Climate change is viewed by the Food and Agriculture Organization of the United Nations (FAO) as a key risk to its mission and to the 2030 agenda for sustainable development. FAO sees forests and trees as key elements of the response to that climate risk. Forests make vital contributions to both people and the planet, bolstering livelihoods, providing clean air and water, conserving biodiversity and mitigating climate change. Effective forest management strengthens resilience and adaptive capacities to climate-related natural disasters, contributes to climate mitigation by sequestering and storing carbon, and reduces emissions from deforestation and forest degradation, which is the second-leading cause of climate change after burning fossil fuels. Recent studies have demonstrated the potential of forest and landscape restoration to contribute to climate change mitigation. This potential is reinforced by political pledges like the Bonn Challenge, the UN decade on ecosystem restoration, and the African Forest Landscape Restoration Initiative (AFR100). To realize this potential and translate political will into results, practitioners need realistic, cost-effective approaches to implement restoration. Based on global work on forestry and food security, we present several proven, scalable approaches involving assisted natural regeneration and direct seeding that can be part of the effort to realize forest and landscape restoration's potential worldwide. We conclude by identifying some gaps that require assistance from researchers to address and with key messages for practitioners and policy-makers.

Resprouts mortality of *Schima superba* following a severe ice storm in early 2008 in Southern China: a six-year study

Yonghui Cao¹, Benzhi Zhou¹

¹Research Institute of Subtropical Forestry, Chinese Academy of Forestry, Hangzhou, China (fjcyh77@sina.com; benzhi_zhou@126.com)

Resprouting by woody plants has received little attention in undisturbed subtropical forest. From mid-January to mid-February 2008, an unexpected severe ice storm occurred in Southern China. We surveyed the damage and resprouts of all tree individuals with a minimum basal diameter of 4 cm for 6 consecutive years, to assess the importance of resprouting for forest dynamics. The decapitation and leaning tree types had the largest mean number of sprouts in the first year, while the uprooted tree in the second year and then all declined with increasing year. At the sixth years after the disaster (in 2013), that of three types of *Schima superba* all declined to a minimum and stable level, only with about 13.28% to 23.42% of that of the disaster year. The new sprouts germinated in each year after disaster for different damaged types of individual had an increasing mortality rate with increasing time, and the sprouts survival rate was much lower over the 5 years recovery for new sprouts germinated in current year after disaster. The new sprouts germinated in current year had a higher mortality rate until the third year and rose to 87.39% ($\pm 3.28\%$) and 96.27% ($\pm 7.47\%$) in the sixth year for three damaged types. The new sprouts germinated in current year had a more exuberant vitality, and about 15% of that for decapitation trees could survive 6 years, while that for uprooted and leaning trees survived for 6 years was about 3.48% - 3.73%, and that could survive 5 years was about 10%.

N₂O and CH₄ fluxes of forested floodplains in the Danube National Park, Austria

Andreas Schindlbacher¹, Erwin Moldaschl¹, Kerstin Michel¹, Barbara Kitzler¹

¹Federal Research and Training Centre for Forests - BFW, Vienna, Austria (andreas.schindlbacher@bfw.gv.at; erwin.mol21@gmail.com; kerstin.michel@bfw.gv.at; barbara.kitzler@bfw.gv.at)

Favorable hydrological properties combined with periodic input of organic matter and nutrients after flooding dispose floodplain forests as potential “hot spots” of carbon (C) and nitrogen (N) cycling. Environmental conditions could also be favorable for the production of nitrous oxide (N₂O) and methane (CH₄). We measured soil N₂O and CH₄ fluxes at 18 sites in the Danube National Park (~ 10.000 ha), spanning natural gradients from frequently to less frequently flooded forest. Intensive monitoring sites were additionally equipped with auto-chambers to measure soil GHG fluxes in daily resolution. Stem N₂O and CH₄ fluxes were measured at the intensive sites as well. Against our expectations, soils acted primarily as CH₄ sinks. Though we observed CH₄ emissions shortly after flooding, the soil at the frequently flooded sites still showed average CH₄ uptake of 18 µg CH₄-C m⁻² h⁻¹ during the first 18 month of our study. Less frequently flooded sites showed soil CH₄ uptake of on average 54 µg CH₄-C m⁻² h⁻¹. Nitrous oxide was mostly emitted from soil and fluxes increased shortly after flooding events. Highest soil N₂O emissions (> 70 µg N₂O-N m⁻² h⁻¹) were, however, measured independently of flooding during freeze-thaw periods in late spring. Tree stems fluxes differed among tree species (poplar, ash) and among stem sampling heights. Poplar showed sharply declining CH₄ and N₂O emissions with increasing stem measurement height. Ash showed opposite trends with regard to CH₄ and no distinctive pattern with regard to N₂O. Generally, stems mostly emitted CH₄ and N₂O, but emissions were very low.

Strategic genetic resources from Uruguay, the Southern limit of the Atlantic forest, on the current scenario of climate change

The Atlantic Rainforest is a Neotropical plant formation, traditionally present in Brazil, Paraguay, and Argentina. In Brazil, it followed the country coastal zone, from Rio Grande do Norte to Rio Grande do Sul, reaching inland the Province of Misiones in North-Eastern Argentina, and east of Paraguay. It is a threatened tropical forest and its surface has been fragmented discontinuously due to intensive deforestation of the biome, mainly in the twentieth century. It still holds one of the greatest biodiversities on the planet. It covered important stretches of mountain ranges and escarpments of the Brazilian plateau and was the extension of the Amazon rainforest. It was the second largest tropical forest in expansion in South America. The largest area continues as original surviving forest, the best preserved of this ecosystem is in the Argentine province of Misiones. However, Uruguay has small remnants of Atlantic forest that make it the final limit of the southern distribution. The edaphoclimatic conditions of Uruguay are different from those in the rest of this biome. It has four distinct seasons with contrasting temperatures. The low relief soil does not represent a physical barrier for the winds, making the changes of weather very variable. The aim of this work is to describe five genetic resources species of this biome, its potential for reforestation and productivity in the current scenario of climate change. These are *Parapiptadenia rigida*, *Ilex paraguariensis*, *Myrcianthes pungens*, *Eugenia involuocrata*, and *Cordia americana*. We propose Conservation in situ, improvement and international germplasm interchange.

Estimation of carbon fluxes from the decomposition of coarse woody debris in *Pinus koraiensis* stands in the Russian Far East

Aleksandr Ivanov¹, Martin Braun², Dmitrii Zamolodchikov³, Stanislav Loshakov¹, Daniil Kosinov¹

¹Primorskaya State Academy of Agriculture, Ussuriisk, Russian Federation; ²University of Natural Resources and Life Sciences, Vienna, Austria; ³Center for Forest Ecology and Productivity of the Russian Academy of Sciences (CEPF RAS), Moscow, Russian Fede (aleksandr86@mail.ru; martin.braun@boku.ac.at; dzamolod@mail.ru; dokgonzo@ya.ru; kosinovdaniil69@gmail.com)

Forests play an important role in global carbon cycles by accumulating carbon in biomass as well as through photosynthesis and respiration. An accurate assessment is complicated because of variations in carbon fluxes for different decomposition stages of wood. The carbon stored in coarse woody debris (CWD) belongs to anthropogenically heavily affected carbon pools in forests available for wood supply (FAWS). The CWD pool in the forest is regulated by natural processes such as mortality and decomposition as well as the activities of the local population such as the use as easily accessible fuelwood. Furthermore, forest fires have a significant impact on CWD stocks. CWD stocks in *Pinus koraiensis* dominated forest stands were investigated in the Primorsky Krai territory of Russia including Bikin national park (no logging) with a CWD stock of 104 -119 m³/ha, and in an Ussuriisk-based forest stand of FAWS with a CWD stock of 10-59 m³/ha. The deadwood basic density for *Pinus* was determined at five consecutive decomposition stages as 0.30, 0.26, 0.20, 0.16, and 0.10 g/cm³. For the different decomposition stages carbon emissions were measured for the CWD surface throughout 2015-2017 with annual emissions ranging from 0.06 to 0.59 t C/ha for the stands investigated. CWD decomposition amounts to 2-7% of total destructive carbon flux. Comprehensive data on CWD differentiated by decomposition stage is useful not only for the refinement of carbon budgets in Primorsky Krai but also for soil scientists, mycologists, forest scientists and biodiversity assessments.

Climate gas emissions from forestry – silvicultural measures about models for allocation

Johann K. Næss¹, Anders Q. Nyruud¹, Lars G. F. Tellnes²

¹Norwegian University of Life Sciences, Ås, Oman; ²Ostfold Research, Fredrikstad, Norway (johann.kristian.nass@nmbu.no; anders.qvale.nyruud@nmbu.no; lars@ostfoldforskning.no)

The Norwegian forest industry is increasingly being requested for environmental documentation, typically environmental product declarations (epds). Currently, the environmental documentation is based on aggregated quantities for industrial roundwood and fiber. This implies that wood products in general do not reflect wood species (spruce or pine). It is therefore important to calculate emissions from products from specific wood species. Climate gas emissions from Norwegian forestry

activities was previously estimated with 2010 as reference year. Hence, the data used for allocation of wood products can be developed further with respect to different products and with respect to year the data are collected from. The study investigates five relevant scenarios: i) estimations based on data from single years, ii) estimations based on calculated averages, iii) estimates based on data from when measures actually took place, iv) sensitivity analysis on effects of fertilization, and v) estimates based on regional data. Climate gas emissions are within the interval 10,6 til 18,9 gwp/m³. Harvesting, transport to roadside and fertilization were the measures with the largest impact on emissions. In general, sawlogs from pine had the largest yearly variation in emissions. Furthermore, there is also substantial differences between emissions from aggregated products (i.e. estimated for both pine and spruce) and estimated emissions from specific tree species. The results indicate that results from the five scenarios differ by up to 30% for single products.

Achieving India's forestry sector NDC: adapting to the changing climate is the key

Promode Kant¹

¹Institute of Green Economy, Gurgaon, India (promode.kant@gmail.com)

Under the Paris Agreement India has promised a Nationally Determined Contribution of 2.5 to 3 billion tons of additional CO₂ sequestration by 2030. This translates roughly into Forest Landscape Restoration over 26 Mha but in the three years since the Agreement almost no progress could be made. This is because the policy approach has been largely to reach the target by bringing 33% of country's geographic area under forest and tree cover from the current level of 24.39% but very little lands are actually available for allowing it to happen. This paper proposes that the NDC targets can only be achieved by enhancing the Net Primary Productivity of all types of forests in India from their currently abysmally low levels by enhancing soil moisture retention, replacement of weeds by ecologically appropriate species, reducing their vulnerability to pests and diseases through the use of innovative silvicultural tools, and drastically reducing the incidences of wildfires. Since these adverse conditions have worsened in the recent decades largely due to the changing climate a very large scale and comprehensive transformational approach to adaptation that would involve the active, and income enhancing, participation of a large number of local population is proposed. The expected high levels of investments in adaptation to the changing climate under the Paris Agreement would make it financially feasible.

B8q: CLIMATE CHANGE AND THE FOREST ENVIRONMENT

Substitution effects of wood-based products in climate change mitigation

Hans Verkerk¹, Pekka Leskinen¹, Giuseppe Cardellini², Elias Hurmekoski¹, Roger Sathre³, Jyri Seppälä⁴, Carolyn Smyth⁵, Mariana Hassegawa¹

¹European Forest Institute, Joensuu, Finland; ²Technical University of Munich, Munich, Germany; ³Institute for Transformative Technologies, Berkeley, USA; ⁴Finnish Environment Institute, Helsinki, Finland; ⁵Natural Resources Canada, Vancouver, Canada (hans.verkerk@efi.int; pekka.leskinen@efi.int; cardellini@hfm.tum.de; elias.hurmekoski@gmail.com; roger@transformativetechologies.org; jyri.seppala@ymparisto.fi; carolyn.smyth@canada.ca; mariana.hassegawa@efi.int)

Forests store carbon in biomass and soil and when harvested, part of the carbon is stored in wood products. These products may substitute functionally similar products made from more emission-intensive materials. We reviewed the existing literature to update and improve the understanding of the climate effects of substituting wood products. We conducted a systematic review covering over 50 studies and yielding over 400 substitution factors. Most studies focused on North America and the Nordic countries in Europe with only few studies from other regions. Most of the substitution factors related to construction materials, and substantially fewer substitution factors were available for other product types (furniture, packaging, and textiles) and even fewer for paper and chemicals. Overall, the reviewed studies suggest an average substitution effect of 1.2 kg C / kg C, which means that per kilogram of wood products that substitute non-wood products, there occurs an average emission reduction of 2.2 kg CO₂. However, the substitution effects vary significantly, depending on the wood and non-wood products considered and the assumptions applied to estimate emissions. We conclude that the use of wood products is generally associated with lower fossil and process-based emissions, compared to non-wood products. However, substitution factors as such are not sufficient to guide policy-making. The fundamental aim should be to minimize emissions, through forest management activities, long-term storage of C in wood products and substituting emission-intensive materials. Resource-efficiency and minimizing material waste for both wood and non-wood based products should be simultaneous policy targets for climate change mitigation.

Environmental heterogeneity of *Araucaria angustifolia* populations in Central-South region of Brazil: a preliminary analysis

Itamar Antonio Bognola¹, Márcia Toffani Simão Soares¹, João Bosco Vasconcellos Gomes¹, Marcos Silveira Wrege¹, Elenice Fritzsos¹, Valderês Aparecida Sousa¹, Ananda Virginia Aguiar¹, Leticia Penno de Sousa¹, Patricia Póvoa de Mattos¹, Maria de Fátima Silva Matos², Andressa Godinho Scarante², Hugo Barbosa Bognola², Gustavo Crizel Gomes³

¹Embrapa Florestas, Colombo, Brasil; ²Embrapa Clima Temperado, Pelotas, Brasil; ³Pontifícia Universidade Católica do Paraná, Curitiba, Brasil; ⁴Universidade Federal de Pelotas, Pelotas, Brasil (itamar.bognola@embrapa.br; marcia.toffani@embrapa.br; joao.bv.gomes@embrapa.br; marcos.wrege@embrapa.br; elenice.fritzsos@embrapa.br; valderes.sousa@embrapa.br; ananda.aguiar@embrapa.br; leticia.penno@embrapa.br; patricia.mattos@embrapa.br; fatimamatosg9@gmail.com; andressa.scarante@hotmail.com; hbbog@yahoo.com.br; crizelgomes@gmail.com)

Araucaria angustifolia (Bert.) O. Kuntze (Araucariaceae) is a subtropical rain forest tree that has social and economic importance due its wood quality and edible seeds. To increase the knowledge about its genetic variability and its probable relationship with the physical environment, we are performing the edaphic, landscape and climatic characterization of natural populations occurring in a wide region including the latitudinal limits of Brazilian territory. From October 2015 to August 2016, we selected *A. angustifolia* trees from natural populations representing four Brazilian States. In those places, individuals were sampled, georeferenced (latitude, longitude, altitude), the relief was characterized and the soil were classified according to Brazilian Soil Classification System. Descriptive and cluster analysis, with field information, allowed the preliminary evaluation of these environments. As for edaphic aspect, the main classes of soil observed are Latosols (Oxisols), Cambisols (Inceptisols), Neosols (Entisols) and Nitosols (Alfisol). The southernmost sampled populations of Brazil (Pelotas region, Rio Grande do Sul State) are distinct from others by their lower altitude, around two hundred and ninety meters, and prevalence of shallow soil. Environments with the greatest contrast to this condition were located in the south of Minas Gerais State, with populations established over two thousand meters of altitude. Populations surviving in stressful environments are very important for conservation purpose, as result of local adaptation driving by extreme conditions. The attributes analyzed compose an information plan that will help to project the present and future occupation of these populations based on the IPCC scenarios.

Tree species managed as fodder shrubs: a strategy to balance the sown plant density and the stocking rate for silvopastoral systems in dry areas

Nelson Pérez Almario¹, Jairo Mora Delgado², Dagoberto Criollo Cruz³, Christian Carvajal Bazurto¹, Sonia Ospina⁴, Eliana Medina Rios²
¹Agrosavia, Espinal, Colombia; ²Universidad del Tolima, Ibagué, Colombia; ³Agrosavia, Florencia, Colombia; ⁴Agrosavia, Palmira, Colombia
 (nperez@agrosavia.co; jrmora@ut.edu.co; dcriollo@agrosavia.co; ccarvajal@agrosavia.co; sospina@agrosavia.co; lizeth1301@hotmail.com)

In order to quantify productivity and forage quality in silvopastoral systems the species *Albizia niopoides*, *Cordia alba*, *Gliricidia sepium*, *Guazuma ulmifolia*, *Leucaena leucocephala*, *Moringa oleifera*, *Senna spectabilis* and *Tithonia diversifolia* were evaluated in El Espinal (C. I Nataima, Agrosavia). The growth form of the tree plant was modified by pruning at 0.8 m (height) and time intervals between harvests (30-45-60 days). In a randomized complete block design, plots with 270 individual plants per species were sown in three rows, and water or nutrients were not added. The species *T. diversifolia*, *C. alba* and *S. spectabilis* had the higher forage averages for 30 days harvest period with 145, 139 and 160g-1DM respectively, however these species presented had high mortality under this harvest's interval. On 45 days harvest period, the survival and the forage production improved for the species. The highest production respectively was presented by *C. alba* 450g-1DM, *S. spectabilis* 395g-1DM and *T. diversifolia* 330g-1DM. On 60 days harvest period the highest production was for *S. spectabilis* 643g-1DM and *C. alba* 612g-1DM. At this interval, some branches were mainly a woody resource and sometimes unattractive for ruminant's consumption. On the other hand, *L. leucocephala* and *M. oleifera* presented the lowest forage biomass production per plant <160 g-1DM and the higher protein content. This evaluation allows to recommend managing these tree species in silvopastoral systems at 0,8 m and harvest intervals of 45 days. Under these recommendations these tree species decrease mortality and improve adaptation to climate seasonality during the establishment of silvopastoral systems in dry zones.

Reproductive phenology of *Eutepe edulis* Mart. in an altitudinal gradient at the Atlantic Forest

Andressa Tres¹, Franciane Pajewski¹, Alexandre França Tetto¹, Jaçanan Eloisa de Freitas Milani², Bruna Kovalskyki¹
¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade do Estado de Santa Catarina, Lages, Brasil (tres.andressa@gmail.com;
 franpajewski@yahoo.com.br; tetto@ufpr.br; jacanan.milani@gmail.com; kovalskyki.b@gmail.com)

Eutepe edulis is considered a key species in the Atlantic Forest and is currently classified as vulnerable at a Brazilian list of threatened species, due to illegal extraction. In order to provide information for future projects of conservation, the present study characterized *E. edulis* reproductive phenology in four altitudes (30, 100, 200 and 400 m) in Salto Morato Natural Reserve – Guaraqueçaba, PR. In each altitude, five individuals were monthly monitored from March/2017 to February/2018. The intensity of phenophases was registered following the methodology proposed by Fournier. Flowering started at the lowest altitude (in September) and lasted for four months with a peak in November. At 200 m, flowering was present only in November. Immature fruits were present in the lowest altitude from December until February (with a peak in January) and, at 200 m, it only occurred in March. Green fruits were observed in three altitudes: at 30 m, it started in February and lasted for three months; at 100 m, it started with one month of delay (in March) and lasted for four months; at 200 m, this phenophase initiated with two months of delay (in April) and lasted also for three months. Mature fruits also presented differences as they initiated at different altitudes: it started in February at 30 m; in June at 100 m and in May at 200 m. There are differences in reproductive phenology of *E. edulis* throughout the gradient, which can be explained by differences in microclimate.

Characteristic of phytodiversity and plants communities in a climate transition area in Burkina Faso (West Africa)

Assan Gnoumou¹, Adjima Thiombiano¹
¹University of Ouaga I Pr Joseph Ki-Zerbo, Ouagadougou, Burkina Faso (agnoumou@gmail.com; adjima_thiombiano@yahoo.fr)

The diversities of plants and ecosystems are sensitive to climate and soils variations, however climate is fast deteriorating at large scale. Therefore, botanical and ecological studies are necessary in climate transition area for phytodiversity monitoring, then to prevent species extinction. In this particular case, we carefully chosen Comoé-Léraba protected area. After inventories, based on the recent plants species listed in Burkina Faso, this protected area provides in proportion 26.12%. The importance of Guineo-Congolian species (113) proved that the Comoé-Léraba flora belongs to the Sudano-Guinean transition sector. It also accounts the highest number of exclusive species (118) in the country. Furthermore, in related to each ecosystem, 11 plants communities' have been clearly defined, according the phytosociological statements (DCA). Among these communities four news taxa were determined based on previous studies in the same phytogeographical zones. Then their direct ordination (CCA) with soil's (physical and chemical) parameters, shows that plants communities' distribution is governed mainly by water regulation on the ground and also its texture. Comoé-Léraba is located at the most humid zone of the country, but due to climate warming, exclusive species and rare plants communities which have been discovered, could move away from the country. Consequently, this protected area required closely attention.

Energy potentials of mountain forests of Eastern European Mid-latitude ecotone as the basis for adaptive forest management under climate change

Roman Vasylyshyn¹, Ivan Lakyda¹, Andrii Bilous¹, Vasyl Holian²
¹National University of Life and Environmental Sciences of Ukraine, Kyiv, Ukraine; ²Lutsk National Technical University, Lutsk, Ukraine
 (vasylyshyn@nubip.edu.ua; ivan.lakyda@nubip.edu.ua; bilous@nubip.edu.ua; golian_v@ukr.net)

Forests act as important components of ecosystems in mountainous areas, where forest management should balance environmental protection and socio-economic development of local communities. Being a part of Eastern European Mid-latitude ecotone, mountain forests of the Ukrainian Carpathians represent a resource-rich forest management hotspot in a developing country. Given the low efficiency of energy use in Ukraine and growing energy demands, forests can and should play an important role as a renewable energy source in the near and far-off prospects. Theoretical and methodological background for quantitative assessment of energy potential of woody biomass in mountain forests shall be based on provisions of sustainable forest management and reflect the balance of the three structural components of sustainable development – environmental safety, economic development, and social interests. Considering certain environmental, economic and social constraints on energy use of wood biomass in mountain forests, we propose to distinguish five types of energy potential: theoretically possible, technically accessible, environmentally safe, economically profitable and socially conditioned. Having implemented the abovementioned principles and approaches, we have assessed energy potentials of wood biomass for Carpathian Mountains region: theoretically possible – 49.4 PJ; technically accessible – 35.2 PJ; environmentally safe – 25.4 PJ; economically profitable – 22.9 PJ and socially conditioned – 20.3 PJ. The last-mentioned type of energy potential expressed in volume of timber means that over 2.2 million cubic meters of wood could be used for bioenergy purposes. The proposed research results can serve as a component of an information system aimed at implementation of adaptive forest management in the Carpathian region.

Interspecific and intraspecific variability of functional traits in two tree species in three ecological scales influenced by the Tatacoa desert, Colombia

Nelson Pérez Almaro¹, Jairo Mora Delgado², Dagoberto Criollo Cruz³, Christian Carvajal Bazurto¹, Oscar Orjuela¹, Eliana Medina Rios²
¹Agrosavia, Espinal, Colombia; ²Universidad del Tolima, Ibagué, Colombia; ³Agrosavia, Florencia, Colombia (nperez@agrosavia.co; jrmora@ut.edu.co; dcriollo@agrosavia.co; ccarvajal@agrosavia.co; oorjuela@agrosavia.co; lizeth1301@hotmail.com)

The dry tropical region of Colombia has periods of 145 to 220 days / year without rainfall. In addition, the average temperature of 29 °C, relative humidity between 56 and 65%, poorly distributed precipitation, however, fall 1272 to 1400 mm / year and evaporates more than the precipitation received. These variables would be directing the behavior of the plants towards different forms of response, since a plant hardly maintains its leaf tissues alive, when periods of drought are long. Using mixed linear models with varcomp statistical function in two key functional features, specific leaf area (SLA) y Wood density (WD) of species (*Cordia alba* y *Guazuma ulmifolia*) found in paddocks at three ecological scales (species, tree and show). Interspecific variability of traits (50.34 - 79.08%) e intraspecific *Árbol* (28.18-17%) and simple (41% para SLA) respectively. Comparisons for SLA and WD, shows that features trees in paddocks with significant differences (P-valor=0,0001. R2=0,77). SLA values in *C. alba* varies between (17,19 + 0,7 to 17,49 + 0,57 mm² mg⁻¹) y *G. ulmifolia* (12,71+0,57 to 13,83+0,57 mm²mg⁻¹), showing stability. The WD for *C. alba* varia between (0,45 + 0,02 to 0,53+0,01 mg mm⁻³) y *G. ulmifolia* entre (0,44+0,02 to 0,53+0,01 mg mm⁻³), being this variable, indicator of adaptation of species to water stress. The high interspecific variability (50-79%), it follows patterns reached in other studies, while intraspecific variability (tree-show), present important variability. Results indicate that intraspecific variability (tree-show) are dominated by interspecific variation (species), but that there is an intra-specific variability in trees and foliar structures that can not be ignored.

Forest amount affects crops productivity in Brazilian agricultural frontier

Ludmila Rattis^{1,2}, Paulo Brando^{2,3}, Marcia Macedo^{2,4}, Michael Coe¹
¹Woods Hole Research Center, Passos, Brasil; ²Instituto de Pesquisa Ambiental da Amazônia, Brasília, Brasil; ³Woods Hole Research Center, Brasília, Brasil; ⁴Woods Hole Research Center, Falmouth, USA (ludmilarattis@gmail.com; pbrando@whrc.org; mmacedo@whrc.org; mtcoe@whrc.org)

The relationship between climate and the agricultural system is well known and described in the literature. However, with the increase in the frequency of occurrence of extreme climatic events - such as prolonged and successive droughts, torrential rains, high daytime, and nighttime temperatures - the agricultural production system has become even more unstable. Given the humanity dependence on increasing agricultural production, here we hypothesized that agriculture is moving to areas less suitable to grow crops and even the consolidated fields could become less suitable in the future. We also tested if different landscape compositions would change the relationship between crop productivity and the weather. Specifically, we 1) quantified the relationship between climate and first and second crops across the Brazilian agricultural frontier; 2) characterized climatically the areas where agriculture is expanding to in recent years; 3) quantified agricultural de-intensification, 4) compared the past and future climatic conditions of agricultural fields; and 5) quantified the relationship between forest amount and crop yield productivity of the second crop. In hotter and drier years, production, productivity, and planted area were lower in the second crop. Agricultural climate space has already changed. At the same time, agriculture expanded into hotter regions, although into places with more precipitation during the wet season. In regions with lower forest cover, the forest plays a positive role in the productivity of the first and second harvests. The crop production stability in the Brazilian agricultural frontier may depend on the standing forest.

B8r: FORESTS AND CLIMATE CHANGE IN SOUTHWESTERN AMAZON

Estimated stocks of volume, biomass, and carbon in vegetation with DBH ≥ 20 cm from the riparian forest along the Acre River in Brasília, Acre, Brazil / Estimativa do estoque de volume, biomassa e carbono em vegetação de mata ciliar ao longo do Rio Acre, com DAP ≥ 20 cm, em Brasília, AC

Reyneberg da Silva Araújo¹, Marco Amaro¹, Ecio Rodrigues Silva¹, Alana Chocorosqui Fernandes²
¹Universidade Federal do Acre, Rio Branco, Brasil; ²Instituto Federal do Acre, Rio Branco, Brasil (reyneberg@hotmail.com; marcoantonioamaro@hotmail.com; ecio@ufac.br; alanafernandes@yahoo.com.br)

Este estudo teve como objetivo quantificar o estoque de volume, biomassa e carbono na mata ciliar do Rio Acre em Brasília, AC, considerando a vegetação com DAP ≥ 20 cm, para subsidiar futuros estudos de valorização da floresta, e ainda conseguir evidenciar a importância da conservação de florestas nativas para redução das emissões de gases na atmosfera. O Inventário Florestal do projeto Ciliar Só-rio foi realizado utilizando unidades amostrais com dois estágios (conglomerados) para coleta dos dados, com emprego de técnicas de amostragem aleatória estratificada pela faixa marginal do Rio Acre por município. Dentre os municípios que são cortados pelo Rio Acre, o escolhido para realização deste estudo foi Brasília, no qual foram instaladas quatro parcelas primárias. Dentro destas foram mensuradas quatro parcelas secundárias cada uma com: 10 m x 250 m, somando 1 ha. Para o cálculo de volume e biomassa utilizou-se equações baseadas no modelo Schumacher e Hall. O estoque de biomassa para demais compartimentos (folhas, frutos, flores e raízes) foi obtido através de percentuais encontrados em trabalhos realizados na Amazônia. Para estimar os estoques de carbono considerou-se 50% da biomassa seca. O volume médio de madeira para o compartimento fuste por ha, para DAP ≥ 20 cm, foi estimado em 61,07 m³. O estoque de biomassa seca e carbono foram de 117,80t ha⁻¹ e 58,90t ha⁻¹ respectivamente. Esses valores são inferiores aos encontrados em alguns estudos, para a mata ciliar do município de Porto Acre.

Biomass and carbon stocks in the vegetation within the Seringal Nova Esperança Ecological Area, in Epitaciolândia, Acre, Brazil / Estoque de biomassa e carbono na vegetação da Arie Seringal Nova Esperança, Epitaciolândia, AC

Saranna Shayra de Freitas Nascimento¹, Marco Amaro¹, Ecio Rodrigues Silva¹, Ricardo de Oliveira Gaspar²
¹Universidade Federal do Acre, Rio Branco, Brasil; ²Universidade de Brasília, Brasília, Brasil (saranna.freitas@gmail.com; marcoantonioamaro@hotmail.com; ecio@ufac.br; ricogasp@foresta@yahoo.com.br)

Este estudo objetivou estimar o estoque de biomassa e carbono na vegetação da Área de Relevante Interesse Ecológico-ARIE Seringal Nova Esperança, em Epitaciolândia, AC, para subsidiar estudos que evidenciem a importância da conservação de florestas nativas, para redução das emissões de gases na atmosfera. Para estimar a biomassa na vegetação com DAP ≥ 5 cm utilizou-se os dados de um inventário florestal realizado em 30 parcelas de 10 x 100 m. Estimou-se a biomassa do fuste utilizando-se equações baseadas em literatura e a da copa pelo uso de fator. Para estimar a biomassa na vegetação com DAP < 5 cm foram instaladas 18 parcelas secundárias de 5 x 5 m, para

pesar toda a vegetação encontrada, para determinação do peso úmido. Foram pesadas amostras deste material, para determinação do peso úmido, as quais foram levadas para laboratório para determinação do peso seco (biomassa). Com a obtenção do peso seco das amostras, a biomassa das parcelas foi estimada. Os estoques de biomassa para folhas, frutos, flores, raízes e serrapilheira foram obtidos através de percentuais encontrados em literatura. A biomassa seca foi convertida em carbono, utilizando o valor de 50% recomendado pelo Serviço Florestal Brasileiro. O teor de umidade médio obtido para a copa foi de 68,70% e para o fuste 50,5%. A biomassa seca total média, abaixo e acima do solo, foi estimada em 400,92 t ha⁻¹, sendo 2,71 na vegetação com DAP < 5 cm; o carbono foi estimado em 200,84 t/ha⁻¹, sendo 1,36 na vegetação com DAP < 5 cm. Valores superiores a maioria de outros estudos realizados no Acre.

Assemblies of ants indicating the type of land use in the Southwestern Brazilian Amazon region / Assembleias de formigas como indicadoras do tipo do uso do solo no Sudoeste da Amazônia brasileira

Francisco Matheus da Silva Sales^{1,2,3}, Fernando Schmidt^{1,2,3,4}

¹Laboratório de Ecologia de Insetos, Rio Branco, Brasil; ²Centro de Ciências Biológicas e da Natureza, Rio Branco, Brasil; ³Universidade Federal do Acre, Rio Branco, Brasil; ⁴Programa de Pós-graduação em Ecologia e Manejo de Recursos Naturais, Rio Branco, Brasil (matheussalles07@gmail.com; schmidt_fa@gmail.com)

A implementação de pastagens é apontada como uma das principais formas de mudança do uso do solo no Sudoeste da Amazônia Brasileira. Considerando a dificuldade de se avaliar a resposta de toda a biodiversidade aos diferentes tipos de impactos antrópicos, tem sido proposto o uso de bioindicadores, grupos de organismos que são facilmente amostrados e que reagem de forma previsível as perturbações antrópicas, como por exemplo as formigas. Assim, temos como objetivos fornecer parâmetros para o uso das assembleias de formigas como bioindicadoras do uso do solo no Sudoeste da Amazônia brasileira. As assembleias de formigas foram caracterizadas em termos de número e composição de espécies. As coletas de formigas foram feitas em três pontos de um fragmento florestal e em três pastagens do seu entorno. Em cada local de coleta, estabelecemos um transecto de 200 m com um ponto amostral a cada 20 m. Cada ponto amostral foi constituído de oito armadilhas de queda sendo quatro epigéicas e quatro hipogéicas. O habitat de floresta acumulou mais espécies de formigas para ambos os estratos. Houve diferença na composição de espécies entre floresta e pasto nos dois estratos. A transformação de áreas de floresta em pastagem impacta as assembleias de formigas, reduzindo a riqueza de espécies e alterando a composição de espécies. Além disso, a identificação das espécies associadas a cada tipo de ambiente é útil para se aferir o estado de conservação/recuperação de um ambiente com base nos parâmetros observados das assembleias de formigas.

B9a: THE ROLE OF FOREST BASED INDUSTRY IN MEETING NDCS WORLDWIDE UNDER PARIS AGREEMENT

New generation plantations, a carbon dioxide reduction technology

Luis Neves Silva¹

¹WWF Brasil, Vila Nova Santo André, Portugal (lnsilva@wwfint.org)

The planet has warmed by 1 °C since the industrial revolution, and staying within 1.5 °C will require action at an unprecedented pace and scale. One part of the solution is removing significant quantities of carbon dioxide from the atmosphere. This is where planting trees comes in. For the last 10 years, the New Generation Plantations (NGP) platform has developed a concept that works, demonstrating how tree plantations can be established and managed in ways that benefit nature and climate while contributing to sustainable development. Research indicates that plantations can provide a variety of ecosystem services beyond simply supplying timber. If expanding plantations follows the NGP concept, trees planted in the right way and in the right places can make a major contribution to reducing carbon dioxide levels. In the Atlantic forest biome, where the NGP Participants manage more than 2 million hectares of land, around half of this area is planted with eucalyptus in former degraded grazing land, while the rest is set aside for conservation. Increasing production in these intensively managed areas frees up land for conservation and forest restoration, while increasing carbon storage. As technology continues to develop, almost everything derived from fossil fuels today could come from trees in the future. The variety of plastics that can now be made from bio-based sources is growing all the time. By providing a reliable, renewable and climate-positive source of fibre, plantations can contribute to reducing emissions and supporting the transition to a sustainable bio-based economy.

Robust projection of carbon stored in harvested wood products for establishing a national forest reference level under the European Union's contribution to the Paris Agreement

Niclas Scott Bentsen¹, Vivian Kvist Johannsen¹

¹University of Copenhagen, Department of Geosciences and Natural Resource Management, Frederiksberg C, Denmark (nb@ign.ku.dk; vkj@ign.ku.dk)

With the 2030 climate and energy framework the European Union (EU) has committed itself to reduce GHG emissions by 2030 at least 40% relative to 1990. The commitment forms the EU's contribution (NDC) to the Paris Agreement. For the first time the land sector is considered to achieving the reduction targets. Since the land sector, particularly forests, is characterized by long time perspectives, it is essential to ensure transparent and coherent accounting and reporting for the sector. For documentation and accounting of the forest sector's contribution, each Member State shall develop a National Forestry Accounting Plan and a Forest Reference Level including Harvested Wood Products to project expected greenhouse gas emissions from the forest sector.

Modeling the use of wood to strengthen its socio-economic and environmental impacts

Martin Moravčík¹, Miroslav Kovalčík¹, Hubert Paluš², Ján Parobek²

¹National Forest Centre, Zvolen, Slovakia; ²Technical University, Zvolen, Slovakia (moravcik@nlcsk.org; kovalcik@nlcsk.org; palus@tuzvo.sk; parobek@tuzvo.sk)

This paper builds on the preliminary results of the ongoing research project aimed at the use of wood as a renewable raw material, the main objective of which is to create an optimal model of wood use in Slovakia. Sustainable production, adequate financial appreciation and increasing social and environmental benefits of timber production are important goals of the forestry sector. One of the options for ensuring better appreciation of felled timber is to increase the production of more valuable assortments. This paper aims at the comparison of actual volume and value structure of raw wood assortments supplies produced by forestry with the possible available structure of assortments. To carry out the above-mentioned analyses these data sources were used: the summary forest management plans, the mathematical and statistical methods of forest national inventory and the sectoral forest market information system. Based on the analysis of and

discussion on the factors affecting wood flows a variant models as alternatives to the current wood flows were developed with the aim to achieve (i) the optimal value utilisation of available raw wood assortments structure, (ii) increased domestic level of wood consumption, and (iii) the improved carbon balance of wood use through the changes in the portfolio of wood products. The difference between the carbon volumes stored in harvested wood products within the mentioned variants were quantified so that they could be assessed from the viewpoint of the best protection of atmosphere from disproportionate CO₂ growth. The carbon balances were calculated using the IPCC procedures.

The role of forest based industry in meetings NDCs worldwide under Paris Agreement

Nathalia Granato Loures¹

¹Indústria Brasileira de Árvores, São Paulo, Brasil (n.granato@iba.org)

The Paris Agreement has been ratified by 179 Parties, which have compromised to National Determined Contributions to be performed in the next decade. Governments, industries and consumers have a huge responsibility in helping meeting the goals and moving towards a new low carbon economy. This session aims to emphasize the significant role played by the forest sector in removing and stocking carbon, besides providing renewable and recyclable raw materials, products and ecosystem services. The event also aims to demonstrate how innovation in technology and management can help forestry adapt in a condition of a growing global demand for forest based products and a climate change environment. Additionally, reinforce the potential of forest based industry in adaptation by investing in research, developing and innovation and adoption of best practices that allow rational use and conservation of natural resources. Cases from Brazil and from other regions that are engaged in the New Generation Plantations Platform will be portrayed as examples of governance, engagement in policy making and management that have helped their respective regions to get closer to implementing the assumed NDC.

Vision 2030-2050: the future of the forests and agriculture in Brazil / Visão 2030-2050: o futuro das florestas e da agricultura no Brasil

Luana Oliveira¹, Laura Lamonica¹, André Guimarães^{1,2}

¹Coalizão Brasil Clima, Florestas e Agricultura, São Paulo, Brasil; ¹Instituto de Pesquisa Ambiental da Amazônia, Brasília, Brasil (assistente@coalizaobrasil.org; admin@coalizaobrasil.org; admin@coalizaobrasil.org)

O Brasil possui um território extenso e diversificado, agropecuária forte e competitiva, capital natural extraordinário e elevada biodiversidade e serviços ecossistêmicos. O país é um grande produtor de alimentos e, portanto, corresponsável pela segurança alimentar do planeta. Ao mesmo tempo, possui a maior floresta tropical do mundo e, por isso, é também corresponsável pela segurança hídrica e climática da humanidade. Nos últimos 40 anos, o país se tornou uma potência agrícola. Passou de importador de alimento a terceiro no ranking dos exportadores de produtos agrícolas, segundo a FAO. Esse salto foi possível graças a uma poderosa combinação entre o que foi garantido pela natureza – fertilidade dos solos, disponibilidade de água, condições climáticas, polinizadores e biocontroladores de pragas e doenças – e os ganhos em produtividade resultantes dos investimentos em pesquisa e inovação. No entanto, ainda somos o sétimo maior emissor de gases de efeito estufa do planeta, com grande parte dessas emissões decorrentes direta e indiretamente das atividades relacionadas à produção agropecuária, especialmente o desmatamento. Na visão da Coalizão Brasil Clima, Florestas e Agricultura, é possível não apenas enfrentar e mitigar os impactos das mudanças climáticas, mas transformar a crise climática em oportunidade para o desenvolvimento do país, a partir do uso harmônico, inclusivo e sustentável da sua terra. Não cabe mais considerar a produção florestal e agropecuária em dissonância com a conservação ambiental. Precisamos adotar práticas produtivas que reduzam emissões e a restauração em larga escala de áreas críticas para a provisão de serviços e produtos a partir da natureza.

Comparison of Life Cycle Analysis (LCA) models for biochemical second-generation (2G) ethanol production from forest residues

Nariê Rinke Dias de Souza¹, Bruno Colling Klein¹, Mateus Ferreira Chagas¹, Otavio Cavalett¹, Antonio Bonomi¹

¹Laboratório Nacional de Biorrenováveis, Centro Nacional de Pesquisa em Energia e Materiais, Campinas, Brasil (narie.souza@ctbe.cnpm.br; bruno.klein@ctbe.cnpm.br; mateus.chagas@ctbe.cnpm.br; otavio.cavalett@bioetanol.org.br; antonio.bonomi@ctbe.cnpm.br)

Bioenergy plays an important role in the decarbonization of the transportation sector and the reduction of fossil fuel dependence worldwide. Second-generation (2G) ethanol is considered an advanced biofuel and has gained prominence due to its potential to reduce greenhouse gas emissions (GHG), which can be quantitatively determined through a Life Cycle Analysis (LCA) methodology. The scope of this study is the comparison and harmonization of 2G ethanol production from forest residues considering three LCA models: GHGenius (Canada), GREET (USA) and VSB (Brazil). In this context, it was possible to identify the main differences and commonalities in methodological structures, calculation procedures and assumptions of each LCA model. In general, there are differences in the inputs data and, also, in the methodological choices. Some of these differences are justified by the particularities of each model, while others can be harmonized. For instance, the location of feedstock production and industrial process are specific for each model and, therefore, variable results are expected in terms of GHG emissions per MJ of 2G ethanol. To demonstrate the possibility of obtaining homogeneous results, the three models were harmonized. For that, default data and parameters (e.g. agricultural and industrial inputs, emission factors and allocation procedure) for the production of 2G ethanol from forest residues were retrieved from the VSB database and entered on the other models. With this approach, it was possible to identify the main differences and to reach similar impacts from different LCA models considering the same production system.

The effects of REDD+ on deforestation and well-being: a panel study in the Brazilian TransAmazon

Cauê Carrilho¹, Carla Morsello²

¹PROCAM/USP, São Paulo, Brasil; ²PROCAM-EACH/USP, São Paulo, Brasil (cauecarrilho@gmail.com; morsello@usp.br)

The REDD+ mechanism was designed to achieve multiple objectives, such as reducing emissions from deforestation and forest degradation and increasing carbon stocks, alongside co-benefits such as reducing poverty and improving the well-being of local inhabitants. Although there are few robust evaluations of REDD+ outcomes, those existing suggest weak effects. However, the discouraging results could be a consequence of the short time-span (i.e., ~3 y.o.) of the evidence evaluated, leaving the question of whether REDD+ work open. This study, therefore, aims to assess the effects of REDD+ interventions on household deforestation (area cleared) and subjective/local perceived well-being over an 8-year time span. To do that, we evaluated a REDD+ initiative in the Brazilian Transamazon Highway region, which combines Payments for Environmental Services and Integrated Conservation and Development Projects (i.e., incentives for low impact activities). Data comes from a panel-based survey design based on interviews of 127 households (treatment: 52; control: 75) on two years (2010, 2019). Analyses will rely on a BACI (i.e., before-after-control-intervention) quasi-experimental design, with pre- and post-intervention data. Effects will be estimated through the difference-in-differences method, matching treatment and control households in characteristics that affect their probability of receiving the treatment (e.g., property area, total income). We believe this information will help us to understand whether REDD+ is achieving the intended results, but also if longer time-spans translate into more expressive effects than those currently observed.

THEME C: FORESTS AND FOREST PRODUCTS FOR A GREENER FUTURE

C1b: ADVANCES IN MANAGEMENT AND SCIENCE FOR THE HIGH-VALUE MELIACEAE

Local adaptation in natural populations of *Toona ciliata* is driven by precipitation and temperatureJun Liu¹¹Chinese Academy of Forestry, Hangzhou, China (ywliu2005@163.com)

Environmental factors are strong drivers of local adaptation in forest tree species. *Toona ciliata*, an endangered tree species endemic to China, is widely distributed across Eastern and Southwestern China. We studied the adaptive variation and genetic structure of *T. ciliata*, using 8 genomic microsatellite markers and 17 EST-SSR markers across 9 populations from Yunnan-Kweichow Plateau and Eastern China. High genetic diversity and significant genetic differentiation were revealed in populations of *T. ciliata*. Patterns of population structure were apparent using a Bayesian clustering program, STRUCTURE, which identified four distinct clusters. We identified four outlier loci that were potentially under selection using multinomial-Dirichlet and hierarchic simulation models. A Mantel test indicated that geographic and climatic factors have jointly affected the genetic structure of *T. ciliata* in the study area. Based on redundancy analysis (RDA), climatic variables are more strongly associated with variation than are geographic variables. Eight alleles from outlier loci were potentially adaptive, being correlated with either precipitation or temperature variables. This shows that the climatic variables including precipitation and temperature are drivers of local adaptation in populations of *T. ciliata*.

