos de investigación paralelos y de servicios ambientales en apoyo a estas áreas de conservación de montaña, favorecen la conservación in situ.

The Potential of Sentinel-2 Images to detect damage levels on *Pinus taeda* stands caused by *Sapajus nigritus* Kerr (1972)

Carla Talita Pertille¹, Marcos Benedito Schimalski¹, Verardo Liesenberg¹

¹Universidade do Estado de Santa Catarina, Lagea, Brasil (carla_pertille@hotmail.com; marcos.schimalski@udesc.br; verardo.liesenberg@udesc.br)

This study aimed to apply both regression and classification methods using Sentinel-2/MSI images to detect damage levels occurred in *Pinus taeda* stands caused by *Sapajus nigritus* (monkey). The forest stands are located in Bocaina do Sul (Santa Catarina State). Three images were selected encompassing different attack periods. We selected images before (May/2017), during (November/2017) and after attacks (April/2018). A total of 46 field plots were verified in the field where tree individuals were classified according to the damage intensity: i) no damage, ii) moderate, iii) severe, and iv) dead. In order to estimate the damage level per plot, spectral reflectance, principal component analysis (PCA), and vegetation indices (VI) were selected as regressor variables for the development of regression models using Stepwise, Support Vector Machine (SVM) and Random Forest (RF) approaches. The best model selection was based on the regression model fit statistics. The most robust indexes were MCARI, NDI45 and NDVIRR, which estimated for the classes a percentage of attack of *S. nigritus* per plot with adjusted R² of 0.8042, 0.4603, 0.8815 and 0.9766; Syx of 13.49, 61.42, 15.11 and 8.69 (% 0.045 ha⁻¹) and RMSE of 1.95, 4.49, 2.11 and 0.32 (% 0.045 ha⁻¹), respectively. It was possible to estimate and to identify areas attacked by this species highlighting the Stepwise model, followed afterward by SVM and RF. However, it is still recommended to evaluate digital images of high and ultra-high spatial resolution sensors in order to corroborate with the proposed methodology.

B8b: COOL FORESTS AND CLIMATE CHANGE: CHALLENGES OF TRANSITION TO SUSTAINABLE FOREST MANAGEMENT

Cool Forests - an introduction

Florian Kraxner¹, Anatoly Shvidenko¹, Dmitry Schepaschenko¹, Charlotte Kottusch¹, Anni Reissell¹, Gerald Steindlegger²

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²Steindlegger ISS – Integrated Sustainability Solutions, Oberneukirchen, Austria (kraxner@iiasa.ac.at; shvidenk@iiasa.ac.at; schepd@iiasa.ac.at; kottusch@iiasa.ac.at; reissell@iiasa.ac.at; gerald@steindlegger-iss.com)

Forests developed in regions of cold climate over thousands of years. These “Cool Forests”, located in boreal and mountain areas, make up more than one third of the global forest extent. They are found from the circumpolar belt in the northern hemisphere to high-elevation zones in temperate, mid-latitude and tropical zones. Cool Forests show many similarities throughout the boreal and high mountain ecozones - especially with respect to species composition, growth patterns, and response to climate exposure. They are tremendously important for carbon storage, together forming the single largest carbon pool of all terrestrial ecosystems. Cool Forests are partially underlined by permafrost soils and deliver much of the world’s harvested wood products including timber, pulp, and paper. Furthermore, they are home to unique landscapes and biological diversity, providing ecosystems that are crucial for the livelihoods of millions of people. Yet, the impacts of current social, economic, environmental, climatic and technological changes on cool Forests remain uncertain. As climate is changing and temperatures rise, the permafrost is thawing, resulting in significant release of greenhouse gases which further accelerate climate change. Permafrost thawing in mountain and boreal ecozones has already caused soil collapses, landslides, rock falls, and mudflows. Rising temperatures are linked to an increase in the frequency and severity of natural disturbances such as wildfire, insect outbreaks, and wind storms and thus present a growing threat to people and nature, the bioeconomy and the climate. This presentation provides an introduction to cool Forests and why they are in danger.

The potential contributions of the forest sector to climate change mitigation and negative emissions

Werner Kurz¹, Carolyn Smyth¹

¹Natural Resources Canada, Victoria, Canada (werner.kurz@canada.ca; carolyn.smyth@canada.ca)

The goals of the Paris Agreement cannot be reached without the support of forests and the forest sector as active carbon sinks that contribute towards net negative emissions. The design of climate effective mitigation strategies must take a systems perspective that takes into consideration the changes in emissions and removals in forest carbon stocks, in harvested wood products (HWP) carbon stocks, and in other sectors where wood products substitute for other emission-intensive materials and fossil fuels. Moreover, all mitigation options have to be assessed relative to a business as usual baseline. New spatially-explicit analyses of forest sector mitigation options in Canada demonstrate the need for regionally-differentiated strategies to climate change mitigation. Cost-effective

opportunities exist through changes in forest management, HWP use and substitution benefits. However, the impacts of climate change and the resulting increases in emissions from drought, insects and fires further complicate the analyses. Adaptation strategies need to be designed that also meet mitigation objectives. For example, post-disturbance salvage logging and fuel reduction treatments to reduce the risk of fires provide opportunities to access biomass that can provide feedstock for engineered long-lived timber products or renewable energy sources such as second-generation liquid transportation fuels. Results from ongoing analyses will be presented.

Opportunity and challenges for transition of Northern Eurasian cool forests to sustainable forest management

Anatoly Shvidenko^{1,2}, Florian Kraxner¹, Dmitry Schepaschenko^{1,3}

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²Institute of Forest SB RAS, Krasnoyarsk, Russian Federation; ³Bauman Moscow State Technical University, Mytishi, Russian Federation (shvidenk@iiasa.ac.at; kraxner@iiasa.ac.at; schepd@iiasa.ac.at)

The Northern Eurasian (NE) cool forests (boreal Russia and mountains of the NE Mid-Latitude ecotone) comprise about one-fourth of the global forest area. Specific features of the NE cool forest and landscapes predestine their extremely high exposure, vulnerability and risks under new climates. The most critical climate change on the planet are expected in continental NE, and some IPCC Scenarios (e.g. RCP6.5/8.5) suppose cool forests as a tipping element. A particular threat to global climate mitigation efforts is generated by thawing permafrost. Decreasing vitality, vulnerability and productivity of forests are expected also in the mid-latitude ecotone. The forests and wetlands of the NE require specific societal, scientific and managerial attention. This presentation considers needs, possibilities, opportunities and challenges of transition to adaptive risk-resilient sustainable forest management (ASFM) in NE. We analyze specifics, points of departure, challenges and strategies of transition to ASFM. A key challenge is assessing future resilience of forest ecosystems, biophysical and economic valuation of all ecosystem services, and quantifying tradeoffs between services. The capacity of transition to ASFM differs substantially over NE. We analyze specifics and commonalities over NE to assess potential, opportunities and challenges of ASFM and identify problems which require both national and global efforts (e.g. slowdown of permafrost thaw). There is no single strategy, which would allow reaching all goals of ASFM. High uncertainty of climatic predictions and lack of knowledge on behavior of boreal and high-elevation forests under new environments require integrated observing systems, new science and technologies realized within regional ASFM programs.

Role, technology, policy of forest resources for the NDC (Nationally Determined Contributions) of the Republic of Korea

Woo-Kyun Lee¹, Boyoung Ham¹, Cholho Song¹, Eunbeen Park¹, Chul-Hee Lim¹, Halim Lee¹, YoungJin Ko¹

¹Korea University, Seoul, Republic of Korea (leewk@korea.ac.kr; tomboy04@gmail.com; cholhosong@gmail.com; heyevvin@gmail.com; limpossibe@korea.ac.kr; halimlee91@gmail.com; ko871004@gmail.com)

The Republic of Korea (RoK) decided to include carbon absorption from forest resources in the Nationally Determined Contributions (NDC) from 2020. About two-thirds of Korean land is covered by forest, and it is reported that about 47 million ton CO₂ can be absorbed per year by forest. This will be included in the NDC that will be submitted by the Republic of Korea. However, the Korean forest is getting older over time and intensive forest management for carbon storage can also face some difficulties in relation to land cover conflicts and environmental issues. It is also predicted that the CO₂ absorption will decrease from 47 to 22 million tons by the year 2030. Securing determined amount of carbon storage and absorption in forest can play an important role in ensuring NDC's soundness. Forest biomass and carbon should be estimated through the analysis of forest activity data and the usage of carbon accounting system. In addition, these two factors should be integrated into forest growth models which can predict future carbon stock under a forest management regime. National Forest Inventory (NFI) system should be well operated for having confidential national forest carbon database. Land cover/use change monitoring is also essential for monitoring national carbon budget in relation to LULUCF (Land Use, Land-Use Change and Forestry) mechanism and MRV (Measurement, Reporting and Verification) system. In this presentation, role, technology and policy of forest resources for the NDC of the RoK will be introduced and some future prospects will be suggested.