Using the logistic model in improvement for propagation by minicuttings in *Toona ciliata* M. Roemer var. *australis* / Uso do modelo logístico no melhoramento para propagação por miniestaquia em *Toona ciliata* M. Roemer var. *australis*Eduardo de Castro Stehling¹ ; Sebastião Carlos da Silva Rosado², Erika Steinmetz Vilela³¹Fuste Consultoria Florestal, Campo Belo, Brasil; ²Universidade Federal de Lavras, Lavras, Brasil; ³Bela Vista Florestal, Campo Belo, Brasil (fusteconsultoria@gmail.com; scrosado@def.ufla.br; erika@belavistaflorestal.com.br)

Com o objetivo de identificar genótipos mais produtivos para a propagação vegetativa de cultivares de cedro australiano, foram avaliadas brotações de minicepas de 73 famílias provenientes de 14 origens da Austrália. O experimento foi instalado na Bela Vista Florestal em Campo Belo, Minas Gerais, no segundo semestre de 2007. A pesquisa fez parte do programa de melhoramento e desenvolvimento de cultivares da empresa. O delineamento foi de blocos ao acaso, com 3 repetições e 8 plantas por parcela. Inicialmente houve a clonagem das mudas seminais originando às minicepas. Após o plantio das minicepas, as miniestacas coletadas foram estaqueadas por 226 dias, sendo individualmente identificadas. Após o enraizamento, obteve-se o número de miniestacas por minicepa e de miniestacas enraizadas produzidas no período, acompanhando o enraizamento de cada miniestaca coletada. Os dados obtidos foram submetidos à uma regressão logística no software S-Plus e as estimativas dos parâmetros genéticos do modelo logístico de cada variável estudada via metodologia REML/BLUP. Os resultados foram obtidos selecionando os indivíduos de maior valor genético aditivo para as variáveis miniestacas enraizadas e miniestacas com e sem a associação da variável enraizamento. Verificou-se grande variabilidade para os parâmetros α , β e E , para as diferentes variáveis. O melhor critério de seleção conjunta obtido foi usando os parâmetros $\alpha+\beta$ e $\alpha+\beta+\gamma$. Foi observada grande variabilidade genética dentro e entre famílias. O uso do modelo logístico foi eficiente na seleção de genótipos superiores de cedro australiano, proporcionando propagação em escala comercial para a cultivares obtidos.

Assessing the anticipated response of tree growth and resilience to drought of candidates of an Australian red cedar population for assisted migration to BrazilSebastião C Rosado¹, Eduardo de Castro Stehling², Luiz M Takarada¹, Lucas R Rosado¹, Ana C. Caxito Araújo¹¹Universidade Federal de Lavras, Lavras, Brasil; ²Fuste Consultoria, Campo Belo, MG, Brasil (scrosado@def.ufla.br; fusteconsultoria@gmail.com; takarada@hotmail.com; lucasrosado@yahoo.com.br; anacaxitoengflor@hotmail.com)

Recurrent droughts are a threat to the cellular homeostasis of plants and can significantly affect the functioning of forests. Under drought trees tend to use their defense mechanisms to evade or diminish the stress load. One such mechanism consists of storage and use of non-structural carbohydrates (NSC), which are energy reservoirs for use in growth or the maintenance of tree integrity. We conjectured that in the growth rings there are “marks of the past” that reveal the trees’ capacities for growth and resilience to droughts that have occurred during their lives and that these marks can be revealed by the levels of NSCs stored in the external ring (in formation) and the internal ones. The growth rings of two trees from each of 16 provenances from eastern coastal Australia (ranging from latitude 12°33’ S – Pascoe River- QLD to 34°38’ S – Kangaroo Valley – NSW) at age 10 years and planted in Campo Belo (Minas Gerais, Brazil) were evaluated, along with their basal area and stocked NSCs. The significant variations in the annual increments of basal areas and patterns of inter-ring variation of CNE contents in the 16 provenances allowed us to identify and select, by transfer models, origins of seed with higher productivity and drought resilience. With these results an appropriate program for assisted migration of Australian Red Cedar populations is proposed, taking into consideration precipitation of the areas of origin and destination sites in Brazil.

Simulation study of Leaf Litter on natural seedling regeneration in *Toona ciliata* var. *pubescens*Lu Zhang¹, Xiaoyan Guo¹, Shenggui Yuan¹, Qiangqiang Cheng¹¹Jiangxi Agricultural University, Nanchang, China (zhlu856@163.com; guoxiaoyan1970@126.com; 1686524177@qq.com; 271374945@qq.com)

The mechanism of litter on seedling formation limitation of *T. ciliata* var. *pubescens* was discussed. The results showed that the effect of litter on seed germination and seedling establishment varies because of its different position and thickness. Litter thickness ≥ 2 cm has a significant negative effect on seedling regeneration of *T. ciliata* var. *pubescens*. Leaching liquor of forest litter, fallen leaves and decomposed fallen leaves of *T. ciliata* var. *pubescens*, have allelopathic effects on seed germination and seedling growth. The allelopathic effect is concentration dependent. It showed inhibitory effect on seed germination. Low concentration (10 g•L⁻¹ leaching solution of the decaying leaves and the humus (decomposed for 3 months) had a promoting effect on seedling growth. Forest litter ≥ 38 g•L⁻¹, fallen leaves ≥ 10 g•L⁻¹, decaying leaves 1000 g•L⁻¹ all had inhibitory effect on seedling root growth. Alcohols, phenols and ketones in water extracts of fallen leaves may be allelopathic constituents. Derivatives of benzoic acid may be the main allelochemicals in the humus. The weak polar components of leaching solution of the decaying leaves is mainly sterols, fatty acids and their esters. Leaf litter of *T. ciliata* var. *pubescens* in decomposition

process had inhibitory effect on seed germination and seedling early growth. The litter amount $\geq 30\text{g/ Basin}$ has a significant negative impact on seedling early growth, mainly affecting the growth of roots. But with the continuous decomposition of litter and the growth of seedlings, the inhibition of leaf litter was relieved and changed to promote the growth of seedlings.

Genetic diversity of *Chukrasia* spp

Chong Wu^{1,2}, Chonglu Zhong¹, Khongsak Pinyopusarek³

¹Research Institute of Tropical Forestry, Chinese Academy of Forestry, Guangzhou, China; ²Shandong Institute of Pomology, Shandong Academy of Agricultural Science, Tai'an, China; ³National Research Collections Australia National Research Collections Aust (wuchongge@163.com; zclritf@126.com; khongsak.pinyopusarek@csiro.au)

There are different views as to whether the genus *Chukrasia* (Meliaceae) consists of one species, *C. tabularis*, or two species *C. tabularis* and *C. velutina*. Despite a clear pattern of variation in many morphological characteristics such as leaves and bark, some authors regard the latter merely an ecotype of the former in seasonal forest. In the present study, ISSR markers were used to determine the genetic diversity and population structure among 23 *Chukrasia* subpopulations from across the natural range in Asia. Molecular analysis clearly differentiated two distinct groups of subpopulations, corresponding to the putative species, as well as well-defined subpopulations corresponding to geographic regions within the two groups. The molecular results are in concordance with morphological differentiation and corresponded to the two recognized taxa. The study has demonstrated that ISSR markers can be used to characterize the genetic diversity and genetic relationships among *Chukrasia* populations from within their natural range. We have shown that *Chukrasia* populations are strongly structured. Firstly, the populations can be apportioned to the two highly distinct groups consistent with morphological characterization for *C. tabularis* and *C. velutina*. Secondly, there are strong affinities among populations within countries. The present study suggests that the current taxonomic classification of the genus *Chukrasia* should be reviewed. The results also have implications in the design of conservation strategies of biodiversity: it is probable that gene conservation stands for the two main taxonomic groups should be managed separately.

Effect of planting density on biocide plants in different agroforestry arrangements involving *Swietenia macrophylla* and *Theobroma cacao* to control *Hypsipyla grandella* Zéller / Efecto de la densidad de siembra de plantas biocidas en diferentes arreglos agroforestales con *Swietenia macrophylla* y *Theobroma cacao* para el control de *Hypsipyla grandella* Zéller

Héctor Guerra-Arévalo¹, Diego Celis Espinoza², Ana Lucia Milagros Vásquez Vela³, Luis Alberto Arévalo López¹, Wilson Franciso Guerra Arévalo¹, Enrique Arévalo-Gardini³, Carlos Abanto-Rodríguez¹

¹Instituto de Investigaciones de la Amazonia Peruana, San Martín, Peru; ²Universidad Nacional de San Martín-Tarapoto, San Martín, Peru; ³Instituto de Cultivos Tropicales, San Martín, Peru (hguerra@iiap.org.pe; mgdiego159@gmail.com; analuciava.2012@gmail.com; larevalol@iiap.org.pe; wguerra@iiap.org.pe; enriquearevaloga@gmail.com; cabanto@iiap.org.pe)

Con el objetivo de evaluar el efecto de la densidad de siembra de plantas de *Azadirachta indica* - AI y *Jatropha curcas* - JC en diferentes arreglos agroforestales con *Swietenia macrophylla* - SM con *Theobroma cacao* - TC para el control de *Hypsipyla grandella*, fue ejecutado un DBCA, con 03 bloques, 05 tratamientos conformados por la asociación agroforestal con 2 plantas biocidas y 2 densidades de siembra, siendo T1: SM + TC (testigo); T2: SM + TC + AI (1 x 3 m); T3: SM + TC + AI (1 x 1 m); T4: SM + TC + JC (1 x 3 m); y T5: SM + TC + JC (1 x 1 m). Se emplearon mallas con 80% de sombra usado para revestir los tratamientos y asegurar la infestación de la plaga (10 pares de insectos hembras y machos). El análisis de varianza para las variables evaluadas infestación de la plaga (%), número de infestaciones (n°) y sobrevivencia de larvas (%) fueron altamente significativas ($p \leq 0.001$). Las comparaciones de medias Tukey indican que los tratamientos 3 y 5 fueron similares estadísticamente ($p \leq 0.05$) reduciendo las infestaciones en 0.95% y 2.86% respectivamente en comparación con T4 = 13.33%, T2 = 16.67% y T1 = 46.67%. Se concluye, que a mayor densidad de siembra de plantas biocidas se reduce significativamente ($p \leq 0.05$) el porcentaje de infestación de *H. grandella* en las plantas de *S. macrophylla*. Dado que en los primeros años el umbral de daño causado por la plaga (*H. grandella*) es perjudicial para su desarrollo, es importante considerar estos resultados para reducir la afectación de la plaga y asegurar la sostenibilidad en el manejo de la especie.

Preference of *Hypsipyla grandella* Zeller (Lepidoptera: Pyralidae) for *Cedrela odorata* L. vs. *Swietenia macrophylla* King and relation to host growth in Colombia

John Alexander Pulgarín Díaz¹ , Verónica Cañas Mesa² , Ángela María Arcila Cardona³ 

¹Corporación Colombiana de Investigación Agropecuaria - AGROSAVIA. Centro de Investigación El Nus – Vereda Ica, Corregimiento San José del Nus, San Roque, Antioquia, Colombia; ²Universidade Federal de Viçosa, Viçosa, Brasil; ³Corporación Colombiana de In (jpulgarin@agrosavia.co; vcanasm@unal.edu.co; aarcila@agrosavia.co)

Hypsipyla grandella, the mahogany shoot borer, attacks up to 100% of *Cedrela odorata* and *Swietenia macrophylla* individuals in forest plantations, what prevents its cultivation. Preference for one of the species has been reported in different ways and strength. *Hypsipyla grandella* preference for the mentioned hosts and their growth was evaluated in three *Cedrela odorata* and four *Swietenia macrophylla* permanent plots of 36 individuals each. Plots were established in October 2013 and assessed until 4.9 years old, with a total of 15 evaluations. Survival was 98.6% in *Swietenia macrophylla* and 94.1% in *Cedrela odorata*. Host preference was not detected considering the complete data pool (proportion of attacked trees: *Cedrela odorata* 16.6%, *Swietenia macrophylla* 17.5%), but preference for *S. macrophylla* was found in three evaluations and for *C. odorata* in one. The proportion of attacked individuals changed over time in each host and maximum attack peaks coincided between hosts. Mean annual increment (MAI) in height (H) and in diameter at breast height (DBH) decreased in time for both hosts. In the period 2.3-4.9 yrs, a significant monotonic relationship (Spearman r_s) between the proportion of attacked individuals of *Cedrela odorata* and H (-0.81) and DBH (-0.83) was found, and between the proportion of attacked individuals of *Swietenia macrophylla* and IMA-DBH (-0.78). Switches in preference could be due to host phenological changes and related to environmental changes. Such preferences could generate intraspecific differences and effects on growth, survival, and reproduction of offspring. The proportion of attacked individuals affects negatively the growth of both hosts.

Morphometric variability of *Hypsipyla grandella* Zeller (Lepidoptera: Pyralidae) in two hosts (*Swietenia macrophylla* King and *Cedrela odorata* L.)

Verónica Cañas Mesa¹ ; John Alexander Pulgarín Díaz² ; Edna Judith Márquez³

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Corporación Colombiana de Investigación Agropecuaria, Centro de Investigación El Nus – Vereda Ica, Corregimiento San José del Nus, San Roque, Colombia; ³Universidad Nacional de Colombia, Medellín, Colombia (vcanasma@unal.edu.co; jpulgarin@agrosavia.co; ejmarque@unal.edu.co)

Hypsipyla grandella, the mahogany shoot borer, affects considerably plantations of different Meliaceae species, being the main limitation for its establishment. *Hypsipyla grandella* has been documented with greater preference for *Cedrela odorata* vs. *Swietenia macrophylla*, on some occasions, which could generate intraspecific variations on wing size and shape. We studied the effect of those two hosts on *H. grandella* phenotypic variation. Larvae were collected in adjacent plantations of each host, in a humid tropical forest (Antioquia, Colombia) and raised in the respective host seedlings. Geometric morphometrics tools were used with 63 right-anterior wings based on 13 landmarks. Wings were larger in individuals collected in *Cedrela odorata*, some occasions the preferred host. Sexual shape dimorphism was significant in terms of direction (even removing allometric effects); therefore only same-sex individuals were compared between hosts. There were no differences in the wing shape by sexes when comparing between hosts but allometric effects were present. Removing the allometric effect and comparing males between hosts shape differences were found, indicating that the larval food source influences wing shape in males but not in females. When comparing each sex between hosts (i.e. males of *Cedrela odorata* vs males in *Swietenia macrophylla*), there were no differences in magnitude and direction of plastic responses, even removing allometric effects. This is the first work showing sexual shape dimorphism and that hosts influence phenotypic changes in *Hypsipyla grandella* wings.

C1c: IMPROVING HIGH-VALUE MELIACEAE YIELDS IN PLANTATIONS

Thinning effects on plantation grown African mahogany

Antonio Carlos Ferraz Filho¹, Andressa Ribeiro¹, Raphael Valle Cruz²

¹Universidade Federal do Piauí, Bom Jesus, Brasil; ²Khaya Woods Group, Belo Horizonte, Brasil (acferrazfilho@ufpi.edu.br; andressa.florestal@ufpi.edu.br; raphacruz@yahoo.com.br)

Thinning is the partial removal of trees from a stand, with the objective of reducing competition and increase the growth of the remaining trees. The objective of this work is to describe how thinning affects the growth of *Khaya* sp. plantations located in Nova Porteirinha, Minas Gerais, Brazil. The stands belong to Khaya Woods Group, were installed with 6 x 4 m spacing and thinned around age 8. Seven permanent sample plots were analyzed, using two measurements before (2015 and 2016) and two after (2017 and 2018) thinning in 2017. One plot was unthinned and used as a control. We evaluated the effect of thinning in stand (mean annual increment in volume per hectare, MAIv) and tree level (mean annual diameter growth, id) characteristics. The mean stand characteristics at the time of thinning were: dbh = 20.2 cm; height = 17.7 m; basal area = 14.1 m²/ha; volume = 127m³/ha; trees per hectare (tph) = 408N/ha. Thinning was carried out from below, removing 17 m³/ha (15% reduction) and 91.1 tph (22.6% reduction). The unthinned plot presented higher MAIv one year after thinning (22.5 m³/ha.year) than the thinned plots (12.6 m³/ha.year), due to the larger number of tph. Contrary to the stand variable, id of unthinned trees averaged 1.15; 1.67 and 0.68 cm/year for plots one year before, one year after thinning and unthinned, respectively. Id increased by 88% one year after thinning, and decreased 57% in the unthinned plot. We found that plots with id lower than 1.2 cm/year one year before thinning were able to better increase the post thinning growth rate, with one case increasing the id by 250%.

Seed source variation for growth and stem-form characteristics of *Khaya senegalensis* and its improvement program in Sri Lanka

Bandara K. M. A.¹, Arnold R. J.²

¹Forest Department, Nuwara Eliya, Sri Lanka; ²China Eucalypt Research Centre, Zhanjiang, China (abandara15@hotmail.com; rogerarnold@y7mail.com)

Khaya senegalensis is an important commercial plantation tree species in Sri Lanka. Genetic improvement of this species was initiated with the establishment of two large provenance trials in the country's intermediate rainfall zone in 2008. These trials included 3 Sri Lankan land race and 21 natural stand sources from sub-Saharan Africa. Both trials were assessed for height and survival at 2 years of age and then diameter at breast height, total height, merchantable height, axis persistence and stem-form traits at age 6 years. For each individual tree, the standardized value of merchantable volume and straightness were used to calculate a merchantable value index (MerVal). Coefficients of variation were calculated for economically important traits to enable to assess the within seed source phenotypic variability. Significant differences were found between seed sources for all traits at both sites. Significant differences were also found among seed sources in the one trial that had remained unthinned for within seed source variability. The best seed sources (based on MerVal) at the site that was unthinned included two from Burkina Faso, one from Senegal and one from Sri Lanka; while for the other site that was selectively thinned at age 5 years included two from Senegal, one from Burkina Faso and one from Mali. The selected seed sources can be used for immediate seed requirements for the Sri Lankan plantation program, while greater benefit will be achieved through plus tree selection within this breeding population, and associated clonal seed orchard development.

Possibilities and limitations for production of mahogany wood (*Swietenia* and *Khaya*) in mixed and multiple-age-class stands within successional agroforests in southern Bahia, Brazil / Possibilidades e limitações para a produção de madeiras de mogno (*Khaya* e *Swietenia*) em stands mistos e inequidanos de agroflorestas sucessionais no sul da Bahia (Brasil)

Gilberto Terra¹, Felipe Martini Santos², Guilherme Chaer³

¹Sucupira Agroflorestas, Valença, Brasil; ²Universidade Federal Rural do Rio de Janeiro, Seropédica, Brasil; ³Embrapa Agrobiologia, Seropédica, Brasil (gilbertoterra@gmail.com; martinisantos@gmail.com; gmchaer@gmail.com)

A produção de madeira de mogno na fazenda Sucupira (Valença - BA, Brasil) é realizada em agroflorestas sucessionais e do tipo "Cabruca", associada à produção de frutas, especiarias e outras madeiras nativas. O stand inicial de madeiras é misto e inequidano, composto por pelo menos 5 espécies de 3 diferentes rotações. Após a realização de plantios experimentais com 8 espécies de Meliaceae, foram selecionadas duas espécies de *Khaya* (*K. ivorensis* e *K. anthothea*) e o mogno amazônico (*Swietenia macrophylla*) para compor a primeira e a segunda rotações, respectivamente. As diferenças ecofisiológicas e silviculturais entre as duas espécies de *Khaya* e entre estas e o mogno amazônico são utilizadas para ocupar com mais eficiência os diferentes ambientes das agroflorestas. Em geral, sob as mesmas condições, *S. macrophylla* tem desempenho produtivo inferior às *Khaya*s e é mais vulnerável ao ataque da broca do

ponteiro (*Hypsipyla grandella*). O mogno com maior incremento volumétrico é *K. anthotheca*, seguido de *K. ivorensis* e *S. macrophylla*. A melhor forma de fuste é observada em *K. ivorensis*, seja sob sombreamento (ca; 50% de sombra) ou a sol pleno. O ataque da *Hypsipyla grandella* foi registrado em 3 espécies de *Khaya*, tanto em tecidos vegetativos quanto nos frutos. Em alguns talhões há mais de 50% das plantas de *Khaya ivorensis* e *K. anthotheca* atacadas pela broca. Evidências de campo apontam para a possibilidade de haver uma relação entre oferta de nitrogênio no solo e susceptibilidade ao ataque de *Hypsipyla grandella* em *K. ivorensis*, *K. anthotheca* e *S. macrophylla*.

The present and future of *Khaya* in Brazil

Andressa Ribeiro¹, Antonio Carlos Ferraz Filho¹

¹Universidade Federal do Piauí, Bom Jesus, Brasil (andressa.florestal@ufpi.edu.br; acferrazfilho@ufpi.edu.br)

The wood of the genus *Khaya* is commercialized since the end of the 20th century. In Brazil its cultivation is recent, the oldest individuals located in the state of Pará are about to become 40-years-old. The objective of this work is to characterize the management of African mahogany, elucidating the growth and market possibilities in the country. It is estimated that a total of 38,000 hectares are planted with the main species of the genus (*K. grandifolia*, *K. senegalensis*, *K. ivorensis* and *K. anthotheca*) concentrated in the Southeast region. In general the plantations are implanted using wide spacings (ranging from 4 x 4 to 12 x 12 m, commonly around 36 m² per plant), with intensified silvicultural treatments and in some places with irrigation system (rainfall < 1000 mm). We monitor plantations located in the states of Minas Gerais, Goiás, Sergipe, Mato Grosso and Pará. These plantations have ages ranging from 2 to 15 years, with an average diameter of 4 to 49 cm and an average height of 3 to 26 m. Some plantations have begun the first thinning (8 to 12 years of age) and the wood was successfully commercialized. The insertion of African mahogany wood of Brazilian origin in the timber market is expected to be a success. Producers associations (such as the ABPMA) are an important tool for the feasibility of the enterprise, as they promote sustainability of the production cycle, guaranteeing the supply of material that meets markets demand, strengthening the individual producers in negotiation processes and visibility of the wood.

State of the art in genetic improvement of Australian cedar (*Toona ciliata* M. Roemer var. *australis*) for cultivation in the bioclimatic conditions of Brazil / Estado da arte do melhoramento genético do cedro australiano (*Toona ciliata* M. Roemer Var. *australis*) para cultivo em condições bioclimáticas brasileiras

Sebastião C Rosado¹, Eduardo de Castro Stehling², Lucas R Rosado¹

¹Federal University of Lavras, Lavras, Brasil; ²Fuste Consultoria, Campo Belo - MG, Brasil (scrosado@def.ufla.br; fusteconsultoria@gmail.com; lucasrosado@yahoo.com.br)

O cedro australiano é uma meliaceae exótica que, quando cultivada no Brasil, se destaca por três razões básicas: estar em áreas de escape de sua broca dos ponteiros, a *Hypsipyla robusta*; ser resistente à broca dos cedros brasileiro e mogno, a *Hypsipyla grandella* e pela produção de toras de alta qualidade a partir de fustes com crescimento monopodial e com forte dominância apical, que conferem alto rendimento no processamento primário da madeira. Entretanto, os cultivos realizados no passado apresentaram baixa produtividade em decorrência, principalmente, do uso materiais de propagação de baixa qualidade e de origem genética desconhecida. Hoje, a solução desses problemas está acontecendo, principalmente, pela implantação de um programa de melhoramento genético específico para as condições brasileiras e fundamentado na migração assistida de 16 origens de sementes da costa leste da Austrália, com ocorrência natural entre as latitudes de 12°33'S (Pascocoe River - QLD) e 34°38'S (Kangaroo Valley - NSW). As estimativas dos parâmetros genéticos e a predição dos valores genotípicos conduzidos em níveis de indivíduos dentro progênes e dentro de procedências permitiram selecionar genótipos promissores para o melhoramento que, em etapas posteriores, foram incluídos em testes clonais e cultivados experimental em escala reduzida. Esse trabalho permitiu a seleção de clones para cultivo em várias regiões do Brasil e apresentaram uma produtividade média superior a 30 m³.ha.ano. Adicionalmente foram selecionadas duas árvores por origem perfazendo um total de 32 genitores que, por cruzamentos controlados, possibilitarão a constituição das gerações avançadas de melhoramento.

Bio grafting in Meliaceae and its role in controlling *Hypsipyla grandella* Zeller / Bioinjertación en meliáceas y su papel en el control de *Hypsipyla grandella* Zeller

Wilson Francisco Guerra Arevalo¹, Hector Guerra Arevalo², Carlos Abanto-Rodriguez¹

¹Instituto de investigaciones de la amazonia peruana, Pucallpa, Peru; ²Instituto de investigaciones de la amazonia peruana, Tarapoto, Peru (wguerra@iiap.org.pe; hguerra@iiap.org.pe; cabanto@iiap.org.pe)

La bioinjertación es una herramienta muy valiosa para mejoramiento genético de especies agroforestales, ayuda a controlar la presencia de plagas, debido a las propiedades fotoquímicas transferidas desde los patrones hacia los injertos. En meliáceas existen especies como el nim (*Azadirachta indica*) que no es atacado por *Hypsipyla grandella* y puede utilizarse como patrón para injertos de cedro (*Cedrela odorata*) y caoba (*Swietenia macrophylla*) susceptibles al ataque de la plaga. El presente trabajo pretende estudiar el efecto compatible de especies meliáceas (Nim, cedro y caoba) en el prendimiento y ataque de *Hypsipyla grandella* en condiciones controladas. El experimento fue establecido bajo DCA, con 03 repeticiones, 06 tratamientos y 10 plantas como unidad experimental. Los tratamientos fueron constituidos por 06 combinaciones de diferentes relaciones de patrones/injertos tal como sigue: T1: nim/cedro; T2: nim/caoba; T3: cedro/caoba; T4: caoba/cedro; T5: cedro/nim y T6: caoba/nim; con técnica "púa central". Las variables evaluadas: prendimiento (%), número de chupones, número de folíolos por injerto, y longitud del brote. Los resultados indican que los tratamientos influyeron significativamente ($p \leq 0.05$) en el porcentaje de prendimiento de plantas injertadas. Las pruebas de medias Tukey reflejaron que el tratamiento T2 presentó un alto porcentaje de prendimiento (90%), seguidamente el tratamiento T4 con 73.3%, alto, comparado a otros tratamientos. Se concluye que, para obtener un alto porcentaje de prendimiento emplear patrones de nim e injertos de caoba, ya que son altamente compatibles, además mejoraron positivamente la resistencia de la planta reduciendo el ataque de *H. grandella*.

Dasymetric modeling of *Khaya nyasica* Stapf ex Baker f in plantations: a corporate case study for conservation in Ciénaga de Zapata / Modelación dasométrica de *Khaya nyasica* Stapf ex Baker f en plantaciones: caso de estudio Empresa para la Conservación de la Ciénaga de Zapata

Héctor Barrero medel¹, Giraldo Cirilo Fagundo Abreu², Germán Padilla Torres¹

¹Univeridad de Pinar del Río, Pinar del Río, Cuba; ²Empresa para la Conservación de la Ciénaga de Zapata, Jagüey Grande, Cuba (hbarrero@upr.edu.cu; silvicultura@eficz.co.cu; odelyn@upr.edu.cu)

Este trabajo tuvo como objetivo definir modelos dasométricos para *K. nyasica* en las Unidades Silvícolas "Jagüey Grande y Calimete" de la Empresa para la Conservación de la Ciénaga de Zapata de la provincia Matanzas. Para el estudio se establecieron parcelas rectangulares de 1000 m² ubicadas al azar en diferentes edades de cada rodal, siendo 101 temporales y 5 permanentes; para la modelación estadística se empleó el procedimiento de Redes Neuronales Artificiales

(RNAs) así como la regresión lineal, en correspondencia con la tendencia que siguieron las variables dasométricas. Resultando un sistema de curvas de índices de sitio para los valores 12, 16, 20, 24, 28 y 32 m a la edad de 22 años determinadas por el valor de la altura dominante, una función de probabilidad de densidad de Weibull que garantiza la predicción de la distribución por clases diamétricas en función de las variables dasométricas diámetro medio y edad, un turno de corta de 25-30 años de edad, así como la demostración del empleo de RNA como una herramienta estadística eficiente en la modelación forestal.

Symptoms of nutritional deficiency in mahogany plants (*Swietenia macrophylla* King) under controlled conditions / Sintomatología en plantas de caoba (*Swietenia macrophylla* King) expresada por deficiencia nutricional en condiciones controladas

¹Instituto de Investigaciones de la Amazonia Peruana, San Martín, Peru; ²Universidad Nacional de la Amazonia Peruana, Iquitos, Peru; ³Instituto de Cultivos Tropicales, San Martín, Peru; ⁴Universidad Nacional Agraria La Molina, Lima, Peru; ⁵Instituto de Investigaciones de la Amazonia Peruana, Ucayali, Peru (hguerra@iiap.org.pe; rusague_18@outlook.com; analuciava.2012@gmail.com; delfin@lamolina.edu.pe; larevalol@iiap.org.pe; wguerra@iiap.org.pe; ololi@lamolina.edu.pe; ololi@lamolina.edu.pe)

Swietenia macrophylla King es una especie maderable de alto valor comercial, que presenta problemas en condiciones de vivero y campo debido a la deficiencia nutricional y sanidad; por ello, el objetivo fue evaluar la sintomatología expresada de *Swietenia macrophylla* por la deficiencia de un elemento faltante de macro y micro-elementos en condiciones controladas, desarrollado bajo un DCA, con 4 repeticiones, 13 tratamientos (N, P, K, Ca, Mg, S, Fe, Mn, B, Mo, Zn, Cu y un control) y 8 plantas por unidad experimental. Las evaluaciones fueron: [1] síntomas basados en el color de la hoja, [2] forma y estado de las hojas, y [3] tallos y puntos de crecimiento. La ausencia de Fe y N influyeron ($p \leq 0.05$) sobre todas las variables sintomatológicas, siendo esencial para el desarrollo y sanidad de las plantas. La ausencia de N, K, Ca, Mg, S, Fe, Mn, B y Mo mostraron síntomas cloróticos en las hojas, asimismo, la ausencia de P, K, Ca, Mg, S, Fe, Mn, B y Mo influyeron ($p \leq 0.05$) en la presencia de puntos de crecimiento. La ausencia de N presentó un crecimiento muy lento comparativamente. En conclusión la ausencia de Fe y N fueron los elementos más esencial en el crecimiento y desarrollo de las plantas de *S. macrophylla*, esto se logró evidenciar al observar la clorosis en las hojas, menor desarrollo en el diámetro y altura total de las plantas, muerte de los tejidos meristemáticos secundarios y malformación del tallo.

CId: MIXED-SPECIES FORESTS AND PLANTATIONS: KNOWLEDGE GAPS AND RESEARCH PRIORITIES

Mixed-species forest stands: from understanding to design

Hans Pretzsch¹

¹Chair for Forest Growth and Yield Science, Center of Life and Food Sciences Weihenstephan, Technical University of Munich, Freising, Germany (hans.pretzsch@lrz.tum.de)

Firstly, this talk will give an overview of the species interactions and growth reactions in mixed-species stands. Species mixing may result in an overyielding of 20-30 % and provide more stabilized growth compared to mono-specific stands. The mixing reactions can be traced from the stand to the tree and organ level, and reveal results primarily from complementarity and facilitation caused by species specific functional traits. The second part of the presentation will deal with the design of forest stands based on functional traits, utilizing models, which integrate existing knowledge on process and structures into forest systems. Exemplary scenario analyses for the transformation of monocultures to mixed species forest stands and management diagrams for mixed stands will be introduced. Their development requires stand simulation models, which consider the functional ecology of tree species. Thirdly, the next steps for research and implementation will be discussed: Mixed-species experiments for a better understanding of species behaviour in inter-specific environments, models for scenario analyses, and guidelines for complex forest stands. The results are based on the EU funded projects REFORM (Mixed species forest management. Lowering risk, increasing resilience # 2816ERA02S) and COST CLIMO (Climate-Smart Forestry in Mountain Regions # CA 15226)

Assessing competition in multi-species stands

Jerry Vanclay¹

¹Southern Cross University, Lismore NSW, Australia (jerry.vanclay@scu.edu.au)

There are few guidelines for the design of mixtures or ways to make efficient prognoses of their performance. Many studies examine pairwise mixtures, but few publications deal with rich mixtures. Nonetheless, insights from pairwise experiments offer useful insights. This presentation examines a planting of 16 diverse species, replicated in 25 randomized blocks. The trial was established in 1991, and has been measured regularly for 25 years, during which time competition and mortality trends have become evident. Hegyi indices were computed for each tree for each measurement interval. In addition to the conventional Hegyi index summing all competitors, partial indices were computed for each species group. Analyses reveal a wide spectrum of competition responses that correlate roughly with the successional status of species (i.e., light-demanding versus shade-tolerant). These trends emerge more clearly in pairwise analyses, and range from facilitation to strong competitors, and the observed trends of all 16 species align with independent prior observations of successional status. This correlation suggests the possibility to calibrate species interactions from empirical trials, and the ability to predict responses without trials for species of known silvics. This trial of 16 species indicates a spectrum of species interaction responses, and suggests that the spectrum is closely aligned with the successional status of the species. If this alignment is confirmed for other species and other trials, it would suggest a way to calibrate species interactions for simulation models, and to predict responses of species with known silvics but for which no trials are available for analysis.

Mode of competition in mixed versus pure stands: does it change over time and environmental conditions?

Andrés Bravo-Oviedo^{1,2}, Miren del Río^{3,4}, Hans Pretzsch⁵

¹MNCN-CSIC, Department of Biogeography and Global Change, Madrid, Spain; ²Sustainable Forest Management Research Institute - IUFOR, Palencia, Spain; ³INIA-CIFOR, Madrid, Spain; ⁴Sustainable Forest Management Research Institute - IUFOR, Madrid, Spain; ⁵Chair of Forest Growth and Yield Science, Technische Universität München, Munich, Germany (bravo@mncn.csic.es; delrio@inia.es; hans.pretzsch@lrz.tu-muenchen.de)

Mixed forests are considered more productive, resilient and resistance to perturbations than monospecific stands. Mechanisms explaining this outperformance are usually related to complementary use of resources over time. However, the identification of the type of competition for resources in mixed versus pure

stands remain rather limited. Competition for resources can be proportional to the size trees (symmetric competition) or more than proportional (asymmetric competition). It is hypothesized that in dry and nutrient-limited conditions competition is symmetric whereas in milder situations competition is asymmetric. In this presentation we investigate the mode of competition (asymmetry versus symmetry) in mixed versus pure stands of European beech and Scots pine. Data from a transect of triplets of both species across Europe was used. A triplet is a set of three plots representing two pure stands and one mixed stand of the corresponding species. Mixing effects, i.e. if the mode of competition of species growing in mixtures differs from that found in pure stands, and modifications of the mode of competition due to changing environmental conditions are assessed using size-growth relationships. Our hypothesis is that symmetric competition is dominant in dry years whereas the strength of the competition is modulated by mixing effects. First results indicated that the mode of competition is site-specific with divergent mixing effects across Europe.

Complementarity in mixed stands of Norway spruce (*Picea abies* L. Karst) and European Larch (*Larix decidua* Mill.): the contribution of stand characteristics

Hubert Sterba¹ ; Gerald Dirnberger¹ ; Tim Ritter¹ 

¹University of Natural Resources and Life Sciences, Vienna, Austria (hubert.sterba@boku.ac.at; gerald.dirnberger@boku.ac.at; tim.ritter@boku.ac.at)

Interactions between complementarity and stand and site characteristics have been found in many investigations. However, mixed stands of Norway spruce and European larch are among the least-investigated mixture types. Twelve plots, sized between 0.25 ha and 1.6 ha, were established within stands of varying age and proportion of European larch and Norway spruce, at altitudes between approximately 880 and 1330 m above sea level located in the northern part of the eastern intermediate Alps in Austria. Tree coordinates, diameter at breast height, tree height, crown height, and crown projection area were measured for all trees within the plots. All trees were cored at breast height, and from a sub-sample of about 200 felled trees, equations for leaf area and for the five-year volume increment were developed. We found a clear interaction between age and the volume increment of a species per its fraction of the stand area (growth efficiency). In mixed young stands, the growth efficiency of both species was less than the reference from the pure stands, while in the older stands especially spruce had a much higher growth efficiency in the mixed stands. Furthermore, we found that the Clark Evans index (i) explained more variance than the species proportion and (ii) revealed an additional influence of stand density on the complementarity of the species.

Fine-root soil exploration and exploitation in mixed and monospecific forest stands across Europe

Janna Wambsganss¹, Friderike Beyer¹, Gregoire Freschet², Michael Scherer-Lorenzen³, Jürgen Bauhus¹

¹Chair of Silviculture, University of Freiburg, Freiburg, Germany; ²Centre d'Ecologie Fonctionnelle et Evolutive, Montpellier, France; ³Institute of Geobotany, University of Freiburg, Freiburg, Germany (janna.wambsganss@waldbau.uni-freiburg.de; friderike.beyer@waldbau.uni-freiburg.de; gregoire.freschet@cefe.cnrs.fr; michael.scherer@biologie.uni-freiburg.de; juergen.bauhus@waldbau.uni-freiburg.de)

Mixed-species forests have often been shown to enhance above-ground ecosystem properties and functions. Despite the significance of fine roots for tree and ecosystem functioning, the role of tree species diversity for below-ground functions driven by fine roots such as nutrient exploitation remains largely unknown. Therefore, the objective of this study was to assess the effect of tree species diversity on fine-root soil exploration and exploitation for 13 different tree species along an environmental gradient at four study sites in Finland, Poland, Romania and Italy. We hypothesized that: (1) owing to niche differentiation among species, the overall exploration and exploitation of soil volume by fine roots would be higher in mixed species stands than in monospecific stands; (2) such complementarity effects would be greater at sites with less favorable environmental conditions such as soil water availability and nutrient status. Soil cores were taken at the level of tree neighborhoods in mature tree species mixtures consisting of three tree species and corresponding monospecific stands in four major European forest types. Morphological, architectural and chemical fine-root traits were measured, in addition to total fine-root biomass. Roots were sorted by species and a functional classification approach was applied to distinguish absorptive from transport fine roots by root order. Initial results show effects of different tree species diversity levels on the measured fine-root traits. If corroborated by further analyses, such changes in fine-root traits related to soil exploration and exploitation could indicate enhanced resource uptake in mixtures and thereby positive effects on overall ecosystem functioning.

Did belowground N transfer in mixed plantations of *Acacia mangium* and *Eucalyptus* meet the Stress Gradient Hypothesis?

Ivanka Rosada de Oliveira¹ ; Ranieri Ribeiro Paula², Bruno Bordron³, Alexandre Vicente Ferraz⁴, José Leonardo Moraes Gonçalves¹,

Iraê Amaral Guerrini⁵, Agnès Robin^{1,6}, Jean-Pierre Bouillet^{1,6}

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo Piracicaba, Brasil; ²Universidade Federal do Espírito Santo, Jerônimo Monteiro, Brasil; ³Embrapa Florestas, Colombo, Brasil; ⁴Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ⁵Universidade Estadual Paulista Júlio de Mesquita Filho, Botucatu, Brasil; ⁶CIRAD, Montpellier, France (ivanka.ivi@gmail.com; ranierirpaula@gmail.com; bruno.bordron@gmail.com; alexandre@ipef.br; jlmgonca@usp.br; iguerrini@fca.unesp.br; agnes.robin@cirad.fr; jean-pierre.bouillet@cirad.fr)

Belowground interactions in mixed forest plantations remain poorly understood as that of short-term nitrogen (N) transfer from N-fixing trees to non-N-fixing trees (Non-NFT) depending on nutrient availability. We investigated if this facilitation process met the Stress Gradient Hypothesis, which predicts that under stressful environmental conditions competition decreases and facilitation increases. A 15N pulse-labelling study was conducted in a five-year-old mixture of 50% *Eucalyptus grandis* x *E. urophylla* and 50% *Acacia mangium* with the hypothesis of higher N transfer from acacia when no fertilization was applied. A complete randomized block design was set up with three replicates of fertilized and non-fertilized mixture. In each treatment of each block, a labeled solution of potassium nitrate (98 atom% 15N-NO₃) was injected into the stem of an *Acacia* tree with the same basal area as the average of the stand. The x (15N) was monitored over two months in each labeled acacia and four neighboring eucalypts. For both species, young leaves and fine roots were sampled at 7, 14 and 30 days after injection. After 60 days, the x (15N) was determined in the wood, bark, branches, total foliage and fine roots of the 6 labeled acacias and 12 eucalypts trees. The preliminary results showed that complete absorption of the labeled solution occurred between 28 and 60 days after labeling depending on *Acacia* trees and treatments. The dynamics in the proportion of *Eucalyptus* N derived from transfer will give insights into how this process may promote N nutrition of non-NFTs growing in unfertile tropical soils.

Tree diversity and fertilization effects on above- and belowground biomass productivity: outcomes from a young tree experiment

Dai Saito¹, Friderike Beyer¹, Grégoire T. Freschet², Charles Nock³, Michael Scherer-Lorenzen⁴, Jürgen Bauhus¹

¹Chair of Silviculture, Faculty of Environment and Natural Resources, University of Freiburg, Freiburg, Germany; ²Centre d'Ecologie Fonctionnelle et Evolutive, UMR 5175 (CNRS – Université de Montpellier – Université Paul-Valéry Montpellier – EPHE), Montpellier, France; ³Department of Renewable Resources, Faculty of Agricultural, Life and Environmental Sciences, University of Alberta, Edmonton, Canada; ⁴Geobotany, Faculty of Biology, University of Freiburg, Freiburg, Germany (niyagisennadai@gmail.com; friderike.beyer@waldbau.uni-freiburg.de; gregoire.freschet@cefe.cnrs.fr; nock@ualberta.ca; michael.scherer@biologie.uni-freiburg.de; juergen.bauhus@waldbau.uni-freiburg.de)

There is substantial evidence that species diverse forests are more productive than monocultures. Selection and complementary effects have been proposed as the main drivers for overyielding; the former may be more predominant than the latter in early-successional communities. However, to date, the linkages between above- and belowground responses to species diversity has rarely been addressed. Additionally, little is known about how the diversity-productivity relationship changes along abiotic gradients, although declining diversity effects on productivity with increasing nutrient availability are often assumed. Moreover, despite recent calls for more mechanistic studies linking traits with ecosystem functions, few studies addressed root traits and belowground functions. Here we present results from a young tree diversity experiment established in 2013 in Freiburg, Germany. Tree seedlings of six European species representing a wide range of functional diversity were planted at high density with combinations of one, two and four species, in order to decouple species richness and functional diversity of communities. We also manipulated nutrient availability, using non-fertilized controls as well as a fertilization treatment with both N and P. For each community, we calculated aboveground stem and fine-root biomass and functional traits. This study explores the following hypotheses: 1) tree diversity in young tree communities promotes above- and belowground productivity mainly through the selection effect; 2) fertilization reduces belowground, but improves aboveground complementarity; 3) certain functional traits determine overyielding to a large degree, and in particular, traits of dominant species are important since the selection effect outweighs the complementary effect.

Silviculture with native tree species - markets, viability and competitiveness

Alan Batista¹, Miguel Calmon¹, Daniel Piotto², Samir Rolim³

¹WRI, São Paulo, Brasil; ²Universidade Federal do Sul da Bahia, Ilhéus, Brasil; ³Amplio Engenharia, Belo Horizonte, Brasil (alan.batista@wri.org; miguel.calmon@wri.org; daniel.piotto@ufsb.edu.br; sgrolim@gmail.com)

In the global capital markets there is a risk and return history of over 100 years for various asset classes and publicly traded companies. Although native species have existed for thousands of years, and some good commercial experience with them, there is no track record of this asset class from a capital market perspective. Thus, the present study had the objective to evaluate the tropical wood market in Brazil and worldwide; the viability of native species forestry through case studies already in place; and the main lever of competitiveness: investments and benefits of an R&D platform with native tree species from Brazil. The discounted cash flow method was used over a period of 30 years. The key metrics used to compare asset returns were internal rate of return, and net present value. Assets valued in this study were: mixed species plantation (native from Atlantic Forest biome); mixed species plantation (exotic and native), monoculture plantation with native species (Amazon Biome); and with exotic species (*Eucalyptus*), the latter is considered the benchmark for the study. Lumber prices in both the domestic and foreign markets had a significant real appreciation, ranging from 0.6% per year to 3.5% per year in the period analyzed between 1997 and 2017. Risk adjusted returns from mixed species plantation are higher than mainstream assets such as our benchmark *Eucalyptus* plantation. Investments in R&D in promising native tree species can increase IRR more than 5% and is the most promising upside potential for native tree species.

Management strategies to increase stand structural and tree species diversity and enhance ecosystem services in coastal rainforests of Alaska

Robert Deal¹, Ewa Orlikowska², Paul Hennon³

¹USDA Forest Service, PNW Research Station, Portland, USA; ²Swedish University of Agricultural Sciences, Skinnkatteberg, Sweden; ³USDA Forest Service, PNW Research Station, Juneau, USA (rdeal@fs.fed.us; ewa.orlikowska@slu.se; nootkatini@gmail.com)

There is worldwide interest in managing forests to improve biodiversity, enhance ecosystem services and assure long-term sustainability of forest resources. Coastal rainforests of southeast Alaska have relatively simple tree species composition but complex structures with high diversity of tree ages, sizes and forest canopy levels, and an abundant understory plant community. Clearcutting has greatly altered these forest ecosystems with significant decreases in structural diversity of forest stands and greatly reduced biodiversity. Well-planned silvicultural systems containing a mixture of broadleaf-conifer species have potential to enhance stand diversity and provide other important ecosystem services earlier than typical even-aged conifer plantations. This paper synthesizes information on management options in older forests that have never been actively managed, and in younger forests to increase diversity of stand structures and their associated effects on biodiversity. Light to moderate levels of partial cutting in old-growth forests can maintain the original diversity of overstory stand structures and understory plant communities. In younger forests that develop after clearcutting, mixed red alder-conifer stands provide more heterogeneous structures and significantly higher understory biomass than in pure conifer forests. Research has shown that red alder clearly benefits understory plants, and provides forage for deer and small mammals. A combination of light partial cutting in older forests along with inclusion of red alder in conifer-dominated forests could provide the greatest amount of diversity and maintain the complex stand structures that are an important component of these forest ecosystems.