Forecast of State of Ukraine's forests under climate change conditions

Ivan Lakyda¹, Anatoly Shvidenko², Roman Vasylyshyn¹, Petro Lakyda¹, Anatolii Karpuk¹, Maryna Lakyda¹

¹National University of Life and Environmental Sciences of Ukraine, Kyiv, Ukraine; ²International Institute for Applied Systems Analysis, Laxenburg, Austria (ivan.lakyda@nubip.edu.ua; shvidenk@iiasa.ac.at; vasylyshyn@nubip.edu.ua; lakyda@nubip.edu.ua; karpuk@nubip.edu.ua; maryna.lakyda@gmail.com)

A precondition for correct forest management planning for mid- and long-term time horizons is accounting for influence of factors of the changing world. This directly influences not only such questions as selecting tree species composition, rotation ages etc., but also is extremely important for correct assessment of forests' ecosystems services, which are deemed to have an increasing importance in current and future economy. When done correctly, forecast of forests' future state with provisions for dynamics of environmental factors can support national and global decision- and policy-making processes in the frame of risk-resilient forest management. This abstract presents research results on first detailed forecast of state of Ukraine's forests under climate change. To enable reaching the research goal, an original methodological approach was applied incorporating the data of stand-level forest management planning (biometric description of stands and their geospatial location), climatology-based forecasts of suitability of certain environmental conditions (climate humidity, continentality and cryoclimate) for the major forest-forming tree species of Ukraine, and the updated information support basis of forestry (systematized numerous models widely applied in forest sector). The forecast results are available as a spatially explicit stand-level biometric information for certain time points in future. The results of our research create preconditions for forecasting growth, productivity and ecosystems services of Ukraine's forests under climate change, and the methodological approach can be used for further scenario analysis accounting for wide combinations of different environmental factors. Also, this research can serve as a platform for international multidisciplinary scientific collaboration in the mid-latitude ecotone.

Projection of fire regimes in Russian forests: the FLAM approach

Andrey Krasovskii¹, Anatoly Shvidenko¹, Dmitry Schepaschenko¹, Nikolay Khabarov¹, Florian Kraxner¹

¹Ecosystems Services and Management Program, International Institute for Applied Systems Analysis, Laxenburg, Austria (krasov@iiasa.ac.at; shvidenk@iiasa.ac.at; schepd@iiasa.ac.at; khabarov@iiasa.ac.at; kraxner@iiasa.ac.at)

Over 2000-2015, wildfire enveloped of about 10 million hectares in Russia annually, mainly in the boreal zone with carbon emissions above 130 Tg C yr⁻¹. Half of this area is presented by closed forests, and almost two-third - by forest land. Climatic projections, particularly for the harsh IPCC

Scenarios (RCP6.5 or RCP8.5), suggest substantial increase of fire risk in Russian forests during the 21st century that puts serious problem on planning the adaptation policies in the Russian forest sector. In this study, we apply wilFire cLimate impacts and Adaptation Model (FLAM) to project future fire regimes in Russia. FLAM estimates burned areas under different suppression activities and allow assessing impacts of fire on the carbon cycle. FLAM is a mechanistic model operating at a daily time step on the grid cell of 0.25 arc degree, the same spatio-temporal resolution as in the Global Fire Emissions Database v4.1s (GFED). By applying historical climate data, we calibrated FLAM against observed burned areas from GFED for the period 2000-2016. Calibration of the spatial suppression efficiency took into account seasonality and other specific features of wildfires in Russia. Fire ignition was estimated based on population density maps and assessment of natural sources such as lightning. FLAM projections of burned areas and expected fire emissions by major land classes are presented for 4 RCP scenarios. The results obtained are used for discussion of appropriate mitigation options to minimize impact of future fires on Russian forest ecosystems and the Earth climate system.

Assessment of the impact of alternative forest management models on cool forests in Europe

Mykola Gusti¹, Anu Korosuo¹, Fulvio Di Fulvio¹, Pekka Lauri¹, Nicklas Forsell¹

¹International Institute for Applied Systems Analysis, Laxenburg, Austria (gusti@iiasa.ac.at; korosuo@iiasa.ac.at; difulvi@iiasa.ac.at; lauri@iiasa.ac.at; forsell@iiasa.ac.at)

Boreal and mountainous forests are highly vulnerable to climate change and the potential changes in forest use. These forests provide a number of ecosystem services important for the environment and people living in and around them (e.g., wood for material and energy, soil protection, regulation of water flow, biodiversity, recreation). Increasing biomass demand, rising population and climate change will challenge the current state of the cool forests and their future ability of providing ecosystem services. Alternative forest management models (AFMM) may be needed to adapt the forests to these challenges. We provide a modelling study of the impact of AFMMs in different EU regions. These potential AFMMs are being developed in ALTERFOR project in a close collaboration with different stakeholders, and with a focus on learning from the experiences from other countries. From the AFMMs suitable for each EU region, a selection of “robust” ones are being implemented in a large-scale modelling framework. A combination of Global Biosphere Management Model (GLOBIOM) and Global Forest Model (G4M) are applied in the study. GLOBIOM is used to assess competition for land use between agriculture, bioenergy, and forestry, while G4M provides detailed representation of forest stand dynamics as a response to forest management aimed at satisfying wood demand and mitigation policies. The results are expected to point out the most relevant AFMMs under the different socioeconomic scenarios, with a specific focus on assessing changes in carbon dynamics, sustainable potentials for forest harvest and residue extraction, employment etc.

From 1990 to 2050: retrospective and projection of carbon budget of Russian forests

Dmitrii Zamolodchikov¹, Wassily Grabowsky¹, Olga Chestnykh¹

¹Center for Forest Ecology and Productivity of the Russian Academy of Sciences (CEPF RAS), Moscow, Russian Federation (dzamolod@mail.ru; wgrab@mail.ru; ochestn@mail.ru)

Earlier we developed the system of carbon balance inventory in forestry of Russia, called Regional Evaluation of Carbon Budget of Forests (RECBF). Evaluations given here refer to the forested lands of the Russian Forest Fund, the area of which increased from 758.7 to 785.6 million hectares from 1988 to 2015. Carbon sink to the forests of Russia was minimal in 1988 (80.3 ± 65.1 Mt C/year). Since the first half of the 1990s, there was an increase in the carbon sink to 239.4 ± 57.7 Mt C/year in 2008. This increase was explained by a significant reduction of the timber harvesting in connection with socioeconomic reforms in Russia. After reaching the maximum value in 2008, the carbon sink was gradually decreased to 206.1 ± 58.9 Mt C/year in 2015. This reduction was by 44.5% due to increased losses in logging operations, by 21.5% due to increase of forest fires and by 34.5% due to a decrease in absorption. The modeling tool RECBF-M was recently developed, based on concept of forest transitions models. If the level of all disturbances including felling and forest fires will not change in future, the Russian forests still decrease carbon sink till 176.5 Mt C/year in 2020, 122.6 in 2030, 86.7 in 2040, 60.8 Mt C/year in 2050. The projected decrease is explained by changes of forest age structure. The massive forest management activities are necessary to maintain carbon sink to Russian forests, from which most effective are regulation of rotation time and forest fire protection.

B8c: FORESTS AND CLIMATE CHANGE IN SOUTHWESTERN AMAZON

Vulnerability to extreme climate events in the Southwestern Amazon region: a case study of the trinational area of the Acre River Basin in the MAP region comprising Madre de Dios, Peru, Acre, Brazil, and Pando, Bolivia / Vulnerabilidade aos eventos extremos climáticos no Sudoeste da Amazônia: um estudo de caso da área trinacional da bacia do Rio Acre, na região MAP (Madre de Dios-PE, Acre-BR e Pando-BO)

Foster Brown^{1,2}, Vera Reis-Brown³, Elsa Mendoza⁴, Hugo Fuentes⁵, Jiang Torres⁶, Wilson Palomino⁷, Fronika de Wit⁸, Sonaira Silva⁹, Juan Fernando Reyes¹⁰, Ronald Gomringer¹¹

¹Woods Hole Research Center, Massachusetts, USA; ²Universidade Federal do Acre, Rio Branco, Brasil; ³Secretaria de Estado de Meio Ambiente do Acre, Rio Branco, Brasil; ⁴Earth Innovation Institute, Rio Branco, Brasil; ⁵Herencia, Cobija, Plurinational State of Bolivia; ⁶Setor de Meio Ambiente e Manejo de Recursos Naturais do Departamento Regional de Madre de Dios, Madre de Dios, Peru; ⁷Universidad Nacional San Antonio Abad del Cusco, Cusco, Peru; ⁸Secretaria Municipal de Meio Ambiente de Rio Branco, Rio Branco, Brasil; ⁹Universidade Federal do Acre, Cruzeiro do Sul, Brasil; ¹⁰Herencia, Cobija, Plurinational State of Bolivia; ¹¹Instituto de Pesquisa de la Amazonia, Iquitos, Peru (fbrown@uol.com.br; vreis.reis21@gmail.com; elsa_mendoza@uol.com.br; hleeoos@gmail.com; jliaoi@hotmail.com; wilsonsurip@hotmail.com; fronikadewit@gmail.com; sonairasilva@gmail.com; jfr@herencia.org.bo; ronaldcorvera@gmail.com)

O sudoeste da Amazônia enfrenta inúmeros desafios para a utilização sustentável dos recursos naturais na medida em que experimenta rápido crescimento populacional e econômico, expandindo setores de agricultura, transporte e energia, associados aos impactos de extremos climáticos frequentes e severos. A parte trinacional da bacia do Rio Acre, situada na fronteira do Peru, Brasil e Bolívia, nas áreas contíguas do Departamento de Madre de Dios, PE, do Estado do Acre-BR e do Departamento de Pando-BO ou da Região MAP, incorpora grande parte desses desafios. Nesse contexto de transição, a Região Amazônica em geral e a bacia do Rio Acre, em particular, se deparam com a necessidade de adaptação às alterações dos contextos sociais e ambientais, em especial aqueles associados às mudanças climáticas. Com o objetivo de abordar a vulnerabilidade da bacia aos eventos extremos climáticos, realizou-se a análise integrada da vulnerabilidade da floresta e dos recursos hídricos, utilizando como referência o Programa Global Water Partnership (Wouters, 2013). Aplicou-se o método do QCCE (2011) para vincular conhecimento científico e local a ações relevantes para a política na Região MAP. As variáveis e elementos climáticos ligados a

floresta e recursos hídricos foram classificados por prioridade ou severidade, a partir dos quais construiu-se uma matriz de risco usando as três prioridades mais altas. Um esquema de classificação ordinal, usando matrizes, permitiu priorizar os riscos e a vulnerabilidade, indicando que as secas prolongadas, os incêndios florestais associados e as inundações são os três riscos prioritários na região.

Project Forest Health: participatory training for community forest monitoring / Projeto saúde das florestas: capacitação participativa para o monitoramento florestal comunitário

Sabina Ribeiro¹ ; Fernando Schmidt¹ ; Foster Brown² ; Galia Selaya³ ; Stephen Perz⁴; Richarly Silva⁵

¹Universidade Federal do Acre, Rio Branco, Brasil; ²Woods Hole Research Center, Falmouth, USA; ³Herencia, Cobija, Plurinational State of Bolivia;

⁴University of Florida, Gainesville, USA; ⁵Instituto Federal do Acre, Cruzeiro do Sul, Brasil (sabina.ufac@gmail.com; schmidt.fa@gmail.com;

fbrown@uol.com.br; gselaya@outlook.com; sperz@ufl.edu; rcosta.bio@gmail.com

O desmatamento na Amazônia contribui para o aumento das secas na região e intensifica o efeito das mudanças ambientais. O pagamento por serviços ambientais, aliado ao aumento da consciência ambiental, podem contribuir para frear o desmatamento na região. Nesse sentido, o projeto Saúde das Florestas objetiva aumentar a capacidade de comunidades extrativistas em compreender a dinâmica das suas florestas e realizar o manejo sustentável de suas áreas. As comunidades extrativistas abrangidas pelo projeto fazem parte da Reserva Extrativista Chico Mendes, no estado do Acre, Brasil. Os comunitários participantes das capacitações abrangeram jovens lideranças das regiões de Xapuri e Assis Brasil. As capacitações foram realizadas de forma voluntária e participativa por meio de oito oficinas que abrangeram temas ligados a orientação em campo, ecologia florestal e taxonomia botânica, protocolo de instalação e remedição de parcelas permanentes (RAINFOR), estabelecimento de uma parcela permanente e análise de dados em planilha eletrônica. O conhecimento adquirido nessas capacitações foi multiplicado para outros comunitários por meio de duas oficinas de disseminação, nas quais os jovens capacitados organizaram e conduziram a multiplicação do conhecimento sobre o monitoramento florestal. Ademais, atendendo as sugestões dos comunitários participantes, foi implementado um segundo projeto em que o tema saúde das florestas é trabalhado através de dinâmicas complementares ao conteúdo do ensino fundamental e médio de escolas rurais do estado Acre. Embora iniciativas como essas enfrentam diversas barreiras, elas são fundamentais para promover a reflexão dos comunitários sobre o impacto de suas atividades na saúde das florestas.

Regulatory and financial mechanisms for environmental conservation, sustainable development, and remuneration for results at REDD+ in Acre, Brazil / Marco regulatório e mecanismos financeiros para conservação ambiental, desenvolvimento sustentável e remuneração de resultados de REDD+ no Acre

Ricardo Assis Mello¹, Sarah Hutchinson², Moacyr Araújo Silva³

¹WWF Brasil, Brasília, Brasil; ²WWF UK, London, United Kingdom; ³WWF Brasil, Rio Branco, Brasil (ricardomello@wwf.org.br; shutchison@wwf.org.uk; moacyr@wwf.org.br)

O objetivo desta apresentação é compartilhar experiências do Programa Jurisdicional ISA Carbono do Estado do Acre, que tem foco na remuneração por resultados de REDD+ e na repartição de benefícios por meio de subprogramas que apoiam provedores de serviços ambientais relacionados com o carbono florestal no Estado do Acre. Além do marco legal regulatório básico, o painel traz uma contextualização do Sistema de Incentivos aos Serviços Ambientais (SISA) e da contribuição do WWF no seu desenvolvimento enquanto mecanismo de diversificação produtiva e de direcionar fluxos financeiros em suporte às cadeias produtivas de base florestal e baixas emissões. O estudo também aborda avanços, lições e desafios que permanecem para a consolidação do SISA Acre e para o desenvolvimento de outros programas de incentivos ambientais considerando elementos como, por exemplo, sociobiodiversidade e água. A implementação do SISA, juntamente com outras políticas estruturantes da economia de base florestal, contribuíram até 2018 para aumentar o volume de investimentos no Estado e reduzir taxas de desmatamento. O grau de conservação ambiental do Estado (87% do seu território total com cobertura florestal mantida), o estoque de capital natural e o potencial de retorno econômico e financeiro das cadeias produtivas de baixo carbono são vantagens comparativas do Acre nos mercados voluntários e regulados de carbono. Tendo em vista as parcerias do Acre com outras iniciativas de REDD+ jurisdicional, espera-se que esta iniciativa seja útil para atores sociais e governantes de outras jurisdições, bem como para investidores e outros interessados em mecanismos financeiros de REDD+.

Education as a sine qua non for strengthening integrated watershed management for extreme climate events in the Madre de Dios-Peru, Acre-Brazil, and Pando-Bolivia (MAP) Region of Southwestern Amazonia

Irving Brown^{1,2}, Guillermo Rioja-Ballivián³, Marta Torres⁴, Ednilza Rocha⁵, Cristina Boaventura¹, Juan Fernando Reyes⁶, Carmen Acho⁷, Elaine Lopes¹, Mercedes Perales^{8,9}, Nazaré Macêdo¹, Cesar Ascorra³, Marília Carmo¹, Andrea Alechandre¹, Quêren Luna¹, George Santos¹⁰

The global trends of tropical deforestation, biotic impoverishment, climate perturbation, and demands for forest-related products and ecosystem services are sobering. Proposals to alter these trends must include societal rethinking of world views and values that have promoted these trends. In this context, education has a critical role to play, particularly in preparing the decision-making capacity of current and future generations. While Sustainable Development Goals do mention education, many publications on forest and water management focus almost exclusively on stakeholders and decision-makers without considering the formation or transformation of their worldviews. To help this societal rethinking we initiated in 2017 a trinational educational effort to promote stewardship of watersheds, using as a theme "Taking care of the Earth's water, starting in the MAP Region." It is part of a program to increase resilience to extreme climate events which have increasingly affected Southwestern Amazonia. One objective was to prepare teachers to apply concepts such as the role of forests as transpiration pumps, river basin dynamics, and extreme climate events to integrated river basin management in their classes. An effective educational device both for formal and informal education was role-playing where participants took on the role of mayors or Civil Defense Coordinators of municipalities suffering extreme climate events. While education is an essential and underutilized tool to alter on-going trends both in the MAP Region and globally, it is not a panacea and needs to be integrated into comprehensive programs to make sustainable development a reality in the 21st Century.

Forests and climate change in the Southwestern Amazon region: supporting training for forestry engineers, research, and graduate study / *Florestas e mudanças climáticas no sudoeste da amazônia: subsídios para formação de engenheiros florestais, pesquisa e pós-graduação*

Marco Amaro¹ ; Margarida Lima de Carvalho¹

¹Universidade Federal do Acre Rio Branco, Brasil (marcoantonioamaro@hotmail.com; margaridalimacarvalho@hotmail.com)

Floresta e clima são duas dimensões fundamentais à vida. Cuidar dessas dimensões é cuidar de nós mesmos. As mudanças climáticas que vivenciamos têm se revelado preocupante para a preservação da floresta. A Amazônia deve ser vista não apenas como produtora de bens e serviços naturais, mas também como produtora de riqueza humana através do processo produtivo, por ser um espaço habitado. Sem ciência e tecnologia não haverá solução plausível. Neste sentido a UFAC entende que é necessário focar nestas questões em suas pesquisa e consequentemente na pós-graduação, bem como que estejam contempladas na formação de engenheiros florestais. Espera-se dos cursos de graduação profissionais que contribuam com o desenvolvimento, assim como para o aperfeiçoamento da qualidade de vida da sociedade. No Acre existem o curso de Engenharia Florestal no campus Cruzeiro do Sul e Rio Branco da UFAC, cujos projetos pedagógicos serão adequados aos avanços e mudanças, contendo estas questões no processo de formação dos alunos. Estes ajustes serão feitos visando definir as opções de caminhos e prioridades na formação. O foco será as habilidades e competências, objetivando o engajamento do aluno como protagonista do processo de ensino aprendizagem. É de fundamental importância que os professores superem o pensamento compartimentado e o conhecimento fragmentado, uma vez que este não consegue mais atender a formação necessária para a compreensão e análise dos acontecimentos e até mesmo para o mercado de trabalho. A prática pedagógica requer a integração, visando superar a fragmentação do saber, em busca da sua totalidade.