Productivity-diversity relationships in mixed-hardwood plantations

Madeline Montague¹, Kliffi Blackstone¹, Lorenzo Cotrozzi¹, Nate Ibarluzea¹, Elizabeth LaRue¹, Taylor Nelson¹, Franklin Wagner¹, John Couture¹; Brady Hardiman¹, Gordon McNickle¹, Douglass Jacobs¹

¹Purdue University, West Lafayette, USA (montague@purdue.edu; kliffi.blackstone@gmail.com; lcotroz@purdue.edu; nibarluz@purdue.edu; elarue@purdue.edu; tmnelson@purdue.edu; wagnerf@purdue.edu; couture@purdue.edu; hardimanb@purdue.edu; gmcnicke@purdue.edu; djacobs@purdue.edu)

The diversity of trees in hardwood forests has conservation and social value, fosters wildlife resources, and generally reduces the risk of pest and disease incidence. Ecologists have shown that productivity and species diversity are positively correlated, but the mechanistic causes of the productivity-diversity correlation remain unresolved in forest trees. Therefore, although we know that mixed-species plantations can be more productive than monocultures, it is currently not possible to predict the number and types of species that should be planted to maximize timber production and other desired attributes. We investigate the productivity-diversity relationship using a 12-year-old experiment of fine hardwoods planted in varying species mixtures and densities. American chestnut (*Castanea dentata* (Marsh.) Borkh.), northern red oak (*Quercus rubra* L.) and black cherry (*Prunus serotina* Ehrh.) were planted as monocultures

and polycultures at 1 x 1 m, 2 x 2 m, and 3 x 3 m spacings in a split-split plot design to assess the effects of species selection, diversity, and competition on productivity. Above and below-ground productivity and an inclusive suite of functional traits were measured in pursuit of a mechanistic understanding of the productivity-diversity relationship. We measured physiological, morphological, chemical, and structural functional traits; for example, canopy structural metrics linked to light interception and above-ground productivity were calculated using Terrestrial LiDAR data. This study addresses the paucity of knowledge on below-ground dynamics in mixed-species plantations, as root growth and root-soil interactions have implications for carbon cycling and competition for water and nutrients. Results are synthesized to generate management advice and identify future research priorities.

Risk resilient management in mixed forests: insights from an European triplet-transects approach

Miren del Río¹, Hans Pretzsch², Hervé Jactel³, Anna Barbati⁴, Felipe Bravo⁵, Magnus Löf⁶, Arne Nothdurft⁷, Quentine Ponette⁸, Xavier Morin⁹, Aris Jansons¹⁰, Gediminas Brazaitis¹¹, Andreas Brunner¹², Maciej Pach¹³

Promoting mixed forests is a strategic element for adapting forest management to climate change. Higher tree species diversity is expected to provide higher productivity, higher temporal stability, lower risk of biotic and abiotic disturbances, and a more diverse portfolio of ecosystem services. There is considerable evidence that tree species interactions vary with species traits, environmental conditions, age, and stand density. However, there is presently not enough knowledge to generalize the patterns of these variations to provide a scientific-based theory. This information is crucial for developing climate resilient forest management regimes for mixed forests that reduce the natural, social and economic impacts of climate change on forests and their services. In this presentation we show our research approach to answer this need based on thinned and unthinned triplets along environmental gradients and forest models. Three triplet-transects (88 triplets, 264 plots) of Scots pine admixed with species with different functional traits (*Picea abies*, *Fagus sylvatica* and *Quercus petraea*) and relevant in European forestry were established along Europe (one triplet includes one mixed plot and two monospecific plots of the component species). Data collected in triplets includes: dendrometric variables, tree growth series, crown damages, soil characteristics, and some variables related to five ecosystem services. This empirical information is finally combined with simulations from forest models to integrate results and for scenario analysis at large temporal and spatial scales. Then we illustrate the strength of the approach by presenting some examples of the results of mixing effects on productivity, stability, and provision of ecosystem systems.

Resistance of mixed forests to insect herbivory in the context of climate change

Hervé Jactel¹, Charlotte Poeydebat¹, Xavier Morin², Bastien Castagnérol¹

¹Institut National de la Recherche Agronomique, Cestas, France; ²Centre National de la Recherche Scientifique, Montpellier, France (herve.jactel@inra.fr; charlotte.poeydebat@inra.fr; xavier.morin@cefe.cnrs.fr; bastien.castagneyrol@inra.fr)

Forests are likely to experience more stressful conditions in the future because of climate change. Mixed forests are expected to be more resistant to specific hazards. However little is known about resistance of mixed-species forests to multiple hazards and particularly to synergistic or cascading effects of biotic and abiotic perturbations. Here we used two experimental platforms to investigate the effect of mixing tree species on associational resistance to pest damage in contrasting climatic contexts. In one experiment, we compared the level of leaf herbivory in a paired comparison of pure and mixed stands at different latitudes and elevations. In the second, manipulative experiment, we compared tree damage by insects in paired comparisons of pure and mixed stands grown in irrigated vs. drought stressed blocks. The patterns of associational resistance (or susceptibility) were often context dependent, as demonstrated by significant interactions between tree diversity and climatic factors on leaf herbivory. We propose mechanisms to interpret those patterns, which are based on change in tree apparency and leaf quality. Our findings provide new insights into the understanding of mixed forest resistance to multiple stresses and pave the way for the design of mixed species plantations better able to cope with climate change.

C1f: SILVICULTURE AND FOREST MANAGEMENT OF DECIDUOUS BROADLEAVED FORESTS

Managing regeneration potential to sustain oak forests in North America

Daniel Dey¹

¹US Forest Service, Columbia, USA (ddey@fs.fed.us)

Today in North America, there is a well-accepted recognition of oak regeneration failure and the widespread loss of oak forests. Similar observations are being reported around the world. Regeneration potential of a species is the probability that the species will be competitive through regeneration and stand development to prevail in the mature stand. It is the summation of a species regeneration potential from all modes of reproduction, including current seed, seed bank, new seedlings that establish after a regeneration disturbance, advance reproduction, and vegetative reproduction from stump sprouting, root sprouting and layering. Regeneration potential has been quantified for some oak species. Large, competitive oak advance reproduction and stump sprouts are essential to sustain oak forests. Regeneration potential is influenced by initial floristics, site quality, competing vegetation, herbivores, and level of management. Oak regeneration potential in modern forests is commonly too low to sustain oak stocking at current levels. Recommendations are given for silvicultural prescriptions designed to increase oak regeneration potential to sustain oak forests.

A review of research-based methods for managing deer herbivory of hardwood regeneration

Caleb Redick¹, Douglass Jacobs¹

¹Purdue University, West Lafayette, USA (credick@purdue.edu; djacobs@purdue.edu)

Pervasive ungulate herbivory poses a major obstacle to forest regeneration in many regions. Various deer species threaten to shift existing forest composition in North America and Europe as they preferentially browse oaks and other high value hardwoods. Herbivory thereby presents a challenge to foresters who want to maintain oak dominated forests. Herbivory also impedes successful afforestation of abandoned agricultural or mined lands. Population control can be difficult to implement, and even small populations of deer can have negative effects. Methods other than hunting to manage deer browse are required until populations are reduced on a regional level. Forest landowners and managers attempting hardwood forestation have come up with many creative solutions to deal with wildlife damage, ranging from fences and shelters, to repellents. Many empirical studies on browse management methods have been published in the scientific literature and results can be generalized. Fences are effective, yet require maintenance. Shelters, though expensive, have been shown to be effective in increasing growth and survival in many cases and promote seedling growth to free-to-grow status. Repellents are a common alternative to physical barriers, but their usefulness is short-lived so reapplication is necessary. In addition, there is much variability in effectiveness depending on the repellent type and local deer population. Systemic repellents have been tested, but success is sporadic and depends upon uptake of the chemical. This literature review catalogs research on browse management methods in the presence of high deer populations and compares the effectiveness of such methods.

Potential of prescribed fire as a management tool for natural oak regeneration in temperate Europe

Linda Petersson¹, Daniel Dey², Annika Felton¹, Emile Gardiner³, Magnus Löf¹

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²USDA Forest Service, Columbia, USA; ³USDA Forest Service, Stoneville, USA (linda.petersson@slu.se; ddey@fs.fed.us; annika.felton@slu.se; emile.gardiner@usda.gov; magnus.lof@slu.se)

Oak-dominated forests provide ecosystem services and harbor biodiversity. However, rapidly changing land-use and disturbance regimes have reduced suitable regeneration niches and unsuccessful natural oak regeneration have caused concern in Europe and North America for over a century. In eastern North America, a fire-oak hypothesis has been developed which attributes some oak regeneration problems to effective fire suppression. Prescribed burns are used to regenerate oak-dominated ecosystems, often combined with thinning to increase light and control competing vegetation. In temperate Europe the role of fire is not clear, but fire suppression is widespread. Our study investigates if the fire-oak hypothesis can be applied to European temperate oaks (*Q. robur* and *Q. petraea*). A field experiment combining effects of light (high-low), browsing (fence-no fence), and fire (burn-no burn) in a complete block design was established in 2016 at five oak-dominated forests in Sweden. We recorded survival and growth of 2357 naturally regenerated oak seedlings. Two growing seasons following burn treatment, oak seedling survival ranged from 52% in low-light*no-fence*burn-treatment to 96% in high-light*fence*no burn-treatment. For all burn treatments, 93% of surviving oaks had re-sprouted. This is the first field study to investigate use of a low-intensity prescribed fire as a management tool in European temperate oak forests. The initial results are positive in that we demonstrate the high sprouting capacity of naturally established oak seedlings that experienced a low-intensity prescribed fire. Our results also highlight the importance of investigating combined effects of multiple factors, continued research will further explore these interactive effects.

The status quo and scope for future development of oak forestry in China

Xiuling Guan¹, Wenhui Zhang¹

¹Chinese Society of Forestry, Beijing, China; ¹North West Agriculture and Forestry University, Yangling, China (guanxiuling@sina.com; 839951676@qq.com)

China boasts rich diversity of oak species (*Quercus* spp.) with a wide distribution. According to the 8th forest resources inventory of China, the total area of oak is 16.10 million ha, accounting for 13.7% of natural forests. Importance of oaks will be going to increase because China is prioritizing mixed forests of native species than monoculture of exotic species to increase resilience of forests. Oaks have been underestimated in China for long, often being used as fuel wood, whereas its economic, ecological and cultural values have been ignored. Since 2015, the CSF has initiated promotion of oak forestry and industry in China. In last three years, apart from involving oak experts from abroad, the CSF has also facilitated the management of secondary forests of oak in over 10 provinces in northern China. The Oak Division of the CSF and China Innovation Alliance of Oak were established in 2018. At present, oak industry is attracting increasing attention from forest departments at different levels, stepping on the path of industry-education-research and coordinated development under the guidance of the CSF. In this presentation, I will present a comprehensive picture of current oak forestry in China and future potentials.

Regeneration and conservation of oaks in Western Himalayan forest of Uttarakhand, India

Manisha Thapliyal¹, Namitha N.K.¹, Pravin Rawat¹

¹Forest Research Institute, Dehradun, India (manishathapliyal98@gmail.com; namithafri@gmail.com; pravinrawat15@gmail.com)

Oak forests are one of the oldest vegetation types of the Himalayan region and a climax community. They have great social and ecological relevance in the Western Himalayan region providing many important ecosystem services like retention and enriching soil, sustaining the hydrological regime of hills. Oaks are also highly valued economically in the region as they are closely linked with hill agriculture and sustenance as an important source of fodder for livestock, litter for compost, fire wood and timber. Owing to the intense anthropogenic pressure, recurrent forest fires and poor acorn production at times, regenerative capacity of oaks is declining in the Himalayan region. The regeneration of *Quercus leucotrichophora* and *Q. semecarpifolia* was studied in Kedarnath Forest Division, of Uttarakhand state. In *Q. semecarpifolia* forests, there are large number of old trees but establishment of sapling and low girth class trees was hampered due to poor acorn production, disturbances like grazing, trampling, etc. In case of *Q. leucotrichophora* poor regeneration was observed due to poor acorn setting, weevil attack, acorn predation, browsing damage to seedlings, lopping, forest fire, etc. Natural regeneration of both the species was poor both in disturbed and undisturbed forests in the study area. Existing Oak forests need to be conserved through active involvement of the community in protection and planting of oak, restricting anthropogenic activities and also planting of other fodder species by the Forest department and Self Help Groups to reduce the people's dependence on oak.

The impact of admixing rich litter tree species on the vitality and growth of pedunculate oak forests

Ellen Desie¹, Leon van den Berg², Bart Nyssen², Maaïke Weijters³, Arnold van den Burg⁴, Gert-Jan van Duinen⁵, Jan den Ouden⁶, Karen Vancampenhout⁷, Bart Muys¹

¹KU Leuven, Leuven, Belgium; ²Bosgroep Zuid Nederland, Heeze, Netherlands; ³B-Ware, Nijmegen, Netherlands; ⁴Stichting BioSFeer, Otterlo, Netherlands; ⁵Bargerveen, Nijmegen, Netherlands; ⁶Wageningen University, Wageningen, Netherlands; ⁷KU Leuven Campus Geel, Geel, Belgium (ellen.desie@kuleuven.be; l.vandenbergh@bosgroepzuid.nl; b.nyssen@bosgroepzuid.nl; m.weijters@b-ware.eu; bsp@upcmail.nl; g.vanduin@science.ru.nl; jan.denouden@wur.nl; karen.vancampenhout@kuleuven.be; bart.muys@kuleuven.be)

Due to the combined effects of land use changes since the Neolithic and more recent atmospheric deposition, many West-European forests are located on degraded and acidified soils. The adverse effects of soil acidity are far reaching, and have resulted in hampered ecosystem functioning and lower delivery of ecosystem services. Forest management, by altering the overstorey tree species composition, can accelerate or counteract soil acidification through the quantity and quality of litter input. The admixture of tree species with nutrient rich litter is hypothesized to be a successful soil restoration intervention improving forest vitality, productivity and resilience. The positive impact of rich litter on the soil nutrient status and belowground ecosystem functioning has already been evidenced in common gardens of monocultures. Given the increasing relevance of mixed forests in a context of climate change adaptation, we aimed to evaluate whether the rich litter effect is substantial enough to also improve the soil nutrient status in mixed forest stands and, moreover, whether it can improve aboveground ecosystem functioning. We studied the effect of admixture of black cherry (*Prunus serotina*) in pedunculate oak (*Quercus robur*) stands on the belowground ecosystem functioning and on the vitality of oak trees. This was done by pairwise comparison of individual oaks in black cherry neighbourhoods with oaks in monospecific neighbourhoods located over Belgium, The Netherlands and Germany. Results of this study allow to better understand the underlying mechanisms of rich litter admixture and make more applied recommendations for forest management.

Ecology and management of young Hungarian oak (*Quercus frainetto* Ten.) stands in the south of Romania

Valeriu-Norocel Nicolescu¹, Valentina Aga¹, Ecaterina-Maria Chirteș¹, Adrian-Vasile Chirteș¹, Alexandru-Sorin Stainbok¹, Adina-Elena Nicola¹, Cătălin Matei², Constantin Mitrică², Marinela Ioniță², Beatrice-Maria Ușurelu¹

¹Faculty of Silviculture and Forest Engineering, Transylvania University of Brasov, Brasov, Romania; ²Olt County Branch, National Forest Administration Romsilva, Slatina, Romania (vnicolescu@unitbv.ro; aga.valentina@yahoo.com; ecaterinachirtes@gmail.com; adrianchr56@gmail.com; stainbokalexandru@gmail.com; adinaelena7@yahoo.com; office@slatina.rosilva.ro; slatina@slatina.rosilva.ro; marinela.valentina93@gmail.com; usurelubeatrice maria@gmail.com)

Hungarian oak (*Quercus frainetto* Ten.) is one of the six oaks in Romania, where it covers ca; 130,000 ha. The species is found chiefly in the south and west of the country, where its occurrence is mostly soil-controlled, as being especially adapted to heavy acidic soils. In the South of Romania (Seaca-Optășani Forest, the largest block of Hungarian oak in the entire native range, ca; 1,560 ha), the species grows under difficult site conditions: local climate specific to a forest steppe zone (mean annual temperature 10.8 °C; mean annual precipitation 559.8 mm; mean annual evapotranspiration 685 mm; mean aridity index 26.9), with heavy soils (Vertisols, developed on loess, marl and clay). Since 1890's, Hungarian oak is managed as high forest, regenerated by seed following the application of group shelterwood cuttings. The resulting young stands are monospecific, highly stocked, with tall and slender trees, and show a high level of mortality (up to 60% of number of trees at 10-15 years of age). Cleaning-respacing interventions - first when mean dbh is ca; 5 cm, second when it reaches 8-9 cm -, carried out in two adjacent Hungarian oak sub-compartments in 2018, have improved the vertical structure and quality of residual stands by performing interventions across the canopy (but mostly from below) and eliminating dead, dying, bent-over, wounded trees, as well as those individuals competing strongly with potential final crop trees, selected based on the vigor-quality-distribution criteria.

Pre-commercial thinning in naturally regenerated stands of European beech (*Fagus sylvatica* L.): effects of thinning pattern, stand density and pruning on tree growth and stem quality

Ditlev Otto Juel Reventlow¹, Thomas Nord-Larsen¹, Jens Peter Skovsgaard¹

¹Department of Geosciences and Natural Resource Management, University of Copenhagen, Frederiksberg C, Denmark; ²Southern Swedish Forest Research Centre, Swedish University of Agricultural Sciences, Alnarp, Sweden (dire@ign.ku.dk; tnl@ign.ku.dk; jps@slu.se)

Pre-commercial thinning in naturally regenerated stands of European beech is often expensive and must be justified by improved development of the remaining crop. Based on a field experiment established in two 14-year-old naturally regenerated beech stands in Denmark, we investigated some effects of pre-commercial thinning and pruning on future crop tree growth and stem quality. The treatments included (1) no thinning, (2) moderate to heavy strip thinning, with or without subsequent selective thinning, and (3) extremely heavy strip thinning in two perpendicular directions (checkerboard thinning), with or without subsequent selective thinning and with or without pruning. The resulting residual stand densities ranged from 105 to only 200 ha⁻¹. Treatment effects were evaluated at age 32 on one potential future crop tree for every 100 m². Total crop tree height was reduced by checkerboard thinning. Stem diameter increased with decreasing stand density but was reduced by pruning. The lower live branch was positioned lower with heavy strip thinning and with checkerboard thinning without pruning. Forks were more frequent and at a lower position in checkerboard thinning. Stem tilt and stem straightness were unaffected by thinning. However, pruned trees tilted less and had straighter stems. Extremely heavy thinning increased the formation of epicormic branches, but these did not reemerge after pruning. In summary, moderate to heavy pre-commercial thinning had no effect on stem quality, while extremely heavy thinning without pruning resulted in unacceptably low stem quality. No-thinning resulted in acceptable growth and stem quality of the crop trees and remains an alternative.

C1g: SILVOPASTORAL SYSTEMS: CONTRIBUTIONS TO LIVESTOCK AND TO THE SUSTAINABLE DEVELOPMENT OBJECTIVE

Effect of plantation spacing in production of wood and forage and economic outcomes in *Eucalyptus globulus* in Eastern Uruguay / Efecto del marco de plantación en la producción de madera y forraje y su resultado económico en *Eucalyptus globulus* en el Este de Uruguay

Mariana Boscana¹, Adriana Bussoni¹, Oscar Bentacur², Eduardo Llanos¹, Fabián Varela¹

¹Universidad de la República, Montevideo, Uruguay; ²Universidad de la República, Paysandú, Uruguay (mboscana@fagro.edu.uy; abussoni@fagro.edu.uy; obent@fagro.edu.uy; edullan20@gmail.com; fabianv.uy@gmail.com)

Los sistemas silvopastoriles constituyen una modalidad con potencial de expansión en Uruguay. El trabajo tuvo como objetivo evaluar la producción de madera, forraje y su resultado económico en dos marcos de plantación en *Eucalyptus globulus* en el Este del Uruguay: 3,5 x 2,7 m (SPC, 1.258 árb/ha) y (2 x 2) + 8 m (SSFC, 1.000 árb/ha). En cada sistema se relevaron: diámetro a la altura del pecho (DAP), Altura total (Ht) y sobrevivencia de los árboles a los 36, 41, 45, 51 y 68 meses de edad. Cada 60 días se midió producción de forraje; finalmente se estimó los indicadores de Valor Actual Neto (VAN) y Tasa interna de retorno (TIR). Los resultados indican que el marco de plantación no tuvo efecto significativo ($p > 0,05$) sobre los valores individuales para DAP y Ht. El sistema SPC resultó en 83,7 m³/ha ($\pm 3,60$) a los 68 meses mientras que el SSFC fue de 62,7 m³/ha ($\pm 3,60$). La producción media estacional de forraje fue 42% mayor para el sistema SSFC en relación al SPC (587,5 kg Ms/ha ($\pm 39,1$)). Considerando tanto la producción de madera como ganado bajo dosel, a los 12 años de edad de cosecha, el sistema SPC resultó en una VAN de 930 U\$S/ha y una TIR de 12,1%, mientras que el sistema SSFC fue de 955 U\$S/ha y 13,4% respectivamente, a los 13 años de edad de cosecha. Los resultados aportan información para la toma de decisiones y la elección del marco de plantación.

SisILPF: software for forest component management in integrated crop-livestock-forest (ICLF) systems

Edilson Batista de Oliveira¹

¹Embrapa Florestas, Colombo, Brasil (edilson.oliveira@embrapa.br)

The SisILPF software suite is built for *Pinus (caribaea, elliottii, taeda)*, *Eucalyptus (grandis, urograndis, dunnii, saligna)*, *Toona ciliata*, *Khaya ivorensis*, and *Tectona grandis*. The software supports management, economic analysis, and planning of the forest component of integrated crop-livestock-forest (ICLF) systems for decision-making related to when, how, and how much to thin, and when to conduct the final harvest. Users can: test for different climate and soil conditions; simulate all tree component management options of ICLFs; forecast present and future production; conduct economic analyses; and decide on the best alternatives to manage their plantation. Built using the Delphi programming language, each software generates prognosis charts and graphs for growth and yield of trees in the ICLF, based on inventory data. The software suite indicates how much wood will be produced at any age and tests any management regime that one wishes to apply. Users can also calculate the carbon (Methane and CO₂ equiv.) stored by the trees and generate tables of wood assortment by industrial use classes such as lamination, sawmill, and fuel, according to log diameters and lengths identified by the user. SisILPFs enables the simulation of several thinning regimes, generating an assortment table for each. The software is available for download on the Embrapa Florestas website (www.embrapa.br/florestas).

Improvement of caívas in Southern Brazil: “milk and meat of the forest” with sustainability

Ana Lúcia Hanisch¹, Raquel R. B. Negrelle², Lígia C. A. Pinotti²

¹Epagri, Canoinhas, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (analucia@epagri.sc.gov.br; negrelle@ufpr.br; ligiapinotti@outlook.com)

The use of native forest remnants for animal production occurs in various parts of the world. These traditional silvopastoral systems contribute to the conservation of these remnants. Valuing them through productive techniques accepted by sustainable livestock is a way to build strategies that combine environmental conservation with the generation of sustainable animal products, such as “milk or meat from the forest.” In the South of Brazil, the caíva are traditional systems that have existed for more than a century, where the animals are raised loose in areas of remnants of the Araucarian Forest. The introduction of the *Axonopus catharinensis* grass, with the adoption of the rational grazing and split fertilization in coverage, was evaluated in caívas. One of the sustainability indicators evaluated was forest regeneration. After two years of use, there was no effect of pasture management on the regeneration component. A total of 49 tree species characteristic of the Araucarian Forest were found. In general, the increase in pasture productivity showed a low correlation with the species richness (-0.20) and the density (-0.24) of the forest regeneration, indicating that the intensification of pasture use did not negatively interfere in these variables. The richness and density of tree regeneration in the caívas confirmed the relevant contribution of this traditional silvopastoral system to the provision of ecosystem services such as the conservation of the vegetal biodiversity of the Araucarian Forest, despite the anthropic use and the presence of the animals for almost a century.

Reducing competition in crop-livestock-forest integrated system by thinning *Eucalyptus* trees

José Ricardo Macedo Pezzopane¹, Willian Lucas Bonani², Eduardo Lopez Fernandes da Rocha³, Alberto Carlos de Campos Bernardi¹,

Patricia Perondi Anhão de Oliveira¹, André de Faria Pedroso¹

¹Embrapa Pecuaria Sudeste, São Carlos, Brasil; ²Universidade de Araraquara, Araraquara, Brasil; ³Unicep, São Carlos, Brasil (jose.pezzopane@embrapa.br; willian_bonani@hotmail.com; lopezrocha19@gmail.com; alberto.bernardi@embrapa.br; patricia.achao-oliveira@embrapa.br; andre.pedroso@embrapa.br)

This study aimed to evaluate the effects of *eucalyptus* trees thinning on yield and nutritive value of corn for silage and palisadegrass in a crop-livestock-forest integrated system. Assessments of plant variables, as well as of photosynthetically active radiation (PAR) incidence and soil moisture were performed between October 2016 and March 2018 in São Carlos, SP, in a crop-livestock-forest and, for comparison, in a crop-livestock system. In the crop-livestock-forest system, eucalyptus trees (*Eucalyptus urograndis* clone GG100) were planted in April 2011, in single rows, with a 15 x 2 m spacing. In 2016, trees were thinned and the spacing changed to 15 x 4 m. In this system, the assessments were performed in four equidistant positions in relation to the eucalyptus rows. Corn was sown first, and palisadegrass was sown after corn harvest. PAR transmission during the corn cycle and the pasture cycles was 65.3% and 60%, respectively. Soil moisture was lower at the 50 to 100 cm depth layer near the tree line than at the other positions, during the dry period. Corn yields were similar between systems with an average of 13.6 mg of dry matter ha⁻¹. Corn silage produced in the crop-livestock-forest system presented higher percentage of grain (41.4 and 42.1%) than that produced in the crop-livestock system (35.6%). No differences in forage yield were observed. Crude protein of corn for silage and palisadegrass was higher in the crop-livestock-forest than in the crop-livestock system. Such results indicate that tree thinning was favorable for production in the crop-livestock-forest system.

Establishment of sustainable agrosilvopastoral systems from degraded soils in the dry Colombian Caribbean

Luis Fernando Chavez^{1,3}, Sonia Ospina¹, Kenica Yulith Mendoza², Adelina Caballero³, Darwin Fabian Lombo³

¹Corporación Colombiana de Investigación Agropecuaria (Agrosavia), Palmira, Colombia; ²El Cerrejon, La Guajira, Colombia; ³Corporación Colombiana de Investigación Agropecuaria (Agrosavia), Agustín Codazzi, Colombia (lchavez@agrosavia.co; sospina@agrosavia.co; kenica.yulith@gmail.com; acaballerol@agrosavia.co; dlombo@agrosavia.co)

The objective was to identify options for the sustainable use of natural resources and to enhance the productivity with agricultural and livestock systems. The research was developed with small-scale farmers in regions with arid and semi-arid conditions of La Guajira (2012) and Cesar (2014), which main activity is cattle raising. Clayey soils predominate with nearly level to gently slopes degraded by burning, monoculture, and overgrazing. The methodology approach

was participatory with qualitative and quantitative variables for monitoring soil and people begin to identify the benefits represented by a sustainable use. This was done by conformation of local researchers committees and the installation of farm field experiments. The methodology resulted in the improvement of productivity and sustainability of farming practices, which in turn has contributed to improve food security. After six years, more than 70 hectares of degraded soils have been recovered and agrosilvopastoral systems (ASPS) have been established incorporating the native woody species: *Acacia farnesiana*, *Prosopis juliflora*, *Cordia alba* y *Guazuma ulmifolia*, and *Panicum máximum* cv *Mombasa* sp. associated with the production of more than 50 tons of food (black beans, watermelons, buttercup squash and corn) that provide food security and increase the productivity of the land through the improvement of the soil. The assessment demonstrates that there is widespread recognition and value of importance from farmers and technicians towards ASPS that include the native woody species. Farmers recognize their contribution to the support of animals in the most critical times and to the provision of services.

Determination of financial risk in agroforestry system using Monte Carlo method

Maisa Isabela Rodrigues¹, Bruno Souza¹, Álvaro Nogueira de Souza¹, Maisa Santos Joaquim¹, Patrícia Aparecida de Souza², Juliana Baldan Costa Neves Araújo¹
¹Universidade de Brasília, Brasília, Brasil; ²Universidade Federal de São João Del Rei, Sete Lagoas, Brasil (maisaisabela@hotmail.com; brunosouza@gmail.com; alvarosouza14@gmail.com; maisaunb@gmail.com; patriciasouza@gmail.com; juliana.bcneves@gmail.com)

This work dealt with the determination of the financial risk in a silvopasture system implemented in the Northern region of the State of Minas Gerais. Five genetic materials were used with the intention to select the best one for the plantation in large scale. There were used traditional methods of analysis (NPV, EPB, IRR) of the investments with the discount tax of 8% p.a. to calculate the profit in a database obtained in a property in the North of the State of Minas Gerais. The analysis with the traditional methods of financial viability of projects yielded a Net Present Value (NPV) of R\$ 2,906.90/ha for the most significant clone. The method Monte Carlo was used for the determination of the risk and the comparison of the values of the deterministic methods. To the values of a historical series of prices of wood and calf was applied GIRP (General Index of Retail Prices) as a deflator. The results showed that the NPV with an application of a CMM has a value of R\$6,342.95/ha with more the 80% of probability of occurrence. Compared with the original activity of the property, the cattle raising, the Silvopasture System offers more investments returning conditions.

Prognoses for growth and timber production and economic assessment of *Pinus taeda* in monoculture and in integrated silvopasture systems / Prognose do crescimento e da produção madeireira e avaliação econômica de *Pinus taeda* em monocultivo e em ILPF

Caroline Cruz de Mello¹, Edilson Batista de Oliveira²
¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil (carol.mello@ufpr.br; edilson.oliveira@embrapa.br)

Este trabalho teve por objetivos estimar o crescimento e produção madeireira e avaliar a rentabilidade econômica de *Pinus taeda* em monocultivo e em sistema de integração lavoura-pecuária-floresta (ILPF). Foram simulados sete regimes de manejo por meio de softwares desenvolvidos pela Embrapa Florestas. Os regimes foram divididos em dois experimentos: o primeiro com quatro tratamentos (R1, R2, R3, R4) em ILPF delineados com espaçamento 3,0 m x 2,0 m e distância de 14 m entre os renques, diferenciando-se entre si pelo número de fileiras no renque (fileiras simples, dupla, tripla e quádrupla); e o segundo com três tratamentos (R5, R6, R7) em monocultivo com 1667 árvores por hectare. R1, R2, R3 e R4 tiveram corte final projetado para 20 anos, com desbaste seletivo de 50% da população aos 10 anos. R5 teve desbaste seletivo de 40% da população aos 10 e 15 anos, com corte final aos 20 anos. R6 teve desbaste seletivo de 50% da população aos 12 anos e corte final aos 20 anos. O tratamento R7 foi projetado sem desbastes e com corte final aos 16 anos. Em nossa simulação, as árvores propiciaram retorno econômico nos sete tratamentos avaliados, indicando que, além de diversificar a produção, a inserção da árvore na propriedade rural pode ser considerada uma atrativa fonte de renda. Com esses tratamentos, mostramos que os softwares para manejo e análise econômica de florestas podem auxiliar produtores na tomada de decisão para a implantação do componente florestal em suas propriedades.

Assessment and seasonal production of herbaceous forage biomass and correlation between environmental variables and basal area / Avaliação e produção estacional de biomassa herbácea forrageira e correlação entre variáveis ambientais e área basal

Talyta Mytsuy Zanardini Galeski Sens¹, Sebastião Brasil Campos Lustosa¹, Luciano Farinha Watzlawick¹, Iris Cristina Bertolini¹, Ana Paula Vantroba¹
¹Universidade Estadual do Centro-Oeste, Guarapuava, Brasil (talytagaleski@hotmail.com; slustosa@unicentro.br; farinha@unicentro.br; iris_cristinabertolini@hotmail.com; paulavantroba@hotmail.com)

Este estudo foi realizado em duas áreas sob formação florestal Floresta Ombrófila Mista, no município de Turvo-PR, uma área de floresta secundária e uma área de sistema silvipastoril natural, tendo como objetivo quantificar a produção estacional de biomassa herbácea forrageira e inferir as diferenças entre as áreas em função do seu manejo. A coleta de biomassa e componente botânico seguiu a metodologia Botanal, a área basal arbórea foi obtida por meio da dinâmica florestal. Foram avaliadas as variáveis ambientais: insolação, precipitação, radiação solar, temperatura máxima, média, mínima e umidade relativa. A maior produção de matéria seca ocorreu na área silvipastoril, no outono, com média de 265,44 kg MS.ha⁻¹, na área de floresta secundária não houve estação de maior produção, com menor média na primavera, 35,33 kg MS.ha⁻¹. *Panicum* sp. apresentou a maior produção de biomassa, no outono no sistema silvipastoril e verão na floresta secundária. A porcentagem de solo descoberto não apresentou diferença significativa entre as estações no sistema silvipastoril, na área de floresta secundária a menor porcentagem foi no inverno 48,90% e a maior na primavera 65,39%. A análise composta por variáveis ambientais, biomassa e área basal, resultou uma correlação alta negativa entre biomassa da área silvipastoril e temperatura máxima, apresentando ainda correlação significativa entre biomassa do inverno na floresta secundária e área basal. O gênero *Panicum* sp. é predominante na produção de biomassa de ambas as áreas, está presente em todas as estações do ano. Temperatura máxima e biomassa do sistema silvipastoril apresentam uma relação inversamente proporcional.

Double and simple entry equations for estimating the volume of trees established in integrated silvopasture systems / Equações de dupla e simples entrada para estimação do volume de árvores estabelecidas em sistemas silvipastoris

Marcelo Müller¹, Alexandre Brighenti¹, Carlos Martins¹
¹Embrapa Gado de Leite, Juiz de Fora, Brasil (marcelo.muller@embrapa.br; alexandre.brighenti@embrapa.br; carlos.eugenio@embrapa.br)

O objetivo deste trabalho foi avaliar a precisão e a acurácia de equações de simples entrada para estimação do volume individual de árvores de eucalipto estabelecidas em sistemas silvipastoris. Foram ajustados sete modelos volumétricos, sendo quatro de simples e quatro de dupla entrada, para dois clones de eucalipto (GG 100 e I 144) plantados em dois diferentes espaçamentos (15 x 3 e 15 + (3 x 2)) e um híbrido de *Eucalyptus grandis* x *Eucalyptus urophylla* propagado por sementes, também em dois espaçamentos (15 + (3 x 2) e 15 + (3 x 2,5)). A partir dos valores das variáveis Ht, Dap e Vt obtidas através do método de cubagem proposto por Smalian, foram ajustadas as equações volumétricas de simples e dupla entrada para cada material. Os modelos foram ajustados pelo

método dos mínimos quadrados não lineares via o algoritmo de Gauss-Newton, e a seleção do melhor modelo para cada estrato foi baseada em três critérios: Índice de Furnival (IF), coeficiente de determinação ajustado (R^2_{aj}) e análise gráfica dos resíduos. De forma geral, os modelos de dupla entrada apresentaram resultados mais satisfatórios para todos os casos, com destaque para os modelos de Spurr logaritimizado e Schumacher & Hall logaritimizado. Entretanto, os modelos de simples entrada demonstraram estatísticas muito próximas daquelas observadas para os modelos de dupla entrada, com destaque para os modelos de Husch e Brenac. Neste sentido, o uso de equações de simples entrada pode ser recomendado, principalmente no caso de pequenos produtores, como forma de tornar a aferição da sua produção menos onerosa.

CIi: TRADITIONAL COPPICES: ECOLOGY, ECONOMY AND ECOSYSTEM SERVICES

Early growth and development of black locust (*Robinia pseudoacacia* L.) in root sucker-regenerated stands in the Northwest of Romania

Valeriu-Norocel Nicolescu¹, Cornelia Hernea², Nicolae Iacob^{1,3}, Beatrice-Maria Uşurelu¹

¹Transylvania University of Brasov, Faculty of Silviculture and Forest Engineering, Brasov, Romania; ²Faculty of Horticulture and Forestry, Banat's University of Agricultural Sciences and Veterinary Medicine, Timisoara, Romania; ³Săcueni Forest District, Bihor County Branch, National Forest Administration-Romsilva, Sacueni, Romania (vnicolescu@unitbv.ro; corneliahernea@yahoo.com; sacueni@oradea.rosilva.ro; usurelubeatricemaria@gmail.com)

In the Northwest of Romania, a region with a warm (mean annual temperature 10.30 °C) and quite dry climate (mean annual precipitation 573.3 mm), forest vegetation covers about 12% of the total area of continental sand dunes part of Carei - Valea lui Mihai Plain, with black locust (*Robinia pseudoacacia* L.) as the main tree species covering ca. 3,000 ha (over 80% of all forestland). Since its introduction in the area, black locust has been treated as low coppice, usually on a rotation of 20-30 years. In these stands the most commonly used rejuvenation method is by root suckers as black locust develops horizontal, shallow and wide-spreading roots which can extend to 15-20 m from the parent tree. The paper outlines the main results of a research and demonstration project on regeneration and early growth of black locust in the NW of Romania started in 2016. It was carried out in two young and pure black locust stands, naturally regenerated by root suckers following simple coppice cuts and removal of stumps. The initial growth of young black locust individuals was quick in both height and diameter. Consequently, the newly established stands have closed the canopy within two years regardless the initial stocking or basal area, resulting in effective sand dune stabilization and control of wind erosion.

Resilience and dynamics of the landscape in the oak forests of the Galicia Eastern mountains (Northwest of the Iberian Peninsula)

Díaz-Maroto Ignacio J.¹

¹University of Santiago de Compostela, Lugo, Spain (ignacio.diazmaroto@usc.es)

The landscape dynamics of the eastern Galician mountains is mostly effect of human intervention during centuries ago. Our research has studied the resilience and changes – environmental, socioeconomic and historical changes – in this region. The objective is to suggest a set of silvicultural actions for the conservation and improvement of the landscape of these lands. The study focused on the progression of the natural broadleaved forests, intensively exploited since ancestral times. These forests were transformed to agricultural land, exploited for the naval, metallurgical and railway industries, joined with Church possessions, suffered forest fires, and were replaced by fast growing species, mainly coniferous and, today *Eucalyptus nitens* Shining Gum. All of these actions have led to a reduction of the occupied area by them. Now, broadleaved forests cover small and generally sloped sites, remaining where the soil features often avoid other land use, however their natural regeneration is very limited by human activities. These sites have a much modified landscape, but with a slow transformation where the biodiversity conservation, the hunting phenomenon and the cultural or environmental tourism have a high importance. Their current situation raises the problem of their socioeconomic reconversion. From a positive standpoint, the area covered by these forests has recently increased, and there is a greater awareness of the importance of their conservation given the recognition as habitats of interest to the European Union, being part of the NATURA 2000 Network.

Influence of plantation stand structure change by thinning operation

Ping-Hsun Peng^{1,2}, Sheng-Lin Tang², Chi-Hua Chang³, Yu-Xuan Zhan⁴, Chih-Ming Chiu², Chaur-Tzuhn Chen⁴, Jan-Chang Chen⁴

¹Graduate Institute of Bioresources, Pingtung, Taiwan; ²Taiwan Forestry Research Institute, Taipei, Taiwan; ³Institute of Tropical Agriculture and International Cooperation, Pingtung, Taiwan; ⁴Department of Forestry, Pingtung, Taiwan (a22312793@gmail.com; a23112793@gmail.com; harry199180116@gmail.com; b10312050@gmail.com; a23112793@gmail.com; cct@mail.npust.edu.tw; zzzjohn@mail.npust.edu.tw)

Taiwan Kagome Co., Ltd has implemented understory thinning operation in their *Swietenia macrophylla* plantation since 2011. Thinning rates set from 25% to 45%. In this study, we investigate the juvenile trees, which from 14 to 20 years. We use Three Parameter Weibull Probability Distribution, conducted from Maximum Likelihood Method to simulate the diameter distribution before thinning and after. As results, the Dn values of K-S test are all lower than threshold value (D0.05). The estimation results by Weibull Probability Distribution of different age trees demonstrate well, validate with 100%. It means this method is effective to display diameter distribution with different age plantations. With parameter of Weibull, a value, which is annual increasing of thinning plots shows from 0.81 to 0.93, all higher than Control plots (0.26). The b values represent three stages, which are before thinning, after thinning and six years after thinning. Operation method contains four groups, which are 1,760 trees/ha (Group A, b value = 13.5, 13.5, 14.5), 1,200 trees/ha (Group B, b value = 12.9, 10.0, 12.2), 1,000 trees/ha (Group C, b value = 9.9, 10.7, 9.1), and 800 trees/ha (Group D, b value = 13.6, 12.3, 14.7). The b value become lower as the distribution curve become smaller in Group A, B and D. After six years, diameter distribution goes bigger as tree age goes on. However, Group C has opposite results. The reason we found that lots of trees were dead because of pest and diseases hazards.

Challenges and options for future coppice management in Europe. Lessons from the pan-European COST Action EuroCoppice

Gero Becker¹, Alicia Unrau¹, Valeriu-Norocel Nicolescu²

¹University of Freiburg, chair of forest utilization, Freiburg im Breisgau, Germany; ²University of Brasov, Faculty of Silviculture and Forest Engineering, Brasov, Romania (gero.becker@fob.uni-freiburg.de; lisch_unrau@hotmail.com; vnicolescu@unitbv.ro)

Coppicing takes advantage of the natural ability of certain tree species to regenerate vegetatively after cutting, releasing fast growing stool sprouts or root suckers. Various forms of coppice management systems have been established worldwide, supplying wood and NWFP to rural societies and local economies. With industrialization and the increased use of fossil fuels many European coppice forests have been converted to high forests or abandoned, but over 20 million

ha, representing over 10% of the forest cover are still showing characteristic features of coppice. The renaissance of wood as renewable resource for energy and bioeconomy, but also concerns about climate change and the loss of biodiversity results in a new interest in this flexible and adaptive, cost-effective sustainable management concept. In a four year project of international cooperation, researchers and experts from 35 EU and neighboring countries collected data and scientific and practical knowledge about all aspects of coppice forests. Their major findings and conclusions and the proposed strategies to preserve and develop further coppice forest management are presented.

Restoration of traditional coppicing positively influences biodiversity: evidence from the Czech Republic

Radim Hédli^{1,2}, Markéta Chudomelová¹, Ondřej Košulic³, Vladan Riedl⁴, Jan Šipoš^{1,5}, Ondřej Vild¹, Pavla Vymazalová³

¹Institute of Botany, Czech Academy of Sciences, Brno, Czech Republic; ²Department of Botany, Palacky University in Olomouc, Olomouc, Czech Republic;

⁴Nature Conservation Agency of the Czech Republic, Brno, Czech Republic; ⁵Department of Zoology, Fisheries, Hydrobiology and Apiculture, Faculty of AgriSciences, Mendel University in Brno, Brno, Czech Republic (radim.hedli@ibot.cas.cz; marketa.chudomelova@ibot.cas.cz; ondra.kosulic@seznam.cz; vladan.riedl@nature.cz; jsipos@seznam.cz; ondrej.vild@gmail.com; vymazalova.pavla@gmail.com)

Traditional coppicing was a very widespread forest management form in the European lowlands. In the area of today's Czech Republic, it was practiced from prehistory to the mid-20th century, frequently comprising 80–90% of forest management in individual estates. The abandonment of coppicing was a gradual process resulting from a transition to high forest management. Various groups of organisms adapted to coppicing vanished as coppicing management was abandoned. Current efforts of nature conservation and some foresters aim at restoring traditional coppicing and biodiversity linked to it. We briefly illustrate the changes in plant communities between the 1950s and 2000s reflecting the period of coppicing abandonment. Shady and nutrient-richer closed-canopy forests support only impoverished communities; many species vanished completely. Light- and warm-demanding species were most significantly influenced by the abandonment of coppicing. Monitoring focused on the effects of coppicing restoration (2008–present), specifically on the biodiversity of vascular plants and invertebrates. Results showed that species richness of vascular plants reacted with a quick increase in the first years after canopy opening. This change is much more pronounced than any fluctuation during time if no management action was taken. Species richness and abundance of spider communities were enhanced immediately after coppice restoration; functional diversity peaked in intensively restored stands. However, the longevity of induced biodiversity changes depends on the continuation of coppicing management. We conclude that coppicing restoration had a fast and strong effect on biodiversity. It may present a suitable way of biodiversity restoration in European lowland forests.

Biomass allocation and carbon potential of beech (*Fagus spp*) coppice forests in Eastern Macedonia

Christian Aeschlimann¹, Marija Sterjovska², Patrick Schwab¹

¹Bern University of Applied Science, Bern, Switzerland; ²St. Cyril and Methodius University, Skopje, Macedonia, Republic of the former Yugoslav (christian.aeschli@gmail.com; marija28sterjovska@gmail.com; patrickschwab20@hotmail.com)

In Macedonia, the great majority of rural people depend on firewood and coppice forests play an essential role in their livelihood strategies. Sustainable coppice forest management can also play an important role as carbon sinks and in adaptive management to climate change. This study aims at analysing the carbon stock potential of beech coppice forests in Eastern Macedonia. Eleven trees were harvested in mountainous Eastern Macedonia, their trunks were excavated and their complete biomass was measured and analysed, both above and below ground. The main research questions included (i) the relation between aboveground- and belowground biomass of beech coppice trees in different age; (ii) the comparison of beech high stem- and coppice forests with regard to biomass stockage and allocation; and (iii) the overall carbon stock potential of beech coppice forests in Eastern Macedonia. The data analysis showed that the rate between above and below ground biomass in beech coppice forests is higher by trend to the one in high stem beech forests and is about 25–27%. With a rotation time of 50 years the average total biomass of 116 t/ha is 60–70% lower than the one in high stem forests located in similar sites. This study provides results, which can be used as instruments for measurements of carbon potential in southern Balkan beech coppice forests. A conclusion, however, can only be made after further forest inventories in order to improve data basis.

Adaptive forestry in Slovakia: in search of alternative forest management models

Róbert Sedmák¹, Yvonne Brodrechtová¹, Ján Bahýľ¹, Michal Bošela¹, Ján Tuček¹

¹Technical University in Zvolen, Zvolen, Slovakia (robert.sedmak@tuzvo.sk; yvonne.brodrechtova@tuzvo.sk; jan.bahyl@tuzvo.sk; michal.bosela@tuzvo.sk; jan.tucek@tuzvo.sk)

Forestry today has to provide robust approaches to forest management when confronted with 21st century challenges. As the current forest management models (FMMs) in Slovakia face uncertainties including command-and-control governance inherited from the past, two alternative FMMs tackling a wide spectrum of ecosystem services (ES) were proposed: model of mixed management concepts and model of flexible aged forests. While the first model focuses on sustainable multifunctional management in partly uneven-aged mixed stands, the second alternative emphasizes sustainable timber provision in even-aged mixed stands (e.g. flexibility of rotation and regeneration periods). The FMMs were simulated for ten decades considering ES provisioning under the influence of climate change, demands for nature protection, changes in forest ownership structure, and various forest owner types. The preliminary simulation results exposed very small differences among current and altered management in comparison to today's situation (both management concepts do not considerably increase the overall multi-criterial utility of the considered ES). Climate had more impact due to differences in final multi-criterial utilities. Changes in nature protection and forest ownership structures had a markedly smaller impact on the provisioning of ES in the tested time span. Finally, on large areas within a longer time period there was an interaction equalizing synergies and negative exchanges in provisioning (trade-offs) among ES. This leads to the conclusion that if alternative FMMs based on more adaptive governance lead to similar outcome then the complicated, heavy regulative command-and-control governance with limited decision freedom could be rationalized to better cope with 21st century challenges.

C1p: PRODUCTION FORESTRY - II

Forage yield of Congo grass (*Urochloa ruziziensis*) in silvopasture systems with *Khaya ivorensis* Chev. / Produtividade da forrageira *Urochloa ruziziensis* em sistema silvipastoril com *Khaya ivorensis* Chev.Filipe Gonçalves de Sousa¹, Francine Neves Calil¹, Sybelle Barreira¹¹Universidade Federal de Goiás, Goiânia, Brasil (filipesousa.fhjf@gmail.com; fncalil@gmail.com; sybelle.barreira@gmail.com)

Os sistemas silvipastoris são sistemas que visam o melhor aproveitamento da terra por meio do consórcio entre o componente arbóreo e animal, intensificando o uso da terra, potencializando os efeitos complementares da interação entre os componentes, como o sombreamento das árvores na criação pecuária e aumentando a renda do produtor, sem comprometer de forma excessiva o meio ambiente. A *Khaya ivorensis* Chev., conhecida popularmente como mogno-africano, possui uso múltiplo e alto valor comercial agregado, além de possuir alta adaptação ao clima do Brasil e crescimento rápido comparado a espécies com madeiras de densidade semelhante. O objetivo deste trabalho foi avaliar a produtividade da forrageira *Urochloa ruziziensis* entre renques de sistema silvipastoril consorciado com *K. ivorensis* Chev. O estudo foi realizado em um sistema silvipastoril com mogno-africano plantado em linhas triplas e com distância entre renques de 26 m, onde se encontra implantada a forrageira *U. ruziziensis*. Foram coletadas, com auxílio de gabarito 50 x 50 cm (0,25 m²), amostras da forrageira nas distâncias 1, 7, 13, 19 e 25 m, considerando a linha mais externa das árvores como referência. A produtividade média da forrageira foi de 517,91 kg/ha, sendo que os valores obtidos para cada distância dentro dos renques foram de 455,44; 492,90; 616,80; 600,57 e 423,86 kg/ha, respectivamente. Há um aumento na produtividade do material vegetal quando o ponto da amostragem está localizado mais ao centro do renque, evidenciando o papel fundamental da radiação solar para o crescimento das forrageiras.

***Parkia multijuga* Benth: a new option for reforestation and remediation of degraded areas in the Amazon region / *Parkia multijuga* Benth: uma nova opção para reflorestamento e recuperação de áreas degradadas na Amazônia**Osmar José de Aguiar¹, Nayanna de Nazaré Brito Freitas¹, Gleiciane de Meireles Batista¹¹Universidade do Estado do Pará, Belém, Brasil (o.aguiarromeiro@gmail.com; nayyyfreitas@hotmail.com; gleicianemeirelesbatista@gmail.com)

Desde o meados do século XX ocorre o desmatamento na Amazônia, intensificado pelos processos de urbanização e industrialização, atualmente, agravado pelas extrações ilegais, muitas vezes estimulados por política de ocupação da região. Em função da grande importância que a floresta Amazônia tem para a humanidade, estudos são desenvolvidos na região, desde a década de 50 pela SUDAM e o INPA, sobre silvicultura de espécie nativas, visando a recuperação de áreas degradadas. Por apresentar rápido crescimento e proteção do solo, a *Parkia multijuga* Benth., é utilizada para a recuperação de áreas de florestas secundárias e solo degradado na região. Assim, o presente trabalho tem como objetivo apresentar a parkia como uma nova opção para reflorestamento e recuperação de áreas degradadas na Amazônia, em função do potencial silvicultural apresentado. O material utilizado para o estudo foi proveniente de um plantio misto de paricá com parkia aos 5 anos, localizado no município de Ipixuna do Pará – PA. Em uma parcela amostral com 7 linhas contendo 30 árvores cada, foram mensurados os DAP de 206 árvores, sendo ao acaso 20 árvores de cada espécie para a determinação do potencial silvicultural por meio do IMA. Resultado que, os valores da espécie parkia foram de 32,83 m³/ha.ano e paricá de 31,23 m³/ha.ano, desta forma, verificou-se que não houve diferença significativa estatisticamente. Portanto, a parkia torna-se uma nova opção para ser utilizada em plantio comercial e recuperação de áreas degradadas no estado do Pará.

Impact of natural shade on the thermal comfort of animals in pastures of Mato Grosso do Sul, Brazil / Influência do sombreamento natural no conforto térmico animal em pastagens do Mato Grosso do SulFabiana Villa Alves¹, Genilson Fernando da Costa², Ariadne Pegoraro Mastelaro³, Pedro Nelson Cesar do Amara², Geovani Ferreira Alves⁴, Valdemir Antonio Laura¹, Roberto Giolo de Almeida¹¹Embrapa Gado de Corte, Campo Grande, Brasil; ²Universidade Estadual de Mato Grosso do Sul, Aquidauana, Brasil; ³Universidade Federal do Paraná, Curitiba, Brasil; ⁴Universidade Federal do Mato Grosso do Sul, Campo Grande, Brasil (fabiana.alves@embrapa.br; genilson.fernando@yahoo.com.br; aripvet@gmail.com; plnelson.@uems.br; geovani.alves@ufms.br; valdemir.laura@embrapa.br; roberto.giolo@embrapa.br)

Uma das práticas mais eficientes para diminuir os efeitos indesejáveis do estresse térmico em animais à pasto, nos trópicos, é a implantação de árvores. Em experimento realizado de junho a agosto de 2018, na Fazenda Boa Aguada (URT Carne Carbono Neutro, da Embrapa Gado de Corte), em Ribas do Rio Pardo, Mato Grosso do Sul, foram avaliados três índices de conforto térmico (ITU, ITGU e CTR) na pastagem em monocultivo (PM), e em dois sistemas silvipastoris (28 x 2 m – S1 e 28 x 2 + (3 + 3 m) – S2), com diferentes arranjos de *E. urograndis* (altura média de 15 m). As mensurações ocorreram ao sol (nos três sistemas) e à sombra (sistemas silvipastoris), em três dias consecutivos, às 13h00 (GMT – 4:00). O ITU e ITGU ao sol foram maiores na pastagem em monocultivo (85 e 89), em comparação aos S1 e S2 (ITU 82 e ITGU 85 em ambos os sistemas). À sombra, o ITU foi ligeiramente menor no S1 (79) em relação ao S2 (80), sendo que o ITGU foi igual em ambos os sistemas (80). A CTR ao sol também apresentou maiores valores para PM (634 W.m⁻²), em comparação ao S1 e S2 (587 e 582 W.m⁻²). À sombra, a CTR no S1 foi maior (531 W.m⁻²) que em S2 (521 W.m⁻²). Áreas sombreadas reduzem de 6 a 8% o ITU, 11% o ITGU, e de 19 a 22% a CTR, segundo o arranjo de árvores implantado, com prováveis benefícios ao bem-estar animal.

Global temperature and humidity index in integration systems in the Cerrado / Índice de Temperatura Globo e Umidade em Sistemas de Integração no CerradoAriadne Pegoraro Mastelaro¹, Fabiana Villa Alves², Geovani Ferreira Alves³, Roberto Giolo de Almeida², Valdemir Antônio Laura², Maity Zopollatto¹¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Gado de Corte, Campo Grande, Brasil; ³Universidade Federal do Mato Grosso do Sul, Campo Grande, Brasil (aripvet@gmail.com; fabiana.alves@embrapa.br; gfalves@hotmail.it; roberto.giolo@embrapa.br; valdemir.laura@embrapa.br; maity@ufpr.br)

A alta incidência de radiação solar é considerada um dos problemas que mais influencia a produção animal em pastagens na faixa intertropical do globo terrestre. Práticas de manejo como a inserção de árvores, com vistas à oferta de sombra, são essenciais ao bem-estar animal nestas regiões. Em experimento realizado na fazenda Boa Aguada, em Ribas do Rio Pardo (MS), em outubro de 2018, objetivou-se verificar os benefícios aportados pela as árvores em arranjos ordenados, do tipo silvipastoril. Para tal, calculou-se o índice de temperatura de globo negro e umidade (ITGU) em 2 sistemas produtivos, implantados em 2016: pastagem monocultivo (PM) e silvipastoril 28 x 2 m (SP), com *E. urograndis* (altura média de 17 m). Para tal, foram mensuradas as temperaturas de globo negro (T_{gn}, °C) e ponto de orvalho (T_{po}, °C), com termohigrômetro digital, no ponto central do piquete (a), em ambos os sistemas, e à 2 m das árvores no SP (b), por 24 horas, durante 31 dias, com duas repetições por ponto. O delineamento experimental foi em blocos casualizados, com médias comparadas pelo teste de Tukey (5%).

O ITGU médio foi diferente ($P \leq 0,05$) entre os sistemas e ao longo do dia. Os maiores valores de ITGU (94) foram encontrados no PM, às 12h00. No mesmo horário, o ITGU no SP foi de 86. Na média, o ITGU foi significativamente maior no PM (a) quando comparado ao SP (78 x 77 (a) e 76 (b)). Os dados obtidos ressaltam a importância da sombra, para os animais, nos horários mais quentes do dia.

Analyzing complete stem growth of *Matayba elaeagnoides* Radlk in a fragment of regenerating seasonal semideciduous forest / Análise de tronco completa de crescimento de *Matayba elaeagnoides* Radlk em fragmento de floresta estacional semidecidual em regeneração

Girlaine Glenda Simplicio Brito¹, Davidson da Silva Novaes¹, Veridiana Padoin Weber¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (girlaine@alunos.utfpr.edu.br; davidsonnovaes@alunos.utfpr.edu.br; veridianapadoin@utfpr.edu.br)

A dendrocronologia é a técnica que melhor permite interpretar e avaliar o crescimento de uma árvore, e observar possíveis relações com fatores ambientais de forma rápida e confiável. A pesquisa foi desenvolvida na Universidade Tecnológica Federal do Paraná, Campus Dois Vizinhos, na área da UNEPE (Unidade de Pesquisa e Extensão) Trilha Ecológica que é um fragmento de Floresta Estacional Semidecidual em Regeneração. A espécie estudada foi a *Matayba elaeagnoides* Radlk, cujas amostras foram obtidas através do projeto: Alternativas de manejo florestal para reestruturação e obtenção de produtos madeireiros de interesse econômico de um remanescente florestal no sudoeste do Paraná. Os dados foram obtidos mediante análise do tronco completa através do software Image Pro Plus. Foram calculados o Incremento Corrente Anual (ICA) em diâmetro e o Incremento Médio Anual (IMA) em diâmetro de acordo com o modelo ajustado de Chapman-Richards. De acordo com a contagem dos anéis a árvore possui 45 anos de idade. O ICA e IMA se encontram na idade 29, essa é a idade em que o ICA passa a decair e fica abaixo do IMA até a idade final. O IMA passa a estabilizar na idade 29. A espécie é tolerante a sombra e é enquadrada como secundária inicial, secundária tardia e Climax. O ponto de intersecção entre IMA e ICA mostra o melhor momento para o corte da árvore estudada ou momento de desbaste para manter o incremento.

Using the modified Liocourt method for managing native forests in Southwestern Paraná, Brazil / Uso do método de Liocourt modificado para o manejo de floresta nativa no sudoeste do Paraná

Mauricio Gorenstein¹, Elisabete Vuaden¹, Veridiana Weber¹, Edgar Vismara¹, Claudio Thomas¹, Amanda Silva¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (mauriciorg@utfpr.edu.br; elisabetev@utfpr.edu.br; veridianapadoin@utfpr.edu.br; edgarvismara@utfpr.edu.br; claudiothomas@utfpr.edu.br; amanda.1994@alunos.utfpr.edu.br)

O trabalho visa desenvolver uma metodologia baseada no Quociente de Liocourt médio atual da estrutura diamétrica para calcular o corte da floresta. A pesquisa foi realizada em um remanescente florestal na UTFPR-DV. Os dados foram coletados em três parcelas de 2400 m², considerando todas as árvores com circunferência à altura do peito (cap) maior que 15 cm. A metodologia consistiu em calcular um quociente de Liocourt atual (q) e um quociente médio (qmédio) obtido pela média aritmética dos quocientes calculados para cada classe diamétrica multiplicado pelo número de árvores presentes em cada classe, pela seguinte fórmula: $[(q - q_{médio})/q] * N$. Os valores de q variaram de 1,2 a 9,2 e o qmédio nas parcelas 1, 2 e 3 foram q1 = 2,9, q2 = 2, q3 = 6,9, respectivamente. Os maiores valores de q foram obtidos nas menores classes diamétricas, o que demonstra alta regeneração de um número limitado de espécies remanescentes, prejudicando a diversidade ecológica do povoamento. Assim, para que a floresta fique balanceada após o corte, somente as árvores abaixo de 34cm de diâmetro à altura do peito deverão ser retiradas. Nas parcelas 1 e 3, 91% dos indivíduos a serem desbastados estão concentrados na primeira classe diamétrica e na parcela 2, 81% das árvores. A porcentagem de árvores desbastadas será: 9,73%, 20,73%, 24,19% nas parcelas 1, 2 e 3, respectivamente. A utilização do método de Liocourt modificado se justifica para aumentar a diversidade de espécies com a retirada da regeneração de indivíduos que dominam o estrato nas primeiras classes diamétricas, garantindo a perpetuidade da floresta.

Physiological dormancy in five shrub species of Rubiaceae native to Brazil / Dormência fisiológica em cinco espécies arbustivas de Rubiaceae da flora nativa brasileira

Susane Raser¹, Flávio Gandara¹, Elza Ferraz¹, Girlei Cunha², Frederico Miranda², Eduardo Gusson², Alexandre Astorino³

¹Escola Superior de Agricultura "Luiz de Queiroz", Piracicaba, Brasil; ²Biodendro Consultoria Florestal, Piracicaba, Brasil; ³AES Brasil, Bauru, Brasil (susanerasera@yahoo.com; fgandara@usp.br; elzamferrazz@gmail.com; girlei.cunha@gmail.com; fredtsmiranda@gmail.com; eduardogusson@gmail.com; alexandre.astorino@aes.com)

Espécies não arbóreas representam aproximadamente dois terços das espécies de plantas da floresta tropical, além de serem fonte de alimento para diversos animais e contribuírem para a formação de nichos ecológicos específicos dentro do sistema florestal. Tendo em vista a baixa regeneração natural desse componente em áreas restauradas, torna-se necessária a introdução dessas espécies em áreas em restauração. Existindo uma grande lacuna de informações sobre essas espécies e sendo a germinação de sementes uma das etapas fundamentais para permitir a introdução delas em campo, o objetivo desse trabalho foi testar o efeito da quebra de dormência na germinação de cinco espécies arbustivas pertencentes à família Rubiaceae: *Psychotria warmingii*, *Psychotria deflexa*, *Psychotria anceps*, *Palicourea* cf. *croceoides* e *Margaritopsis* cf. *schuechiana*. O estudo foi desenvolvido no Laboratório de Ecologia Vegetal e Agroecologia da ESALQ/USP. Primeiramente, foi testada a possibilidade de dormência tegumentar, usando-se como tratamentos: H₂SO₄ 98% (1, 5, 10 e 15 minutos); H₂O 80 °C (1, 5, 10 e 15 minutos) e imersão em água (8, 12, 24 e 48 horas). Como não houve resposta germinativa aos tratamentos, foi testada a possibilidade de dormência fisiológica, com o uso de Ácido Giberélico (GA3) por 24 horas em diferentes concentrações: i) GA3 100 ppm (exceto para *Margaritopsis* cf. *schuechiana*); ii) GA3 250 ppm; iii) GA3 500 ppm; iv) GA3 750 ppm; e v) Testemunha. Todas as espécies responderam ao uso do Ácido Giberélico, sendo as maiores taxas de germinação obtidas para concentrações de 500 e 750 ppm, evidenciando a dormência fisiológica existente nessas espécies.

Economic radius as an instrument for guiding adoption of sustainable forest management in the Amazon region: a case study in Acre, Brazil / Raio econômico como um instrumento para orientar a adoção do manejo florestal sustentável na Amazônia: um estudo de caso no estado do Acre

Zenobio Abel Gouvêa Perelli da Gama e Silva¹, Karine Silva¹

¹Universidade Federal do Acre, Rio Branco, Brasil (zenobio.siva@gmail.com; karinemilene26@gmail.com)

Este estudo aborda a produção racional de madeira na Amazônia brasileira. Seu objetivo foi identificar a distância econômica limite entre uma floresta, sob regime de manejo florestal sustentável (MFS), e o pátio de uma firma madeireira, e assim colaborar na formulação de políticas que fomentem o uso racional dos recursos florestais-madeireiros regionais. Para tal, adotou-se, como área de estudo, as florestas localizadas no estado do Acre. Os dados usados nessa pesquisa

foram obtidos em entrevistas com os proprietários de serrarias que atuavam, nesse estado, no período 2008-2010. Os conceitos adotados para quantificar o raio econômico para atividade florestal-madeira nessa região, foram: 1) renda líquida, na venda da madeira serrada, para diferentes distâncias entre uma floresta manejada e o pátio da serraria e 2) valor esperado da terra (VET), válido para uma terra destinada à produção florestal manejada. A partir dos resultados gerados, conclui-se que: 1) considerando-se os custos de uma serraria com a produção e comercialização de madeira serrada e o preço de venda dessa mercadoria, tem-se que o raio econômico, para essa atividade florestal-madeira, no Acre, é de 282 km e 2) uma comparação do preço médio da terra florestal, na região, com o VET obtido indica que só é viável, economicamente, um empresário manejar e explorar uma floresta, e vender a madeira em tora, posto no pátio da serraria, e esse processo lhe render uma taxa de juros de 6% ao ano, se a distância dessa floresta até a firma madeireira for, no máximo, igual a 125 km.

C1q: PRODUCTION FORESTRY - I

Estimating the microfibrillar angle using fiber biometrics and physical properties of African mahogany wood / Estimativa do ângulo microfibrilar por biometria das fibras e propriedades físicas da madeira de mogno africano

Sofia Maria Rocha¹, João Gabriel Missia¹, Graziela Vidaurre¹, Ramon Oliveira¹, Alexa Melo¹, Daniela Minini¹, Maria Naruna Félix¹

¹Universidade Federal do Espírito Santo, Jerônimo Monteiro, Brasil (sofiamaria.r@hotmail.com; j.gabrielmissia@hotmail.com; grazividaurre@gmail.com; oliveira.r.eim@gmail.com; alexabmelo@hotmail.com; daniminini16@gmail.com; narunafelix@gmail.com)

O ângulo microfibrilar (AMF) da parede celular influencia a estabilidade dimensional e as propriedades mecânicas, e sua estimativa permite compreender o comportamento da madeira de *K. ivorensis* e *K. senegalensis* no beneficiamento e como produto. A mensuração do AMF pela microscopia de luz polarizada, é onerosa, demorada e dependente da perícia do observador [SM1], por isso, teve-se por objetivo estimar o AMF por outras propriedades da madeira [SM2], de mais fácil determinação. Foram colhidas 3 árvores por espécie, em parcela experimental (espaçamento de 3 x 2 m) da Reserva Natural Vale, Linhares - ES, Brasil. De discos do DAP, determinou-se a biometria das fibras (dimensões e índices) e dos vasos (dimensões e número), as contrações lineares e volumétrica e o fator anisotrópico. Pelo método exhaustive search, que determina a melhor combinação de variáveis independentes para estimar a dependente, selecionou-se equações que melhor estimaram o AMF por outras propriedades da madeira [SM3]. A variação do AMF da *K. ivorensis* foi 82% explicada em modelo de 5 variáveis, espessura de parede + índice de esbeltez + índice de Runkel + densidade básica + contração longitudinal, com erro de 5%. O AMF da *K. senegalensis* foi apenas 18% explicado por modelo de 4 variáveis, comprimento das fibras + índice de esbeltez + coeficiente de flexibilidade + espessura de parede, com erro de 10,1 [SM4] %. O AMF da *K. ivorensis* pode ser estimado por outras propriedades de determinação mais simples. Para a *K. senegalensis*, o AMF não expressou relação clara com as propriedades da madeira.

Volumetric estimates for forest concession areas in the Amazon Forest

Mateus Sanquetta¹, Ana Paula Dalla Corte¹, Vinicius Cysneiros¹, Carlos Sanquetta¹, Luciane Schmidt¹

¹Universidade Federal do Paraná, Curitiba, Brasil (mateus.sanquetta@gmail.com; anapaulacorte@gmail.com; vccysneiros.florestal@gmail.com; carlossanquetta@gmail.com; lunaimkeschmidt@gmail.com)

Forest concession consist in an important mechanism to reduce deforestation rates and develop social and economically the Amazonian region. Estimating the commercial volume and better planning the use of resources are essential for concessionaires. This study aimed to evaluate different approaches to estimate the commercial tree volume of under concession species in the National Forest of Jamari, located in the state of Rondônia, Northern Brazil. Regression models of simple and double inputs were fitted and then compared with form factor (average value of 0.7). The Schumacher and Hall model showed the best estimates. The inclusion of random effects related to stand (plot) and specie provided major gain in accuracy and bias. This study serve as a technical subsidy for concessionaires of public forests, adopting more reliable approaches to estimate the commercial volume of tropical species.

Controlling larvae of *Hypsipyla grandella* Zéller with biocide extracts / Control de larvas de *Hypsipyla grandella* Zéller con extractos biocidas

Héctor Guerra-Arévalo¹, Fernando Flores Fasanando², Agustín Cerna Mendoza², Ana Lucia Milagros Vásquez Vela³, Enrique Arévalo-Gardini³, Wilson Francisco Guerra Arévalo⁴, Carlos Abanto-Rodríguez¹

¹Instituto de Investigaciones de la Amazonia Peruana, San Martín, Peru; ²Universidad Nacional de San Martín-Tarapoto, San Martín, Peru; ³Instituto de Cultivos Tropicales, San Martín, Peru; ⁴Instituto de Investigaciones de la Amazonia Peruana, Ucayali, Peru (hguerra@iiap.org.pe; floresfer1996@gmail.com; agucerna@hotmail.com; analuciava.2012@gmail.com; enriquearevaloga@gmail.com; wguerra@iiap.org.pe; cabanto@iiap.org.pe)

En Perú existen una alta diversidad de especies biocidas nativas e introducidas con potencial insecticida para el control de plagas y enfermedades en sistemas productivos, siendo así, el objetivo de este trabajo fue evaluar el efecto de dosificaciones de extractos biocidas (*Ruta graveolens*-RG.; *Azadirachta indica*-AI; *Simarouba amara*-SA; *Tagetes erecta*-TE) en el control de larvas de *Hypsipyla grandella* Zéller. El experimento fue conducido mediante un Diseño Completamente al Azar (DCA), en esquema de parcelas subdivididas, con 5 tratamientos, 3 repeticiones y 10 discos foliares de *Swietenia macrophylla* por unidad experimental. Las parcelas fueron constituidas por 5 concentraciones (T1: 0%; T2: 10%; T3: 20%; T4: 30%; y T5: 40%) para cada extracto biocida y las sub-parcelas fueron constituidas por 4 tiempos de evaluación (6h, 12h, 18h y 24h) durante el día. Las variables evaluadas fueron: consumo del disco foliares-CDF (%), incremento de consumo foliar-ICF (%), mortalidad - ML (%) y actividad larval-AL (%). Los extractos que ocasionaron los mejores efectos significativos ($p \leq 0.05$) fueron RG y SA con 48.67% y 49.14% respectivamente de consumo foliar, 13.3% y 10% de larvas muertas y menor actividad larval. De este modo, las concentraciones menores fueron menos eficientes en el control de larvas. Se concluye que, los extractos de RG y SA, actuaron como insecticida en el control de larvas de *H. grandella* y la mayor mortalidad de larvas ocurrió en las altas concentraciones de la mayoría de los extractos.

Characteristics of integrated silvopasture systems utilizing *eucalyptus* in Paraguay / Caracterización de sistemas silvopastoriles con eucalipto en el Paraguay

María Alexandra Perrone González¹, Tobias Marcelo Ybañez Roman¹, María Laura Quevedo Fernandez¹, William Tomaz Folmann¹
¹Universidad Nacional de Asunción, Asunción, Paraguay; ¹Independiente, Asunción, Paraguay (alexandraperrone@gmail.com; tobias.ybanhez@gmail.com; marialauraquevedo@gmail.com; wfolmann@gmail.com)

Con el objetivo de caracterizar los sistemas silvopastoriles (SSP) con Eucalipto en el Paraguay, se realizó a 7 empresas la aplicación de un cuestionario contemplando aspectos de identificación, técnico, económicos y factores críticos. Además, se ha estimado el crecimiento de plantaciones bajo SSP mediante la instalación y medición de 134 parcelas permanentes en 3 empresas. La preparación de terreno generalmente es realizada con rastra pesa en todos los casos en combinaciones que varían con rastra liviana, subsolado, taipado y en 71% de los casos son realizadas con canalizaciones. Entre los principales meses de preparación de terreno se destacan enero a abril y julio a noviembre. La plantación es realizada de forma manual principalmente entre los meses de abril a mayo y octubre a noviembre. El control de hormiga es realizado con Fipronil. Todas las empresas realizan fertilización y 71% encañado, en cuanto que el control de malezas realizado en la línea de plantación es principalmente químico combinado con manual. Son realizadas de 4 a 10 podas hasta los 11 a 15 metros y 2 raleos selectivo o mixto con cosecha mecanizada y semimecanizada. El inventario evidenció que los mejores valores correspondieron al I144 con 32m³/ha/año, en cuanto a la estimación de la viabilidad económica la empresa 7 resultó con los indicadores mayormente viables con un VAN de 1.254US\$/ha, una TIR de 19%, una RB/C de 1,48 y un VPE de 165US\$/ha/año. Como principal factor crítico se destaca "Falta de referencia de precios de mercado de productos forestales".

Using greenhouses, substrates, and rooting agents to root cuttings of *Guazuma crinita* Martius / Uso de invernaderos, sustratos y aditivos enraizantes en el enraizamiento de miniestacas de *Guazuma crinita* Martius

Wilson Francisco Guerra Arevalo¹, Yanisse Basauri Torres², Carlos Abanto-Rodríguez¹, Guillermo Eduardo Gorbitz Dupuy³, Dennis del Castillo Torres¹, Hector Guerra Arevalo¹
¹Instituto de investigaciones de la Amazonia Peruana, Pucallpa, Peru; ²University of Eastern Finland, Kuopio, Finland; ³DIPTERYX SAC, Pucallpa, Peru

La falta de métodos adecuados para producir plantas de *G. crinita* en vivero, viene siendo la principal desventaja para garantizar el éxito de las plantaciones forestales, por tanto, técnicas de propagación deben ser utilizadas. Así, el objetivo en este trabajo fue determinar el mejor invernadero, sustrato y aditivo enraizante para la producción de plantas mediante el enraizamiento de miniestacas de *Guazuma crinita* M. Para ello fue utilizado material apical de 5.0 cm de longitud, 4.0 mm de diámetro y 2/3 de área foliar (20-30 cm²), provenientes de brotes sanos y vigorosos de plantas de bolaina. Después de 20 días, fue determinado entre 93.3 y 100% de enraizamiento, 100% de sobrevivencia y 100% de brotes en las miniestacas ubicadas en los invernaderos policarbonato y malla raschel® asociados con los sustratos y aditivos arena fina-sanix® y jiffy®-rapid root®. También fue determinado 18.9 raíces en la combinación de policarbonato-arena fina-rapid root®. En malla raschel® y policarbonato con jiffy®-rapid root® y rapid root®-sanix® fue determinado 14.5 y 12.6 raíces, respectivamente. En condiciones de policarbonato-arena fina fue constatado 46,1 cm y en jiffy® con malla raschel® y policarbonato las raíces presentaron 41.4 y 35.3 cm de longitud, respectivamente. Los invernaderos contruidos de policarbonato y de malla raschel® asociados con los sustratos arena fina y jiffy® más los aditivos enraizantes rapid root® y sanix® fueron las mejores condiciones para el enraizamiento de miniestacas de *Guazuma crinita* M.

Production and diameter classes of eucalyptus wood in two spatial arrangements within an integrated crop-livestock-forest system / Produção e sortimento de madeira de eucalipto em dois arranjos espaciais, em sistema agrossilvipastoril

María Tereza Angeletti Nunes¹, Silvio Nolasco de Oliveira Neto¹, Simone Silva¹, Amana de Magalhães Matos Obolari¹, Ricardo Fernandes Pena¹, Bruno Leão Said Schettini¹
¹Universidade Federal de Viçosa, Viçosa, Brasil (mtangeletti@hotmail.com; snolasco@ufv.br; simone.silva.ufv@gmail.com; amanaobolari@gmail.com; ricardopena.mg@gmail.com; blsschettini@gmail.com)

O aumento da produção em equilíbrio com a qualidade ambiental é um dos grandes desafios no cenário agrícola atual. A adoção de sistemas agrossilvipastorais é uma das alternativas potenciais para lidar com essa questão, logo, pesquisas sobre esse tema tornam-se fundamentais. Sendo assim, o objetivo desse trabalho é avaliar a possível influência da variação de espaçamento na produção e sortimento de madeira de eucalipto em um sistema agrossilvipastoril aos 7 anos de idade. O sistema em questão foi implantado em dezembro de 2007 com milho (*Zea mays*) e espécies forrageiras (*Brachiaria* sp.), combinados com dois arranjos de espécies arbóreas constituídos por eucalipto (*Eucalyptus grandis* x *E. urophylla* – clone 3336) em monocultivo e em plantio misto com Acácia (*Acacia mangium*), em espaçamento 12 x 2 m. Quatro anos após a implantação realizou-se o desbaste da acácia, condicionando o eucalipto aos espaçamentos 12 x 2 m e 12 x 4 m. Após realização de um inventário seguido da cubagem de três árvores representativas para cada classe de diâmetro, foram avaliados modelos para estimativas do volume e análise de sortimento. A variação do espaçamento não influenciou o crescimento em altura das árvores, mas favoreceu o crescimento em diâmetro. O espaçamento 12 x 2 m apresentou maior produção volumétrica por unidade de área apesar de o 12 x 4 m apresentar maiores diâmetros. O modelo de Dermaerschalk (1972) foi utilizado para análise de sortimento e indicou, para os dois espaçamentos, a destinação conjunta para serraria e lenha.

Assessing the state of the art in research and development of agroforestry systems in Colombia / Evaluación del estado del arte de la investigación y desarrollo en sistemas agroforestales en Colombia

Paula Alejandra Alba Martínez¹, María Fernanda Riaño Peláez¹
¹Forestal Ingeniería, Bogotá, Colombia (pau.alba.m@gmail.com; mfrianop@gmail.com)

El propósito de la investigación es identificar hasta donde se ha avanzado en las temáticas agroforestales del país por medio de la crítica y el uso de publicaciones de manera ordenada, precisa y analítica. El conocimiento del estado del arte, la seriedad en términos de publicación, justificación con datos de respaldo, aceptación, entre otros; y la rigurosidad de la investigación en los sistemas agroforestales no lo hacemos únicamente con la finalidad de hacer investigación. La importancia de esta revisión resulta en brindar una herramienta básica para avanzar en la práctica; abre las puertas a la inspiración y difusión de nuevas ideas, poniendo sobre la mesa las contradicciones en los conocimientos actuales. Este proyecto posibilita la evaluación de las prácticas vigentes y formulación de recomendaciones.

C1r: PRODUCTION FORESTRY - III

Temporal variation in species composition, diversity and regeneration status along altitudinal gradient and slope: the case of Chilimo Dryfromontane forest, Central Highlands of Ethiopia

Mehari A Tesfaye¹, Oliver Gardi², Tesfaye Bekele¹, Jurgen Blaser²

¹EEFRI, Addis Ababa, Ethiopia; ²HAFI-BERN, Bern, Switzerland (meharialebachew25@gmail.com; olivergardibfh.ch; tebean77@yahoo.com; juergen.blaser@bfh.ch)

The aim of this study was to investigate temporal variation in species composition, diversity and regeneration status of Chilimo dry fromontane forest, Central Highlands of Ethiopia. A total of 35, 20 m x 20 m permanent squared sampled plots were established. Two times inventory in 2012 and 2017 were conducted. Three subplots, 5 m x 5 m and 1 m² were laid out inside main plots for saplings, shrubs and seedlings data collection. However, biometric and stump data were collected in the main plots. Spp composition, diversity, IVI and regeneration data were analyzed using appropriate formulas. Data analysis and graphics were performed using R software. A total of 31 Spp of trees and shrubs, representing 25 families were recorded, 20 (64.52%) were trees and 11 (35.48 %) were shrubs. The 5 most dominant tree Spp were: *Juniperus procera*, *Podocarpus falcatus*, *Olea europea*, *Olinia rochetiana* and *Allophylus abyssinicus*. Growth and regeneration were significantly varied among the Spp, altitudinal gradient, forest patch and slope. The mean annual increment was ranged from 4.223 to 0.228 m³ ha⁻¹ yr⁻¹ and the basal area increment was ranged from 0.85 to 0.020 m² ha⁻¹ yr⁻¹. Ten Spp had fair, 5 poor and 14 no regeneration.

Chronological change and resilience of oak forests in areas occupied by autochthonous broadleaf forests of the Northwestern Iberian

Díaz-Maroto Ignacio J.¹

¹University of Santiago de Compostela, Lugo, Spain (ignacio.diazmaroto@usc.es)

The present ecosystems are the consequence of a mixture of anthropogenic involvement and vegetation dynamics in the last glacial-interglacial cycle, and their progression can be described by different methods (dendrochronology, isotope dating, palynology,...). In the Northwest Iberian there is confirmation of the presence of *Quercus* species since the Cretaceous and their diversification in the Tertiary. The decline of broadleaved forests began in prehistoric period and coincided with the increase of human activity and the establishment of crops and pasture. The expansion of agriculture and cattle breeding began between 4000-5000 years BC. Other causes were the expansion of the naval industry, extraction of wood and firewood for domestic/industrial use and forest fires. All the actions have caused a diminution in the area occupied by woodlands until the middle of the 19th century, without making any management action to allow the natural regeneration. The forests were either not managed at all or were subjected to inappropriate silviculture, such as pollarding and felling of the best trees. In the second half of the century there was an increase in the area occupied by broadleaved species. This growth was due to the abandonment of certain activities such as the use of firewood, agriculture and extensive pasture, and the reduction in the shipbuilding. Much of smallholder farms have recently disappeared, and have been replaced by protection forests, reforestation with fast growing species and unproductive land. As a result, in the last decades, there has been an important increase in the area occupied by natural forests.

Growth and sustainable management of *Cedrela fissilis* Vell. in the Atlantic Forest in Southern Brazil

Rafael Schmitz^{1,2}, Luciano Farinha Watzlawick³, Patricia Póvoa de Mattos⁴ ; Evaldo Muñoz Braz⁴ 

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Instituto Federal de Santa Catarina, Florianópolis, Brasil; ³Universidade Estadual do Centro-Oeste, Irapit, Brasil; ⁴Embrapa Florestas, Colombo, Brasil (schmitz.efd@hotmail.com; farinha@unicentro.br; patricia.mattos@embrapa.br; evaldo.braz@embrapa.br)

This study aimed to determine the annual diameter increment and the time passage between diameter classes of *Cedrela fissilis* Vell. in a remnant of the Deciduous forest in the Atlantic Forest biome, near the border between Brazil and Argentina. We also aimed to adjust diameter growth models according to age, to develop the basis of management and conservation plans. The assessment was in traversal tracks in 41.9 ha. All *C. fissilis* trees were sampled for dendrochronological analysis, using increment cores. We found 126 trees with diameter varying between 11 and 82 cm. The maximum mean increment was 0.62 cm yr⁻¹ (170 years old with DBH = 81.9 cm) and the minimum 0.29 cm yr⁻¹. Schumacher growth model presented better adjustment to the species growth pattern. It was observed that the optimum moment for interventions, considering the increment in diameter, occur, in the class of 25 cm of DBH, in cutting cycle of 21 years. This would allow the maintenance of the population under sustainable management system in the studied forest remnant.

Phytosociological structure on edaphic aspects of an Atlantic Forest fragment in Southern Brazil

Rafael Schmitz^{1,2}, Luciano Farinha Watzlawick³, Patricia Póvoa de Mattos⁴ ; Evaldo Muñoz Braz⁴ 

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Instituto Federal de Santa Catarina, Florianópolis, Brasil; ³Universidade Estadual do Centro-Oeste, Irapit, Brasil; ⁴Embrapa Florestas, Colombo, Brasil (schmitz.efd@hotmail.com; farinha@unicentro.br; patricia.mattos@embrapa.br; evaldo.braz@embrapa.br)

In this work an analysis of the floristic, phytosociological and soil characteristics aspects was carried out in a remnant of Deciduous Seasonal Forest in the extreme west region of Santa Catarina, Southern Brazil. We aimed to provide information for the understanding of biogeographic patterns and to add subsidies to the determination of priority areas for sustainable management in fragmented forest formations; The study area presented 41.9 ha of Deciduous Seasonal Forest in the Atlantic Forest Biome near the border between Brazil and Argentina. The surveys were carried out in 30 circular sample units with a variable area. All trees with circumference at 1.30 m from the soil \geq 10 cm were identified. Soil samples were collected for chemical and physical analysis. There were 94 tree species, distributed in 33 families. From those, 33 species are considered important for timber production (representing 14 families). The families Lauraceae, Meliaceae, Myrtaceae, Rutaceae and Papilionaceae represented 52.1% of the total species identified. The Shannon Diversity Index was 3.96 and three subareas were differentiated by soil and species frequency in the forest remnant. Organic matter, phosphorus, pH, calcium and clay basically defined the subareas. These results, in the exploratory context of the Atlantic Forest biome, indicate that the remnant still presents high diversity and also of timber tree species, therefore, the forest resources could be sustainably managed for use or conservation.

Growth and forage yield of tropical grasses in silvopastoral systems in Brazil

Valéria Santos¹, Roberto Almeida², Valdemir Laura², Fabiana Alves²

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo Piracicaba, SP, Brasil; ²Embrapa Gado de Corte, Campo Grande, Brasil (valeria.corvala@usp.br; roberto.giolo@embrapa.br; valdemir.laura@embrapa.br; fabiana.alves@embrapa.br)

The interest in the knowledge of the establishment of grasses under shading increased, aiming to provide subsidies for the successful implantation of silvopastoral systems. In this study, we analyzed tiller growth and forage production of *Brachiaria brizantha* (cultivars BRS-Paiaguás, BRS-Piatã and Marandu) and *Panicum maximum* (cultivars Massai and BRS-Tamani) in silvopastoral systems, at Campo Grande, MS, Brazil. The experiment was arranged in randomized complete block design, with strip plots and two replications. The plots were implanted in March 2016, among the *Eucalyptus urograndis* adult tree rows, with an average height of 28 m, in 22 x 2 m arrangement. The tiller count (tiller.m⁻²) was performed every 30 days at five equidistant points (A, B, C, D and E) between rows of eucalyptus and one point at full sun (F). To determine forage yield, three cuts (at 60 day intervals), at the height of 10 cm of soil residue, were performed. The points presented different solar transmittances: F = 100%, A = 85%, B = 87%, C = 77%, D = 25% and E = 15%. The shading points presented a reduction of 74% in tiller population compared to the sun. The biomass production of *Brachiaria* cultivars (1,466 kg.ha⁻¹ DM) was higher than that of *Panicum* cultivars (980 kg.ha⁻¹ DM), with no differences in the same species. In general, the grasses showed biomass reduction decreasing from point A to E (36 to 67%). The cultivars of *Brachiaria brizantha* are more suitable for implantation in silvopastoral systems with adult trees, as an establishment strategy in fall-winter (off-season).

Cattle productivity and carbon stock in silvopastoral systems with *Cratylia argentea* in the Colombian Dry Caribbean

Jose Edwin Mojica¹, Milton Rivera Rojas¹, Darwin Fabian Lombo¹, Juan Ricardo Zambrano¹, Jaime Andres Arias Rojas¹, Sonia Ospina Hernandez²

¹Agrosavia, Agustín Cosazzi Cesar, Colombia; ²Agrosavia, Palmira Valle del Cauca, Colombia (jmojica@agrosavia.co; mrivera@agrosavia.co; dlombo@agrosavia.co; jzambiano@agrosavia.co; jarias@agrosavia.co; sospina@agrosavia.co)

Dual-purpose cattle systems in department of Cesar are based on grazing of grasses. Milk yield total solids, fat and protein content for cows Zebu x Swiss brown at mid lactation stage were evaluated for silvopastoral systems with *Eucalyptus camaldulensis* and *Cratylia argentea* cv Veranera associated with *Brachiaria hybrid* Mulato II (T1), *Bothriochloa pertusa* (T2), *Brachiaria brizantha* cv. Toledo (T3) and *Megathyrus maximus* cv. Tanzania (T4). The initial establishing density of tree was 500 units per hectare with harvest projection for fencing post at six years and final plot density of 300 trees. A simple crossover design was used to analyse the variables. The saleable milk yield was higher ($P < 0,05$) in T1 (6,0 l/v/d) in comparison to the other associations. The treatment did not affect ($P > 0,05$) the milk quality variables. The total timber volume of *E. camaldulensis* was 56,2 when considering 17,1 m and 13,9 cm as total height and diameter at breast height, respectively. For carbon stock aerial biomass, the reserve was estimated as 11,65 tC/ha with fixation rates of 1,94 tC/ha/yr. The association Mulato II – *Cratylia* – *E. camaldulensis* was identified as a silvopastoral system that increase the saleable yield of milk compared with the predominant open grass (*Bothriochloa pertusa*) in the Colombian dry Caribbean region, that has shown a milk production of 3,9 l/v/d at the midterm of the lactating curve for dual-purpose cows. This system also represents an opportunity to contribute to mitigation from carbonfixation rates of 1,94 tC/ha/yr at the cattle production system and farm level.

Paspalum umbrosum: a possible option C4 grass for silvopastoral systems in subtropical zones.

Jaime Gonzalez-Talice¹, Jean Fedrigo², Adriana Bussoni¹, Gonzalo Amarillo¹, Javier Frigerio¹, Eugenia Cabrera¹, Pablo Speranza¹

¹Universidad de la Republica, Montevideo, Uruguay; ²Universidad de la Republica, Cerro Largo, Uruguay (jaimetalice@yahoo.com; jkfedrigo@gmail.com; abussoni@gmail.com; yayo.amarillo@hotmail.com; jfrigerio.smc@gmail.com; euyi.17@hotmail.com; pablosperanza@gmail.com)

Silvopastoral Systems is a sustainable production alternative. The success of these systems is based on the interaction among its components. The use of forage species tolerant to understory conditions is crucial to keep a positive balance. Instead, keeping within the structure of the C4 and C3 pastures components gives them more resilience, productivity and proliferation of weeds. In winter of 2018, a trial was established to determine the response of three species of *Paspalum* (*P. dilatatum*, *P. notatum* y *P. umbrosum*) in three understories conditions under an old plantation of *E. dunnii*; 16 plants of each were placed thrice in plots located on the stand's boundary; 10 m inside and outside it. The yield by plant was determined from the October 1 to the November 16, leaf water potential (Ψ_L) and leaf temperature. There was interaction between specie and condition. *P. dilatatum* produced more than the double of dry weight than *P. umbrosum* in the exterior condition, meanwhile the last is 20% superior in the internal. Simultaneously, *P. dilatatum* showed Ψ_L de -1.9 Mpa in the external, while *P. notatum* and *P. umbrosum* reached -2.9 y -3.1 Mpa, respectively. However, there were no differences between species in the internal, with a mean of -2 Mpa. Leaf temperature was superior to 30 °C outside the stand and less than 23 °C on the boundary and inside. *P. umbrosum* presents a good perspective to be used as a C4 forage for silvopastoral. Its tolerance may be associated to water relation at high radiation.