Woody biomass in bamboo forests in the Southwestern Amazon region / *Biomassa lenhosa em floresta com bambu no Sudoeste da Amazônia*

Égon Lima¹ ; Sabina Ribeiro¹ ; Angélica Santos¹ ; Richarly Silva² 

¹Universidade Federal do Acre, Rio Branco, Brasil; ²Instituto Federal de Educação, Ciência e Tecnologia do Acre, Cruzeiro do Sul, Brasil (egon.fabricio@hotmail.com; sabina.ufac@gmail.com; angelicams.ali@gmail.com; rcosta.bio@gmail.com)

A floresta Amazônica tem papel importante no ciclo de carbono global, com a biomassa florestal representando um expressivo reservatório de carbono. Essa biomassa poderá variar conforme a tipologia florestal, o que tem motivado pesquisas em diferentes regiões da Amazônia. No sudoeste da Amazônia, o bambu predomina em 165.000 km² de floresta e isso pode afetar a capacidade de estoque de biomassa na região. Nesse estudo avaliamos a influência do bambu no estoque de biomassa lenhosa acima do solo em quatro parcelas permanentes da RAINFOR, monitoradas durante o período de 2000 a 2016, no estado do Acre, no sudoeste da Amazônia. A biomassa acima do solo foi calculada usando-se uma equação alométrica (Chave et al., 2014). Em média, encontramos 254,3 Mg ha⁻¹ de biomassa lenhosa estocada por parcela, valor que está de acordo com o estoque de biomassa obtido por outro estudo na região (250-320 Mg ha⁻¹). Por meio de uma ANOVA, identificamos que quanto maior a densidade de bambu, menor é a quantidade de biomassa lenhosa acima do solo estocada na parcela (F3,16=542,16; p < 0,01), e que as parcelas com menor densidade de bambu têm, em média, 204 Mg ha⁻¹ mais de biomassa estocada. Esses resultados demonstram que o estoque de biomassa e carbono florestal é afetado pelo bambu, e que programas de REED+ deveriam considerar a influência do bambu no processo de contabilização do estoque de biomassa e carbono na região do sudoeste da Amazônia.

Forests and climate change in the Southwestern Amazon region: a productive arrangement for community-managed wood from the Chico Mendes Extractivist Reserve / *Florestas e mudanças climáticas no sudoeste da amazônia: arranjo produtivo para madeira manejada comunitária da Resex Chico Mendes*

Moacyr Araújo Silva¹

¹WWF Brasil, Rio Branco, Brasil (moacyr@wwf.org.br)

O WWF Brasil apoia e incentiva a mais de 20 anos diversas iniciativas de manejo florestal comunitário, de certificação florestal FSC e de organização/ fortalecimento de cadeias de valor da sociobiodiversidade na Ecorregião Sudoeste da Amazônia. A apresentação levada ao painel B8c busca uma abordagem focada nos trabalhos do arranjo produtivo da madeira comunitária, trazendo lições aprendidas, resultados sistematizados, aspectos promissores e desafios para governos, comunidades, pesquisadores e ONGs socioambientais e indigenistas apoiadoras das comunidades tradicionais daquela região. No tocante ao arranjo produtivo da madeira, a parcerias institucionais em curso permitiram à Cooperativa dos Produtores Florestais Comunitários (Cooperfloresta) estar atuando a quase 15 anos na articulação de 210 famílias de extrativistas da Resex Chico Mendes e de Projetos de Assentamentos Agroextrativistas do entorno desta UC. Neste arranjo produtivo atua também a UFAC, conduzindo capacitações e pesquisas de monitoramento do crescimento florestal e dos aspectos socioeconômicos da atividade. Em parceria com a Cooperfloresta o ICMBio o WWF Brasil tem avaliado a fauna silvestre presente nas áreas do plano de manejo florestal da Resex. O manejo em 2018/19 envolveu e beneficiou diretamente um total de 80 famílias agroextrativistas, que através da dedicação de 15 a 20 dias por ano nas atividades de campo, reuniões e treinamentos relativos às práticas do manejo florestal madeireiro, alcançaram valores médios de repartição de benefícios de R\$ 4.500,00, que tem garantido interesse de outros produtores para ingressar no grupo/Cooperativa e, no geral tem sido uma boa alternativa de complementação da renda familiar para atuais cooperados.

Volumetric yield coefficient for timber species obtained from a small sawmill in Rio Branco, Acre, Brazil / *Coefficiente de rendimento volumétrico para espécies madeireiras, obtido em uma serraria de pequeno porte no município de Rio Branco, Acre*

Adeilson Veiga¹, Marco Amaro¹ 

¹Universidade Federal do Acre, Rio Branco, Brasil (nascimentoadeilson18@gmail.com; marcoantonioamaro@hotmail.com)

A fixação de um valor de Coeficiente de Rendimento Volumétrico-CRV em 35% na Resolução nº; 474/2016, do Conselho Nacional do Meio Ambiente – CONAMA, é controverso porque o rendimento madeireiro em serra fita é variável, uma vez que inúmeros fatores podem interferir em algum momento do processo de desdobra, gerando valores de CRV inferiores ou superiores ao estabelecido na legislação. Como base no exposto o objetivo deste trabalho foi determinar o CRV de espécies madeireiras do Acre, bem como as circunstâncias que influenciaram o rendimento. O estudo ocorreu em uma serraria situada no município de Rio Branco, AC. Foram amostradas 80 toras, divididas entre as espécies *Manilkara bidentata* (A.DC.) A.Chev, *Couratari guianensis* Aubl., *Zanthoxylum amapaense* Albuq. P.G. Waterman, *Brosimum alicastrum* Sw. subsp. *Bolivarense pittier* C. C. Berg, *Agonandra brasiliensis* Miers ex Benth, *Cassia* Sp., *Bouchenavia* Sp. Eichler e *Ficus glabra* Vell. Para o cálculo do volume total, volume serrado e determinação do rendimento utilizou-se os métodos previsto na Resolução. O CRV médio para todas espécies foi de 36,25%, em serra fita, valor que está dentro dos limites estabelecidos pela legislação, uma vez

que atende a probabilidade de 95% de confiança e erro máximo de 10% do valor médio. Dentre os fatores que influenciaram no rendimento, os mais importantes foram a qualidade das toras, maquinário e a baixa qualificação de mão de obra, além da diferença entre o comprimento da tora e a maior peça desdobrada para todas espécies, que representou a perda em 6,14% do volume de total.

Potential impacts on vegetation structure from severe drought in the southwestern Amazon region / Possíveis impactos na estrutura da vegetação frente aos eventos de secas severas no Sudoeste da Amazônia

Richarly Silva¹ ; Sabina Ribeiro² ; Angélica Santos² ; Égon Lima² 

¹Instituto Federal de Educação, Ciência e Tecnologia do Acre, Cruzeiro do Sul, Brasil; ²Universidade Federal do Acre, Rio Branco, Brasil (rcosta.bio@gmail.com; sabina.ufac@gmail.com; angelicams.ali@gmail.com; egon.fabricio@hotmail.com)

Os efeitos negativos das mudanças no clima sobre a vegetação arbórea têm sido avaliados ao longo dos anos em diferentes regiões da Amazônia. Estudos de dinâmica da vegetação arbórea podem colaborar para a avaliação da possível perda ou substituição de espécies estruturalmente dominantes durante eventos de secas severas. Neste sentido, nosso objetivo foi investigar possíveis respostas das espécies arbóreas aos eventos de secas severas (2005 e 2010) considerando mudanças na representatividade estrutural, com base no valor de cobertura de cada espécie. Os dados utilizados neste estudo são de quatro parcelas permanentes (RAINFOR) na região sudoeste da Amazônia, estado do Acre. Cada parcela utilizada foi monitorada por aproximadamente 16 anos (2000 a 2016). Assim, realizamos o cálculo de valor de cobertura utilizando informações do diâmetro de 3595 indivíduos de 527 espécies. Os resultados encontrados para valor de cobertura mostraram que entre oito e dez (variação entre parcelas) espécies representam 50% do valor de cobertura total da parcela e as 50 espécies com maiores valores de cobertura representam em média 83,88% (SD ± 2,57) da cobertura total, demonstrando alta dominância na estocagem de carbono. Porém, não foi encontrada diferença significativa nos valores de cobertura entre anos secos e não secos, indicando que os efeitos estruturais da seca não devem ser refletidos a curto prazo. Dada a resposta estrutural retardada das florestas em resposta às secas severas, este tipo de abordagem deve ser realizada em maiores escalas, o que pode revelar respostas regionais da estrutura vegetal em função de secas severas.