Morphometry of *Peltophorum dubium* in a silvopasture system in Southwestern Paraná, Brazil / Morfometria de *Peltophorum dubium* (*Canafistula*) em sistema silvipastoral no Sudoeste do Paraná

Marjorie Reis¹, Debora Kreczkiuski¹, Gabriel Michalichen¹, Eleandro José Brun¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil; ¹Universidade Tecnológica Federal do Paraná, Programa de Pós-graduação em Agroecossistemas, Dois Vizinhos, Brasil (marjorieeliza99@hotmail.com; debora-kreczkiuski@hotmail.com; gabrielmichalichen@gmail.com; eleandrobrun.utfpr@gmail.com)

Canafistula é nativa do Brasil, secundária inicial, de ocorrência em Floresta Estacional Decidual e Semidecidual, usada na arborização urbana e rural, pelo ótimo sombreamento. É estudada em sistemas silvipastoris, pela influência da sua área de copa na luminosidade do sub-bosque e a altura de copa no período ideal para introdução de animais no sistema. Avaliaram-se estas variáveis em um experimento de sistema silvipastoral no Sudoeste do Paraná-Brasil (Universidade Tecnológica Federal do Paraná, Dois Vizinhos), implantado em quatro linhas duplas (repetições), espaçadas 10 metros entre elas e 2 m x 1,5 m na linha/entrelinha de cada linha dupla. Em um inventário florestal, em junho/2018, quatro anos após o plantio, foram obtidas as variáveis deste estudo. Área de copa média foi de 4,1 m²/árvore (CV% 92,0), considerada suficiente para abrigar um animal de pequeno até de grande porte. A altura de copa teve valor médio de 2,4 m (CV% 23,6), ainda abaixo da altura adequada para inserção de animais de grande porte, que é de pelo menos 3 metros. Contudo, as árvores possuem 6,8 cm de DAP, variável apropriada ao emprego de animais no sistema, onde o mínimo estabelecido é 6 cm. E, para melhor eficiência, faz-se a adoção de cercas eletrificadas para impedir o contato direto dos animais com as árvores. A canafistula, aos 4 anos, já pode abrigar animais de pequeno porte, porém necessita aumentar sua altura de copa para evitar danos por animais de grande porte, caso sejam soltos sem uso de cerca elétrica circundando os renques.

C1s: BROADLEAVED AND MIXED-SPECIES FORESTS

Release cutting for cost-effective restoration of temperate broadleaved forests

Magnus Löf¹, Björn Norden², Per Kristian Rørstad³

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²The Norwegian Institute for Nature Research, Oslo, Norway; ³Norwegian University of Life Sciences, Oslo, Norway (magnus.lof@slu.se; bjorn.norden@nina.no; per.kristian.rorstad@nmbu.no)

Expansion of agriculture has during the last millennium led to a steep decline of temperate broadleaved forest in Europe. This biome is of outstanding importance for biodiversity, and presently covers only a small fraction of its former distribution area. However, the total area and standing volume of temperate deciduous trees are now increasing and mainly due to re-colonization of trees on abandoned (marginal) agricultural land. These relatively recent forests may or may not have a natural species composition, and management approaches may need to be applied to restore biodiversity and ecosystem services. For example, a semi-open canopy following release cuttings may favour flowering plants, pollination, the regeneration of less shade adapted shrubs and trees, and simultaneously increase the recreation value of such forests. The potential for economy and biodiversity however need to be evaluated. We used data from national forest inventories and from 26 field experiments in Norway and Sweden. We found that there are large areas potentially available for this kind of restoration, and that the biomass harvested following the release cutting many times may cover the costs for this operation. Moreover, there are probably many positive effects on biodiversity although additional studies are needed.

Cultivation Improvement of *Dalbergia odorifera* in Southern China

Xiaojin Liu¹, Daping Xu¹, Zhiyi Cui¹

¹Research Institute of Tropical Forestry, Chinese Academy of Forestry, Guangzhou, China (xjliu@caf.ac.cn; gzfsrd@163.com; cuizhiyi2012@126.com)

Dalbergia odorifera T. Chen (Leguminosae) is a semi-deciduous tree species endemic to Hainan province in Southern China. It is renowned for its fragrant heartwood which shows widely applications in furniture manufacturing, crafting and traditional Chinese medicines. Plus trees were selected through provenance & family trials, and the corresponding cultivation media was optimized for clone propagation of plus trees. The most suitable seedling age for plantation establishment was 2~3 years old at the height of 1~1.5 m. In this case, weed control and fertilization were very useful for early growth, stem shape and plantation development. As young trees usually have large amount of flowers and fruits when they are more than 2 years old, fertilizer or phytohormone application can alter the growth of reproductive and vegetative. Foliar application of gibberellins can promote the vegetative growth of 10-year old *D. odorifera* significantly, while phosphorus and potassium application was helpful for reproductive growth. Heartwood formation of young *D. odorifera* can be induced through many approaches under field condition, such as pruning, transplanting, fertilization, water and acid stresses, plant growth regulates etc. Ethylene and H₂O₂ played important roles in the process of heartwood formation, and may be used as an indicator for heartwood formation. Keep the plantation soil dry for a long period can induce heartwood formation, and stem injection of ethrel can also promote young trees to form fragrant heartwood. The rotation period can be reduced by 1/3, and corresponding economic values can be increased by 30% approximately through the above technique improvement.

Effects of organic and inorganic fertilizer in different methods on growth and nutrient responses of three economic tree species in South Korea

Byung Bae Park^{1,2}, Huong Thi Thuy Dao¹, Don Koo Lee^{1,3}, Jeong Min Seo¹, Aung Aung¹, Woo Bin Youn¹, Si Ho Han¹

¹Department of Environment and Forest Resources, Chungnam National University, Daejeon, Republic of Korea; ²Korean Society of Forest Science, Seoul, Republic of Korea; ³Park Chung Hee School of Policy and Saemaul, Gyeongsan, Republic of Korea (bbpark@cnu.ac.kr; thuyhuong.150495@gmail.com; leedk@snu.ac.kr; jmseo3@naver.com; aungaung1361986@gmail.com; dbsdnl95@naver.com; bupleurumhan@cnu.ac.kr)

Applications of fertilizer are needed to improve soil fertility and to increase crop yields in the short term. The effects of organic composts vs. inorganic fertilizer amounts on plant responses have been widely observed, but application of these fertilizers in different positions in soil has rarely tested in forestry sector. We used 767 g/pot vermicompost (VC) and 84 g/pot solid compound fertilizer (SCF) with three economic tree species: *Betula platyphylla*, *Chamaecyparis obtusa*, and *Larix kaempferi* in our study. Seven fertilization methods were applied in greenhouse at Chungnam National University, Republic of Korea as follows: no fertilization as control, VC surface fertilization (VCs), VC circular fertilization (VCc), mixed VC with soil (VCm), bottom application VC (VCb), surface application of SCF at 4-spots (SCFs), and bottom application of SCF (SCFb) with 9 replications. Results showed significant effects of treatments on each species. Most of results showed the highest growth of *B. platyphylla*, *C. obtusa* in the SCFs treatment. RCD and height growth of *L. kaempferi* were affected by both VCc and SCFs. VC treatments can improve belowground biomass for all three species. Meanwhile, aboveground biomass was shown the highest with treatment of SCFs. Quality index followed the same trend with RCD and height growth. Generally, VCc in *L. kaempferi* and SCFs in the other species with the longest vectors identified the most responsive treatments. Our results suggested that SCFs is the best for those three economic species and VCc could be good for *L. kaempferi*.

Ecological trends of evergreen and deciduous oaks of India

Prachi Gupta¹, Sangeeta Gupta¹

¹Forest Research Institute, Dehradun, India (prachi.gpta@gmail.com; sangeeta.fri@gmail.com)

The economically and ecologically important genus *Quercus* (oaks) dominates in the Northern Hemisphere, from tropical and temperate forests to dry thorn scrub and semi-desert. In India, different species of evergreen and deciduous oaks dominate the temperate broad-leaf forests in the Eastern and Western Himalayas. The Eastern Himalayas have high temperature and high rainfall as compared to Western Himalayas. The local inhabitants of the hills rely on oaks for direct provisioning services. Oak forests play important ecological roles such as mutualistic interactions with fungi and epiphytes, cycling of nutrients, sustenance of wildlife and maintaining biodiversity. However, huge dependency of humans on oaks and changes in climatic conditions have adversely affected oak forests. This has resulted in replacement of oaks by pines which can grow in nutrient-poor soils. Considering the economic and ecological significance of oaks, the present study is an attempt to understand the ecological trends of Indian oaks based on wood microstructure. The wood anatomical characteristics of sixteen species of Indian *Quercus* were examined in accordance with terminology given by the International Association of Wood Anatomists. The study revealed that the deciduous oaks are ring-porous and evergreen oaks are diffuse porous. Interestingly, based on cluster analysis of quantitative wood anatomical characters, our study revealed that the microstructure of Indian oaks is largely governed by different environmental conditions of Eastern and Western Himalayas. Ecological adaptability of different species to mesic conditions was well reflected by values of mesomorphy and vulnerability indices.

Wood quality and assortment determination through non-destructive acoustic analysis: a case study in chestnut coppices in Aspromonte National Park (Southern Italy)

Diego Russo¹, Pasquale Antonio Marziliano¹, Giorgio Macri¹, Giuseppe Zimbalatti¹, Fabio Lombardi¹

¹Mediterranean University of Reggio Calabria, Reggio Calabria, Italy (diego.russo@unirc.it; pasquale.marziliano@unirc.it; giorgio.macri@unirc.it; gzimbalatti@unirc.it; fabio.lombardi@unirc.it)

Chestnut is one of the most important species for timber production in Italy, even if the related woody supply chain is not able to enhance enough the market value of the woody assortments. The internal production is negatively conditioned by the market demands, mainly due to the absence of enough information on the wood quality. The acoustic technologies applied to predict the mechanical properties of timber are well-established practices in forest research. In this context, experimental trials have been applied in the "Aspromonte National Park" (Southern Italy) to identify and verify the wood quality in the early stages of chestnut growth and among their cutting cycle of 18-20 years. Specifically, in a chestnut coppices characterized by an homogeneous stand density and a good site index, we aimed to evaluate the biological response to the applied silviculture, analysing the dendrometric parameters and estimating the wood quality in the first years of growth and at different ages, taking also into account the wood assortments and amounts available. The study was focused on three experimental areas characterized by different slopes. The results showed similarities on the wood quality, even if significant differences among the average annual increment parameters for hectare were observed. This study then provided relevant results useful to support the wood supply chain of the chestnut through information on the quality of woody products.

Management of African economic trees for new research, the review of *Entandrophragma* genus (Meliaceae)

Emmanuel Kasongo Yakusu^{1,2,3}, Nils Bourland², Dominique Louppe⁴, Wannes Hubau², Jan Van Den Bulcke¹, Joris Van Acker⁴, Hans Beeckman²

¹Ghent University, Ghent, Belgium; ²Royal Museum of Central Africa, Tervuren, Belgium; ³University of Kisangani Kisangani Congo, Republic of the Democratic; ⁴Centre de coopération Internationale en Recherche Agronomique pour le Développement, Montpellier (emmanuel.kasongoyakusu@ugent.be; nils.bourland@aigx.be; dominique.louppe@cirad.fr; wannes.hubau@africamuseum.be; jan.vandenbulcke@ugent.be; joris.vanacker@ugent.be; hans.beeckman@africamuseum.be)

Entandrophragma genus includes exclusively African species (10 to 12), five of which are on the IUCN Red List. Characterized by a taxonomic evolution that has resulted in an important synonymy of species names (36-37) and insufficient ecological knowledge, it is the richest in valuable species exploited as timber in Africa. This important exploitation is likely to compromise their durability in the absence of sustainable management. Our study is mainly based on scientific data (e.g., publications), economic data (production and export statistics) and legal data (laws and regulations); on management plans and inventory reports. The heavy industrial exploitation as artisanal does not always proceed in the respect of a validated management plan, nor of the duration of the rotations which would make it possible to reach a rate of reconstitution likely to perpetuate the resource which these species represent. Their sustainable management requires the development and respect of management measures to make their exploitation sustainable in the long term. This exploitation must be based on an adequate management of natural stands and on reforestation as well as on conservation measures. The research to be developed must focus on their growth rate (eg, in the face of climate change), the analysis of stable rings and isotopes, the evaluation of their stocks (production, biomass, carbon), their spatial distribution and molecular phylogeny, the improvement of their natural regeneration, their reproduction, phenology and anatomy, as well as the reinforcement of other relevant lines of research to guarantee the durability of these forest species.

Functional trait plasticity as an empirical basis to improve our understanding about the productivity and functioning of mixed-species stands

Hernán Serrano-León¹, David Forrester², Michael Scherer-Lorenzen³, Charles Nock⁴

¹European Forest Institute, Cestas, France; ²Swiss Federal Institute for Forest, Snow and Landscape Research, Birmensdorf, Switzerland; ³University of Freiburg, Freiburg, Germany; ⁴University of Alberta, Edmonton, Canada (hernan.serrano@efi.int; david.forrester@wsl.ch; michael.scherer@biologie.uni-freiburg.de; charles.nock@gmail.com)

In order to promote mixed forests, forest managers need to be provided with empirical evidence of how tree species mixing improves forest productivity and resilience. However, there is still a limited understanding about how intra-specific variability influences tree species interactions and their role in regulating forest ecosystems. Interactions between different species may cause plastic adjustments in the phenotype expression of functional traits related to tree resource-use efficiency, which in turn alters ecosystem productivity. We examined the effects of tree species mixtures on leaf trait plasticity in a case study at the BIOTREE diversity experiment. We analyzed the intra-specific variability of leaf functional traits (specific leaf area, nitrogen content) in monocultures and mixed stands of three important species in Central Europe (*Fagus sylvatica*, *Quercus petraea*, *Picea abies*). Results showed a significant effect of the species mixture on the trait distributions, indicating that intra-specific variability of key leaf traits was already influenced at young development stages by inter-specific interactions in mixed stands. Further research findings on the links between leaf trait plasticity and tree species interactions will provide a basis for the parameterization of process-based forest growth models, improving the prediction of growth dynamics and functioning in mixed forests. This will help to identify the most efficient tree mixtures for sustainable forest management in order to increase the forest managers' acceptance for mixed forests.

The Classification of forest types for ecological forest management in the deciduous and mixed forests of South Korea

Young Keun Lee¹, Sang Tae Lee¹, Sang Hoon Chung¹, Joo Han Sung¹, Yong Sik Hong², Young Han You²

¹Forest Technology and Management Research Center, National Institute of Forest Science, Pocheon-si, Republic of Korea; ²Department of Biology, Kongju National University, Gongju, Republic of Korea (yghanna@korea.kr; ist9953@korea.kr; chsh80@korea.kr; jhs033@korea.kr; hongjin@smail.kongju.ac.kr; youeco21@kongju.ac.kr)

South Korea is classed as having a temperate climate with four distinct seasons and belongs to the vegetative zone of the temperate deciduous forests. According to the forestry statistics in 2016, the area of deciduous forest is 2,029,000 ha (33.4%) and the area of natural mixed forests is 1,706,000 ha (28.1%). In order to classify the forest types with similar ecological attributes, the NFI (National Forest Inventory) vegetative data for 2,814 sampling points were used. The forest types were grouped by TWINSpan (Two-way Indicator Species Analysis) according to the importance value of tree species in the upper layer. The correlation between forest types and environmental factors was analyzed by CCA (Canonical Correspondence Analysis). The sampling points were classified into ten forest types such as *Quercus mongolica* - *Tilia amurensis* forest, *Q. variabilis* - *Q. serrata* forest, *Pinus densiflora* - *Q. variabilis* forest, etc. The species composition, stand structure and growth characteristic of each forest type are described to establish the foundation of ecological forest management. The correlation between

forest types and environmental factors showed that the elevation, slope, and annual average temperature were identified as the main influencing factors. Since the main forest types were classified according to the distribution ratio of the oak, the quality grade of standing trees was evaluated by considering the utilization of wood. The evaluation factors of the grade were the bending of stem, branch, stem damage and other defects. The results were as follows: *Q. acutissima* > *Q. variabilis* > *Q. serrata* > *Q. aliena* > *Q. mongolica* > *Q. dentata*.

C1t: PLANTATION FORESTS

Early growth of planted Norway spruce and Scots pine after site preparation in Sweden

Oscar Nilsson¹, Karin Hjelm² ; Urban Nilsson¹

¹Swedish University of Agricultural Sciences - SLU, Southern Swedish Forest Research Centre, Alnarp, Sweden; ²Forestry Research Institute of Sweden, Ekebo, Sweden (oscar.nilsson@slu.se; karin.hjelm@skogforsk.se; urban.nilsson@slu.se)

Norway spruce (*Picea abies* (L.) H. Karst) and Scots pine (*Pinus sylvestris* L.) have different site preferences, but silvicultural recommendations for their regeneration at planting (including site preparation) are often the same. Thus, there is a clear need for greater understanding of species-specific interactions between site preparation and site properties. To meet this need, the species' growth and survival have been monitored at both fertile and poor sites in Northern and Southern Sweden. At each of these sites, effects of three types of site preparation — removed humus (RH), deep soil cultivation (DSC) and control (C, no site preparation) — were compared. Results show that Scots pine grew more rapidly initially than Norway spruce, and DSC site preparation promoted growth of both species. However, on poor sites there was a delay in growth responses. In addition, removal of organic material in the RH treatment caused a sustained growth check of Norway spruce, but not for Scots pine. This study confirms that it is beneficial to use site preparation as it increases survival of both species and may increase growth. However, site preparation methods that reduce the amount of organic material in the planting spots should be avoided for Norway spruce.

Tree planting spatial arrangements and eucalypt clones interaction in southern Brazil: effect on growth

Filipe V. P. Cacau¹, Geraldo G. Reis¹ ; Maria G. F. Reis¹, Thales G. V. Martins¹, Jônio P. Caliman¹, Catia C. Silva¹

¹Universidade Federal de Viçosa, Departamento de Engenharia Florestal, Viçosa, Brasil (filipecacau@gmail.com; greisufv@gmail.com; mgfreis@ufv.br; thales.eng.florestal@gmail.com; jpcaliman@gmail.com; catiasilvaforestal@gmail.com)

Eucalypt stands in Brazil are, usually, highly productive and have been exploited at short rotations (≤ 7 years) as a result of the genotype selection for specific sites and the use of appropriate silvicultural techniques. The present study aimed at the selection of genotypes and spatial arrangements to obtain high productivity in plantations in the Brazilian Southern region. Hybrid clones of *Eucalyptus urophylla* x *E. grandis* (A, B) and *E. urophylla* x *E. globulus* (C, D) were planted in the arrangements 3.75 x 2.40 m; 6.0 x 1.5 m and 4.0 x 3.0 m. The stand variables were estimated by Gompertz model. The total height (Ht) and diameter (dbh) were measured annually up to 88 months. The Ht and dbh were the highest ($p \leq 0.05$) for clone B in the arrangement 4.00 x 3.00 m. The reduction of the distance between trees in the planting line (6.00 x 1.50 m), leading to increasing rectangularity, resulted in smaller dbh in relation to the 3.75 x 2.40 m, both with 9 m² per plant and, the individual volume was the largest in the 4.0 x 3.0 m, for all clones. Clone B showed the highest yield in the arrangement 3.75 x 2.40 m and, presented the largest annual mean increase at tree harvesting age. The regulatory rotation at 5, 6 and 7 years should be adopted. The results allow inferring that the tree planting arrangements with greater rectangularity should be avoided because they result in lower productivity and diameter growth. Wider spacings are more adequate to produce logs of larger diameter.

Identification of planting habitats and wood demand regions for *Micropholis venulosa* (Mart. & E. ex Miq.) and *Simarouba amara* Aubl. in Minas Gerais, Brazil

Thales G. V. Martins¹, Geraldo G. Reis¹ ; Maria G. F. Reis¹, Jônio P. Caliman¹, Filipe V. P. Cacau¹, Heitor E. F. C. M. Filpi¹

¹Universidade Federal de Viçosa, Departamento de Engenharia Florestal, Viçosa, Brasil; ¹Universidade Federal de Viçosa, Departamento de Engenharia Florestal, Viçosa, Brasil (thales.eng.florestal@gmail.com; greisufv@gmail.com, mgfreis@ufv.br; jpcaliman@gmail.com; filipecacau@gmail.com; heitor.filpi@gmail.com)

The native wood species plantations are an alternative for supplying high quality wood demand of the Brazilian industries. Planting habitats and wood demand regions were identified for the state of Minas Gerais (MG), for *M. venulosa* and *S. amara*, largely used in the timber industry of that state (95,152 and 22,587 m³ of wood consumed in the last 11 years, respectively). The MaxEnt model was used for the environmental zoning, based on matching mainly climatic variables constraints and requirements of the natural occurrence sites with the planting sites. The wood demanding zoning was performed with the clustering algorithm (ArcGIS), using the Brazilian consumption records by species (DOF System - Document of Origin of the Wood). The total area suitable for planting was 208,820 km² for *M. venulosa* and 158,254 km² for *S. amara*. The models showed high precision (AUC ≥ 0.80). The variables temperature seasonality and warmer month maximum temperature were the most important ones to match species origin to planting sites. Three wood demand zones for these species were identified (R² ≥ 0.90) for Minas Gerais. The high demand zones included the microregions of Montes Claros (North MG) for *M. venulosa*, and Belo Horizonte (Centre MG), Juiz de Fora and Ubá (East MG) for *S. amara*. By planting these species in suitable habitats, near the industries based on indigenous wood species, implies in greater conservation of the species in their natural occurrence region and strengthening of the economy in the consumer centers (Supported by CAPES, CNPq, FAPEMIG and UFV).

Management units for pine in lands of the western Santa Catarina State, Brazil: development and application of methodology

João Bosco Vasconcellos Gomes¹, Itamar Antonio Bognola¹, Lorena Stolle², Paulo Eduardo Telles dos Santos¹, Shizuo Maeda¹, Lorenzo Teixeira de Melo Silva³, Antonio Francisco Jurado Bellote¹, Guilherme de Castro Andrade¹

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do, Chapadão do Sul, Brasil; ³F&W Forestry, Porto Alegre, Brasil (joao.bv.gomes@embrapa.br; itamar.bognola@embrapa.br; lorenastolle@yahoo.com.br; paulo.telles@embrapa.br; shizuo.maeda@embrapa.br; lorenzotms@hotmail.com; antonio.bellote@embrapa.br; guilherme.andrade@embrapa.br)

This study was carried out in order to develop and implement (in pilot area of 457.7 ha) an enhanced methodology for establishing management units for pine tree plantations, in lands of the west of Santa Catarina associated to the effusive rock spill of the Serra Geral Formation. The regional pine production system disregards the hypothesis of response to the nutrient deficiency improvement (DN). The methodology preferably requires semi-detailed soil mapping

and secondary local climate information. Each polygon of the soil map was associated with a database, which allowed the definition of the land limitation degrees (DN, water deficiency, oxygen deficiency, erosion susceptibility and management impediments) for the pine cultivation. The management units classes of pine cultivation were defined by a set of criteria, considering the different land limitation degrees achieved for each land polygon (from soil map). The most important land limitation degree for pine growth in the pilot area was the management impediments, due to limitations of the soil depth, terrain slope and rocky fragments. The following quantitative data from the management units were obtained in the pilot area: 111.6 ha of Lowly suitable (24.8% of the area); 282.0 ha Upper marginal (62.6% of the area); and 57.2 ha Lower marginal (12.7% of the area).

Biodegradable containers in the production of *Pinus maximinoi* seedlings.

Leticia Miranda¹, Fabricio Antônio Biernaski¹, James Stahl¹

¹Klabin S/A, Telêmaco Borba, Brasil (lemiranda@klabin.com.br; fbiernaski@klabin.com.br; jstahl@klabin.com.br)

Pinus maximinoi is an important and promising species in Brazilian forestry. This species has a sensitivity to physical impediments during its root system formation, requiring adjustments in its silviculture management. Biodegradable containers, specifically the paperpot system have been an alternative for seedlings production. However, the paper degradation range may affect the survival of the seedlings after planting, causing impediments to roots expansion. Therefore, the objective of this work was to evaluate five commercial papers with different degradation times in the production of *P. maximinoi* seedlings. Five types of paperpots were tested, three of them of Ellepot® brand, with durability times: (T1) + 12 months, (T2) 8-12 months, (T3) 4-6 months, one of Plantpaper® (T4) brand, and one of BCC® brand (T5), both without specification of durability. At 135 and 210 days of nursery, the quality of the seedlings and the level of the papers degradation was evaluated, using a percentages scale with four levels. At 210 days, the seedlings were planted in the field for future evaluations. The degradation levels were statistically different at 1% of significance in both evaluation periods. The T5 reached 100% degradation at 210 days, while the T4 paper showed no signs of degradation at the same period. T3 was the most promising paper, with an average of 54 and 75% degradation at 135 and 210 days respectively. The other two papers had 54% of degradation average at the end of the seedling production cycle.

The determinants of optimal leaf area in eucalypt plantations

Rose Brinkhoff¹, Mark Hovenden¹, Mark Hunt¹

¹School of Natural Sciences and ARC Training Centre for Forest Value, University of Tasmania, Sandy Bay, Australia (roseb2@utas.edu.au, mark.hovenden@utas.edu.au, mark.hunt@utas.edu.au)

It is well understood that stand leaf area index (LAI) is extremely responsive to fertiliser application in Australian temperate *Eucalyptus* plantations. At energy-limited but nonwater-limited sites a high LAI is beneficial for maximising productivity and there is limited evidence to suggest that some of the leaf area may operate below the light compensation point and act primarily as a nutrient store. Conversely, on seasonally water limited sites, a high LAI has the potential for negative consequences for rotation-length plantation growth. The dynamics of these relationships, particularly the role that fertiliser application plays, are not yet well understood, and thus constitute an impediment to developing accurate, informed management prescriptions. In our study a range of fertiliser experiments in *Eucalyptus nitens* and *E. globulus* plantations were established along a temperature and precipitation gradient in southern Australia. We explored the relationship between nitrogen and phosphorus fertiliser treatments and stand LAI, the vertical distribution of leaf area and the longevity of N and P stored in leaves. We also explored differences in photosynthesis and respiration as a function of light, temperature and nutritional status. The outcomes of this research will include robust assessments of how the costs and benefits to plantation production of an increase in LAI are related to climatic conditions. This will facilitate the development of fertiliser prescriptions better tailored to local climatic conditions and assist with our understanding of how plantation nutrition may explain part of the inter-rotation productivity decline that has been observed at some water-limited sites across the estate.

Shade area and microclimate under the canopy of Cerrado trees in silvopasture systems / Área de sombra e microclima sob a copa de árvores do Cerrado para sistemas silvipastoris

Diego Fonseca¹, Silvia Pereira², Valdemir Laura^{1,2,3}, Ariadne Mastelaro⁴, Fabiana Alves^{3,4}, Roberto Almeida³

¹Universidade Federal de Mato Grosso do Sul, Campo Grande, Brasil; ²Universidade Anhangüera, Campo Grande, Brasil; ³Embrapa Gado de Corte, Campo Grande, Brasil; ⁴Universidade Federal do Paraná, Curitiba, Brasil (diegorezende1@gmail.com; silviaraha@gmail.com; valdemir.laura@embrapa.br; arimpvet@gmail.com; fabiana.alves@embrapa.br; roberto.giolo@embrapa.br)

Em dezembro de 2015 implantamos um arboreto com 13 espécies arbóreas nativas do Cerrado (24 mudas de cada espécie) em uma área de aproximadamente 1,0 ha, na Embrapa Gado de Corte, Campo Grande – MS. Medimos a temperatura, a umidade relativa do ar e a radiação solar sob a copa de quatro indivíduos de oito espécies e a pleno sol, entre maio e junho de 2018. A partir dos dados coletados, calculamos os Índices de Temperatura e Umidade (ITU) e determinamos a porcentagem de bloqueio de radiação solar sob a copa das árvores. Adicionalmente determinamos a área projetada de copa às 12h00 em junho de 2018 com base das dimensões das árvores e o ângulo de elevação do sol. Comparamos as dimensões das árvores e área de sombra entre as espécies, e o índice de temperatura e umidade (ITU) entre espécies e ao longo das horas do dia, através da Análise da Variância (ANOVA) e teste Tukey a 5%. *Pterogyne nitens* e *Peltophorum dubium*, apresentaram maiores dimensões e maiores áreas de sombra projetada, dois anos e meio após plantio. Não houve diferenças ($p > 0,05$) entre as espécies e a pleno sol para ITU; diferindo apenas ao longo do dia ($p < 0,05$), com menores valores ao final da tarde. Em relação a porcentagem de bloqueio de radiação, *P. nitens* está entre as espécies com maior bloqueio enquanto *P. dubium* de menor bloqueio de radiação. Com base nessas características *P. dubium* e *P. nitens* são as espécies de maior potencial para uso em sistemas silvipastoris.

Survival of *Eucalyptus* spp. clones in different spacing arrangements in the semi-arid region of Pernambuco, Brazil / Sobrevivência de clones de *Eucalyptus* spp. em diferentes espaçamentos com condições climáticas extremas no semiárido pernambucano

Rinaldo Luiz Caraciolo Ferreira¹, José Antônio Aleixo da Silva¹, José Wesley Lima Silva¹, Marília Regina Costa Castro²

¹Universidade Federal Rural de Pernambuco, Recife, Brasil; ²Instituto de Educação, Ciência e Tecnologia de Pernambuco, Recife, Brasil (rinaldo.ferreira@ufrpe.br; jaaleixo@uol.com.br; wesleylima_silva@hotmail.com; mariliarcastro@uol.com)

O Polo Gesso do Araripe, situado no semiárido pernambucano, é uma região bastante afetada pelas mudanças climáticas e grande consumidor da vegetação nativa com fins energéticos para indústria do gesso. Florestas de eucaliptos foram implantadas na região para atender a alta demanda energética da indústria gessosa, responsáveis por 95% da produção nacional. Desta forma, objetivou-se com esta pesquisa avaliar a sobrevivência de clones de *Eucalyptus* spp. em diferentes espaçamentos em condições de seca extrema. Os dados foram provenientes de um experimento inteiramente aleatório com três clones de *Eucalyptus*

em cinco espaçamentos na idade de 8 anos. O experimento foi desenvolvido na Estação Experimental do Instituto Agronômico de Pernambuco (IPA) em Araripina que apresenta uma temperatura média anual de 25 °C e precipitação média anual é de aproximadamente 750 mm, com concentração de 70% entre os meses de dezembro a março. Durante o período experimental a precipitação média anual foi 529.4 mm, concentrada nos meses de janeiro a abril, o que configura uma mudança temporal severa e faz dessa década uma das mais secas da história. A taxa de sobrevivência média do experimento foi de 90%, constatando-se diferenças significativas entre os clones, sendo o C11 no espaçamento 3 m x 3 m o que apresentou maior taxa de sobrevivência 98.40%. Pelo teste de Scott-Knott ($p < 0.05$) os tratamentos foram divididos em três grupos sendo o espaçamento 2 m x 1 m o que apresentou as menores taxas de sobrevivência. Mesmo em condições climáticas severas os clones de eucaliptos conseguem se desenvolver e apresentam baixo índice de mortalidade.

C11: MIXED-SPECIES FORESTS AND PLANTATIONS: KNOWLEDGE GAPS AND RESEARCH PRIORITIES

Mixed settlements of *eucalyptus* and acacia in transition area between Brazilian Savana (Cerrado) and Amazon Forest biomes

Diego Camargo¹, Maurel Behling², Jean-Pierre Daniel Bouillet³, Ivanka Rosada de Oliveira⁴, José Leonardo de Moraes Gonçalves⁴, Murilo Campos Pereira¹
¹Universidade Federal do Mato Grosso, Sinop, Brasil; ²Embrapa Agrossilvopastoral, Sinop, Brasil; ³CIRAD, Piracicaba, Brasil; ⁴Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (camargo.die@gmail.com; maurel.behling@embrapa.br; jean-pierre.bouillet@cirad.fr; ivanka.ivi@gmail.com; jlmgonca@usp.br; murilo_camposcol@hotmail.com)

The adoption of mixed planting with eucalyptus and legume tree specie - able to fix nitrogen, is a sustainable alternative to provide nitrogen to the *eucalyptus*. Our objective was to evaluate if the mixed planting of eucalyptus and acacia yields basal area equivalent to homogeneous eucalyptus planting. The treatments evaluated were: *Eucalyptus* (E, clone I144 - *E. urophylla* x *E. grandis*) with and without nitrogen fertilization (0A: 100E + N e 0A: 100E-N), acacia (A, *Acacia mangium*) (100A: 0E), acacia and eucalypt ratio 1:2 (33A: 67E) and 1:1 (50A: 50E). Randomized blocks design (RBD) was used, with four replicates and plot with 1,296 m² (12 x 12 trees) and 576 m² of useful area (double surround, with spacing 3 x 3 m). The trees were measured at three years of age by circumference at breast height (CBH) and basal area (BA, m² ha⁻¹). BA was different among treatments ($p < 0.000$), the higher was in homogeneous acacia planting (14.5 m² ha⁻¹). The mixed planting was no different from the eucalyptus homogeneous fertilized with N ($p > 0.35$, in both acacia represented 60% and 84% of the BA for 1:2 and 1:1 ratio between eucalyptus and acacia. The interspecific competition was positive for acacia and negative for eucalyptus.

Developing founding forest species in a disturbed area within the city of Rio Branco, Acre, Brazil, after three decades of age / Desenvolvimento de essências florestais plantadas em uma área alterada na cidade de Rio Branco-Acre após três décadas de idade

Harley Araújo da Silva¹, Veronica Telma da Rocha Passos¹, Thiago Augusto da Cunha²
¹Universidade Federal do Acre, Parque Zoológico, Rio Branco, Brasil; ²Universidade Federal do Acre, Centro de Ciências Biológicas e da Natureza, Rio Branco, Brasil (harleyaraujo@ufac.br; veronica.passos@ufac.br; etsfor@yahoo.com)

Poucas são as experiências de plantios florestais na Amazônia com idade avançada e que reúnam grande número de espécies arbóreas, como é o caso do Experimento Arboreto, localizado no Parque Zoológico da Universidade Federal do Acre. Nesse caso, em duas áreas de 1,38 ha cada, foram plantados indivíduos de 138 espécies diferentes no espaçamento de 2,5 m x 2,5 m, sendo a roçagem e coroamento os únicos tratamentos silviculturais aplicados. Buscando saber o estado atual das espécies, trinta e cinco anos após o plantio foi realizado o censo dos indivíduos plantados, bem como mensuração de variáveis dendrométricas como o diâmetro à altura do peito (DAP) e a altura total (Ht). Das espécies plantadas, 59 apresentam indivíduos vivos merecendo destaque a palmeira *Syagrus sancona* e *Handroanthus serratifolius* por apresentarem sobrevivência acima de 75%. Espécies como *Annona montana*, *Aspidosperma vargasii*, *Ceiba samauma*, *Couepia bracteosa*, *Dalbergia inundata*, *Hymenaea courbaril*, *Hymenaea parvifolia* e *Simira rubescens* apresentaram taxas regulares de sobrevivência, variando entre 50% e 69%. Essências comumente usadas pelo mercado madeireiro como *Aspidosperma vargasii*, *Cedrela odorata*, *Dipteryx odorata*, *Hymenaea courbaril* e *Hymenaea parvifolia* se destacaram perante as demais por apresentarem médias de DAP com valores variando entre 26 cm e 31 cm, e Ht entre 17 m e 19 m. A importância desse trabalho reside na necessidade de, passados 35 anos do plantio, se determinar quais espécies melhor se adaptaram em uma área onde foram aplicados os tratamentos silviculturais mais básicos ao pleno desenvolvimento das mudas.

Integrating the intra- and inter-species-groups competition effects into an individual diameter at breast height growth model for mixed-species forests in Mexico

Geronimo Quiñonez Barraza¹, Dehai Zhao², Héctor Manuel de los Santos Posadas³, José Javier Corral Rivas⁴
¹Campo Experimental Valle del Guadiana, Instituto Nacional de Investigaciones Forestales Agrícolas y Pecuarias, Durango, DGO, Mexico; ²Warnell School of Forestry and Natural Resources, University of Georgia, Athens, GA, USA; ³Postgrado en Ciencias Forestales (quinonez.geronimo@inifap.gob.mx, dzhao@warnell.uga.edu, hmsantos@colpos.mx, jcorral@ujed.mx)

The forest management-planning in Northwest of Durango, Mexico involve mixed-species stands and the selection method is normally applied for uneven-aged stands in such forests. An individual distance-dependent model without age was used to evaluate the diameter at breast height (dbh) growth and neighborhood effects for four species groups in mixed-species stands. The dataset considers 44 stem-mapped re-measurement plots and twenty-two species were grouped as: *Pinus* (seven species), other conifers (three species), other broadleaves (four species) and *Quercus* (eight species). Four methods were used to select neighboring trees, 12 distance-dependent competition indices were computed, and the con-group and hetero-group neighborhood effect were carried out for species groups. The dbh growth model was fitted separately under the assumptions of no-competition effect (without competition term), equivalent and nonequivalent neighborhood effects. The dbh growth models under the assumption of nonequivalent neighborhood effect outperformed the models under the assumptions of equivalent neighborhood effect and without competition effect. The intra-species-group competition negatively affect the diameter growth for all species groups, except for the *Quercus* group. In all cases, the fitted age-independent dbh growth models showed a good of fit to the stem-mapped plots data with adjusted coefficient of determination values larger than 0.97 and root mean square error values smaller than 1.33 cm. The growth models can be used to predict the dbh growth for the species groups in mixed-species forests.

Growth of native Cerrado tree species with potential for use in foresting pasture / Crescimento de árvores nativas de Cerrado com potencial de uso na arborização de pastagens

Diego Fonseca¹, Silvia Pereira¹, Valdemir Laura^{1,2,3}, Camila Miranda¹, Ariadne Mastelaro⁴, Fabiana Alves^{3,4}, Roberto Almeida³

¹Universidade Federal de Mato Grosso do Sul, Campo Grande, Brasil; ²Universidade Anhanguera, Campo Grande, Brasil; ³Embrapa Gado de Corte, Campo Grande, Brasil; ⁴Universidade Federal do Paraná, Curitiba, Brasil (diegozendes1@gmail.com; silviaraha@gmail.com; valdemir.laura@embrapa.br; camilaoliveiramiranda20@gmail.com; aripvet@gmail.com; fabiana.alves@embrapa.br; roberto.giolo@embrapa.br)

Em sua maioria, as espécies arbóreas utilizadas em sistemas silvipastoris no Brasil são exóticas, principalmente pela ausência de estudos que investiguem o potencial de uso de espécies nativas brasileiras. Deste modo, o objetivo deste estudo foi avaliar o crescimento de 13 espécies arbóreas do Cerrado, notadamente com potencial de uso em sistemas silvipastoris. Em dezembro de 2015 foi implantado um arboreto com 13 espécies nativas do Cerrado, em uma área de aproximadamente 1,0 ha, na Embrapa Gado de Corte, Campo Grande – MS. As espécies foram selecionadas com base no potencial de uso e disponibilidade de mudas nos viveiros da região. O delineamento foi inteiramente casualizado, com 24 mudas de cada espécie, no qual foram mensurados crescimento em altura e diâmetro à altura do solo, em dezembro dos anos 2016, 2017 e 2018. A fim de comparar as diferenças de crescimento entre as espécies, foi aplicado o teste Scott-Knott para agrupamento das médias com nível de significância de 5%. Ao final do primeiro ano, quatro grupos de espécies foram formados, enquanto que nos segundo e terceiro ano, formaram-se cinco grupos. Guazuma ulmifolia e Peltophorum dubium foram as espécies com maior crescimento em altura e diâmetro, enquanto *Dipteryx alata* e *Hymenaea stigonocarpa* foram as espécies de menor altura. *H. stigonocarpa* foi a espécie que apresentou menor diâmetro nos anos avaliados. Com base nos achados deste experimento, ressalta-se a importância da escolha correta do componente arbóreo em sistemas silvipastoris para o total alcance dos objetivos pré-definidos.

Ecological restoration: evaluating models and site factors in areas degraded after agricultural and livestock use in Medellín-Antioquia, Colombia / Restauración ecológica: evaluación de modelos y factores de sitio en zonas degradadas por uso agropecuario en Medellín-Antioquia (Colombia)

Diana Carolina Becerra Merchan¹, Cristobal Ordoñez Alonso², Felipe Bravo Oviedo², Luis Fernando Osorio Velez¹, Juan Carlos Salazar Uribe¹

¹Universidad Nacional de Colombia, Medellín, Colombia; ²Universidad de Valladolid, Valladolid, Spain (dcbecerr@unal.edu.co; a_cristo@pvs.uva.es; fbravo@pvs.uva.es; lfosoriv@unal.edu.co; jcsalaza@unal.edu.co)

El área rural del municipio de Medellín (Colombia), se ha caracterizado por un acelerado proceso de praderización y uso intensivo del suelo, disminuyendo los remanentes de bosque nativo en la ciudad. Para mitigar y compensar los efectos negativos, se viene implementado el proyecto “Mas Bosques Para Medellín”, con el que se pretende aumentar la cobertura boscosa mediante reforestación mixta de especies nativas propias del Bosque Húmedo premontano (Bh-PM) y bosque húmedo montano bajo (Bh-MB). Estos ensayos se monitorearon mediante el establecimiento de parcelas permanentes, evaluando variables dendrométricas (diámetro a la base del cuello, diámetro a la altura de pecho (DAP) y altura total), y de mortalidad, desde el año 2010 hasta el año 2016. Generalmente, variables como la mortalidad se evalúan como el número de individuos muertos, sin tomar en consideración las dinámicas asociadas a través del tiempo. Para determinar los factores que inciden en la mortalidad de los árboles plantados, se realizaron curvas de supervivencia mediante el uso de estimadores de Kaplan-Meier y factores de riesgo por medio de la regresión de Cox, empleando como factores de sitio, el tipo de cobertura anterior a la plantación, suelos, precipitación y altura sobre el nivel del mar, y se estimaron modelos de sitio para las especies *Montanoa cuadrangularis*, *Croton magdalenensis*, *Citharexylum subflavescens*, *Chamaessena colombiana*, *Retrophyllum rospigliosii*, *Quercus humboldtii*, *Cedrela montana*, *Alnus acuminata*, *Tecoma stans* y *Calophyllum brasiliense*. Estos resultados se pueden emplear como base para el desarrollo de nuevas plantaciones mixtas en zonas tropicales de Bh-PM y Bh-MB.

Stocks of leaf litter in a mixed eucalyptus and acacia plantation / Estoque de serapilheira em área de plantio misto de eucalipto e acácia

Júlia Graziela da Silveira¹, Renato de Aragão Ribeiro Rodrigues², Maurel Behling³, Diego Camargo⁴, Leticia Helena Campos de Souza⁵,

Natassia Magalhães Armacolo⁶, Jacqueline Jesus Nogueira da Silva⁷, Antonio de Arruda Tsukamoto Filho⁵

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Embrapa Solos, Rio de Janeiro, Brasil; ³Embrapa Agrossilvipastoril, Sinop, Brasil; ⁴Universidade Federal de Mato Grosso, Sinop, Brasil; ⁵Universidade Federal de Mato Grosso, Cuiabá, Brasil; ⁶Universidade Estadual de Londrina, Londrina, Brasil; ⁷Universidade Federal Fluminense, Niterói, Brasil (juliagrazielasilveira@gmail.com; renato.rodrigues@embrapa.br; maurel.behling@embrapa.br; camargo.die@gmail.com; leticiahelena_cs@hotmail.com; nmarmacolo@gmail.com; jacqueufmt@gmail.com; tsukamoto@ufmt.br)

Plantios mistos de eucalipto com espécies fixadoras de nitrogênio podem aumentar o aporte de serapilheira, favorecendo a ciclagem de nutrientes e sendo fonte de matéria orgânica. O objetivo do trabalho foi quantificar o estoque de serapilheira em monocultivos e plantios mistos de *Eucalyptus urograndis* (*E. urophylla* x *E. grandis*) e *Acacia mangium*, após 29 meses de plantio. Foi desenvolvido na Embrapa Agrossilvipastoril (Sinop, MT), com cinco tratamentos: monocultivo de eucalipto com fertilização nitrogenada (E+N); monocultivo de eucalipto sem fertilização nitrogenada (E-N); monocultivo de acácia (A); plantio misto com 67% eucalipto e 33% acácia (67E+33A); plantio misto com 50% eucalipto e 50% acácia (50E+50A). O delineamento experimental foi em blocos casualizados, com três repetições. Amostras de serapilheira foram coletadas com gabarito 0,5 x 0,5 m no ano de 2017. O estoque médio de serapilheira foi 5,38 Mg ha⁻¹ no E + N, 4,89 mg ha⁻¹ no E - N, 6,31 Mg ha⁻¹ na A, 5,17 Mg ha⁻¹ no 67E + 33A (2,18 Mg ha⁻¹ de E e 2,99 Mg ha⁻¹ de A) e 5,48 Mg ha⁻¹ no 50E + 50A (1,97 Mg ha⁻¹ de E e 3,51 Mg ha⁻¹ de A). A serapilheira diferiu estatisticamente nos contrastes E + N vs. E-misto, E - N vs. E-misto, A vs. A-misto e A vs. E d/50E + 50A. Mesmo os plantios mistos não promovendo aumento na deposição de serapilheira, foi observado a contribuição da acácia em 58 e 61% nos tratamentos de 67E + 33A e 50E + 50A respectivamente, para produção de serapilheira, evidenciando a importância dessa espécie para o aumento da quantidade de material vegetal depositado sobre o solo.