B8d: RESPONSE OF FOREST ECOSYSTEMS TO CLIMATE CHANGE: LEARNING FROM EXPERIMENTAL MANIPULATIONS AND NATURAL GRADIENTS

Testing the sensitivity of humid temperate forests to drought: results from a superimposed experimental manipulation and severe natural drought in New Hampshire, U.S.A.

Heidi Asbjornsen¹, Cameron McIntire², Matthew Vadeboncoeur¹, Carter Berry³, Adam Coble⁴, Katie Jennings¹

¹University of New Hampshire, Durham, USA; ²University of New Mexico, Albuquerque, USA; ³Chapman University, Orange, USA; ⁴Oregon Department of Forestry, Corvallis, USA (heidi.asbjornsen@unh.edu; cameron.d.mcintire@gmail.com; matthew.vadeboncoeur@unh.edu; zcberry@gmail.com; coble.adam@gmail.com; katie.jennings22@gmail.com)

The Northeastern U.S. is expected to become both wetter and drier, yet the response of the region's moisture-adapted forests to drought is limited. We conducted a throughfall exclusion experiment in a mature New Hampshire forest, coinciding with the severe 2016 drought. Physiological and growth measurements were collected in two species with contrasting drought strategies: *Quercus rubra* (anisohydric) and *Pinus strobus* (isohydric). As expected, *P. strobus* exhibited greater growth reduction (51%) in response to drought compared to *Q. rubra* (22%); however, *Q. rubra* showed continued growth declines (35%) the following year while *P. strobus* growth modestly increased (control) or remained stable (treatment). Sensitivity to drought, indicated by the relationship between sapflow and soil volumetric water content (VWC), was greater for *P. strobus* than, *Q. rubra* (R² = 42 vs; 22, respectively). While both species reduced sapflow during drought, the effect size between drought and control trees was much greater for *Q. rubra*. Both species nearly ceased transpiring during peak drought (VWC = 8%), and exhibited a similar threshold when sapflow declined sharply (14%). These findings suggest that despite much higher resistance to drought, *Q. rubra* experienced greater post-drought legacy effects and longer recovery times. The greater effect size on *Q. rubra*'s sapflow may indicate that physiological thresholds were reached, whereby its anisohydric strategy (and low safety margins) may have prevented it from avoiding catastrophic hydraulic failure. Current work focuses on unraveling the underlying mechanisms of how differing adaptive strategies and growth phenologies contribute to drought response in these humid temperate forests.

Natural and simulated ice storms, droughts, soil freezing and soil warming shed light on response and recovery of Northern Hardwood Forests to extreme weather

Lindsey Rustad¹, Pamela Templer², Heidi Asbjornsen³, John L. Campbell¹, Matthew Vadeboncoeur³, Charles Driscoll⁴, Timothy Fahey⁵, Robert Fahey⁶, Peter Groffman⁷, Paul Schaberg⁸, Andrew Reinmann⁹, Katie Jennings³

¹USDA Forest Service, Durham, NH, USA; ²Boston University, Boston, MA, USA; ³University of New Hampshire, Durham, NH, USA; ⁴Syracuse University, Syracuse, NY, USA; ⁵Cornell University, Ithaca, NY, USA; ⁶University of Connecticut, Storrs, CT, USA; ⁷Cary Institute of Ecosystem Studies, Millbrook, NY, USA; ⁸USDA Forest Service, Burlington, VT, USA; ⁹Hunter College, New York, NY, USA (lindsey.rustad@usda.gov; ptempler@bu.edu; heidi.asbjornsen@unh.edu; jlcampbell@fs.fed.us; matthew.vadeboncoeur@unh.edu; ctdrisc@syracuse.edu; tjf5@cornell.edu; robert.fahey@uconn.edu; groffmanp@caryinstitute.org; paul.schaberg@usda.gov; andrew.reinmann@asrc.cuny.edu; katie.jennings@unh.edu)

A feature of a changing climate is the increase in the frequency and severity of extreme weather events. Although less is known about the impacts of these events on forested ecosystems, a consensus is emerging that they may have an equal or greater impact on forest biogeochemistry, stand structure and species composition than the more gradual, chronic changes in mean temperature and precipitation that are typically associated with climate change. In the northeastern United States, increased intensity of ice storms, increased occurrence of short- and mid-term droughts and increased frequency and depth of soil frost are among the anticipated types of extreme weather events associated with a changing climate. At the Hubbard Brook Experimental Forest, we combine ad hoc retrospective studies of how these types of events have impacted the biogeochemistry of forests and surface waters in the past with a new suite of experimental studies to better tease apart cause-and-effect relationships between these above and belowground extreme disturbances on the biogeochemistry of forests of today.

Early results from a temperate deciduous forest free-air carbon dioxide (CO₂) enrichment facility: seasons 0, 1, 2 (& 3) of 10

Land carbon sink is calculated to be the most important carbon cycle feedback to 21st century climate change, yet forecasts are highly uncertain and Earth-system models of the process contain significant ‘known unknowns’. Nutritional constraints and environmental stress may limit the land sink, especially mature forests (a dominant part of this sink). This would mean that current model climate projections — dependent upon an accurate assessment of the carbon cycle — are overly optimistic because scenarios, such as those used to inform the Paris-Katowice agreement, rely on a continuing strong sink. Experimental data underpinning current projections are from ‘1st generation’ Free Air CO₂ Enrichment (FACE) experiments on young, vigorously growing, recently planted trees. Ample evidence exists that mature forests behave differently, especially in critical aspects of water/nutrient cycling, intraspecific competition, stress responses and resilience. Birmingham Institute of Forest Research (BIFoR) FACE is set in UK broadleaf forest dominated by 160-year-old and 25 m tall oak interspersed with sycamore, hazel, hawthorn and holly. CO₂-enrichment, scheduled to run until 2026, commenced in spring 2017 and has performed to very high engineering standards. The whole canopy volume of three replicate 30 m-diameter (0.07 ha) plots is immersed in air containing 150 ppm CO₂ above ambient. We report an overview of results from 2017-2019 growing seasons of eCO₂ combined with baseline (2015 - March 2017) pre-treatment measurements. We find species-dependent increased carbon assimilation, increased fine root production, and prompt responses in water and nutrient cycling with which we begin to evaluate year-ahead predictions using the Joint UK Land Environment Simulator.

More to a tree than diameter at breast height: how tree form varies with environmental variables

Robert Schneider¹, Tommy Simard¹

¹Université du Québec à Rimouski, Rimouski, Canada (robert_schneider@uqar.ca; tommy.simard@uqar.ca)

Studies on the effects of global changes on tree or forest productivity often use diameter at breast height increments. However, trees change their vertical growth distribution along the bole with both shifts in biotic and abiotic factors. It has been long known that stem taper increases with site richness, crown size and less competition. Biomechanics have been used to explain these changes, where trees will change their stem form in order to support their crown. Using a unique database of more than 9000 stem analysis across a large climatic gradient from the temperate to the boreal forest, recent studies have however shown that tree taper will also change with climatic variables, with these shifts having been related to certain functional traits of the trees. More precisely, the yearly bole increment changes with both climatic and wind variables. Vapour pressure deficit and precipitations seem to play a key role. Wind also shifts the growth distribution along the stem. The effects of wind and climate on stem taper however have been reported to have the same importance in the Canadian boreal forest. Thus both biomechanical and physiological constraints must be taken into account in understanding stem form, and this has to be accounted for when looking at large scale changes in forest productivity, in order to not introduce biases.

Effects of repeated drying-wetting cycles on the forest soil greenhouse gas emissions. A manipulation study

Eugenio Diaz-Pines¹, Sonja Leitner², Sophie Zechmeister-Boltenstern¹

¹Institute of Soil Research, University of Natural Resources and Life Sciences, Vienna, Austria; ²Mazingira Center, International Livestock Research Institute, Nairobi, Kenya (eugenio.diaz-pines@boku.ac.at; s.leitner@cgiar.org; sophie.zechmeister@boku.ac.at)

Climate change forecasts shifts in precipitation patterns, involving both longer dry spells and more frequent heavy rainfall events. As a consequence, the intensity and frequency of the so-called drying-wetting cycles will increase in the future, with unknown overall consequences on soil biogeochemical processes. Here, we present results from a precipitation manipulation experiment in a beech forest in Austria. Two intensities of drying-wetting cycles during the vegetation period were simulated (moderate and severe stress, involving different rainfall exclusion length and amount of rainfall during rewetting) with rain-out shelters from 2013 to 2015, followed by a “recovery” year without manipulation in 2016. Soil-atmosphere exchange of CO₂, CH₄ and N₂O were monitored automatically with sub-daily resolution. Soil microbial parameters and nutrient dynamics were also investigated. Our results show a decrease in the production of CO₂ and N₂O in the soil during drought periods which was not compensated by the rainfall-triggered pulse events. Thus, soil CO₂ and N₂O efflux decreased by roughly 30 and 55 %, respectively, in the severe stress treatment. Soil CO₂ effluxes returned to reference levels when manipulation was discontinued. Methane uptake was enhanced during drought probably due to higher CH₄ diffusivity. However, a legacy effect suggests some adaptation of the microbial community. Highly dynamic responses after rewetting in GHG turnover and N cycling strongly call for high temporal (< daily) measurements. Overall, differences between environmental control and moderate stress treatments were absent or very modest, suggesting that, in order to see effects of extreme weather events, extreme manipulations are required.