Mixed forest stands in Europe: can we spot them from high-resolution satellite remote sensing?

Loredana Oretti¹, Francesca Giannetti², Anna Barbati¹

¹Università degli Studi della Tuscia, Viterbo, Italy; ²Università degli Studi di Firenze, Firenze, Italy (loredanaoretti@unitus.it; francesca.giannetti@unifi.it; barbati.sisfor@unitus.it)

In forest inventories stands dominated by one tree species are classified as monospecific stands even if containing several forest species, if these contribute less than 10-20% to canopy cover or stand density. Official statistics provided by the State of Europe forests report that about two-thirds of the European forests contain from two up to six (or more) forest tree species. But mixed forest stands, where two or more tree species contribute each to more than 10-20% to canopy cover/stand density, might indeed not be sampled with sufficient intensity by traditional forest inventories, compared to monocultures, especially in forest

landscapes where the average stand condition is relatively species poor. This limits the set up of replicated experiments, at single or several sites, to analyse in real-world conditions e.g. the effect of mixing of two (or more) tree species on forest ecosystem properties and services. Designing such experiments would greatly benefit from high resolution maps of monospecific vs mixed stands. Today, Sentinel 2 multispectral satellite imagery allows to cover large areas over a short period of time, with a relatively high spatial resolution (10-20 m). The aim of this contribution is to offer an exploratory analysis of the capabilities offered by Sentinel 2 and Random Forest classifier, for the detection and mapping of widespread mixed forest stand types in Europe, based on a case study characterized by different admixtures of coniferous and broadleaved tree species.

Using hydrogel in germination and seedling establishment of white ipê (*Tabebuia roseo-alba* (Ridl.) Sand.) / Uso de hidrogel na germinação de sementes e estabelecimento de plântulas de Ipê branco (*Tabebuia roseo-alba* (Ridl.) Sand.)

Juliano Miranda de Oliveira¹, Anderson Marcos de Souza¹

¹Universidade de Brasília, Brasília, Brasil (julianooliveira.engflorestal@gmail.com; anderssouza@yahoo.com.br)

O ipê-branco (*Tabebuia roseo-alba* (Ridl.) Sand.) é uma espécie bastante utilizada em reflorestamentos mistos destinados à recomposição de áreas degradadas e de preservação permanente. O objetivo do trabalho foi avaliar o uso de hidrogel na germinação e no desenvolvimento das plântulas de sementes de ipê branco. As sementes foram submetidas aos tratamentos: com hidrogel: 0,5 g/l, 1,0 g/l, 1,5 g/l, 2,0 g/l, e sem hidrogel. Foram realizados as avaliações de: Número de sementes germinadas (NSG); número de folhas (NF); comprimento da parte aérea (CPA); número de raízes (NR); peso fresco (PF); peso seco (PS) e número de sementes não germinadas duras (NSNGD). O delineamento adotado foi o inteiramente casualizado, com quatro repetições e a média dos dados obtidos foram submetidos a análise de variância utilizando o software estatístico SISVAR e foram discriminadas pelo teste de tukey ao nível de 5% de probabilidade. As variáveis NR, PF e PS apresentaram os maiores valores de coeficiente de variação (23,30 a 42,96%). As demais variáveis apresentaram valores de coeficiente de variação entre 13,04 e 15,02%. Conforme a análise de variância, verificou-se que para a maioria das variáveis avaliadas a incorporação de hidrogel no substrato não apresentou resultados significativos. A dosagem de 1,5 g/l pode ser indicada nos estudos de germinação e estabelecimento de plântulas de *Tabebuia roseo-alba* (Ridl.) Sand. por terem apresentado valores que favoreceram a germinação assim como o estabelecimento de plântulas com melhores médias de padrões morfológicos.

CIv: MIXED-SPECIES FORESTS AND PLANTATIONS: KNOWLEDGE GAPS AND RESEARCH PRIORITIES

Admixture of rich-litter species as a management concept boosting forest resilience

Bart Muys¹, Ellen Desie¹, Bart Nyssen^{1,2}, Karen Vancampenhout¹

¹KU Leuven, Leuven, Belgium; ²Bosgroep Zuid-Nederland Heeze Netherlands (bart.muys@kuleuven.be; ellen.desie@kuleuven.be; bart.nyssen@kuleuven.be; karen.vancampenhout@kuleuven.be)

Many forests Europe-wide are growing on nutrient-imbalanced acid soils, and are often composed of monocultures of adapted tree species that further amplify this oligotrophic regime. But study of palynological records and relict forests suggests that even on the poorest sands a rich, more productive alternative stable state, dominated by rich-litter tree species exists. From an evolutionary point of view, rich-litter is a more recent functional trait supporting fast nutrient turnover, earthworm bioturbation and mull humus. Research in common gardens has shown the potential of rich-litter species to maintain or restore resilient mesotrophic systems. But restoration is not straightforward: oligotrophic system interactions induce and maintain conditions that are hostile for rich-litter species. But restoration is hampered by the conditions of the oligotrophic system, which are hostile for rich-litter species. Successful large-scale restoration therefore implies deeper understanding of the factors underlying the attractor behavior of the oligotrophic system, which may be soil type and context dependent. As a result, integrated soil restoration combines actions supporting the introduction of rich-litter species, e.g. fertilization with rock dust, inoculation of earthworms, or introduction of accompanying shrub and herb species. This perspective paves the way for large-scale admixture of rich-litter species, from the fundamental research on litter decomposition and soil effects of mixtures, over the conceptual framework of rich-litter species and alternative stable states in forest soils, to the first results of restoration management experiments. It concludes with some considerations on the validity of this new concept in other continents.

Are mixtures a good option to reduce drought-induced risk of forest decline? Carbon accounting and economic approach

Sandrine Brèteau-Amores¹, Mathieu Fortin², Pablo Andrés-Domenech³, Nathalie Bréda⁴

¹Institut National de la Recherche Agronomique - BETA, Nancy, France; ²Canadian Forest Service, Ottawa, Canada; ³AgroParisTech - BETA, Nancy, France;

⁴Institut National de la Recherche Agronomique - SILVA, Nancy, France (sandrine.breteau-amores@inra.fr; mathieu.fortin@agroparistech.fr; pablo.andres-domenech@agroparistech.fr; nathalie.breda@inra.fr)

Drought is the principal source of stress limiting forest health and it causes financial losses for forest owners and amenity losses for society. The major part of the forested area in the Grand-Est region (France) is dominated by beech, which is predicted to decline in the future due to repeated drought events driven by climate change. Beech forests need to adapt and mixture is known to decrease drought risk. In this context, the objective of the paper was to compare, from an economical perspective, different forest adaptation strategies aiming at reducing drought-induced risk of decline. For this purpose, we studied two types of mixture that we analysed separately and jointly: mixture of beech with oak and age mixture (i.e. from an even-aged to an uneven-aged forest), which is rarely considered as an adaptation strategy. We also considered two types of loss (financial, and in terms of carbon sequestration) under different recurrences of drought, that are a consequence of climate change. We combined a forest growth simulator (MATHILDE) with a traditional forest economic approach (Fautsmann's LEV and Hartman's LEV). The maximisation of the two LEV criteria made it possible to identify the best adaptation strategies in economic terms. We also developed the carbon approach considering different accounting methods (from the market value to the social cost of carbon). The results are discussed taking into account the trade-offs between the financial balance and the carbon balance, and the underlying question of the additivity (or not) of the two adaptation strategies.

How richness of tree species affects stand volume and stability in Hemiboreal Forest of Lithuania?

Gediminas Brazaitis¹, Ramūnas Mazėtis¹, Hans Pretzsch², Miren del Rio³, Gintaras Kulbokas⁴, Remigijus Žalkauskas⁴

¹Institute of Forest Biology and Silviculture Vytautas Magnus university, Kaunas, Lithuania; ²Chair for Forest Growth and Yield Science, Technical University of Munich, Freising, Germany; ³Department of Silviculture and Forest Management, INIA, Forest Research Centre INIA-CIFOR Forest Research Centre, Madrid, Spain; ⁴Institute of Environment and Ecology Vytautas Magnus university, Kaunas, Lithuania (gediminas.brazaitis@asu.lt, rmazetis@mmu.lt; hans.pretzsch@lrz.tum.de; delrio@inia.es; g.kulbokas@amvmt.lt; remigijus.zalkauskas@vdu.lt)

This study analyses the effects of tree species richness on stand stability and volume in Hemiboreal Forest in Southwest Lithuania (54°22'-54°38'N, 22°47'-23°49'E). Field surveys were conducted in 586 systematically dispersed circular plots (500 m² in size). We recorded tree species, tree condition and tree volume in each plot. In total, we recorded 15 tree species with plots containing between 1-10 tree species. However, most plots contained 3-7 tree species. Results show, survival rates of *Betula pendula*, *Betula pubescens*, *Carpinus betulus*, *Alnus glutinosa* and *Quercus robur* were better in stands with higher species richness. In contrast, *Fraxinus excelsior*, *Populus tremula*, and *Picea abies* showed a slight survival increase in stand with lower tree species richness. Finally, *Ulmus minor*, *Tilia cordata* and *Salix caprea* showed highly reduced survival in stands with high richness. In all stands < 60 years of age, tree survival decreased as stand age increased. However, in stands 60-120 years, survival was negatively dependent on tree species richness. The survival of trees in stands containing 3-7 species was stable among the oldest stands (130-160 years). Total stand volume, containing up to 6 species, showed increased stand volume, reaching peak stand volume at age 100-120. However, for all stands between 90-110 years there were no effects on stand volume. In young stands species richness had a positive effect on stand volume, but in stands > 110 years was a negative relationship between stand volume and species richness. Thus, species richness does effect stand volume and tree survival.

Structure of old-growth mixed broad-leaved stands in the Caspian Forests

Khosro Sagheb Talebi¹, Pejman Parhizkar¹, Majid Hassani¹, Assadollah Karimidoost¹, Karim Maghsudloo¹, Hossein Ghorbani¹

¹Agricultural Research, Education and Extension Organization, Research Institute of Forests and Rangelands (RIFR), Tehran, Islamic Republic of Iran (saghebtalebi@rifr-ac.ir; parhizkar@rifr-ac.ir; hassani@rifr-ac.ir; karimidoost@yahoo.com; karimmaghsudloo@yahoo.com; ghorbani_32@yahoo.com)

Caspian mountainous temperate deciduous forests containing diverse broad-leaved species are located in the south of the Caspian Sea. These ancient forests date back to the early Pleistocene and were not affected strongly by glaciations. Our research aims to study the diversity of tree species, vertical and horizontal structure as well as the regeneration process within the mixed stands. For this purpose, we selected 9 sample plots, each 1 ha within an intact stand with no silvicultural interventions. All trees with diameter at breast height (dbh) larger than 7.5 cm were assessed, and dbh, height and coordination of trees were measured. Results showed a multi-aged stand containing 12 woody species with stem number between 308 and 560 trees ha⁻¹. The proportion of common hornbeam (64.6%) was higher than large-leaved lime (18.6%) followed by chestnut-leaved oak (5.4%). The frequency of other companion species, including Cappadocian maple, velvet maple, wild cherry, wild service, field maple, elm, ash, Persian ironwood and common medlar was 11.4%. The largest measured trees were lime and oak with a dbh of 225 cm and 165 cm, respectively. Forming the upper storey, oak and lime were the tallest trees and other species occupy the middle and lower stories. Lack of oak regeneration is noteworthy which could be the main challenge for the future of the stand. While the spatial pattern of oak showed a random pattern, that of lime and maple showed clump pattern. Results could be applied for management of natural forests as well as in planted mixed forests.

Management alternatives of spontaneously regenerated mixed stands of Birch and Norway spruce in Sweden.

Felicia Lidman¹, Emma Holmström², Tomas Lundmark¹, Nils fahlvik³

¹Swedish university of Agricultural Sciences, Umeå, Sweden; ²Swedish university of Agricultural Sciences, Alnarp, Sweden; ³Skogforsk, Ekebo, Sweden (felicia.lidman@slu.se; emma.holmstrom@slu.se; tomas.lundmark@slu.se; nils.fahlvik@skogforsk.se)

More than 75% of clearcuts in Sweden are regenerated by planting coniferous tree species followed by subsequent pre-commercial thinnings to secure growth on the main crop trees. However, areas on clearcuts without active regeneration methods, tend to be spontaneously forested with a mixture of naturally regenerated Birch (*Betula pendula* Roth and *Betula pubescens* Ehrh.) and Norway spruce (*Picea abies* (L.) Karst.) The aim of this study is to compare the alternatives and effect of first thinning and extraction of forest fuel on stand development and future tree species composition, in areas with low investment regeneration. A long term experiment with a randomized block design was established 2007 (22 years after clearcutting) on two naturally regenerated sites, on the east-central coast of Sweden. Treatments included thinning of forest fuel leaving (1) 1300 stems ha⁻¹ of Norway spruce, (2) 1200 stems ha⁻¹ of birch, (3) a tree-wise mixture with 1200 stems ha⁻¹ of birch and 1300 stems ha⁻¹ of Norway spruce and (4) an unthinned control. A second thinning was made 2016 in treatment (2) and (3), to favor the main crop trees. Treatment (1) created a stand suitable for a longer rotation period, (2) for a medium length rotation period, (3) for two harvests of crop trees during a longer rotation period and (4) for a short rotation period. All treatments had different levels of forest fuel outtake and management intensity. These results can be used to optimize the different silvicultural practices strategically towards the goal of the forest owner.

Wild pear tree and wild service tree pure and mixed plantations for high-quality timber production

Verónica Loewe-Muñoz¹, Rodrigo Del Río¹, Claudia Delard¹, Mónica Balzarini²

¹INFOR, Santiago, Chile; ²Universidad Nacional de Córdoba, Córdoba, Argentina (vloewe@infor.cl; rdelrio@infor.cl; cdelard@infor.cl; vloewe@infor.cl)

Wild service (*Sorbus torminalis*) and wild pear (*Pyrus pyraeaster*) are sporadic species with highly priced timber for noble uses (cabinet-making, musical instruments). However, adequate management is necessary to obtain valuable logs. Pure and mixed plantations of both species were compared to explore the benefits of species associations on productivity and timber quality. Growth, straightness and survival were measured during 12 years. Besides both monocultures, five mixtures were tested: T1: *Pyrus pyraeaster* + *Sorbus torminalis*; T2: mixture incorporating one arboreal N-fixing companion (T1 + Italian alder (*Alnus cordata*)); and three associations including shrub nurse species (T3: T1 + hazelnut (*Corylus avellana*), T4: T1 + dwarf elderberry (*Sambucus ebulus*) and T5: T1 + black elderberry (*Sambucus nigra*)). Wild pear in T2 presented the highest height (10.7 m), with statistical differences from the monoculture (7.2 m). The monoculture presented 47% of straight trees, whereas the association including *Sambucus ebulus* showed a higher proportion of straight trees (57%). Wild pear survival was high in all associations (~80%), except for T1 (60%). Wild service also presented the highest height (8.9 m) in T2, with significant differences from the monoculture (5.8 m); the same effect was recorded for DBH (10.0 vs 6.5 cm). The monoculture presented 38% of straight trees, and T1 50%. The highest wild service tree survival occurred in T2 (67%), being 58% in monoculture. Both species are suitable for being planted for quality timber production, with higher growth in associations including Italian alder than in monoculture. Some companion species favored wild pear and wild service tree growth, vigor and survival.

Light use efficiency in pure and mixed *Eucalyptus* and *Acacia mangium* plantations with different stocking densities

Ivanka Rosada de Oliveira¹, Guerric le Maire^{2,3}, Jean-Paul Laclau^{3,4}, Carolina Braga Brandani⁵, José Leonardo de Moraes Gonçalves¹, Joannès Guillemot^{1,3}, Iraê Amaral Guerrini⁴, Jean-Pierre Bouillet^{1,3}

Competition for light in mixed-species plantations is a main limiting factor for tree growth. Understanding the light absorption and light use efficiency for each species at different planting densities and spatial arrangement of trees is essential for improving these plantations management. The study was conducted in Itatinga-SP, Brazil. A complete randomized block design was set up with 4 blocks and 10 treatments per block with pure and mixed plantations of *Eucalyptus grandis* (E) and *Acacia mangium* (A), a N₂-fixing species (NFS). The treatments were composed with different planting densities (6 m x 3 m, 3 m x 3 m and 3 m x 2 m) and arrangements (100% A, 100% E, 50% A and 50% E, 33% A and 67% E) between species. Tree growth and biomass were monitored at 38, 45 and 52 months after planting. The absorbed photosynthetically active radiation (APAR) for each tree was simulated with the MAESTRA model. The leaf area of each tree, leaf angle distributions and leaf area density was estimated in situ to parameterize the model. Hemispherical photos were taken over the same period of time (every 2 months) and used to test MAESTRA simulations and validate the light interception simulations. Computed Light Use Efficiency (LUE) for trunk wood production was estimated as the ratio of the wood growth and the MAESTRA simulated APAR, showing contrasted patterns of LUE for each treatment. The results will give insights to choose the best design, decreasing light competition and improving the association between eucalyptus and NFS, for a more sustainable management of pure and mixed forest plantations.

Rehabilitating evergreen forests through supplementary planting of native wood species in Pumillahue, Chile / Rehabilitación de bosques siempreverdes mediante plantación suplementaria de especies madereras nativas en Pumillahue, Chile

Las áreas cosechadas de bosque siempreverde son profusa y rápidamente invadidas por *Chusquea quila*, inhibiendo el desarrollo de la regeneración y dinámica del bosque. El quilantal resultante varía de ½ a algunas decenas de ha. La importancia económica para sus propietarios, amerita su rehabilitación mediante plantación mixta de especies nativas de valor maderero, para recuperar la biodiversidad, minimizar endogamia y acercar este nuevo bosque al ecosistema de referencia. De acuerdo a un inventario florístico y al interés del propietario, en el predio Pumillahue se seleccionó las especies madereras roble, ulmo, tepa, lingue y olivillo, y como especie de relleno raulí, estas se clasificaron según su ecología en pioneras o finales. Para coleccionar semillas que minimicen la endogamia y garanticen la adaptación local, se establecieron rutas semilleras con una distancia mínima de 30 a 50 m entre árboles de igual especie, bajo ellos se instalaron mallas para coleccionar sus semillas, luego se viverizó manteniendo la identificación de cada madre para evaluar posteriormente su desempeño según su estructura familiar. Se plantó endiseño de parcelas al azar en tres bloques o quilantal. Se probó 6 tratamientos de estructura factorial 3 x 2, tres niveles de espaciamiento (3 x 5, 3 x 3 y 3 x 2 m) y dos proporciones entre especies pioneras/finales (50/50 y 67/33). La plantación es en líneas de biodiversidad. La supervivencia y altura se evaluó en dos mediciones. La supervivencia fue cercana al 100% y las especies pioneras ulmo y roble presentaron los mayores incrementos en altura. La heredabilidad también alta y significativa.

C1w: SILVICULTURE FOR EUCALYPTUS PLANTATIONS

Quality control for forestry in cultivating eucalyptus in the state of São Paulo, Brazil / Controle da qualidade das atividades silviculturais na cultura do eucalipto no estado de São Paulo, Brasil

Diana Carolina Vasquez Castro^{1,2}, Thiago Romanelli², Marcos Milan²

¹Grupo de Investigación Navarra Ambiental, Facultad de Ingenierías, Fundación Universitaria Navarra - Univarra, Neiva, Colombia; ²Universidade de São Paulo, Piracicaba, Brasil (carito1986@hotmail.com; romanelli@usp.br; macmilan@usp.br)

O setor florestal tem grande importância econômica na formação do PIB do Brasil e o reflorestamento contribui para a redução do desmatamento das florestas nativas. A demanda crescente pela cultura do eucalipto exige do setor florestal a busca pela competitividade, e essa competitividade está associada à produtividade. A produção do eucalipto é uma atividade complexa que envolve inúmeras operações e atender às exigências da planta em cada operação é um dos requisitos para se obter uma boa produtividade da cultura. Para tanto, padrões que atendam às necessidades das plantas devem ser estabelecidos e mantidos constantes ao longo dos processos de instalação, condução e colheita da cultura. Com isso, o objetivo da pesquisa foi avaliar se operações de preparo do solo e de plantio estão sendo realizadas dentro dos padrões estipulados. A metodologia empregada foi o controle estatístico do processo. O trabalho foi realizado em dois locais, localizados nos municípios de Itirapina e Agudos no estado de São Paulo no Brasil em áreas com preparo do solo convencional e preparo do solo reduzido utilizando o implemento savanah. Os resultados mostram que embora as profundidades de subsolagem atendem ao especificado, o processo não está sob controle. Já para o plantio, o processo está sob controle nas áreas avaliadas.

Change in height-diameter relationship with age for six clones of *eucalyptus* under different spacing

Silvio Henrique Menezes Gomes¹, João Luís Ferreira Batista¹, Kálita Luis Soares¹, Luciana Duque Silva¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (silviogomes@usp.br; batista.jlf@usp.br; kalitasaes@usp.br; lucianaduques@usp.br)

Height-diameter relationship is a basic attribute of forest stands that changes with age and can be affected by silvicultural practices such as genetic material and planting spacing. In this paper, we studied the change height-diameter relationship of trees of six *eucalyptus* clones planted in three different planting spacing and remeasured along seven ages. Planting spacing was transformed to planting stand density. Three basic models were applied to the height-diameter

relationship in each specific condition of clone, age and planting spacing: the simple linear model, simple linear in logarithmic scale and exponential model. For each eucalyptus clone, the basic model parameters (intercept and slope) were taken as linear functions of age and planting spacing and eight effect models were fitted: 1) null model, don't change with age and spacing; 2) full model, change as function of age, spacing and interaction age-spacing; 3) age effect model, only; 4) spacing effect model, only; 5) age-interaction model, change with age and interaction; 6) spacing-interaction model, change with spacing and interaction; 7) age and spacing model, change with age and spacing, but no interaction; and 8) interaction model, only with the interaction. Models were fitted and their performance were compared using Akaike Information Criterion (AIC). In five of the six clones, the exponential age-interaction model performed best, while in one clone the exponential age-spacing model was best. Generally, the full model was a second best option, showing that, along with age, silvicultural practices have important effect on shaping height-diameter relationships in eucalyptus plantation forests.

Biometric parameters of *Eucalyptus* after pure and composted sewage sludge application

Iraê Amaral Guerrini¹, Camila Rocha Pergentino da Silva¹, Luciane Cristina Lazzarin¹, Sérgio Augusto Rodrigues¹, Caroline Moura D'Andréa Mateus¹, Roberto Lyra Villas Boas¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Brasil (irae.guerrini@unesp.br; camilapergentino@hotmail.com; lucianelazzarin@unc.br; sergio.rodrigues@unesp.br; caroline_mateus@hotmail.com; roberto.lyra@unesp.br)

Because of the prohibitions of using pure sewage sludge (PSL) in forest plantations in Brazil, this work had the objective of identifying the dose of composted sewage sludge (CSL) that proposes the best development of *Eucalyptus*. The experiment was conducted in plastic greenhouse and was composed of 48 vessels containing 50L of dystrophic medium texture. It is a factorial experiment 2 x 5 (pure and composted sewage sludge x dose 20, 30, 40 and 50 mg ha⁻¹), in addition to absolute control and mineral fertilization, with four repetitions per treatment. The parameters evaluated were: index of green color (IGC), measured monthly during six months, dry mass (DM) and leaf area (LA), evaluated in the end of the experiment. After six months, the dose of 40 Mg ha⁻¹ of CSL promoted the highest value of IGC, whereas the dose of 50 mg ha⁻¹ of CSL promoted the highest LA of plants. The doses of 40 and 50 mg ha⁻¹ of CSL of both sludges promoted the highest production of biomass in each part of plants (leaf, branch, trunk and root). The highest production of total DM occurred in the dose of 50 mg ha⁻¹ of CSL (868.95g/plant), similar to MS produced by the dose of 40 mg ha⁻¹ of PSL (852.08g/plant). In relation to mineral fertilization, the gains with fertilization of PSL and CSL were similar in all the parameters evaluated and the recommendation is to use the dose of 50 mg ha⁻¹ of composted sewage sludge in *Eucalyptus* plantations.

The effect of a curtain of *Eucalyptus dunnii* in reducing wind speed in Flores, Uruguay / Efecto de una cortina de *Eucalyptus dunnii* en la reducción de la velocidad del viento en el Departamento de Flores, Uruguay

Carolina Munka¹, Juan Pablo Chiara¹, Celmira Saravia², Adriana Bussoni³, Marcelo Rachetti⁴

¹Universidad de la República, Facultad de Agronomía, Departamento de Sistemas Ambientales, Montevideo, Uruguay; ²Universidad de la República, Facultad de Agronomía, Departamento de Sistemas Ambientales, Salto, Uruguay; ³Universidad de la República, Facul (macamunka@gmail.com; jp@fagro.edu.uy; tsara@unorte.edu.uy; abussoni@gmail.com; chelorchetti@yahoo.com.ar)

Existe escasa evidencia nacional sobre los efectos de forestaciones para servicio a la ganadería, a pesar de ser el principal motivo para incorporar montes en la producción ganadera. Este trabajo describe el efecto del abrigo de una forestación en un predio ganadero del sur de Uruguay. El estudio se realizó en una cortina semipermeable de *Eucalyptus dunnii* (3,5 m x 2 m) de 9 años, y 20 m de altura media. Entre julio y setiembre de 2018 se midió la velocidad del viento (m/s) en cuatro puntos sobre una transecta perpendicular a la orientación de la cortina (NE a SO): un punto a barlovento (SE) a una distancia horizontal a la cortina de 80 m y otros tres puntos a sotavento (NO), área protegida por la cortina de árboles, a distancias de 40 m, 80 m y 160 m. A sotavento (NO), el viento del sureste, generalmente frío, se redujo en promedio (% ± desvío estándar), en: 57 ± 18,7, 82 ± 14,6 y 48 ± 22,2, a una distancia de 2, 4 y 8 veces la altura de la cortina, respectivamente. La mayor reducción se dio a una distancia de 4 veces la altura de la cortina. En todos los casos se observó una disminución del viento, condicionante para mejorar el confort animal por reducción del estrés térmico por frío, que conlleva a una potencial mejora productiva del ganado. Se debe profundizar el estudio de la interacción del árbol con las variables que más inciden en el confort animal.

Development and quality of *Eucalyptus grandis* x *Eucalyptus urophylla* seedlings under different covering materials / Desenvolvimento e qualidade de mudas de *Eucalyptus grandis* x *Eucalyptus urophylla* sob diferentes coberturas de canteiros

Jhuan Lucas Melo Maciel¹, Jheyson Jerzel Valdivia Gómez¹, Andrew Kim Lopes Ferraz¹, Magali Ribeiro da Silva¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil (jhuanlucas@outlook.com; jheyson540@gmail.com; andrewkim.lf@gmail.com; magaliribeiro@fca.unesp.br)

Filmes plásticos podem alterar os microambientes e, conseqüentemente, a qualidade das mudas florestais, havendo a necessidade de compreender a dinâmica planta-substrato-água-atmosfera por meio das variáveis de crescimento e fisiológicas das mudas. O objetivo deste trabalho foi avaliar como os microambientes afetam a fisiologia de mudas clonais do híbrido *Eucalyptus grandis* x *Eucalyptus urophylla*. Os microambientes testados foram: canteiros suspensos a pleno sol sem cobertura plástica; minitúnel com cobertura de filme plástico difusor de 150 microm; e minitúnel com cobertura de filme plástico azul. Cada tratamento continha 4 repetições de 32 mudas. As variáveis analisadas ao final do ciclo de produção, 90 dias após a estaquia, foram altura, diâmetro do colo, massa seca aérea (MSA), radicular e total, índice de qualidade de Dickson (IQD), número de folhas, área foliar, transpiração e índice SPAD. Aos 90 DAE, altura e diâmetro do colo das mudas foram maiores quando produzidas em minitúnel independente do filme plástico. A MSA foi maior nas mudas do minitúnel com filme plástico difusor e a pleno sol. Embora neste último as mudas tenham sido menores em altura, elas tiveram maior número de folhas, sendo estas mais espessas, o que levou a uma mesma MSA. Não houve diferença significativa entre os microambientes para as variáveis massa seca radicular e total, área foliar e IQD. O índice SPAD foi maior nas mudas a pleno sol. A transpiração foi menor nas mudas produzidas a pleno sol, indicando maior rusticidade nestas plantas.

Microenvironmental influence on production of *Eucalyptus grandis* Hill ex Maiden x *Eucalyptus urophylla* S. T. Blake seedlings / Microambientes influenciam a produção de mudas de *Eucalyptus grandis* Hill ex Maiden x *Eucalyptus urophylla* S. T. Blake

Jhuan Lucas Melo Maciel¹, Jheyson Jerzel Valdivia Gómez¹, Andrew Kim Lopes Ferraz¹, Magali Ribeiro da Silva¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brazil (jhuanlucas@outlook.com; jheyson540@gmail.com; andrewkim.lf@gmail.com; magaliribeiro@fca.unesp.br)

Filmes plásticos proporcionam ambientes favoráveis para o desenvolvimento de mudas florestais aumentando qualidade e produtividade, onde a criação de microambientes adequadas no interior dos ambientes protegidos pode ser obtida pela combinação de diferentes materiais de cobertura. O objetivo deste trabalho

foi quantificar a influência do microambiente sobre variáveis de crescimento em mudas clonais de *Eucalyptus grandis* x *Eucalyptus urophylla* (*E. urograndis*) em fase de viveiro. A pesquisa foi composta por dois experimentos (clone IPB02 e IPB13) em delineamento experimental inteiramente casualizado com três tratamentos (microambientes): canteiros suspensos a pleno sol sem cobertura plástica; minitúnel com cobertura de filme plástico difusor de 150 micron; minitúnel com cobertura de filme plástico azul. As variáveis morfofisiológicas analisadas no final do ciclo de produção, 90 dias após a estaquia, foram altura, diâmetro do colo, números de folhas, área foliar e transpiração. Aos 90 DAE, a altura média das mudas foi maior quando produzidas em minitúnel com os filmes plásticos azul e difusor, para os dois clones. Minitúnel com filme plástico azul promoveu maior diâmetro das mudas de IPB 2. Não houve diferença significativa entre os diferentes microambientes para as variáveis número de folhas e área foliar das mudas do clone IPB02. Para as mudas do clone IPB13, tanto a área foliar quanto o número de folhas das mudas foram maiores a pleno sol. Os microambientes, proporcionados pelas diferentes coberturas, influenciaram diferentemente os clones de *Eucalyptus urograndis*. As mudas do clone IPB13 apresentaram maior rusticidade quando produzidas a pleno sol.

Collecting trays versus traditional trays in the production of *Eucalyptus grandis* Hill ex Maiden x *Eucalyptus urophylla* S. T. Blake seedlings / Bandejas coletoras x bandejas tradicionais na produção de mudas de *Eucalyptus grandis* Hill ex Maiden x *Eucalyptus urophylla* S. T. Blake

Jheyson Jerzel Valdivia Gómez¹, Jhuan Lucas Melo Maciel¹, Magali Ribeiro da Silva¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil (jheyson540@gmail.com; jhuanlucas@outlook.com; magaliribeiro@fca.unesp.br)

Existe no mercado uma nova bandeja que coleta e direciona a água de irrigação para o tubete, reduzindo as perdas causadas pelos espaços vazios e, portanto, influenciando o manejo hídrico e consequentemente o uso da água no viveiro. O objetivo deste trabalho foi avaliar como bandejas e lâminas de irrigação interagem no desenvolvimento de mudas de *Eucalyptus urophylla* x *E. grandis* (*E. urograndis*) e qual lâmina mais adequada para cada bandeja. O delineamento experimental foi o inteiramente casualizado em esquema fatorial 2 x 4, totalizando 8 tratamentos com 4 repetições de 32 mudas, sendo os tratamentos compostos de dois tipos de bandejas, bandeja tradicional (BT) e bandeja coletora (BC) e quatro lâminas de irrigação diárias de 8, 11, 14 e 17 mm. As variáveis analisadas ao final do ciclo de produção, 80 dias após estaqueamento (DAE), foram: altura, diâmetro do colo e índice SPAD. Aos 80 DAE, a altura das mudas foram maiores quando utilizadas as BC (média de 26,0 cm). Para diâmetro do colo houve interação entre os fatores, sendo que nas mudas produzidas com menores lâminas (8 e 11 mm) os maiores diâmetros foram das mudas que estavam na BC, mas nas lâminas maiores (14 e 17 mm) não houve diferença entre as bandejas. O Índice SPAD foi menor nas mudas provenientes da lâmina 17 mm. Considerando as variáveis analisadas e o uso racional da água conclui-se que as lâminas de 8 mm e 14 mm são os indicados quando se usam a BC e BT, respectivamente.

Enhancing genetic deployment strategies using an understanding of clonal sensitivity to differences in soil proprieties for *Eucalyptus* hybrids in Indonesia

Jonggi P. Simanungkalit¹, Paul Anthony Clegg¹, Adventris Hutagaol¹, Jeremy Brawner², Jupiter Muro Abad¹

¹Toba Pulp Lestari, Porsea, Indonesia; ²USC, Queensland, Australia (jonggi_simanungkalit@tobapulp.com; paul_clegg@tobapulp.com; adventris_hutagaol@tobapulp.com; jbrawner@usc.edu.au; jupiter_abad@tobapulp.com)

Eucalyptus clones that are adapted to high-elevation climates in North Sumatra have been developed for cellulose production over the past 23 years. Hybrids among *E. grandis*, *E. pellita* and *E. urophylla* were evaluated across the diverse soils in the region using a trial network that replicated clones in large-plots across many sites to provide estimates of productivity. To clarify what soil properties caused clones to perform differently than expected, productivity estimates from 28 trials were paired with 975 soil samples that were assessed for 32 chemical and physical properties. In areas where the local climate is very similar, the volcanic soils and topography encompass a wide range of chemical and physical properties that are associated with significant changes in tree growth. In addition to environmentally induced changes in productivity, major changes in productivity are evident when different clones are planted; data from the clonal trials indicate there is a clear genetic signal (Heritability (H²) = 0.40 ± 0.06). Nevertheless, significant changes in clonal rankings across the different sites were evident (Among-site genetic correlation (rg) = 0.61 ± 0.07). These clone by site interactions were associated with the underlying soil properties in order to identify individuals that were sensitive to differences in soil properties. It is hoped that targeting clones to sites similar to those where they have performed better than expected will lead to improved productivity as well as reduce abiotic stress and sensitivity to pathogens.

C1x: GERMINATION AND PROPAGATION

Effects of substrates on germination and growth of *Moringa oleifera* Lam, *Acacia mellifera* and *Zizyphus mauritiana* seedlings

Antoine Sambou¹

¹Assane Seck University of Ziguinchor, Ziguinchor, Senegal (tonysambouegos@yahoo.fr)

This study focuses on *Moringa oleifera* Lam, *Acacia mellifera* and *Zizyphus mauritiana* Lam which constitute a significant source of food and economic value for the populations of Casamance. In addition to a germination test, a follow-up of seedlings on different substrates was carried out in the nursery, in order to determine the effect of substrates on growth parameters (number of leaves, height, diameter and biomass). The substrates used were three potting mixtures of forest soil of *Faidherbia albida* (FSFA), *Elaeis guineensis* (FSEG) and *Anacardium occidentale* (FSAO) with sand with the following proportion: 1/3 sand + 2/3 forest soil). Based on species, the germination rate was higher for *A. mellifera* (84%) followed by *M. oleifera* (55%) and *Z. mauritiana* (50%). The germination rate was more important in FSFA and FSEG than in FSAO. For growth parameters, there was a significant effect (P < 0.05) of substrate type on height, diameter, number of leaves and root biomass. In term of growth parameters, the seedling performed better in FSFA and FSEG than in FSAO. The species effect was also significant (P < 0.05) with higher root biomass and diameter found in *M. oleifera* and height and number of leaves in *A. mellifera*. The most important total biomass was found in FSFA followed by FSEG. Comparing the fraction of biomass according the part of the seedling, the stem and branch had the higher fraction of biomass for *A. mellifera* (43%) and *M. oleifera* (38%) and the leaves for *Z. mauritiana* (46%). Better results were recorded in FSFA and FSEG substrates.

Germination of *Aristida riparia* Trin: a native Cerrado grass species / Germinação de *Aristida riparia* Trin: gramínea nativa do CerradoBrenda Barbara Araujo Ribeiro¹, Thiago Sampaio Teles¹, Sybelle Barreira¹¹Universidade Federal de Goiás, Goiania, Brazil (brendabarbara33@gmail.com; thiagosampateles@gmail.com; sybelle.barreira@gmail.com)

A maneira segura de conhecer a qualidade de um lote de sementes é através da análise física e fisiológica, objetivando cumprir a legislação o MAPA organizou as Regras de Análise de Sementes – RAS, que descreve protocolos para análise de sementes. Desta forma o objetivo deste trabalho foi validar o protocolo de germinação da RAS e testar diferentes substratos para germinação de sementes de *Aristida riparia* Trin. As sementes foram coletadas no ano de 2017 e transportadas para o Laboratório Reprodução de Espécies Florestais para limpeza e triagem. Os testes de germinação iniciaram-se em 2018 e foi realizado com 4 repetições de 25 sementes. Como substratos foram utilizados rolo de papel com duas folhas de papel germitest (RP) e papel mata borrão (SP). Na condução dos testes foram utilizados solução a 0,2% de KNO₃ (1) e 6 ml de H₂O (2) deionizada totalizando-se 4 tratamentos. Os testes foram conduzidos com luz fluorescente branca e controle da temperatura de 30°C e fotoperíodo de 12 horas. Os dados obtidos foram submetidos a análise de variância, empregando-se o teste de Tukey a 5% de probabilidade. A taxa de germinação apresentou foi de 10% SP1, 7% RP1, 17% SP2 e 12% RP2. O tratamento sobre papel a 6 ml de água deionizada difere significativamente dos demais. Este resultado demonstra que as sementes de *Aristida riparia* Trin tiveram maior taxa de germinação em água deionizada, sugerindo que o disposto na RAS pode não ser válido para esta espécie.

Assessing germination of *Tibouchina granulosa* Cogn seeds collected during different periods / Avaliação da germinação de sementes de *Tibouchina granulosa* Cogn coletadas em diferentes períodosÁlvaro de Oliveira Moreira¹, Thiago Augusto Sampaio Teles¹, Sybelle Barreira¹¹Universidade Federal de Goiás, Goiania, Brasil (alvaroom96@gmail.com; thiagosampateles@gmail.com; sybelle.barreira@gmail.com)

Tibouchina granulosa Cogn., planta da família Melastomataceae, popularmente conhecida como Quaresmeira, é uma espécie nativa brasileira amplamente utilizada para fins ornamentais e para recuperação de áreas degradadas. Todavia, o tamanho reduzido de suas sementes e o baixo grau de germinação são empecilhos para a propagação sexuada da espécie, dificultando a produção comercial da mesma. Neste sentido, o presente trabalho objetivou estudar a taxa de germinação de sementes de quaresmeira e a melhor época de colheita. O material vegetal foi obtido de uma planta matriz localizada no Campus II da UFG, Goiânia-GO. Durante os meses de abril e maio de 2018 foram coletadas amostras de frutos, sendo uma coleta por semana, totalizando 9 coletas. Os frutos foram conduzidos ao Laboratório de Reprodução de Espécies florestais (REFLOR) para ser efetuado o teste de germinação. O teste de cada coleta foi composto por 4 repetições de 25 sementes, sendo estas acondicionadas em gerbox com auxílio de pinças, sobre papel autoclavado afim de se evitar contaminações por agentes biológicos. As gerbox foram colocadas em estufa de germinação, com temperatura constante de 30 °C, sendo estas avaliadas semanalmente. A germinação foi avaliada pela porcentagem de plântulas normais, sendo a protrusão da radícula o indicador de germinação. Não houve germinação até a primeira quinzena de maio, e, a maior porcentagem de germinação foi obtida entre a sétima e oitava semana de avaliação, com 39% das sementes de quaresmeira consideradas germinadas.

Variation in soil organic matter in an irrigated plantation of *Toona ciliata* M. Roemer var. *australis* / Variação da matéria orgânica do solo em plantio irrigado de *Toona ciliata* M. Roemer var. *australis*Eduardo de Castro Stehling¹, Eduardo Aparecido Ribeiro², Sebastião Carlos da Silva Rosado³, Erika Steinmetz Vilela⁴¹Fuste Consultoria Florestal, Campo Belo, Brasil; ²Natureza Reflorestamento, Belo Horizonte, Brasil; ³Universidade Federal de Lavras, Lavras, Brasil; ⁴Bela Vista Florestal, Campo Belo, Brasil (fusteconsultoria@gmail.com, eduardoribeiro.natureza@yahoo.com; scrosado@dcf.ufla.br; erika@belavistaflorestal.com.br)

O cedro australiano é uma espécie caducifólia de rápido crescimento. Com o objetivo de acompanhar a influência dos tratos culturais e do comportamento caducifólio na variação da matéria orgânica do solo (M. O.), foram realizadas análises nos diferentes talhões, na profundidade de 0-20 cm entre agosto/2014 e junho/2018 em 6 diferentes momentos. O plantio irrigado por gotejamento pertence a Natureza Reflorestamento consistindo em uma área de 130 ha situados no distrito de Santana da Caatinga, João Pinheiro, MG. O solo possui textura franco-arenosa (8% silte, 18% argila e 74% areia). Após limpeza e preparo, o plantio foi realizado em maio de 2016. Não foram utilizadas outras fontes de matéria orgânica. Entre agosto e novembro de 2016, as linhas de plantio foram consorciadas com melancia e abóboras capotí e sergipana. Foram realizadas 2 podas anuais após a implantação, totalizando 6, com a maior intensidade em 2018. Os resultados médios da M.O. obtidos em dag/kg, foram respectivamente: ago/2014 (área bruta, 0,4); out/2014 (pós-gradagem, 1,24); jun/2016 (antes-consórcio, 1,05); set/2017 (pós-consórcio, 1,02); jun/2018 (pós-queda de folhas e desrama, 1,54). Não foi observada variação da M. O. após a erradicação das abóboras e melancias. O incremento médio de M. O. no período foi de 1,1 dag/kg (aumento de 275%). O aumento da M. O. deveu-se aos tratos culturais requeridos pela cultura (controle de mato-competição e desrama) com grande contribuição da queda de folhas devido ao comportamento caducifólio da espécie. Ocorreu um aumento da fertilidade do solo após a implantação da cultura considerando o parâmetro matéria orgânica.

Height of complete bark girdling in *Ilex paraguariensis* to produce epicormic shoots / Alturas de anelamento completo em *Ilex paraguariensis* para produção de brotações epicórmicasBruno Nascimento¹, Alexandra Cristina Schatz Sá¹, Marcio Carlos Navroski¹, Mariane de Oliveira Pereira¹¹Universidade do Estado de Santa Catarina, Lages, Brasil (b.nascimento_92@hotmail.com; alexandra.schatz.sa@gmail.com; marcio.navroski@udesc.br; maripereira.florestal@gmail.com)

O uso de brotações epicórmicas em espécies florestais é de grande importância para o sucesso de sua propagação vegetativa. Este fato está relacionado com a idade ontogenética do material, pois quanto mais próximo da base da planta forem obtidas as brotações, maior vigor e possibilidade de enraizamento. O objetivo deste trabalho foi testar alturas de anelamento completo em genótipos de *Ilex paraguariensis* para produção de brotações epicórmicas. Foram selecionadas plantas nativas da espécie, sombreadas e fenotipicamente semelhantes, sendo aneladas em três diferentes alturas do solo (30, 60 e 90 cm), no município de Urupema – SC em agosto de 2016. A altura foi obtida com uma trena milimétrica e o anelamento efetuado com um facão, removendo-se somente a casca externa, não afetando o lenho, com aproximadamente 5 cm de largura. Com 210 dias avaliou-se: genótipos com brotações (%), número médio de brotos formados e comprimento médio de brotos (cm). A maior média de genótipos com brotações foi obtida para o anelamento a 90 cm (53%), enquanto os demais tratamentos apresentaram a mesma média (27%). Consequentemente, o número médio de brotos também foi maior para este tratamento (1,6), seguido por 60 cm (0,5) e 30 cm (0,3 cm). A mesma ordem decrescente foi constatada para o comprimento médio de brotos (1,6 cm; 0,9 cm e 0,4 cm). A maior brotação obtida aos 90 cm pode ter sido ocasionada pelo maior acúmulo de gemas dormentes nesta região. Ressalta-se que quanto mais altas forem produzidas as brotações epicórmicas, mais ontogeneticamente maduro é o material vegetal.

Effects of biofertilizers on survival and development of native seedlings used in pasture restoration in San Félix, Colombia / Efectos de biofertilizantes en la supervivencia y desarrollo de plántulas nativas en restauración de potreros en San Félix, Colombia

Mateo Molina López¹, Jaime Polania¹, Jessica López López¹, Carolina Serna¹

¹Universidad Nacional de Colombia Sede Medellín, Medellín, Colombia (mmolinal@unal.edu.co; jhpolaniav@unal.edu.co; jplopezl@unal.edu.co; csernac@unal.edu.co)

La biofertilización y la asociación con microorganismos permiten a las plantas mejorar la captación de nutrientes y desarrollar sus raíces, lo cual constituye una herramienta importante para sobrevivir procesos de reforestación y restauración ecológica. Además, los menores costos de mantenimiento contribuyen al éxito de estos proyectos. Un experimento de biofertilización en un predio con historial de uso ganadero en el altiplano occidental del Valle de Aburrá (Medellín, Colombia), incluyó *Psidium guajava*, *Tecoma stans* y *Citharexylum subflavescens*, elegidas por su rápido crecimiento y carácter heliófilo. Se utilizaron como biofertilizantes bacterias de los géneros *Azospirillum* y *Trichoderma* y, además, dos cubiertas para evitar el crecimiento de arvenses. El diseño fue en bloques aleatorios con cuatro tratamientos (i. control, sin tratamiento; ii. biofertilizante; iii. biofertilizante + cubierta de cartón; y iv. biofertilizante + cubierta de *Arachis pintoi*) y cuatro repeticiones; 64 individuos en total. Se midieron tasas de supervivencia/mortalidad, crecimiento y ancho de copa durante los siguientes seis meses. La supervivencia superó resultados de otro proyecto de mayor escala en Santander (Colombia: 85%) y, aunque no hubo diferencias significativas entre los tratamientos, las mayores alturas fueron alcanzadas por *C. subflavescens*. Todas las especies presentaron una tendencia general, mientras que el ancho de copa fue variable. Las diferencias entre tratamientos se atribuyen a la heterogeneidad espacial, la corta duración, dificultades del monitoreo y cuidado. La diferencia en supervivencia con Santander pudo derivar de condiciones distintas de clima, suelo, especies, y un mayor número de repeticiones.

Brightness in mini-cuttings of *Sequoia sempervirens* (D. Dom.) Endl. / Luminosidade na miniestaquia de *Sequoia Sempervirens* (D. Dom.) Endl.

Liliane Schicora¹, Marcio Carlos Navroski¹, Mariane de Oliveira Pereira¹, Tamara Rosa Gerber¹

¹Universidade do Estado de Santa Catarina, Lages, Brasil (lilianeschicora@yahoo.com.br; marcio.navroski@udesc.br; maripereira.florestal@gmail.com; tamygerber@hotmail.com)

A busca pela introdução de novas espécies florestais no Brasil é crescente e a valorização daquelas consideradas de madeira nobre inquestionável, podendo assim destacar-se *Sequoia sempervirens*. A produção de mudas da espécie por sementes possui vários empecilhos que dificultam sua propagação, sendo a miniestaquia uma alternativa viável. Objetivou-se comparar a produção e enraizamento de miniestacas de *Sequoia sempervirens* em diferentes condições de luz no minijardim clonal. O experimento foi desenvolvido em casa de vegetação, utilizando-se um clone (A228). Foi empregado o delineamento inteiramente casualizado com 15 repetições por tratamento, sendo cada repetição constituída de um vaso (uma minicepa). Os três tratamentos constaram de diferentes níveis de luminosidade, sendo: T1 – controle (sem sombreamento), T2 – minicepas com camada simples de sombrite (33% de sombreamento) e T3 - minicepas com camada dupla de sombrite (66% de sombreamento). Após 60 dias da aplicação dos tratamentos foi realizada avaliação de produção de miniestacas, sendo estas coletadas e postas para enraizar em estufim. Posteriormente (95 dias) realizou-se avaliação de sobrevivência (%), enraizamento (%) e número de raízes emitidas por miniestaca. A produção de miniestacas não apresentou diferença entre os tratamentos de luz, sendo a média de miniestacas por minicepa de 7,0. Não houve diferença entre os tratamentos na sobrevivência das miniestacas (100%) e também no número de raízes (média de 5,0). Quanto ao enraizamento das miniestacas, T3 foi superior 16% em relação ao tratamento controle, apresentando 93,7% de enraizamento. Apesar de não incrementar a produção de miniestacas, o sombreamento das minicepas eleva o enraizamento.

Fertilizing in clonal minihedges of *Sequoia sempervirens* (D. Dom.) Endl. / Adubação em minijardim clonal de *Sequoia sempervirens* (D. Dom.) Endl.

Marcio Carlos Navroski¹, Luís Fernando Chaves Duarte¹, Mariane de Oliveira Pereira¹, Pedro Henrique Tavares da Fonseca¹

¹Universidade do Estado de Santa Catarina, Lages, SC, Brasil (marcio.navroski@udesc.br; luisfchavesdt@gmail.com; maripereira.florestal@gmail.com; pedrohentavares@hotmail.com)

A adubação em minijardim clonal é indispensável em função da necessidade de uma nutrição adequada para a produção de miniestacas a partir de minicepas. Dessa forma, objetivou-se verificar a produção de miniestacas em função de diferentes tratamentos de adubação no minijardim clonal em vasos de *Sequoia sempervirens*. O minijardim clonal é formado por vasos (5 L), preenchidos com substrato comercial a base de casca de pinus e cobertura de vermiculita. Após o plantio nos vasos as mudas foram conduzidas com podas durante dois meses até o início do experimento. O delineamento utilizado foi inteiramente casualizado (DIC), com 5 repetições de uma minicepa cada. Testou-se quatro clones (A116, A117, A138 e A200) e quatro adubações, compostas por dois adubos administrados via diluição em água - fertilizante para fertirrigação (19-19-19) 1 g L⁻¹ e fertilizante organomineral (8-6-7) 10 ml L⁻¹ (1 L de solução por vaso) - e dois adubos adicionados aos vasos - fertilizante de liberação controlada (15-9-12) 10 g por vaso e fertilizante de liberação imediata (5-20-20) 5 g por vaso. A aplicação ocorreu quinzenalmente durante dois meses, momento em que foi realizada a coleta e contagem de miniestacas por minicepa. O fertilizante de liberação controlada apresentou a maior produção de miniestacas por minicepa em todos os clones (média de 31,5), seguido pelo fertilizante de liberação imediata (22,2). O fertilizante para fertirrigação apresentou menor média (10,5). Em relação aos clones, A200 foi superior em relação aos demais (29,2). Recomenda-se o uso do fertilizante de liberação controlada na adubação de minicepas de sequoia.

C1y: SILVICULTURE, NURSERY TECHNIQUES AND FERTILIZERS

Recognizing a non-industrial method as an alternative for germinating *Juglans neotropica* Diels / Reconocimiento del método artesanal como alternativa para la germinación de *Juglans neotropica* Diels

Yair Villanueva¹, Diego Rincon¹

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (yair_villanueva@yahoo.com, drinconprieto@gmail.com)

Las semillas de *Juglans neotropica* en relación con su testa, se caracterizan por ser muy duras y gruesas, impidiendo la disponibilidad de agua para el embrión y facilitando la latencia por lapsos de tiempo muy prolongados; considerando así su importancia en el estudio de tratamientos que disminuyan su tiempo de emergencia. Se desarrollaron dos métodos con el fin de disminuir el tiempo en la germinación de esta especie, procediendo a tapar las semillas con una bolsa negra durante el día y retirándola en la noche, la escarificación mediante la ruptura de la testa con una prensa, y el testigo sin tratamiento alguno. Controlando

variables de riego y suelo, se valoró porcentajes de germinación en cada tratamiento, donde sus resultados indicaron la mayor cantidad de semillas de *Juglans neotropica* germinadas en el método artesanal, teniendo en cuenta las diferencias significativas encontradas entre los testigos y las semillas del método artesanal.

Feasibility of composting sewage sludge from a treatment plant in Balneário Camboriú, Santa Catarina, Brazil for use as fertilizer / Análise da viabilidade da compostagem do lodo de esgoto da Estação de Tratamento de Esgoto de Balneário Camboriú, SC, para fins de adubação

Carla Claudino¹, Tania Pedrelli², Caio Rebouças², Pedro Cardoso¹

¹Universidade do Vale do Itajaí, Itajaí, Brasil; ²Empresa Municipal de Água e Saneamento, Balneário Camboriú, Brasil (carlaclaudino@yahoo.com; tania.p@emasa.com.br; caio.cardinali@emasa.com.br; pedrocardoso1056@gmail.com)

O lodo de esgoto possui elevada quantidade de matéria orgânica e nutrientes, de forma que, após receber tratamento adequado pode ser considerado um adubo. Logo, o presente estudo teve como objetivo efetuar e analisar o processo de compostagem como alternativa para o tratamento do lodo de esgoto da ETE - Nova Esperança, localizada no município de Balneário Camboriú - SC, para fins de adubação. Realizou-se a análise da composição física, química e biológica do lodo desidratado da ETE de amostras coletadas nos meses de abril a agosto de 2018, teste do tratamento do lodo desidratado com processo de compostagem com areação natural em formato de pilha, bem como avaliação da viabilidade da utilização do composto como adubo por meio da comparação das propriedades analisadas com o que estabelece as diretrizes do MAPA. Como resultado obteve-se que há alteração nas características físico-químicas e biológicas entre o lodo desidratado e composto final, que para se atingir a fase termófila, a pilha de compostagem do lodo da ETE – Nova Esperança precisa ser realizada com volume mínimo de 3,45 m³, atingindo com esse volume temperatura média de 53 °C em menos de um mês após o início do processo, bem como que o setor de paisagismo do município de Balneário Camboriú configura fonte insuficiente de material estruturante para compostagem de 100% do lodo de esgoto gerado na ETE – Nova Esperança. Por fim, o composto final foi classificado como adequado para utilização como adubo de forma a diminuir o passivo ambiental da ETE Nova Esperança.

Corn and soy productivity in integrated agroforestry and direct planting systems using organic or mineral fertilizers / Produtividade de milho e soja em sistemas ILPF e PD com adubação orgânica ou mineral

Paulo Hentz¹, Juliano Coruli Correa², José Juscelino de Oliveira¹, Luciane Cristina Lazzarin³, Gauana de Abreu Clamer¹

¹Instituto Federal Catarinense Campus Concórdia, Concórdia, SC, Brasil; ²Embrapa Suínos e Aves, Concórdia, SC, Brasil; ³Universidade do Contestado, Concórdia, SC, Brasil (paulo.hentz@ifc.edu.br; juliano.correa@embrapa.br; jose.oliveira@ifc.edu.br; luciane.lazzarin@unc.br; gauanadeabreu01@gmail.com)

A geração de fertilizantes orgânicos provenientes dos sistemas produtivos de suínos e aves no sul do Brasil traz a responsabilidade de utilizá-los na agricultura de acordo com recomendações técnicas para que não sejam encarados como potencial poluidor do ambiente e sim como fertilizantes aptos ao aumento da produtividade. A sua utilização em sistema de produção integrado pode resultar em ganhos econômicos e ambientais. O objetivo do trabalho foi avaliar a resposta da adubação com cama de aves (CA), dejetos de suínos (DS) e fertilizantes minerais (M) em relação à produtividade de milho e soja nas safras 2015/16 e 2016/2017 em sistema de produção integração lavoura-pecuária-floresta (ILPF) e sistema plantio direto (PD). O experimento foi conduzido no município de Concórdia-SC, onde o delineamento experimental foi blocos casualizados, com 3 repetições, em fatorial 2 x 4, sendo dois tipos de sistemas de produção (ILPF e PD) em interação com três tipos de fertilizantes DS, CA, M e o controle (sem adubação). A produtividade de milho apresentou diferenças em razão do sistema de produção, onde o PD foi superior ao iLPF, provavelmente em função do efeito de sombreamento do componente arbóreo sobre a cultura. A produtividade da cultura da soja demonstrou superioridade dos tratamentos CA e DS quando comparado com o mineral no PD em relação ao iLPF.

Influence of liming on growth of *Cedrela odorata* L. seedlings and attack by *Hypsipyla grandella* Zeller (Lepidoptera: Pyralidae)

John Alexander Pulgarín Díaz¹, Lucas Esteban Cano Gallego², Ángela María Arcila Cardona³

¹Corporación Colombiana de Investigación Agropecuaria, Centro de Investigación El Nus, Vereda Ica, Corregimiento San José del Nus, San Roque, Antioquia, Colombia; ²Agrosavia, Bogotá, Colombia; ³Corporación Colombiana de Investigación Agropecuaria, Centro (jpulgarin@agrosavia.co, lcanog@agrosavia.co; aarcila@agrosavia.co)

Cedrela odorata is one of the most important neotropical forest species; its commercial plantation is limited by *H. grandella* attacks. Inverse relation of available calcium concentration for *C. odorata* in the soil and *H. grandella* attacks had been reported; moreover, its height growth had been correlated with available phosphate concentration. The effect of adding dolomitic limestone (CaCO₃ 57.8% and MgCO₃ 36.7%) on the height-growth, aerial-biomass and attack by *H. grandella* on *C. odorata* seedlings was evaluated. Two months seedlings were planted in pots (21205 cm³) with vermicompost and sand (50%), pH 6.75, high saturation of calcium, magnesium and potassium. Treatments were 0 (T1), 200 (T2), 300 (T3) and 400 gm (T4) of dolomitic limestone. The seedlings were exposed to full sunlight for four months. Survival was 99.9% in all treatments. Height growth was positively influenced by liming, T3 showed the higher mean height (93.9 cm). Shoot-dry-weight was also affected by treatments, being T4 the one with the higher mean weight (59.96 g). T2 had the highest proportion of dry mass (38.9%). There was no difference in the number of attacks by *H. grandella* between treatments; however, the fact that the seedlings had a better growth, possibly due to a better nutrition, will help them reach commercial height in less time, reducing exposure to damage by *H. grandella*. Improving soil nutritional properties should be part of an integrated pest management scheme, although plants with better nutrition could improve the development of *H. grandella* larvae.

Cariniana pyriformis Miers growth in two light environments in Antioquia, Colombia

John Alexander Pulgarín Díaz¹, Lucas Esteban Cano gallego², Juan Pablo Gil Restrepo²

¹Corporación Colombiana de Investigación Agropecuaria, Centro de Investigación El Nus, Vereda Ica, Corregimiento San José del Nus, San Roque, Antioquia, Colombia; ²Agrosavia, Bogotá, Colombia (jpulgarin@agrosavia.co, lcanog@agrosavia.co; jpgil@agrosavia.co)

Cariniana pyriformis is a valuable species in South America wood market. It is harvested in the natural forest, in spite of being in critical danger of extinction. There is a substantial lack of information about the growth of Neotropical forest species, which constitutes the first steps to develop the forestry sector. Growth in height (H) and diameter at breast height (DBH) of *Cariniana pyriformis* were compared in two light environments and related to temperature, precipitation, evapotranspiration and relative humidity. In October 2013, three plots were established with 109 individuals at full-sunlight, and six with 59 individuals with 35– 43% shade, in a Neotropical humid forest; 15 dasometric evaluations were done, until 5.17 years old. Survival was 81% in full-sunlight and 89.8% in partial-sunlight. From 0.5 - 1.42 years old, full-sunlight individuals showed a greater mean annual increment (MAI) in H (1.58) than the ones in shade (1.35)

(pairwise comparisons). In the period of 1.42 - 5.17 years no differences were detected; nor were differences in MAI-DBH in pairwise comparisons in the 1.42 - 5.17 years period. At 5.17 years no differences in mean H between systems (7.1 m in full sunlight and 6.97 m shade) were found; but DBH was greater in full sunlight (8.46 cm) than in shade (6.03 cm). Relation between climate variables and MAI were not detected. Insects damage were only present until 2.31 years in partial shading in 64 individuals. This is the first work assessing the initial growth of *Cariniana pyriformis* in plantations, providing information for future plantations.

Ecological contribution of the Siempre Verde Forest in the Guangras community within Sangay National Park, Ecuador / Contribucion a la ecología del bosque siempre verde de la comunidad de guangras en el parque nacional sangay ecuador

Daniel Adrián Vistín Guamantaquí¹ , Héctor Barrero Medel²

¹Escuela Superior Politécnica de Chimborazo, Riobamba, Ecuador; ²Universidad de Pinar del Río, Pinar del Río, Cuba (daniel.vistin@epoch.edu.ec, hbarrero@upr.edu.cu)

Este trabajo tuvo como objetivo determinar el efecto de las variables ambientales edáficas y dasométricas sobre el bosque siempre verde de la comunidad de Guangras en la Parroquia Achupallas, Ecuador a partir de conocer su estado de estructura y composición actual. Se establecieron 4 transeptos de 3600 m² cada uno, dos en la parte baja y dos en la parte alta del área, distribuidos al azar, se realizó un estudio florístico, determinándose la diversidad, el Índice de valor de importancia ecológica (IVIE), el volumen por especie y un Análisis de Correspondencia Canónica (CCA) para analizar el efecto de las variables ambientales sobre la vegetación. Como resultados. Se registran un total de 18 especies arbóreas pertenecientes a 15 familias y 15 géneros siendo las más representativas las familias Cunoniaceae, Asteraceae y Myrtaceae, las especies de mayor IVIE resultaron *Miconia* sp, *Aegiphila* sp y *Weinmannia mariquitae* así como la inexistencia de un gradiente al resultar un CCA con inercia igual a 0.3564 donde las variables de mayor peso son las del suelo específicamente la pedregosidad, la textura y la fisiografía.

Aniba perutilis Hemsley and *Pachira quinata* (Jacq.) W.S. Alverson initial growth in a tropical humid forest in Antioquia, Colombia

John Alexander Pulgarín Díaz¹ , Lucas Esteban Cano Gallego², Juan Pablo Gil Restrepo²

¹Corporación Colombiana de Investigación Agropecuaria, Centro de Investigación El Nus, Vereda Ica, Corregimiento San José del Nus, San Roque, Antioquia, Colombia; ²Corporación Colombiana de Investigación Agropecuaria, Bogotá, Colombia (jpulgarin@agrosavia.co, lcanog@agrosavia.co; jpgil@agrosavia.co)

Aniba perutilis and *Pachira quinata* are valuable species in South America wood market. These species are harvested in the natural forest, taking their populations to high-degree of degradation. Information about their initial growth and interaction with environmental conditions are scarce and are essential for planning purposes. We correlated the growth in total height (H) and diameter at breast height (DBH) of *Aniba perutilis* and *Pachira quinata* with climate variables. In October 2013, three plots were established with 73 individuals of *Aniba perutilis*, and three plots with 107 individuals of *Pachira quinata* at full sunlight in an abandoned grassland for cattle; 15 dasometric evaluations were done until 5.17 years old. Monthly average temperature, relative humidity, precipitation, and evapotranspiration were registered; 16.5 % of individuals of *A. perutilis* survived. At 5.17 years mean annual increment (MAI) in H and MAI-DBH were 0.44 m and 0.35 cm, respectively. MAI-H correlated negatively with temperature, precipitation and evapotranspiration, and positively with relative humidity. All individuals of *P. quinata* survived. At 5.17 years MAI-H and MAI-DBH were 0.92 m and 1.41 cm, respectively. MAI-H correlated negatively with temperature and evapotranspiration, and positively with relative humidity; MAI-DBH correlated negatively with temperature and relative humidity, and positively with precipitation and evapotranspiration. In all assessments, 37.4% of the *P. quinata* individuals were leafless. Insect attacks were not significant in *P. quinata*, but *A. perutilis* presented 73 attacks in the 5 years of evaluation. This is the first assessment of the initial growth of *Aniba perutilis* and *Pachira quinata* providing information for future plantations.

Assessing restriction resulting from container volume on growth and allocation of resources in Cerrado tree species / Avaliação da restrição do volume do recipiente de cultivo no crescimento e alocação de recursos em espécies arbóreas de Cerrado

Caroline Stritar¹, Valdemir Laura², Silvia Pereira³, Fabiana Alves², Roberto Almeida²

¹Universidade Federal do Mato Grosso do Sul, Campo Grande, MS, Brasil; ²Embrapa Gado de Corte, Campo Grande, Brasil; ³Universidade Anhanguera, Campo Grande, MS, Brasil (carolramires.silva@gmail.com; valdemir.laura@embrapa.br; silviaraha@gmail.com; fabiana.alves@embrapa.br; roberto.giolo@embrapa.br)

O tipo e volume do recipiente utilizado no cultivo de mudas tem um efeito significativo na distribuição de recursos entre raiz e parte aérea, causando prejuízo significativo no desempenho das mudas. O objetivo foi avaliar o efeito do volume do recipiente de cultivo em três espécies florestais nativas no crescimento em altura e na alocação de recursos entre raízes e partes aéreas. O experimento foi conduzido em casa de vegetação, na Embrapa Gado de Corte em Campo Grande, MS, entre abril a outubro de 2018. As espécies utilizadas foram *Anadenanthera peregrina* var. *falcata* (Benth.) Altschul, *Hymenaea stigonocarpa* Mart. ex Hayne e *Myracrodruon urundeuva* Allemão. Após a germinação das sementes, as mudas foram cultivadas em recipientes de 110 cm³ (tubetinho), 290 cm³ (tubetão) e 7000 cm³ (citropote). O crescimento das mudas foi monitorado individualmente por 120 dias, através da medida da altura da parte aérea (cm). Ao final do experimento foram registradas as seguintes medidas: massa seca da raiz, massa seca da parte aérea, fração de massa na raiz e massa seca da planta. As diferenças em altura da parte aérea entre os tratamentos foram significativas apenas em *A. peregrina* e *M. urundeuva*. A massa seca da raiz também diferiu significativamente apenas em *A. peregrina* e *M. urundeuva*, recipientes de maior volume apresentaram valores maiores. A alocação de recursos para as raízes em *A. peregrina* e *M. urundeuva* foi negativamente relacionado com o tamanho da planta, já em *H. stigonocarpa* a relação com o tamanho da planta foi positiva.

C1z: SILVICULTURE AND PLANT COMMUNITIES

Population distribution and structure of *Afzelia* species in Southwestern Nigeria

Adejoke Akinyele¹, Akintunde Solomon¹

¹University of Ibadan, Ibadan, Nigeria (akinyelejo@yahoo.co.uk; solomonakintunde32@gmail.com)

Investigation was conducted to assess the population distribution and structure of *Afzelia* species in Southwestern Nigeria. The study areas are Omo Biosphere Reserve, Gambari Forest Reserve and Akure Forest Reserve. Data were collected in 125 plots of 2500 m² on diameter at breast (DBH ≥ 10 cm), total height and bole height of *Afzelia* species. Tree variables such as Blackman and Green indices, basal area, average diameter, height of Lorey and density were calculated and

interpreted. Density (0.06), diameter (0.01 cm), basal surface area (0.01 cm²), Lorey height (0.07 m) and Green index (0.03) were significant across locations while medium basal surface area (0.01 cm²) and Blackman index (0.01) were not. Density (0.23), stand/hectare and stand diameter (cm) (0.01) were significant for regeneration status while basal surface area (cm²) (0.00) was not significant for saplings. Diameter/hectare (0.01) and basal surface area (cm²) (0.23) were significant for seedlings while stand density/hectare (0.01) was not. Shannon index (1.54), Simpson index (0.82), and Shannon Maximum diversity index (2.89) in Akure Forest Reserve was highest while Gambari Forest Reserve had the least (0.80 and 0.45, respectively). Gambari Forest Reserve had the highest value for species evenness (0.28). The high diversity recorded from Akure Forest Reserve could be because of the management of the reserve under Forestry Research Institute of Nigeria (FRIN) which provided more security against illegal activities.

Tree community reassembly after selective and clear-cut logging in an Afro-tropical rainforest

Arthur Arnold Owiny^{1,2}

¹Uganda Christian University, Mukono, Uganda; ²Makerere University Biological Field Station, Kampala, Uganda (owinyiarnthor@yahoo.com)

Understanding the process of community reassembly is crucial for the conservation of biodiversity and rehabilitation of degraded forest ecosystems. This study tested whether tree communities in logged forests follow an equilibrium (deterministic) or nonequilibrium (stochastic) model of succession. We assessed reassembly of tree communities in different size classes along a successional gradient consisting of nine differently aged successional forests, namely, four regenerating former clear-cuts (9 to 19 years), three selectively logged (42 to 43 years) and two primary forests (PFs) in Kibale National Park, Uganda. The results show that the forests are converging and undergoing reassembly towards primary forest. The species composition of seedlings, saplings and poles declined in similarity to the PF with age but that of mature trees in the different successional stages increased towards the PFs. These differences in tree species composition among the different size classes might be due to dominance of some particular species. Recovery of tree species density, diversity and dominance in all the size classes showed directional patterns as predicted by the deterministic model of succession. Compared to other variables, tree species density and diversity in selectively logged forests recovered relatively faster and was equivalent to or higher than that of PFs at 43 years. The results of the present study indicate that community reassembly in smaller sized trees followed a stochastic model of succession. However, as trees matured, they conform to the deterministic model of succession. Disturbance had variable long-term effects on tree community structure, highlighting need of management and conservation priorities.

Pandanus spp.: A minor forest produce of cultural and economic significance in Southeast Asia

Wan Rasidah Kadir¹, Siti Fadzuari Radzali², Ahmad Kamal Ariffin²

¹Forest Research Institute Malaysia, Selangor, Malaysia; ²South East Johore Development Authority, Johor, Malaysia (rashidah@frim.gov.my; sitifadzuari@kejora.gov.my; kamal@kejora.gov.my)

Pandanus spp., having over 750 species, are integral part of rural and indigenous peoples' cultures. The species spread well over wetlands and coastal shores, has its own genus in Pandanales order and Pandanaceae family. Endemic to the tropics and subtropics, Pandanaceae are monocot and flowering plants. Species most sought after by the locals are *Pandanus amaryllifolius* for food preparation and *P. atrocarpus* for weaving and handicrafts. Village weavers are dwindling in numbers and this traditional knowledge will soon disappear without effective steps to promote the industry. Random survey carried out in Peninsular Malaysia showed that only one out of five premises still in operation. This is alarming thus a program to revive the industry was initiated. Recent finding revealed that *Pandanus* spp. are also exploited for medicinal and health food, as well as filler for fibreboard. Apart from their important resource for downstream, these species are integral in the daily lives of aborigines in their rituals. The Mah Meri tribes in Carey Island is one example. The species are fast declining partly due to shrinking interest by young generation, slow replanting effort, land use change and urbanization. A number of *Pandanus* species are known to be under threat as reported in the IUCN Red List Categories and Criteria 2015. This paper highlighted current effort undertaken to replant selected *Pandanus* species aimed at securing raw material for downstream product development particularly weaving industry. As *Pandanus* leaves are reputed to having strong fibre strand, product development could be extended to fibreboard production.

Effect of irrigation and fertilization on the growth and physiological characteristics of *Populus sibirica* at the afforestation site in dry-steppe of Mongolia

Byambadorj Ser-Oddamba¹, Park Byung Bae², Sainbuyan Zoljargal¹, Nyam-Osor Batkhuu¹

¹National University of Mongolia, Ulaanbaatar, Mongolia; ²Chungnam National University, Daejeon, Republic of Korea (seroddamba@gmail.com; bbpark@cnu.ac.kr; szoljargal13@gmail.com; nbatkhuu@gmail.com)

We have conducted comparative analysis of growth and physiological performances of planted Poplar (*Populus sibirica* Tausch) trees in dry-steppe of Mongolia with the objectives of 1) to determine effects of irrigation and fertilizer on the growth of trees; 2) to evaluate the physiological responses of planted trees on different irrigation and fertilization treatments. Two-year-old seedlings were planted in 2011 at four different irrigations (ambient, ambient+42mm / tree⁻¹, ambient + 84mm / tree⁻¹, ambient + 182 mm / tree⁻¹) and two fertilizer NPK (16:12:10); sheep manure (COMP) treatments and seven years of monitoring results on revealed that all measured variables (root collar diameter, height, survival rate, stomata number and their aperture, leaf water potential and leaf biomass) were significantly differed among treatments. Excellent growth performance was observed in trees grown at ambient + 8 l / hour tree⁻¹ and fertilized with NPK, respectively. Mean survival rate was 96.4% and the lowest was observed in ambient treatment with 12.5%. Diurnal measurement of leaf water potential revealed that trees were stressed by water deficit between 12:00 - 14:00 with lowest water potential in irrigation treatment ambient + 84 mm / tree⁻¹ (-3.3 ± 0.06MPa). Poplar trees grown in ambient treatment were more stressed by water deficit and could not recovered its required water even at predawn. Stomata aperture (open, half-closed, closed stomata) of trees tend to have more closed stomata in ambient treatment and trees in ambient + 182 mm / tree⁻¹ treatment showed high fluctuation of stomata aperture such as opening at predawn and closed at noon. Consideration of ecologically and physiologically important genetic variation within species is important which could be integrated into species selection strategies for successful ecological restoration.

Post-planting survival of *Anadenanthera colubrina* (Vell.) Brenan var. cebil [Griseb.] Altschul inoculated with mycorrhizal fungi under nitrogen and potassium fertilization in the Brazilian Pantanal

Márcia Toffani Simão Soares¹, Gustavo Ribas Curcio¹, Fernando Antônio Fernandes², Sérgio Gaiad¹, Shizuo Maeda¹, Alexander Silva de Resende³, Marcos Silveira Wrege¹, Gustavo Ibarreche Menezes⁴

¹Embrapa Florestas, Colombo, Brasil; ²Embrapa Pantanal, Corumbá, Brasil; ³Embrapa Agrobiologia, Seropédica, Brasil; ⁴Guará Ambiental, Corumbá, Brasil (marcia.toffani@embrapa.br; gustavo.curcio@embrapa.br; fernando.fernandes@embrapa.br; sergio.gaiad@embrapa.br; shizuo.maeda@embrapa.br; alexander.resende@embrapa.br; marcos.wrege@embrapa.br; guarambiente@gmail.com)

The objective of this work was to compare the post-planting survival of *Anadenanthera colubrina* (Vell.) Brenan var. [Griseb.] Altschul inoculated with mycorrhizal fungi (MF) under nitrogen plus potassium fertilization in Brazilian Pantanal. The experimental area is located in the sub-region of Nhecolândia, in a physiognomy called “cordilheira”, where there was almost complete suppression of tree vegetation, with few individuals remaining. The experimental design was randomized blocks with subdivided plots and three replicates. The main treatments consisted in seedlings planted (March 2015) in 6 m² (3 x 2 m) space, submitted or not to MF (*Glomus clarum* and *Gigaspora margarita*) inoculation. The secondary treatments received at the planting pit, respectively, 15 g + 5 g (A), 30 g + 10 g (B) and 30 g + 15 g (C) of ammonium sulphate and potassium chloride. At two months after planting, there was no effect of MF inoculation on survival and regrowth of seedlings. However, the survival were higher in the plots located in the inferior position of the “cordilheira”, closer to the watercourse, and under a lower dose of nitrogen plus potassium fertilization ($p < 0.01$). The results obtained suggested that, in Pantanal Wetland conditions, it is extremely recommended the monitoring and adaptation of soil fertility management in function of soil water supply, to reduce the environmental vulnerability related with the typical hydric and climatic fluctuations of this region.

Modelling diametric distribution of *Brachystegia spiciformis* Benth. in Miombo forest, Mozambique

Celio Josefa¹, Helder Juliao¹, Arnaldo Uetela¹

¹Instituto Superior Politecnico de Manica, Chimoio, Mozambique (celiovasconcelos22@yahoo.com.br; juliaohelder@gmail.com; autela@gmail.com)

The identification and estimation of quantitative characteristics of tree species are considered as the initial requirement for forest planning. Therefore, it was intended with this work, to select among Weibull, Gamma, Beta, Sb Johnson, Normal and Log-normal, provide the most appropriate to describe the diametric distribution *Brachystegia spiciformis* Benth. The quality adjustment produced by the methods of probability distribution was measured by the nonparametric adherence index Kolmogorov-Smirnov a 5% level of probability. The results indicated that there are more trees on the smaller diameter class than in larger diameter class. The functions of Weibull and Gamma, were selected to describe the diameter distribution of *Brachystegia spiciformis* Benth.

Genetic variability for juvenile characteristics of progeny of *Apuleia leiocarpa* Vog. Macbride / Variabilidade genética para caracteres juvenis de progênes de *Apuleia leiocarpa* Vog. Macbride

Queli Cristina Lovatel¹, Marcio Carlos Navroski¹, Tamara Rosa Gerber¹, Mariane de Oliveira Pereira¹, Franciele Sombrio¹, Luciana Magda de Oliveira¹, Ligiane Lissandrina Ongaratto¹

¹Universidade do Estado de Santa Catarina, Lages, Brasil (queli.lovatel@edu.udesc.br; marcio.navroski@udesc.br; tamygerber@hotmail.com; maripereira.florestal@gmail.com; fran_sombrio@hotmail.com; luciana.oliveira@udesc.br; ligiane.ongaratto@edu.udesc.br)

Os estudos de variabilidade genética em populações de espécies nativas servem de subsídio para a busca de progênes com alto desempenho, que podem ser utilizadas para restauração florestal ou em estudos para plantios comerciais. Com este foco, o objetivo do trabalho é verificar a existência de variabilidade genética para caracteres juvenis em 13 progênes de *Apuleia leiocarpa*. As matrizes foram marcadas em área de Floresta Estacional Decidual no Sul do Brasil, destinadas à coleta de sementes. Realizou-se a biometria (comprimento e largura) em um lote de 100 sementes de cada matriz. A semeadura foi efetuada em blocos acaso com 13 tratamentos (progênes), 17 plantas por parcela linear e oito repetições. Coletou-se informações sobre o índice de velocidade de germinação e taxa de germinação (%). A análise dos dados foi realizada por análise de variância (ANOVA) com o auxílio do software estatístico SELEGEN (modelo 82). Os resultados apontam que a maior taxa de germinação foi de 92,6% para a matriz AL 09 e menor taxa de 33% para a matriz AL 37. Para a biometria de sementes, houve diferença significativa entre as matrizes pela ANOVA ($p < 0,05$), sendo que a matriz AL 09 obteve as menores médias de comprimento e largura, não interferindo na taxa de germinação. Para análise genética, a herdabilidade individual no sentido restrito foi alta, com valor de 1,40 ($\pm 0,58$) para a variável comprimento de sementes e 3,04 ($\pm 0,86$) para a variável largura, sendo características com alto potencial de herdabilidade.

Leaf litter decomposition and nutrient content of selected agroforestry tree species

Adejoke Akinyele¹, Ugonma Donald-Amaechi¹

¹University of Ibadan, Ibadan, Nigeria (akinyelejo@yahoo.co.uk; u.longman81@gmail.com)

Litter decomposition and nutrient release are major sources of nutrient return into the soil. Investigation was carried out on leaf litter decomposition and nutrient content of three agroforestry species - *Annona muricata* L., *Senna siamea* (Lam.) and *Cola nitida* (Vent.). Oven-dry leaf litters of each species was put in 144 litterbags of 23 g each. These were divided into two sets with a set placed on soil surface (SSP) and the other, soil incorporated (SIP) mode of leaf litter decomposition giving a 3 x 2 factorial in RCBD. Initial nutrient content (INC), decay constant and half-lives (weeks) were determined. Decomposition rates, nitrogen release pattern (NRP), total organic carbon (TOC) and litter quality were measured fortnightly for 24 weeks after litter placement (WALP). Data collected were subjected to descriptive statistics and ANOVA at $p < 0.05$. The INC was significantly different among the species. N concentration decreased from *C. nitida* < *A. muricata* < *S. siamea*. P was significantly higher in *S. siamea* (0.38%) than *C. nitida* (0.22%) and *A. muricata* (0.32%). In SSP, decay constant and half-lives for *A. muricata* and *S. siamea* (0.004) (24.8) were significantly higher than *C. nitida* (0.005) (19.8) while *C. nitida* and *S. siamea* (0.002) (49.5) were significantly higher than *A. muricata* (0.003) (33.0) in SIP. Results on decomposition rates, NRP, TOC and litter quality are shown in the figures. These species could be effective in soil nutrient addition in an agroforestry system.

C2a: TECHNICAL INNOVATIONS IN FOREST REGENERATION AND RESTORATION

Slash and burn agriculture as silvicultural treatment to regenerate *Swietenia macrophylla* King

Patricia Negreros-Castillo¹ , Imelda Martínez-Salazar², Claudia Álvarez Aquino³, Angélica Navarro Martínez⁴, Carl W Mize⁵

¹Academia Nacional de Ciencias Forestales, Ciudad de México, Mexico; ²Investigador Independiente, Chetumal, Mexico; ³Universidad Veracruzana, Xalapa, Mexico; ⁴Colegio de la Frontera Sur, Chetumal, Mexico; ⁵Iowa State University, Ames, USA (patri_nc@yahoo.com, ims_puma@hotmail.com; aacaudia@yahoo.com; manavaster@gmail.com; carlmize@gmail.com)

Swietenia macrophylla King (mahogany) is the most important tree species commercially in tropical America. It is so important that it could be considered a 'financial' keystone species because its absence increases the likelihood of conversion of a forest to another, more profitable land use. Slash and Burn Agriculture (SBA) has been used in the Maya region of the Yucatan peninsula, Mexico for more than 3,000 years, and it is the most spatially distributed disturbance in the region. Abandoned SBA fields seem to create suitable regeneration conditions for mahogany; in fact, mahogany populations in the Yucatan Peninsula exhibit strong spatial correlations with abandoned SBA fields. This research reports on direct seeding of mahogany in three slash and burn fields in Betania, Quintana Roo, Mexico during the last cropping year. In each field 121 planting sites were located in a 0.25 ha plot, and five seeds were sown at each planting site. Soil color and shading of each planting site were noted. Height, diameter and indications of damage by *Hypsipyla grandella* of all sprouted seeds were recorded at 2, 11, 23, 38, 45, and 58 months after sowing. Five years later 63% of seedlings had died, leaving 7.4% of the planting sites occupied by a seedling. Seedling height varied from 0.3 to 8 m after 58 months. Remarkably, none of 212 seedlings showed indications of damage by *H. grandella*.

From past to future: approaches to protect seeded acorns against consumption by granivorous rodents

Adrian Villalobos¹, Mattias Engman¹, Magnus Löf¹

¹Swedish University of Agricultural Sciences, Alnarp, Sweden (adrian.villalobos@slu.se; mattias.engman@slu.se; magnus.lof@slu.se)

As one of the oldest methods for forest restoration, direct seeding has the potential to improve the cost-efficiency of oak restoration programs around Europe. However, acorn consumption by granivorous rodents such as the bank vole (*Myodes glareolus*) and the wood mouse (*Apodemus sylvaticus*) is one of the major drawbacks for the implementation of this low-cost method. Through the years several techniques have been developed in order to protect acorns from consumption. These techniques are classified into chemical, ecological, physical and site preparation approaches. The goal of these methods is to reduce the consumption of acorns, without impairing germination and seedling performance. But at the same time operation costs may increase and therefore reduce the benefits of direct seeding when compared to planting. Therefore, here we present the advantages and disadvantages of the different methods developed for acorn protection. We show the results of our current state of the art field and laboratory projects using volatile organic compounds from feces, urine or fur of rodent predators such as the stoat (*Mustela erminea*), American mink (*Neovision vision*), and the red fox (*Vulpes vulpes*) to deter acorn consumption from rodents. Additionally we used acorn based volatile compounds to camouflage seeded acorns. Finally, we aim to review the best available methods and the potential upcoming technologies for acorn protection in direct seeding.

Subirrigation effects on larch seedling growth, root morphology, and media chemistry

Fangfang Wan¹, Amy Ross-Davis², Wenhui Shi³, Christopher Weston⁴, Xiehai Song¹, Xiaochao Chang¹, Anthony Davis², Yong Liu¹, Fei Teng¹

¹Beijing Forestry University, Beijing, China; ²Oregon State University, Corvallis, USA; ³Zhejiang A&F University, Zhejiang, China; ⁴the University of Melbourne, Creswick, Australia (wanfangfang1991@163.com; rossdava@oregonstate.edu; shiwenhui2008@163.com; weston@unimelb.edu.au; sxiehai@163.com; changxiaochao@bjfu.edu.cn; anthony.davis@oregonstate.edu; lyong@bjfu.edu.cn; tengf7@chinaunicom.cn)

Subirrigation (SI) is regarded as an environmentally-responsible method of delivering water and fertilizer to nursery-grown plants. But a potential higher salt concentration in the upper layers of growing media under SI may inhibit root growth and result in decreased plant quality, few studies have focused on how root morphology is altered by SI. This study assessed the growth response of larch seedlings when subjected to three rates of fertilization and grown using SI or overhead irrigation (OI) for one nursery season. Associated changes between rhizosphere electrical conductivity (EC) and root morphology of different root size classes were analyzed. Results show that (1) SI and OI seedlings had similar height, root-collar diameter, and root volume. However, (2) compared to OI-seedlings, SI-seedlings had less root mass, length, and surface area but greater average root diameter (ARD). (3) Morphological differences were evident primarily in root diameter size classes I – III ($D \leq 1.0$ mm). (4) Fertilizer rate influenced root length and surface area up to 130 days after sowing. (5) As the growing season progressed, SI-media had significantly higher EC compared to OI-media and EC increased with increasing fertilizer rate under SI but not under OI. These results indicate that SI can produce larch seedlings of similar height and root collar diameter (RCD) compared to OI, but root systems are smaller overall with fewer small-diameter roots, which may be related to high EC levels in SI-media. Therefore, the EC in the media should be monitored and adjusted by reducing fertilizer rates under SI.

Interactive effects of seedling stock size and vegetation management treatments on Douglas-fir plantation productivity after 10 growing seasons

Maxwell Wightman¹, Carlos Gonzalez-Benecke¹, Eric Dinger¹

¹Oregon State University, Corvallis, USA (maxwell.wightman@oregonstate.edu; carlos.gonzalez@oregonstate.edu; ericd@rfpco.com)

Forest vegetation management (FVM) treatments and seedling stock type selection are important considerations in any reforestation project. The growth and survival of Douglas-fir seedlings has been shown to benefit from FVM, but the interactive effects of stock size and FVM are less well understood. This study tested the combined effects of three FVM regimes and three containerized stock sizes on Douglas-fir growth over ten years. Stock types included styro-8, styro-15, and styro-60 seedlings creating large differences in seedling size at the time of planting. FVM treatments included a no action control, a pre-planting herbicide treatment followed by a spring release during the first growing season, and a pre-planting herbicide treatment followed by a spring release during the first and second growing seasons. Plots that received an herbicide application had lower competing vegetation cover and higher stand volume than the no action control after ten growing seasons. The herbicide treatments applied in this study also had a long-term effect of the cover of shrubs, especially *Gaultheria shallon*, and shrub cover was well correlated with stand growth. Styro-60 seedlings were also larger than styro-8 seedlings after ten growing seasons but did not differ from the styro-15 seedlings. At age 10 years, the only significant stock type by FVM interactive effect was the styro-60 seedlings growing under the no action control treatment having a higher mortality rate than all other treatment combinations.

Pre-planting root system as a quality parameter for forest species seedlings / Sistema radicular pivotante pré plantio - como parâmetro de qualidade das mudas de espécies florestais

Osmar José de Aguiar¹, Jaqueline Sousa Almeida¹

¹Universidade do Estado do Pará, Belém, Brasil (o.aguiarromeiro@gmail.com; jaqueline_almeida23@hotmail.com)

Apesar das altas produtividades e competitividades das florestas plantadas no Brasil, problemas fisiológicos e de fitossanidades ocorrem com frequência na região Norte. Como forma de justificar esses problemas, levantou-se a seguinte hipótese: “Mudas florestais com meristema apical radicular danificado, serão mais susceptíveis ao estresse, principalmente, nos períodos de déficit hídrico”. Sabendo-se que, com a retirada dessas células, a raiz pivotante se atrofia, e a eficiência na busca de umidade no solo, torna-se reduzida, como consequência a baixa resistência natural, aumentando a susceptibilidade à pragas e doenças. Na avaliação do desenvolvimento comparativo da parte aérea com a raiz, das mudas de *Khaya ivorensis* A. Chev., e *Genipa americana* L., semeadas em sacos plásticos de 17 cm x 27 cm, no viveiro em São Francisco do Pará. Selecionou-se mudas com 5 cm, 10 cm e 15 cm de altura da parte aérea, com dez repetições cada. Foi observado uma correlação direta, entre o comprimento da parte aérea e raiz, quando a parte aérea atinge altura de 10 cm, a raiz atinge o fundo do saco, o que induzirá ao envelhecimento da pivotante ou se ultrapassar, será danificada, na remoção do saco no canteiro. Deste modo, parâmetros de qualidades como: idade, parte aérea e a relação da sua massa seca com a da radicular, podem não serem suficientes para garantir bom desenvolvimento das mudas nos plantios. Espera-se que no final dessa pesquisa, poder desenvolver um novo sistema de produção de muda, onde a integridade das raízes pivotantes seja considerado como parâmetro de qualidade.

Detecting seedling physiology with a Near Infrared (NIR) Consumer digital camera

Francesca Giannetti¹, Sabrina Raddi¹, Sofia Martini¹, Alberto Maltoni¹, Andrea Tani¹, Gherardo Chirici¹, Barbara Mariotti¹ 

¹Università di Firenze, Firenze, Italy (francesca.giannetti@unifi.it; sabrina.raddi@unifi.it; sofia.martini@unifi.it; alberto.maltoni@unifi.it; andrea.tani@unifi.it; gherardo.chirici@unifi.it; barbara.mariotti@unifi.it)

The development of new methods to monitor plantation physiological status is a key point to strengthen the success of forest restoration projects in a climate change context. An innovative forefront role can be played by NIR Consumer digital cameras. This technology, considered by remote-sensing communities as a cost-effective forest monitoring method over large area, can provide highly detailed data also at single plant scale. Our study aimed to test the possibility of monitoring seedlings physiology by NIR camera images (i.e. CANON S110 NIR) and their derived vegetation indices with the leaf physiological measurements by spectrometer and fluorimeter (i.e. USB-2000 Ocean Optics and PAM-2000 Walz). The final objective was to evaluate if in future NIR camera can be a reliable tool to assess seedling physiology both in nursery and after transplanting. In 2018, two parallel experiments were carried out on seedlings coming from the same nursery stock grown in 2017 in Central Italy: six different combinations of three *Quercus* species grown in two substrates (peat and coconut fiber), and three different fertilizations (nursery standard, P-enriched, K-enriched). We concurrently monitored seedlings both during a water test under controlled conditions (three water regimes) at leaf and plant scale, and at plantation scale by an Unmanned Aerial Vehicle. The first results revealed a good correlation between spectrometer and NIR camera bands, with the advantage for NIR camera of collecting information on images that cover one or several entire leaves and, potentially, the whole plant in comparison with the on-time punctual data obtained by spectrometer.