Changing Environments in Northern Peatlands: the SPRUCE Experiment

Randy Kolka¹, Paul Hanson²

¹USDA Forest Service Northern Research Station, Grand Rapids, MN, USA; ²Oak Ridge National Laboratory, Oak Ridge, TN, USA (kolka003@umn.edu; hansonpj@ornl.gov)

The Spruce and Peatland Responses Under Changing Environments experiment, or SPRUCE, is an ambitious ecosystem-level experiment that is testing the response of high-carbon northern peatland ecosystems to increased temperatures and elevated carbon dioxide. The experiment is being conducted in a black spruce peatland in northern Minnesota, USA, at the USDA Forest Service's Marcell Experimental Forest (MEF). SPRUCE is supported by the US Department of Energy and is a collaboration between Oak Ridge National Lab, the USDA Forest Service and numerous other scientists from across the globe. Northern peatlands are an ecosystem considered especially vulnerable to climate change, and anticipated to be near their tipping point with respect to their carbon balance, especially at the southern margin of their range at MEF. Responses to warming and interactions with increased atmospheric CO₂ concentration are anticipated to have important feedbacks on the atmosphere and climate. The manipulation is evaluating the response of the existing communities to a range of warming levels from ambient to + 9 °C, with and without elevated CO₂, provided via large, open-top chambers. Belowground heating began in 2014, aboveground heating in 2015, and elevated CO₂ treatments commenced in June 2016. We anticipate running the experiment for 10 years. I will give an overview of SPRUCE and some initial results, including pre-treatment characterization of the peatland and some early findings following the establishment of the treatments.

Throughfall exclusion in New Zealand native forest – effects of drought on *Agathis australis*

Cate Macinnis-Ng¹, Benjamin Cranston¹

¹University of Auckland, Auckland, New Zealand (c.macinnis-ng@auckland.ac.nz; benjamin.cranston@auckland.ac.nz)

Global analysis indicates that large trees and those from mesic environments are most vulnerable to drought impacts. New Zealand kauri (*Agathis australis*) is amongst the largest and longest-lived trees in the world. Kauri are endemic to the north of the north island of Aotearoa, a region that is predicted to become hotter and drier under future climates. We have developed a tree-centred throughfall exclusion experimental design to simulate drought for large trees. Our sample trees are instrumented with sap flow sensors, point dendrometers, and soil moisture probes. We are also conducting periodic canopy sampling of leaf gas exchange, water potential and tissue water content to explore how trees respond as the drought develops. We have found that *A. australis* has some adaptations for drought survival including access to deep water stores and loss of leaves in a drought-deciduous response. Ongoing measurements will help us identify the limits of drought avoidance and tolerance in these iconic trees.

Can we assist the migration of cloud forest trees?

Tarin Toledo-Aceves¹ ; Fabiola López-Barrera¹, Vinicio Sosa¹, María de los Angeles García-Hernández¹

¹Instituto de Ecología A. C., Xalapa, Veracruz, Mexico (tarin.toledo@inecol.mx; fabiola.lopez@inecol.mx; vinicio.sosa@inecol.mx; mag_10f@yahoo.com.mx)

In response to increased temperatures caused by global climate change, shifts and retractions have been reported in the distribution range of cloud forest tree species. Evaluating the establishment of introduced saplings along an elevation gradient offers an opportunity to assess the capacity of species to respond to the observed or predicted effects of climate change, the influence of environmental factors on early establishment and the potential response of species to assisted migration at higher elevations as a mitigatory management strategy. We evaluated early establishment in 13 shade tolerant cloud forest tree species in enrichment plantings in nine forests subjected to traditional selective logging, along an elevation gradient (1250-2517 m a.s.l.) in southern Mexico. In each site, 30 saplings were planted and their survival and relative growth rate (RGR) recorded, along with the environmental factors temperature, canopy cover and humidity. After three years 10 species displayed high survival (> 80%). Survival increased at lower temperature in four species and with canopy cover in five species. RGR increased with elevation, followed by a decrease at the highest plots in nine species. RGR decreased with canopy cover in five species. Humidity had no effect on sapling performance. Our results indicate that most of the species have a high probability of sapling survival under canopy cover, even beyond the limits of their reported range of elevation distribution. This study supports the potential of assisted migration of cloud forest tree species with narrow distributions, as a climate change mitigation strategy.

Experimental warming reduced topsoil carbon content and increased soil bacterial diversity in a subtropical planted forest

Hui Wang¹, Shirong Liu¹, Andreas Schindlbacher², Jingxin Wang³, Zuomin Shi¹, Angang Ming⁴, Lihua Lu⁴, Daoxiong Cai⁴

¹Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China; ²Department of Forest Ecology, Federal Research and Training Centre for Forests, Natural Hazards and Landscape-BFW, Vienna, Austria; ³Division of Forestry and Natural Resources, West Virginia University, Morgantown, USA; ⁴Experimental Center of Tropical Forestry, Chinese Academy of Forestry, Pingxiang, China (wanghui@caf.ac.cn; liusr@caf.ac.cn; andreas.schindlbacher@bfw.gv.at; jxwang@wvu.edu; shizm@caf.ac.cn; minggang0111@163.com; kjc8526136@163.com; rlzxcdx@126.com)

The potential effects of global warming on the soil carbon (C) dynamics of subtropical forests are still uncertain. To assess the effects of warming on soil C and tree roots, combined soil warming (infrared heaters, +1.5 °C soil temperature) and trenching experiments were conducted in a subtropical *Castanopsis hystrix* plantation. Topsoil C content was reassessed after five years of warming, and the effects on soil organic carbon (SOC) quality and microbial diversity were analyzed. Compared with corresponding controls, the topsoil (0–10 cm) SOC content was significantly lower in un-trenched warmed soil (-13.6%) as well as in trenched warmed soil (-15.4%). However, the range of SOC content after five years of warming was similar to that observed after two years of warming (-14.6%, -19.2%), indicating that the warming effect on SOC content leveled off during the latter three years. In trenched plots, warming significantly decreased the carbohydrate C as well as the ratio of carbohydrate C to N-alkyl/methoxyl C ratio, suggesting that labile C was preferentially decomposed. In un-trenched plots, SOC quality was unaffected, indicating a compensatory input of labile root C. Bacterial α -diversity increased under warming, whereas no significant warming effects on fungal community diversity were observed. Both the SOC content and the proportion of soil carbohydrate C were negatively correlated with soil bacterial α -diversity, suggesting that the abundance of more recalcitrant SOC increased soil microbial diversity. Overall, soil warming resulted in a reduction in SOC in the first two years, and then SOC content was sustained.

Physiological performance of temperate seedlings in a FACE experimental forest

Carolina Mayoral^{1,2}, A. Rob Mackenzie^{1,2}, Michael Tausz³

¹Birmingham Institute of Forest Research, Birmingham, United Kingdom; ²University of Birmingham, Birmingham, United Kingdom; ³CQUUniversity, Cairns, Australia (c.mayoral@bham.ac.uk; a.r.mackenzie@bham.ac.uk; m.tausz@cqu.edu.au)

In a changing climate, understanding the behaviour of tree species subjected to elevated CO₂ is crucial to predicting the future of forest ecosystems. We selected the five most representative tree species coexisting in a mature, unmanaged, oak-dominated, FACE forest to assess their performance during one growing season. We measured leaf-level physiological traits on naturally regenerated seedlings coming from seeds that were developed under elevated atmospheric CO₂. We also introduced self-irrigated, nursery-sourced, potted seedlings from the same five species into the treatment and control patches in order to have an estimation of the physiological baseline of these species under somewhat more controlled conditions and elevated CO₂. A Non-linear model was fitted to each set of measurements from each seedling to describe the temperature effect on photosynthetic capacity. More than one hundred and fifty combinations of ecologically meaningful parameters (Amax at saturating light and Topt) were obtained. Under field water capacity (potted seedlings), the five species showed similar photosynthetic capacity to each other and under both treatments. However, natural *Quercus robur*, *Crataegus monogyna* and *Ilex aquifolium* seedlings exhibited higher maximum photosynthetic capacity (Amax) under elevated CO₂, suggesting a positive effect of increasing CO₂ on Amax with decreasing soil moisture. We did not find differences in the optimum temperature to maximize photosynthetic capacity, excepting for naturally regenerated *Acer pseudoplatanus* seedlings. Under the forecasted scenario of increasing CO₂, our preliminary results suggest a competitive advantage at the regeneration stage of species able to maximise photosynthetic capacity with elevated CO₂ under drier conditions over the other species.

B8e: FOREST ADAPTATION AND RESTORATION UNDER GLOBAL CHANGE: FROM GLOBAL TO REGIONAL PERSPECTIVE

Results of a global online survey on forest adaptation and restoration

Markus Höhl^{1,2}, John Stanturf³, Peter Spathelf⁴, Michael Kleine⁵, Peter Elsasser⁶, Andreas Bolte¹

Adaptive Forest Management and Forest Landscape Restoration are major challenges for forest management in times of global change and there is a need for information regarding the implementation of such measures. We present results from a global online survey on real-world examples of forest adaptation and restoration. The survey gathers information on the location, environmental conditions, management regimes, involved actors, targets, silvicultural measures and success factors for the respective forest adaptation and restoration projects. The survey audience can be classified as forestry experts. We examine the possibility to combine forest restoration and -adaptation and present results regarding targets, species selection (native vs. non-native), and forest management as reported by the survey participants. We further identify success factors derived from the survey information. Almost half of the reported projects pursue an approach that combines forest restoration and adaptation. Forest adaptation is associated with very high human development (HDI < 0.8) in contrast to forest restoration which is associated with low human development (HDI < 0.55). Native tree species are often preferred. Silvicultural interventions targeting existing stands (e.g. changing species composition, thinning etc.) are associated with adaptation whereas measures related to stand establishment are associated with restoration. Adaptation measures are likely to play a role in the future management of restored forests. Capacities in silviculture and the production of seedlings of native species should be assessed and developed to reach restoration goals. Restoration goals and objectives need to be clearly defined in a participatory process and monitored using criteria and indicators.

Do we have sufficient data and information for a knowledge based adaptation of forest management to climate change?

Pavel Cudlín¹, Harald Vacík², Nicola La Porta^{3,4}, Filip Lysak¹, Michal Marek⁵

¹Global Change Research Institute, Ceske Budejovice, Czech Republic; ²Institute of Silviculture BOKU, Wien, Austria; ³LASMA Research and Innovation Centre, Fondazione Edmund Mach, San Michele all'Adige, Italy; ⁴The EFI Project Centre on Mountain Forests (MOUNTFOR), Trento, Italy; ⁵Global Change Research Institute, Brno, Czech Republic (cudlin.p@czechglobe.cz; harald.vacik@boku.ac.at; nicola.laporta@fmach.it; filip.lysak@tiscali.cz; marek.m@czechglobe.cz)

Scientifically based data on the relationship of forest ecosystem functioning, forest stand naturalness and biodiversity status are urgently needed for a better understanding of the effects of forest management adaptation strategies under climate change. The contribution will summarize information on i) natural processes in forest ecosystems; ii) natural disturbance history, iii) differences between ecosystem processes during grow stage and mature stage and iv) the sustainability of forest management compared to the natural forest ecosystem processes. A framework of indicators will be proposed to quantify the key elements of natural processes (succession), the forest biodiversity status (genetic, species, ecosystem and landscape level) and the effects of sustainable forest management. The framework will allow to answer questions with regard to quantitative and qualitative aspects of forest management and maintaining forest ecosystem functioning (e.g. genetic pools, energetic-material fluxes, including soil nutrient level, water regime and forest microclimate and the incremental risks of natural forest disturbance, including resilience processes in disturbed forests). In addition, the possibility of comparison the primary (with an emphasis on improving soil properties) and secondary forest succession (similarity of clear cutting with natural disturbance) will be discussed. The findings will be exemplified by case studies from different forest ecosystems in Europe.

From commitment to commitment? Translating multiple FLR targets

Stephanie Mansourian^{1,3}, John Stanturf²

¹Mansourian.org, Gingins, Switzerland; ²Estonian University of Life Sciences, Tartu, Estonia; ³University of Geneva, Geneva, Switzerland (smansourian@infomaniak.ch; drdirt48@gmail.com)

Restoration, and forest landscape restoration (FLR) in particular, has become a widely used tool to reverse forest loss and degradation. Several countries have identified restoration opportunities via the restoration opportunities assessment methodology (ROAM) and have also committed to restore vast areas under the Bonn Challenge on FLR. For a selection of the countries with publicly-accessible ROAM reports we explore, analyse and compare their commitments under the

three main (Rio) environmental conventions (UNCCD, UNFCCC and CBD). Our aim is to compare and contrast these commitments and intended restoration interventions. We also seek to understand the extent to which commitments under the Bonn Challenge, areas and methods identified under ROAM and commitments under the three Rio conventions are realistic and what they might entail in practice in terms of their social, economic and ecological consequences.

Landscape restoration for sustainable forests in Europe: navigating multi-scale governance and management dynamics in diverse contexts

Lucas Dawson¹, Marine Elbakidze²

¹Stockholm University, Stockholm, Sweden; ²Swedish University of Agricultural Sciences, Skinnkatteberg, Sweden (lucas.dawson@natgeo.su.se; marine.elbakidze@slu.se)

Conventional intensification of forestry has dramatically reduced biodiversity and threatens the sustainable provision of ecosystem services important for human wellbeing. Landscape restoration is an important strategy for improving the functionality, resilience, and long-term productivity of forests. National and transnational institutions – e.g. the Bonn Challenge and the New York declaration – are recognised as important drivers of restoration. However, complex system dynamics make it difficult to evaluate the effectiveness of policy interventions, and little is known about how landscape restoration initiatives are influenced by the governance contexts in which they are situated. Adaptive management (AM), whilst frequently suggested as essential for the sustainable management of natural resources, is an emergent phenomenon and is thus strongly shaped by surrounding governance constraints. We used a qualitative complex systems approach to explore the causal dynamics of forest landscape restoration in the context of global drivers of forest degradation. Against this backdrop, we then examined a number of successful landscape restoration case studies at different scales and in different governance contexts in Europe. We found five processes that are key to restoration outcomes, viz. planning, garnering stakeholder support, adequacy of inputs, implementation, and knowledge management. Whilst aspects of AM emerged in all cases, the degree to which surrounding governance contexts proved conducive to AM varied. Major constraints relate to formal and informal institutional contexts, regulatory flexibility and funding. Key strategies identified relate to management of positive feedback loops concerning stakeholder perceptions, risk mitigation, learning cycles, and knowledge sharing practices.

Seeds without borders: a transnational approach to adapt European forests to climate change

Forest trees exhibit manifold local adaptations to the climate of their local habitat guaranteeing optimal growth and survival under stable environmental conditions. Climate is predicted to change at a significantly faster pace than the natural migration and adaptation capacity of trees, thus disrupting the link between climate and local adaptations. Planting alternative tree species and utilizing the tree species' intrinsic adaptive capacity are considered to be the most promising adaptation strategy. In Europe, the utilization of forest reproductive material is regulated by European and National legislation which define National Regions of Provenance. These Regions differs among countries and do neither reflect climate conditions nor climate change. However, climate change may render the local seed sources maladapted, while optimum seed sources may be the ones located outside of these defined regions. Therefore a transnational approach is required to integrate the link between local adaptation and climate change into reforestation policies. In the cooperation project SUSTREE, we develop transnational delineation models for forest seed transfer and genetic conservation based on species distribution models and trait-based intra-specific climate response functions. These models are being connected to registers of forest reproductive material as basis for decision support tools such as a Smartphone App and WEB-GIS which shall guide the selection of adapted planting materials under climate change. We recommend that legislation governing reforestation and seed transfer should be based on range-wide local adaptations of trees to assist management of genetic resources under climate change.

Global Forest Landscape Restoration: opportunities, benefits, and challenges for Canada in the context of cumulative effects

Nicolas Mansuy¹

¹Canadian forest service, Edmonton, Canada (nicolas.mansuy@canada.ca)

Global Forest Landscape Restoration (GFLR) offers an unprecedented opportunity to restore degraded lands into functional and working landscapes that deliver co-benefits to multiple stakeholders. Recent efforts by non-governmental organizations have been launched with the goal of achieving large-scale restoration targets. Over 20 countries and regional initiatives have already committed to restore close to 150 million hectares of degraded land and are seeking ways to integrate restoration strategies into a sustainable forest management and conservation agenda. However, the path towards achieving these goals is unmapped due to the challenges of navigating poorly understood ecological, socio-economic and governance impediments and the complexity of integrating multiple benefits and stakeholders. We put in perspective the opportunities and challenges for Canada to be an active player in respect to these international initiatives by addressing multidisciplinary knowledge gaps and issues: What are the international organizations and landscape-scale restoration programs; what are the principles of a GFLR approach; Are they relevant for the Canadian context; What are the tools and strategies available to move from target to implementation, and what key policies are needed to facilitate restoration at large scale. Sustainable forest management practices in Canada could be valued to support international commitments. However, recurrent large-scale anthropogenic disturbances cumulated with natural disturbances may challenge effective restoration in Canada. Policies driven by multi-stakeholder decision-making may also be needed to move towards a national framework supported by a multidisciplinary research agenda.

Forest landscape restoration initiatives and opportunities in India as an effective strategy to combat climate change

Vindhya Prasad Tewari¹, Suresh Gairola²

¹Himalayan Forest Research Institute, Shimla, India; ²Indian Council of Forestry Research and Education, Dehradun, India (vptewari@yahoo.com; scgairola@hotmail.com)

Protecting forests from degradation, deforestation and fragmentation, and tree-based landscape restoration are globally recognized as cost-effective solutions for combating climate change. India's Nationally Determined Contribution to the Paris Agreement commits to sequester additional 2.5 to 3 billion tons CO₂ equivalent by 2030 through increased forest and tree cover and this ties in with the Bonn Challenge commitment to restore 21 mha of deforested and degraded lands by 2030 as well as the SDGs. This commitment can only be achieved if existing forests are protected and improved and tree cover is extended by 25 to 30 m ha. Forest Restoration works in India need to tackle three questions: Where can forest and tree cover be protected and increased, and how much carbon sequestration this will result in? Which tree-based interventions have been implemented in different states and who are the principal actors who have implemented these projects?, What necessary enabling conditions need to be in place and what risks addressed to ensure achievement of protection and restoration goals? Here, we present how India can achieve the NDC and Bonn Challenge through forest protection and landscape restoration. Information about the areas suitable for protection, wide-scale restoration, and mosaic restoration have been presented and potential for increase in forest and tree cover and the associated carbon sequestration that can be achieved has been discussed. This will support planning for landscape restoration through the past and on-going initiatives which identifies different types of interventions implemented in different states by various implementing actors.

Adaptation trial with exotic species in Iran and Denmark considering climate change

Khosro Sagheb Talebi¹, Palle Madsen², Bahram Naseri³, Ole Kim Hansen⁴, Farhad Asadi⁵, Shirzad Mohammadnejad Kiasari⁵, Mohammad Vatanparast⁴, Assadollah Karimidoost⁶, Karim Maghsudloo⁶, Baba Khanjani Shiraz⁷

Caspian forests cover 1.8 million hectares of the north facing slopes of the Elburz Mountains on the South coasts of the Caspian Sea. These forests include a range of broad-leaved species, which are the same species or same genera as important European trees including beech, oak, maple, hornbeam, ash, and lime. These ancient forests date back to early Pleistocene and were not affected strongly by glaciations; thus they can be considered as refugial area. Relative to European forests, the Caspian forest has higher species diversity as well as greater genetic diversity within species. As climate change challenges cause increasing concern for maintaining future forest functions and ecosystem services for the next generations, we are gradually realizing how much we need robust forests and tree species with a great capacity for adaptation to new conditions. Therefore, we are testing the reaction, survival, growth and adaptation of some of the most important Euro-Asian species and provenances under very different climatic conditions. For this purpose, we have selected a total of ten species; five species of the Caspian forests including oriental beech, chestnut-leaved oak, velvet maple, common ash and Caucasian alder and five species from southern latitudes of Europe including sessile oak, pedunculate oak, Norway maple, sycamore maple and small-leaved lime. Seedlings are planted in long-term field trials in northern Iran and Denmark. The outcome of the project will be a unique research infrastructure that provides the basis for future and long-term research in forest and tree species adaptation capacity to climate change.

How is European forestry prepared to face the intensifying outbreaks of bark beetles?

Tomáš Hlásny¹, Rupert Seidl², Kenneth Raffa³, Jorg Müller⁴, Clair Montagne-Huck⁵, Andrew Liebhold¹, Hua Qin⁶, Mart-Jan Schelhaas^{7,8}, Paal Krokene⁹, Miroslav Svoboda¹, Heli Viiri¹⁰

¹Czech University of Life Sciences, Faculty of Forestry and Wood Sciences, Prague, Czech Republic; ²University of Natural Resources and Life Sciences, Department of Forest- and Soil Sciences, Vienna, Austria; ³University of Wisconsin, Madison, Department of Entomology, Madison, USA; ⁴Julius-Maximilians-University Würzburg, Field Station Fabrikschleichach, Department of Animal Ecology and Tropical Biology, Würzburg, Germany; ⁵Université de Lorraine, Université de Strasbourg, AgroParisTech, CNRS, INRA, BETA, Strasbourg, France; ⁶University of Missouri-Columbia, Division of Applied Social Sciences, Columbia, USA; ⁷Wageningen Environmental Research, Wageningen, Netherlands; ⁸Wageningen University and Research Wageningen Netherlands; ⁹Norwegian Institute of Bioeconomy Research, Division of Biotechnology and Plant Health, Høgskoleveien, Norway; ¹⁰Natural Resource Institute, Helsinki, Finland (tomas.hlasny@gmail.com; rupert.seidl@boku.ac.at; kfraffa@wisc.edu; joerg.mueller@uni-wuerzburg.de; claire.montagne-huck@inra.fr; aliehold@gmail.com; qinh@missouri.edu; martjan.schelhaas@wur.nl; paal.krokene@nibio.no; svobodam@fld.czu.cz; heli.viiri@luke.fi)

Bark beetle outbreaks have intensified in recent years and expanded to new parts of Europe, Siberia, Canada and USA. These outbreaks have affected regional economies but also precipitated often contradictory reactions among forest professionals, ecologists and other stakeholders in their attitudes toward forest protection. Climate change will further facilitate bark beetle survival and development and thus add further challenges to forest management. In response to these challenges, European governments requested that the European Forest Institute (EFI) undertake a study on the current understanding of bark beetle outbreaks and options to address them in the future. This study was conducted by an international team of scientists from Europe and the USA, and will be published as an EFI "Science to Policy" report. The study emphasized that management objectives must be clearly defined before the advantages or disadvantages of various mitigation options can be weighed. The study showed that in much of Europe outbreak management overly relies on risk reduction through extensive sanitation logging and beetle trapping. This is not adequately combined with management fostering forest resilience, and may likely result in increased forest vulnerability to other disturbances. A stand-scale oriented management approach dominates, while the importance of landscape configuration in controlling bark beetle spread is not sufficiently considered. The study proposed recommendations on how to improve the overall preparedness of the European forestry to face intensifying bark beetle outbreaks. Finally, it pointed out areas where heightened outbreak management might interfere with other management objectives, such as biodiversity maintenance and carbon accumulation.

Potentials and risks of selected introduced forest tree species in the Central European forestry

Vilém Podrázský¹

¹Czech University of Life Sciences, Prague, Czech Republic (podrazsky@fld.czu.cz)

Forestry is periodically focusing on silviculture of introduced tree species, which is connected with problems related to native species usually. At present, many species, including Norway spruce, European ash, alder and others show serious problems concerning stability and vitality of their stands, as a consequence of climatic change and connected abiotic and biotic harmful factors activation. Partial solution of these problems can be represented by more intense use of non-native tree species. In the conditions of the Czech Republic, the main species used in the forestry are: black locust (*Robinia pseudacacia* L.), exotic spruces (*Picea* spp.), Douglas-fir (*Pseudotsuga menziesii* /Mirb./ Franco), American red oak (*Quercus rubra* L.), grand fir (*Abies grandis*/Dougl. ex D.Don/ Lindl), and black walnut (*Juglans nigra* L.). Other introduced species are of minor economic importance. Aim of the presented study is the documenting of the original and summary review results concerning these species in the Czech forestry, and dissemination of knowledge on their functions in the Central Europe. The results focused on the comparison of their production capacity comparing to relevant native species, and especially the presentation of original and unique data evaluating their environmental effects – benefits and risks – are presented. Douglas-fir represents the most productive species with high-quality timber, with less unfavorable site effects comparing to Norway spruce. Exotic spruces finished the preparatory functions in the air polluted areas, reconstruction of the stands is urgent. Other species can be used in strictly defined conditions with high production gain and minimized environmental risks.

B8p: CLIMATE CHANGE AND THE FOREST ENVIRONMENT

Forest adaptation to climate change - is non-management an option?

Robert Jandl¹, Peter Spathelf², Andreas Bolte³, Cindy Prescott⁴

¹Bundesforschungszentrum für Wald, Vienna, Austria; ²HNE Eberswalde, Eberswalde, Germany; ³Thünen Institute, Eberswalde, Germany; ⁴University of British Columbia, Vancouver, Canada (robert.jandl@bfw.gv.at; peter.spathelf@hnee.de; andreas.bolte@thuenen.de; cindy.prescott@ubc.ca)

Climate change is posing a considerable challenge to foresters. The intensity of required adaptive measures and the relevance of old-growth forests as benchmark for managed forests are debated. Forest managers need to make decisions on stand treatment that are based on climatological and biological parameters with high uncertainties. We provided the conceptual basis for adaptive forest management and provide a number of case studies that reflect the options and limitations of ways of coping with climate change. The examples are derived from the experience of the authors. We conclude that only few forest types are either not strongly affected by climate change or do not require immediate adaptations of forest management. Many productive forests have stand properties that are decisively shaped by past management decisions, such as tree species composition, age distribution, rotation period, and stand structure. Maintaining these properties under the influence of climate change requires continuous and even increasing efforts of forest managers.

Forest pathways for sustainable development – emergent trends and good practice for forest and landscape restoration from the grassroots

Kenichi Shono¹, Yelena Finegold¹, Benjamin Caldwell¹, Faustine Zoveda¹

¹Food and Agriculture Organization of the United Nations, Rome, Italy (kenichi.shono@fao.org; yelena.finegold@fao.org; benjamin.caldwell@fao.org; faustine.zoveda@fao.org)