Restoring native forests in Brazil with direct seeding / Restaurando florestas nativas no Brasil com semeadura direta

Eduardo Campos Filho¹, Guilherme Carmo², Heber Alves², Lara Costa², Juliano Nascimento³, Rodrigo Junqueira⁴

¹Instituto Socioambiental, São Paulo, Brasil; ²Instituto Socioambiental, Canarana, Brasil; ³Instituto Socioambiental, Eldorado, Brasil; ⁴Instituto Socioambiental, Brasília, Brasil (eduardomalta@socioambiental.org; guilhermepompiano@socioambiental.org; heber@socioambiental.org; lara@socioambiental.org; juliano@socioambiental.org; rodrigojunqueira@socioambiental.org)

A semeadura direta de muvuca de sementes tem sido utilizada e aperfeiçoada desde 2006 no Xingu, pelo ISA - Instituto Socioambiental e parceiros, onde tem sido considerada uma forma ágil, barata e eficaz de restauração florestal, com aspectos que dialogam com as habilidades dos proprietários rurais e, conseqüentemente, com a restauração em larga escala: flexibilidade técnica para a implantação, desde a mecanização até o plantio manual, melhor desenvolvimento de raízes e resistência a secas, densidade dos grupos ecológicos e distribuição espacial mais semelhante a capoeiras naturais e rápida cobertura do solo. O método é recente no Brasil, embora seja utilizado há décadas em outros países. Serão apresentadas técnicas e resultados de semeaduras diretas de muvuca monitoradas em MT, SP, BA e ES nos biomas Amazônia, Cerrado e Mata Atlântica. Os cuidados desde a escolha de espécies, coleta, beneficiamento e armazenamento das sementes, preparo do solo, plantio, monitoramento e manejo, incluindo uso ou não de herbicidas serão abordados. Serão discutidas questões sobre a cadeia produtiva para a semeadura direta, custos, resultados ecológicos e sociais, gargalos e principais lacunas para o aprimoramento do método. A estruturação de uma cadeia regional de produção de sementes, que seja capaz de atender à demanda da semeadura direta e de produzir os benefícios sociais, econômicos e de biodiversidade almejados pelos diferentes atores envolvidos, depende da governança sobre a produção de sementes e sobre a demanda por sementes nativas decorrentes das áreas a restaurar a cada ano.

C2b: TOLERANCE OF EUCALYPTUS CLONES TO ABIOTIC AND BIOTIC STRESSES: BUILDING THE FOUNDATION FOR THE FUTURE PLANTATIONS

ENVIROTYPING in forest tree breeding: exploitation of genotype by environment interaction to avoid misallocation of genotypes in field deployment

Rafael Tassinari Resende^{1,2}, Orzenil Bonfim Silva-Junior², Dario Grattapaglia^{2,3}

¹Universidade Federal de Goiás, Goiânia, Brasil; ²Embrapa Recursos Genéticos e Biotecnologia, Brasília, Brasil; ³Universidade Católica de Brasília, Brasília, Brasil (rafael.tassinari@gmail.com; orzenil.silva@embrapa.br; dario.grattapaglia@embrapa.br)

We present GIS-GE, which is a strategy for exploiting G x E interaction aimed at maximizing genetic gain, allowing for recommending genotypes in a geospatial way. In our approach, a land area represents an envirome from which genetic traits of organisms, develop. An envirome is a set of envirotypes from the expression of all the environmental factors in that area that interact with the genetic makeup of the organisms resulting in rank differences based on estimates of breeding value. Here, we used GIS-GE on simulated data to develop maps of 100 envirotypes and estimate their effects simultaneously from a limited number of phenotypic records for a trait gathered from genotypes in field deployments. In the simulation, a square land area is a geoprocessing

environment of 10,000 pixels, wherein 50 breeding trials of the same genotypes (i.e. eucalyptus clones) are randomly allocated. We used 100 non-related genotypes expressing a low heritability quantitative trait that mimics yield. GIS-GE uses spatial interpolation to environmental data, referring either to climatic and landscape variables, to define Environmental Indexes (EI) by their relationship to the phenotypic data, totaling 1 million of envirotypic markers (100 envirotypes * 10,000 pixels). For this envirotype, we used advanced genetic modeling to estimate the EI effects across the whole set of pixels. We show that GIS-GE presents advantages in breeding, including matching of genotypes to their most appropriate sites; definition of breeding areas of highest genetic correlation to genotypes; and indication of the locations that maximize the capture of lost phenotypic heritability in trials.

Full-rotation carbon, water and energy fluxes in a tropical eucalypt plantation

Yann Nouvellon¹, José-Luiz Stape^{2,3}, Gueric le Maire^{1,4}, Jean-Marc Bonnefond⁵, Joannès Guillemot^{1,6}, Mathias Christina¹, Jean-Pierre Bouillet^{1,6}, Otávio Campoe^{3,7}, Jean-Paul Laclau^{1,3}

Eucalyptus plantations in Brazil are among the most productive forests of the world, reaching mean annual increments of about 50 m³ ha⁻¹ yr⁻¹ over short (6 - 7 yrs) rotations. We continuously monitored water vapor, CO₂ and energy flux through the eddy-covariance method over a 9 year-period in southeastern Brazil. Tree growth, Leaf Area Index (LAI), water table depth, and soil water content (SWC) down to 10 m depth were also monitored. Rooting depth and vertical fine root distribution were assessed at various ages. Mean annual evapotranspiration (AET; 1383 mm yr⁻¹) represented 90% of the annual precipitations (P; 1539 mm yr⁻¹). AET reached maximum values (1598 mm yr⁻¹) about 2-3 years after planting (a.p) when LAI peaked and when deep rooting (about 15 m deep 2.5 yrs a.p) provided access to the large amount of water stored in deep soil layers during the first months after clear-cutting and replanting. Most (88%) of the available energy (3852 MJ yr⁻¹) was partitioned to the evaporation process (latent heat fluxes), with very low sensible heat fluxes over the rotation, except after harvesting and replanting when LAI was low, and later in the rotation during dry events. Deep drainage after harvest of the first stand allowed the water table to rise from -18 to -12 m over the first 2 years after replanting. Both measurements of SWC and model simulations showed that deep water storage and subsequent uptake played a major role in supporting the very high wood production and dampening seasonal droughts.

Light use efficiency and productivity of 16 genotypes of *Eucalyptus* along a 6-year rotation in Brazil

Gueric le Maire^{1,2}, Joannès Guillemot^{1,3}, Otávio Campoe^{4,5}, José-Luiz Stape^{5,6}, Jean-Paul Laclau¹, Yann Nouvellon¹

¹CIRAD, Montpellier, France; ²Universidade Estadual de Campinas, Campinas Brasil; ³Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Piracicaba, Brasil; ⁴Universidade Federal de Santa Catarina, Curitiba, Brasil; ⁵Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu Brasil; ⁶Suzano Pulp and Paper, Suzano, Brasil (gueric.le_maire@cirad.fr; joannes.guillemot@cirad.fr; otavio.campoe@ufsc.br; t ape@suzano.com.br; laclau@cirad.fr; yann.nouvellon@cirad.fr)

Forest stemwood productivity depends on the amount of absorbed light and on the Light Use Efficiency (LUE), i.e. the amount of stemwood produced per amount of absorbed light. Other growth limiting factors than absorbed light are for instance water and nutrients, carbohydrates allocation processes, and management practices. In fertilized eucalyptus plantations in Brazil, a shift in the main factor limiting growth is expected, from light at the beginning of the rotation (not limited by water because soil has been recharged during the interval between rotation) to other factors such as water in the subsequent years. Changes of allocation patterns and foliar traits also occur along the rotation. These trends may differ between genotypes. These hypotheses were tested along a 6-year rotation, with 16 contrasted genotypes planted in 10 randomized repetitions in São Paulo Region, Brazil. Absorbed light was estimated using the MAESTRA 3D model precisely parameterized at tree scale for each plot. Stand growth was computed based on allometric relationships calibrated on regular destructive biomass measurements. Results at stand scale showed that 1) LUE increased with stand age for all genotypes, from 0.15 to 0.70 g_{dry_matter}/MJ on average; 2) light was the main limiting factor during the first year of growth (R² between 0.5 and 0.95). Subsequently, the variability of wood production explained by light was variable among genotypes (R² of 0.25 on average); 3) The effect of genotype on stemwood production remains high and significant along the rotation. These results and their implications for plantation management are discussed.

Unraveling drivers of growth dominance and its impact on stand growth of *Eucalyptus* plantations across Brazil

Alvaro A. V. Soares¹, Otávio Campoe², Rafaela Carneiro³, David I. Forrester⁴

¹Universidade Federal de Uberlândia, Monte Carmelo, Brasil; ²Universidade Federal de Lavras, Lavras, Brasil; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ⁴Swiss Federal Institute for Forest, Snow and Landscape Research-WSL, Birmensdorf (alvaroavsoares@gmail.com; otavio.campoe@gmail.com; rafaela@ipef.br; david.forrester@wsl.ch)

Growth dominance (GD) occurs when trees grow disproportionately to their size compared to other trees. High growth dominance indicates that stand growth is concentrated in larger trees, leading to further increase in size heterogeneity in stand structure. Growth dominance increases have been associated with lower productivity in tree monocultures, especially in monoclonal stands such as the eucalypt plantations in Brazil. Understanding how GD develops for different eucalypt genotypes and the effects of site and age are fundamental to understand the link between stand structure and productivity. We used data from the TECHS-IPEF cooperative research program, a continental experimental platform, in which different genotypes were planted in sites ranging from north Brazil to Uruguay. We chose four contrasting sites regarding soil water deficit, in which 18 genotypes were planted in monoclonal plots at 3 m × 3 m spacing (genotype differed among sites). Two adjacent plots were established for each genotype, one treated with 30% throughfall exclusion. We investigated whether there was difference in the development of GD among genotypes; whether water stress (represented by the contrasting sites and by throughfall exclusion within site) affects GD; and whether GD is associated with decreasing plot volume increment. We found significant differences in GD, as well as in its development throughout time, among genotypes. GD increased with age and tended to be lower with slowest development for the drier sites as well as for the throughfall exclusion plots. After other factors were accounted for, increasing GD was associated with decreasing plot volume increment.

Variation in basic wood density of *Eucalyptus* clones in tropical regions of Brazil

Maria Almeida¹, Sofia Rocha¹, Graziela Vidaurre¹, Rafaela Carneiro², Otávio Campoe³

¹Universidade Federal do Espírito Santo, Jerônimo Monteiro, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ³Universidade Federal de Santa Catarina, Curitiba, Brasil (narunafelix@gmail.com; sofiamaria.r@hotmail.com; grazividaurre@gmail.com; rafaela@ipef.br; otavio.campoe@ufsc.br)

Wood density is considered one of the main attributes of wood quality. Edaphoclimatic differences are commonly used for selection of species and planting sites, with wood density being influenced differently by meteorological variables. The aim was to assess the variation of wood density in eucalyptus clones planted in tropical regions of Brazil by the correlation of density with meteorological variables. Eucalyptus clones (R9 - *E. urophylla*, B2 - *E. urophylla* x *E. grandis*, H8 and D4 - *E. grandis* x *E. urophylla*) were analyzed at 4 years, in 10 sites distributed in wide climatic variation of the TECHS-IPEF Cooperative Research Program. Three trees from each site were sampled and the basic wood density (BD) was determined. For each clone, BD was correlated with mean annual increment (MAI), temperature (T), precipitation (P), soil water deficit (SWD) and maximum vapor pressure deficit (VPD). Only clone B2 showed significant correlations between BD and T, SWD, VPD and MAI. In the others, density didn't correlate with any variable, which may be associated to low BD variation coefficient between sites (10%) or indicating a nonlinear relationship. In humid sites (Arapoti/Telêmaco), clones showed same densities values, ranging from 0.37 to 0.42 g cm⁻¹. The same behavior was observed in the site with greatest SWD (Bocaiúva), however with densities ranging from 0.49 to 0.55 g cm⁻¹, while in sub humid sites, similar values of SWD was associated with different densities means. In general, the effects of meteorological variables in BD are more evident in extreme situations related to high or lower SWD.

Development of dynamic dominant height equations with parameters refined by water availability in clonal eucalypt stands in Brazil

Henrique Scolforo¹, Cristian Montes², John Paul McTague², Otávio Campoe¹, José Stape¹

¹Suzano, Limeira, Brasil; ²University of Georgia, Athens, USA; ³Federal University of Santa Catarina, Curitiba, Brasil (hscolforo@suzano.com.br; crmontes@uga.edu; forestbiometrician@yahoo.com; tavio.campoe@gmail.com; stape@suzano.com.br)

Growth models refined by environmental variables are capable of updating forest inventories and recomputing site quality in clonal eucalypt stands. However, there is a lack of studies quantifying the uncertainty associated with modeling mean response as well as the bias involved in the dominant height estimation. A modeling approach that accounts for the impact of water availability in the projection of dominant height, as well as in the projection uncertainty, is desired. This study aims to calibrate the best dominant height projection curve to be applied for a variety of clones in Brazil. Two approaches are compared: 1) the data assimilation approach, as implemented by a Kalman-Filter; 2) the difference approach, as implemented by the algebraic difference approach combined to mixed modeling. The first approach separates observation error from process error, which quantifies the impact of climate variation on dominant height growth and provides a measure of the uncertainty in the height projection. The second approach assumes estimation error as process error only and is commonly applied to assess site quality in Brazil. The dataset is part of the Cooperative Research Program TECHS-IPEF and originates from remeasurements of 16 sites across a climatic gradient in Brazil. At each site, the same eleven eucalypt clones were planted in single plots. We propose a new dominant height curve that possesses the ability to make long-term projections with better and sounder biological behavior for eucalypt stands.

Use of process-based models for sustainable intensification of *Eucalyptus* plantations by yield gap analysis

Elvis Felipe Elli¹, Paulo Cesar Sentelhas¹, Cleverson Henrique de Freitas¹, Rafaela Carneiro², Clayton Alcarde Alvares²

¹Escola Superior de Agricultura "Luiz de Queiroz" - Universidade de São Paulo, Piracicaba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (elvisfelipeelli@usp.br; pcsentel.esalq@usp.br; sonhfreitas@gmail.com; rafaela@ipef.br; caalvares@yahoo.com.br)

Eucalyptus growth is conditioned by climate, genetics, soil conditions, incidence of pests and diseases and forest management. From this, a huge temporal and spatial variability of *Eucalyptus* yield is observed, leading to yield gaps. Identifying yield gaps may be a valuable opportunity for increasing *Eucalyptus* yield in a sustainable way and improve forest planning and management. This study aimed to assess the *Eucalyptus* yield gaps using a multimodel approach from different producing locations in Brazil and to identify the main causes and the possible mitigation strategies. Potential and attainable yields were assessed by three process-based models properly calibrated and evaluated. Actual yields were obtained from 30 producing locations in Brazil from the TECHSProject. The yield gap at all locations in Midwest and Northeast regions were predominantly caused by water deficit. In Southeast and North regions, the water deficit was the main cause of yield gaps in 87 and 67% of the locations, respectively. In Southern Brazil, the management was the main cause of yield gap at all locations. As water deficit represented the main cause of *Eucalyptus* yield gaps in Brazil, the possible strategies to surpass that is the use of genotypes more tolerant to water deficit, to use more open planting spacing, and adoption of soil practices that could improve water infiltration and roots deep growth. Yield gaps by management may be mitigated by adequate fertilizer management, better control of the genotype x environment interaction, use of high-quality seedlings, forest protection (weeds, pests and diseases), control of forest fires and increasing resiliency to windstorms and waterlogging events.

Gauging the effects of climate variability for improved planning and management of *Eucalyptus* plantations: a process-based modelling application

Elvis Felipe Elli¹, Neil Huth², Paulo Cesar Sentelhas¹, Rafaela Carneiro³, Clayton Alcarde Alvares³

¹Escola Superior de Agricultura "Luiz de Queiroz" - Universidade de São Paulo, Piracicaba, Brasil; ²National Research Collections Australia Toowoomba, Australia; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (elvisfelipeelli@usp.br; neil.huth@csiro.au; pcsentel.esalq@usp.br; rafaela@ipef.br; caalvares@yahoo.com.br)

Process-based simulations for assessing environmental and management effects on *Eucalyptus* yield may be a valuable decision support tool in the pursuit of appropriate forest planning and management. This study aimed to gauge the effects of climate variability on *Eucalyptus* yield in different producing regions of Brazil using a process-based modelling approach. The APSIM Next Generation *Eucalyptus* model was properly calibrated and then was used to perform the long-term assessments. Thirty-one simulations of stem biomass production for a seven-year rotation were performed using weather data from 1980 to 2017. This was reproduced for eight Brazilian locations with contrasting climates and soil conditions: Rio Verde, GO (07-CCO), Inhambupe, BA (8-COP), São Gabriel, RS (18-CMS), Peixe, TO (19-GMR), Mogi Guaçu, SP (20-IPB), Telêmaco Borba, PR (22-KLT), Coração de Jesus, MG (26-PLA) and Urbano Santos, MA (29-SUZ). The mean annual volume increment at 7 years-old (MAI) and its coefficient of variation (CV), growth modifiers by water deficit and temperature were evaluated. The long-term simulations identified the spatial and temporal climate variability in Brazil. The average MAI were 48.6, 45.7, 60.8, 39.4, 63.6, 69.8, 36.0 and 37.6 m³ ha⁻¹ year⁻¹ for 7-CCO, 8-COP, 18-CMS, 19-GMR, 20-IPB, 22-KLT and 29-SUZ, respectively. The CV ranged from 2.9% (19-GMR) to

14.7% (08-COP). Higher MAI found at locations 22-KLT and 20-IPB are justified by lower effects of both water and temperature deficits. Climate variability assessments have been demonstrated to be effective in identifying climatic risk in Eucalyptus plantations and may be used for improved planning, breeding strategies, management and decision-making on the forest sector.

Productivity of *Eucalyptus* in Brazil and Uruguay: exploring the genetic x environment interaction

Understanding the interaction between genetic and environment is crucial to reduce risks of reduced productivity and high mortality in regions with low supply of resources, and also provide opportunities to increase Eucalyptus productivity. The TECHS-IPEF project (Tolerance of Eucalyptus Clones to Hydric, Thermal and Biotic Stresses), was developed to explore the ecophysiological processes controlling productivity of Eucalyptus. The experimental network with 36 sites was installed in 2012, covering a wide range of latitudes, from 1°S to 33°S in Brazil and Uruguay, across a strong climatic gradient (temperature (T): 12 to 35 °C; precipitation (P): 700 to 2300 mm yr⁻¹). To intensify soil water deficit (SWD), and explore impacts of climate change, at each site, throughfall exclusion systems removed 33% of the water since planting. At each site 11 different Eucalyptus clones were planted. The most productive sites, near the tropic of Capricorn, (P > 1200mm, evenly distributed) reached mean annual increment (MAI, age of 6 years) of approximately 65 m³ ha⁻¹ year⁻¹. Conversely, regions with intense SWD (> 500mm for more than 5 months) showed MAI of approximately 20 m³ ha⁻¹ year⁻¹. Differences of productivity among clones within site reached 100%. The effect of rainfall reduction on productivity was positively correlated with SWD (R² = 0.33, p = 0.01). Ecophysiological studies related to carbon allocation, water use, fine root dynamics, and stomatal behaviour provided explanations for tolerance to stresses for some clones, and high productivity for others. The dataset is completed, and will be used to parameterization of process-based models and zoning of Eucalyptus.

Diseases of eucalypts in China

ShuaiFei Chen¹, Michael J. Wingfield²

¹China Eucalypt Research Centre (CERC), Chinese Academy of Forestry (CAF), Zhanjiang, China; ²Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa (cerccsf@126.com; mike.wingfield@fabi.up.ac.za)

Eucalypt plantations cover approximately 4.5 million ha in China, constituting 6.5% of the plantation area in the country. Numerous disease problems have emerged in these plantations during the course of the last two decades. These include leaf blight/spot caused by species of Teratosphaeriaceae, Mycosphaerellaceae, Calonectria and Quambalaria, seedling stem/leaf rot caused by *Botrytis cinerea* and *Calonectria* spp., stem canker/wilt caused by species of Botryosphaeriaceae, Cryphonectriaceae, Ceratocystis and Teratosphaeria, and bacterial wilt associated with infection *Ralstonia pseudosolanacearum*. Glasshouse and field trials have been conducted to test the relative pathogenicity of these fungi on plantation-grown eucalypt genotypes. Results have revealed that there are significant differences in the susceptibility amongst eucalypt genotypes and showing that breeding and selection of disease resistant planting stock can be achieved in the future. Results of studies have also shown that the species and genetic diversity of some of these pathogens is high, suggesting that they are native to China. More extensive research is required to better understand the geographic distribution, genetic diversity and biology of eucalypt pathogens in China and thus to reduce the negative impact on an important and growing industry.

C2c: TOWARDS SUSTAINABLE DEVELOPMENT OF THE GLOBAL TEAK SECTOR IN A CHANGING WORLD

Enhancing conservation and sustainable management of teak forests and the legality of wood supply in the Greater Mekong Sub-region

Tetra Yanuariadi¹

¹International Tropical Timber Organization (ITTO), Yokohama, Japan (tetra@itto.int)

Natural teak forest area has reduced substantially in all native teak growing countries mainly due to over exploitation, agriculture expansion, and shifting cultivation. Old-growth high-quality teak stands have declined significantly for many years. There is a risk of losing their diversity of genetic traits and wood characteristics. ITTO is implementing a project aimed at assisting governments, local communities and smallholders to enhance natural teak forest management, production and marketing to facilitate the establishment of legal and sustainable wood supply chains while improving national economy and local communities' livelihood in the Greater Mekong Sub-region. The project will also provide an opportunity to build-up sustainable forest management capacities which pursue livelihood improvement and ecological significance in all countries of the Greater Mekong Sub-region (GMS). The following outputs will contribute to meet the objective of the project: 1) The conservation of teak genetic resources, sustainable management and use of natural teak forests and market accesses of teak from legal sources have been improved; 2) Community-based and smallholders teak forest management and agroforestry systems have been strengthened with improved legal and sustainable supply chains; and 3) Regional and international collaboration, information sharing and knowledge management, networking, policy development and outreach on the sustainable management of teak forests, including sustainable use of teak genetic resources have been strengthened. The project comprises interventions at regional, national, and community levels. It promotes policy adjustments at regional and national level, building up trained human resources, implementing joined research programs, and generating and sharing new information and knowledge.

Improving structural diversity of teak monocultures and economic implications

Anja Nölte¹, Henrik Meilby², Rasoul Yousefpour¹

¹Chair of Forestry Economics and Forest Planning, University of Freiburg, Freiburg, Germany; ²Department of Food and Resource Economics, University of Copenhagen, Copenhagen, Denmark (anja.noelte@ifef.uni-freiburg.de; heme@ifro.ku.dk; rasoul.yousefpour@ifef.uni-freiburg.de)

High timber prices and increasing demand made *Tectona grandis* (teak) cultivation attractive to many private investment companies especially in tropical Latin America. While timber production and economic return are usually the main objectives in teak plantation forestry, there is globally a growing interest in sustainable forest management, i.e. managing for a system that is resilient to changing environmental conditions and contributes to biodiversity and other ecological benefits from degraded lands and to socio-economic development. We addressed the sustainable management of teak plantations by applying a threefold strategy: First, we simulated teak growth affected by future climate scenarios under low input management in Costa Rica by calibrating a process-based forest growth model (3PG). Second, we used the model to simulate management strategies that enhance carbon storage in biomass and evaluated them with regard to their economic performance, including revenues from payment for ecosystem services (PES). Third, we simulated a management approach of group harvesting, which was hypothesized to increase structural heterogeneity (Gini coefficient) and canopy continuity, thus contributing to habitat provision and biodiversity conservation. The latter may further increase forest resilience and provides a more regular income. We further discuss other important management actions and open research questions to realize a true ecological economy of teak plantations.

Growth performance and physical properties of 15 year old TEAK clones from Kerala, India

Thulasidas P K¹, Hrideek T K², Sabu Saji¹

¹Wood Science & Technology Division, Kerala Forest Research Institute, Peechi - 680653, Kerala, India; ²Tree Breeding & Genetics Dept, Kerala Forest Research Institute, Peechi - 680653, Kerala, India (pktdas@gmail.com; drhrideek@gmail.com; sabusajiks777@gmail.com)

Teak clonal forestry is considered to be a rapidly expanding true-to true type massive multiplication method expected to produce higher yield with uniform quality timber in shortest possible time. In this context, an evaluation of teak clonal plantations established by KFRI in the year 2000 was undertaken in a locality in Kerala, India. The performance of ten clones, namely T1, T3, T4, T5, T6 and T10 originated from its parent plus trees of teak (Nilambur), T11 and T16 (Konni), T24 and T46 (Ariyankavu) were studied for the dbh, ring width, physical properties like wood colour, density and heartwood/sapwood percentage. The clones were planted at a spacing of 5x5 m. Nilambur clones (T1, T3, T4 & T10) showed significant difference ($P \leq 0.05$) in terms of DBH, ring width, heartwood percentage and density than Konni and Ariyankavu clones. The density of clone T11 and T16 are significantly less (0.55 g/cm^3) when compared to Nilambur (0.630 g/cm^3) because of higher earlywood percent with thin walled fibres. Tree height and sapwood percentage was found to be insignificant ($P \geq 0.05$) among all the clones studied. At 15 years, Nilambur clones attained maturity with respect to density (0.630 g/cm^3) and growth performance was found to be superior in terms of higher DBH and heartwood percentage. The wood colour as studied by CIE L*a*b* system showed no significant colour difference (dE) between the clones. However, the redness index (a*) of clone T1, T16 and T46 are distinctly different ($P \leq 0.5$) than other clones.

Growth performance of 18 years old Teak of different planting stocks

Zar Chi Hlaing¹ 

¹Forest Research Institute, Nay Pyi Taw, Myanmar (zarchihlaing08@gmail.com)

The growth of a tree is dependent on a complex series of interactions between genetics and environmental factors, and also planting methods. For the successful establishment of a plantation, the economically effective means should be explored, as teak plantation is being established in Myanmar especially for commercial purposes including forest rehabilitation purposes. This study was conducted in the 18 years old Teak plantation that was established in the compartment No. (9) of Ngalaik Reserved Forest managed by Forest Research Institute. This teak plantation was established with the stored stump, fresh stump and potted seedlings in 2000. As a preliminary step, in 2002, the stored stumps planting was significantly better in height growth as compared to those of fresh stumps and seedling plantings, nonetheless, survival percentages among them were not significant. Now, we conduct this follow-up study to explore the growth performance of this 18 years old teak plantation of different planting stocks. We expect this study's finding will be supported the useful and applicable information for the commercial plantation programme to raising environmentally friendly and economically successful teak plantations.

Development of sustainable livelihoods for forest fringe communities from Teak plantations in Ghana

Valerie Fumey Nassah¹, Hugh Brown², Alexander Asare¹

¹Forestry Commission, Kumasi, Ghana; ²Forestry Commission, Accra, Ghana (valfn2003@yahoo.co.uk; hughbrown03@hotmail.com; abasare99@yahoo.com)

The adoption of massive forest plantations initiatives to promote the rehabilitation and restoration of degraded landscapes has been emphasized as one of the main strategic objectives of the 2012 Forest and Wildlife Policy of Ghana. In addition to the policy Ghana participated in Kigali 2016 Ministers roundtable conference and agreed, signed and is committed to convert two million hectares of degraded and deforested lands under landscape restoration initiative and is committed to the AFR100 for Africa which is a regional implementation platform for the Bonn Challenge. Ghana's two million hectare target is based on the national goals and targets agreed in the National plantation strategy 2016 to 2040 to establish and manage 625,000 ha of forest plantations and 100,000 ha enrichment planting and 3.75 million hectares of agricultural landscapes, by year 2040 through the application of best practice principles. Approximately 80% of forest plantations are Teak based on multiple benefits received by government agencies, communities, farmers and private developers. This paper highlights the sustainable livelihood opportunities generated by forest plantations of teak from 2002 to date under the National Forest Plantation Development Programme as well as the Community Forestry Management Project which was implemented by the government of Ghana with support from African development Bank. Successes and challenges of the livelihood initiatives generated and benefits received will be discussed.

Technological characterization of *Tectona grandis* sawing wood waste and considerations of its potential uses

Marina Coelho¹, Caio Almeida¹, Francides Silva Júnior¹, Geraldo Bortoletto Júnior¹, Vanderlei Benedetti¹

¹Universidade de São Paulo, Piracicaba, Brasil (marina.ulian@usp.br; caio.cfalmeida@usp.br; fjr@usp.br; gbjunior@usp.br; vabenedetti@gmail.com)

The objective of this study was to evaluate the technological characteristics of 14-year-old *Tectona grandis* (Teak) wood, aiming the multiple use of its sawing waste. For that, it was used *Tectona grandis* slabs, obtained on the primary sawing of its wood logs. The technological wood analysis realized were: wood

chemical (total extractives and lignin contents), wood physical (basic density) and calorific value as higher heating value. Teak wood presented average total extractives content of 9.5%, average lignin content of 37.5%, wood basic density of 0.538 g/cm³ and higher heating value of 4753 kcal/kg. From the wood technological characterization, some challenges for its multiple use were observed: the high extractive content can negatively affect wood glued products, particleboard panels and pulp production. On the other hand, the high extractives content can provide natural protection to wood degrading agents, which favors its use in outdoor environment, such as floors, boards and furniture. Another potential is the refining of teak extractives for use in the chemical industry. Due to the high values observed of lignin content, basic wood density and calorific content, it is suggested the use of *Tectona grandis* slab for energetic purposes, especially because the results observed are near to species traditionally used for coal, briquette and pallets, such as *Eucalyptus*, *Acacia* and *Mimosa* spp. The results of this study allows to conclude that the *Tectona grandis* wood slabs presents considerable potential for energetic and outdoor environment uses, but its application for pulp and panels need further studies to be endorsed.

Strategies and practices to manage teak plantations in south China

Zaizhi Zhou¹, Xiyang Wang¹, Guang Yang¹, Guihua Huang¹

¹Research Institute of Tropical Forestry, CAF, Guangzhou, China (zzzhou@caf.ac.cn; teakpro@qq.com; yangguang200510@126.com; hghmhx@163.com)

Motivated by attractive marketing and financial return, some private companies and individuals have invested in teak plantations by using superior clones since 1980s. Strategies and practices to manage these plantations in a sustainable way are urgently needed for forest products. In recent years, high priority and attention have also been given to the tree increment and quality through using rational operational regimes by Chinese forestry authorities. Pilot demonstration sites for younger teak plantations are being established in Guizhou, Yunnan, Fujian, Guangxi and Guangdong Province by the support of technique and demonstration project of teak, issued by State Key Research and Development Plan from 2017 to 2020. The objective of the paper is to provide some strategies and methods in the area of establishing high-yielding and fast-growing teak plantations by an intensive way, and available fertilizing, pruning and thinning regimes for promoting growth and straight stem with less knots. Some intercropping operations were also practiced in teak plantations for livelihood enhancement. Meanwhile the relationship between teak clone growth, wood properties and planting sites are also focused on.

TEAKNET towards the Development of Teak Sector

Sreelakshmy MP¹, Thulasidas PK¹

¹TEAKNET, Kerala Forest Research Institute, Peechi, India (secretariat@teaknet.org; coordintaor@teaknet.org)

Food and Agricultural Organization of the United Nations with an aim to bring together the stakeholders of teak worldwide, constituted a network named TEAKNET (International Teak Information Network) in 1995. The Kerala Forest Research Institute, Peechi, India hosts the Secretariat of the network and is actively functioning at its current location since 2007. The vital focus of this network is to share information on the needs of the global teak sector. The major stakeholders of this network is teak growers, traders, researchers apart from policy makers among others. Each category requires different information or support and TEAKNET circulates all authentic information through its wide network. By linking the various international institutions, the network acts like a virtual research and development organization for the species. Scientific data on seed handling techniques, clonal propagation, tissue culture, silvicultural practices, timber quality, marketing information and anything related to teak is available from this network. The information exchange of this network reached to the public through its website, quarterly online newsletter, conferences & training programmes and expertise sharing invitations. The network collaborates with international organizations like FAO, IUFRO, ITTO and formulates action plans for the sustainable management and development of the global teak sector and improve the livelihood support by promoting smallholder teak farming. The network is successfully functioning with wider participation and members who are concerned with the conservation, management and utilization of teak.

C2d: TREE GENOMICS AND BIOTECHNOLOGY

Draft genome assembly of the tropical tree *Bertholletia excelsa* using long-read sequence data

Lais Rossetto F. de Barros¹, Lúcia Helena de Oliveira Wadt², Mateus Mondin³, Georgios Pappas Junior⁴, Rodrigo Theodoro Rocha⁴, Marília de Castro Rodrigues Pappas⁵, Renato Kenji Kimura¹, Karina Martins¹

¹Universidade Federal de São Carlos, Programa de Pós-Graduação em Biotecnologia e Monitoramento Ambiental, Sorocaba, Brasil; ²Embrapa Rondônia, Porto Velho, Brasil; ³Universidade de São Paulo, Escola Superior de Agricultura Luiz de Queiroz, Departamento de Genética, Piracicaba, Brasil; ⁴Universidade de Brasília, Brasília, Brasil; ⁵Embrapa Recursos Genéticos e Biotecnologia, Brasília, Brasil; ¹Universidade Federal de São Carlos, Departamento de Biologia, Sorocaba, Brasil (laisrossetto015@gmail.com; lucia.wadt@embrapa.br; mmondin@usp.br; gpappas@unb.br; theodorobotec@gmail.com; marilia.pappas@embrapa.br; renato-kimura@ufscar.br; karimartins@yahoo.com)

The availability of reference genomes has revolutionized the study of biology, allowing major advances in understanding the relationship between genotype and phenotype. The reference genome is the backbone of numerous lines of research that utilize genomic resources. However, the quantity and availability of well annotated reference genomes are still limited, especially for forest species. *Bertholletia excelsa* Bonpl. (Lecythidaceae), popularly known as Amazon nut or Brazil nut, is an economically and ecologically important tropical tree widely distributed throughout most of the Amazon forest. To advance landscape genomics, phylogeography, functional genomics, and breeding programs across the Brazilian Amazon using genome-wide markers, we aimed to advance the development of genomic resources for *B. excelsa* by assembling and annotating a reference genome. Genome size was estimated by flow cytometry in 930–940 Mbp. Long-read SMRT PacBio sequencing resulted in a coverage of ~100× and an average read length of 12.5 kb. We used Quast to compare the efficiency of two assemblers, Falcon and Miniasm, which were run with different settings. We compare results of N50 and discuss the best strategy for *B. excelsa* considering its high heterozygosity. Funding: São Paulo Research Foundation (Grant FAPESP 2017/06102-0)

Reference genome of yellowhorn *Xanthoceras sorbifolium*: a wood oil tree in China

Quanxin Bi¹, Yang Zhao¹, Xiaojuan Liu¹, Haiyan Yu¹, Libing Wang¹

¹State Key Laboratory of Tree Genetics and Breeding, Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China (biquanxin@caf.ac.cn; 15736874202@163.com; liuxiaojuan@caf.ac.cn; yuhaiyan@caf.ac.cn; wlbing@caf.ac.cn)

Yellowhorn (*Xanthoceras sorbifolium*) was a woody oil species, which belongs to the Sapindaceae family and the monotypic genus *Xanthoceras*. As an endemic and economic species in Northern China, it was widely used for conserving soil and water due to the capacity to survive in arid, saline, alkaline land

and in extreme temperature even below -40°C . The oil content of its seed kernel could be as high as 67%, of which 85% - 93% is unsaturated fatty acid, including 37.1% - 46.2% linoleic acid and 28.6% - 37.1% oleic acid, which are essential fatty acids in diets. Recently, yellowhorn as one of the major woody oil plant species has drawn government and people's attention again for the shortage of vegetable oil resources in China. Notably, an essential nutrient for brain growth and maintenance — nervonic acid, which is rarely contained in plants, reached nearly 3.04% in the seed oil of yellowhorn. In this study, we generated 15 pseudomolecules of the yellowhorn chromosomes, on which 97.04% of scaffolds anchored, using Illumina HiSeq, Pacific Biosciences and Hi-C technologies. The final genome assembly of yellowhorn is 504.2 Mb with a contig N50 size of 1.04 Mb and a scaffold N50 size of 32.17 Mb. Genome annotation revealed that 68.67% of the yellowhorn genome is composed of repetitive elements. Gene modeling has predicted 24,672 protein-coding genes. The high-quality yellowhorn genome and conduct the annotation and genomic structures, evolution and the data provide a rich resource of genetic information for developing these resources and understanding the special space of *Xanthoceras* and Sapindaceae in plant evolution.

Genome-wide analysis of laccase genes in moso bamboo highlights PeLAC10 involved in lignin biosynthesis and in response to abiotic stresses

Zhimin Gao¹, Lichao Li¹, Sining Wang¹, Hao Xu¹, Xueping Li¹

¹Institute of Gene Science for Bamboo and Rattan Resources, International Center for Bamboo and Rattan, Beijing, China (gaozhimin@icbr.ac.cn; lilichao1991@126.com; wangsining@icbr.ac.cn; xuhao@icbr.ac.cn; lixueping@icbr.ac.cn)

Laccases (LACs) have multifunction involved in the processes of cell elongation, lignification and stress response in plants. However, the laccases in bamboo are still not well characterized. A total of 23 laccase proteins were identified in moso bamboo (*Phyllostachys edulis*) which were clustered into four groups. The diversity of gene structures and expression patterns of PeLACs suggested that their regulation and function should be spatiotemporal and complicated. It was predicted that 18 of the 23 PeLACs were identified as the targets of ped-miR397. The putative ped-miR397-binding site in the coding region of PeLAC10 was further confirmed by RLM-5' RACE, indicating that PeLAC10 was regulated by ped-miR397 after transcription. With the shoot height increasing, the expression abundance of PeLAC10 increased and reached the maximum in 15 cm shoots, while that of ped-miR397 was relative lower and showed the minimum in 15 cm shoots. PeLAC10 was up-regulated obviously under the treatments of ABA ($100\ \mu\text{mol}\cdot\text{L}^{-1}$) and NaCl ($400\ \text{mmol}\cdot\text{L}^{-1}$), and it was down-regulated under the treatment of GA3 ($100\ \mu\text{mol}\cdot\text{L}^{-1}$). The transgenic Arabidopsis plants over-expressing PeLAC10 became smaller and their petiole were shorter than those of Col-0. However, they had a stronger capacity in resistance to drought and phenolic acids besides higher lignin content. These results indicated the complex expression regulation and functional diversity of PeLACs. Overexpression of PeLAC10 was helpful to increase the content of lignin in transgenic Arabidopsis and improve the adaptability to drought and phenolic acid stresses.

Integrated mRNA, microRNA transcriptome and degradome analyses provide insights into stamen development in moso bamboo (*Phyllostachys edulis*)

Jian Gao¹

¹International Centre for Bamboo and Rattan, Beijing, China (gaojianicbr@163.com)

Moso bamboo is a large and woody bamboo of great economic and ecological value, a typical clonal plant and simultaneously flowers happened at the end of very long vegetative growth phases, followed by the death of large areas of them. Long-term clonal reproduction led to the decline of bamboo forests, however, the setting rate of moso bamboo is very low, which largely affects the regeneration of bamboo forest. The floral organs, especially stamens, are essential for sexual reproduction of flowering plants. However, abortion mechanism of moso bamboo is unknown till now. Transcriptomic, small RNA and degradome analyses to characterize miRNA-mediated pathways of moso bamboo stamens were studied; 16 conserved miRNAs were specific highly expressed, including miRNA159 and miRNA166. In situ hybridization showed that miRNA159 might play an important role in the regulation of stamen development while expression levels of its targets PheMYB98 and PheMYB42 were hard to detect. Furthermore, overexpression of Phe-PremiR159 could cause anther dehiscence failure, and the mature pollens could not be dispersed and further reduce fertility. Semi-thin section result showed that anther endothelial layer of Phe-PremiR159 overexpressing lines weren't detected in secondary thickening, resulting in lack of the force required for opening. The expression levels of MYB26, NST1, NST2 related to anther dehiscence in overexpression lines were significantly verified, indicating the Phe-miR159 might regulate these genes associated with secondary thickening through negative regulation of AtMYB33, thus affect the anther dehiscence. Together, this study provides a foundation for further investigations of the RNA-mediated silencing mechanism in stamens of moso bamboo.

The *Salix* SmSPR1 involved in light-regulated directional cell expansion by modulating microtubule elongation

Rao Guodong¹, Liu Xiaoxia¹

¹Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China (rgd@caf.ac.cn; shiyoo01@163.com)

Light signaling and cortical microtubule (MT) arrays are generally recognized to be important for anisotropic growth of plant cells. Microtubule associated proteins (MAPs) function as regulators that mediate plant cell expansion or elongation by altering arrangements of MT arrays. However, little is known about molecular mechanism of MAPs are affected by light to regulate cell expansion or elongation. Here, we found the microtubule associate protein SPR1 was involved in light-regulated directional cell expansion by modulating microtubule elongation in *Salix matsudana*. Overexpression of SmSRP1 in Arabidopsis result in right-handed helical orientation of hypocotyls in dark-grown etiolated seedling, while phenotype of transgenic plants was indistinguishable from those of wild type plants in the condition of light. Characterization of the transgenic plants phenotypes showed reduced anisotropic growth and left-handed helical MT arrays in etiolated hypocotyl cells. Protein interaction assays revealed that SPR1, CSN5A (subunits of COP9 signalosome, a negative regulator of photomorphogenesis), and ELONGATED HYPOCOTYL 5 (HY5, transcription factor, function in promote photomorphogenesis) were interacted to each other. Phenotype of Arabidopsis AtSPR1 overexpressing transgenic lines were similar to that of SmSPR1 overexpressing transgenic plants, and overexpression of *Salix* SmSPR1 can rescue the spr1 mutant phenotype, indicating a generality function of SPR1 in plants. Taken together, our study reveals that the *Salix* SPR1, COP9, and HY5 may form different protein complex to regulate MT arrays arrangement and anisotropic growth of cells in the condition of light and dark.

Transcriptional regulation of cell cycle genes during the temperature-modulated larch tree dormancy release and reactivation

Wan-Feng Li¹, Yanhui Kang¹, Yao Zhang¹, Li-Wang Qi¹

¹State Key Laboratory of Tree Genetics and Breeding, Key Laboratory of Tree Breeding and Cultivation, National Forestry and Grassland Administration, Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China (liwf@caf.ac.cn, kk15110057556@126.com; 243165265@qq.com; lwqi@caf.ac.cn)

Dormancy release and reactivation of temperate-zone trees in spring involve the temperature-modulated expression of cell cycle genes. However, information on the detailed regulatory mechanism is limited. Here, we compared the transcriptome of stems of active and dormant larch trees, emphasizing the expression patterns of cell cycle genes and transcription factors, their relationships and responses to temperatures. The results showed that 12 cell cycle genes and 31 transcription factor, belonging to 17 families, were highly expressed in active stage, indicating regulatory relationships might exist between them. Bioinformatics analysis of the promoter sequences of 12 cell cycle genes suggested that they might be regulated by the transcription factors from 10 families. Altogether, 16 transcription factors from 7 families co-expressed with 12 cell cycle genes, and 73 regulations were predicted; while yeast one-hybrid assay showed that three regulations occurred between three transcription factors and two cell cycle genes. Last we measured their expression patterns during dormancy release and reactivation induced by temperatures naturally or artificially, and found that they almost had the same expression patterns, indicating that these regulatory modules functioned in the temperature-modulated dormancy release and reactivation of temperate-zone trees. These findings provide new insights into the links between the temperature signals and the expression of cell cycle regulators, helping to understand the temperature control of tree growth and development in the context of climate change.

Genetic background hidden by methylation in hickory (*Carya cathayensis*) --- a view based on the construction of genetic and epigenetic linkage maps

Ang Dong¹, Xuli Zhu², Wenchong Chen¹, Yanyao Tang¹, Ning Jia¹, Yanru Zeng¹, Huwei Yuan¹, Bingsong Zheng¹, Rongling Wu³

¹The State Key Laboratory of Subtropical Silviculture, Zhejiang A&F University, Hangzhou, China; ²Center for Computational Biology, Beijing Forestry University, Beijing, China; ³Center for Statistical Genetics, Pennsylvania State University, Hershey, US (fantasys05227@gmail.com; 349082942@qq.com; 506396307@qq.com; 790930248@qq.com; 981183096@qq.com; yrzeng@zafu.edu.cn; yuanhuwei86@163.com; bszheng@zafu.edu.cn; rww@phs.psu.edu)

Recent studies have suggested epigenetic mechanism, one of which is DNA methylation, is involved in heterosis and apomixis in plant species. Hickory (*Carya cathayensis*), a woody nut species quite different from its relative pecan (*C. illinoensis*), has so far had no cultivar developed, presented a low DNA polymorphism by conventional molecular markers although propagated by seeding, but shown heterosis, apomixis and imprinted quantitative trait loci (iQTLs). To figure out the DNA methylation status in hickory, we analyzed the cytosine methylation pattern of two mapping populations resulting from reciprocal crosses between a hickory tree and a pecan cultivar "Mahan" using MSAP (methylation-sensitive amplified polymorphism) markers. With the locus information from MSAP, both non-methylation loci (NML) or methylation sensitive loci (MSL), and that from other molecular markers such as RAPD, ISSR and SRAP markers on the same mapping populations, we constructed a genetic and an epigenetic maps in hickory. Our results show that the epigenetic map (7742.3 cM) was doubled as compared with the genetic map (3580.2 cM) either in terms of the total length of linkage groups or in terms of the number of molecular markers. In addition, makers from MSAP, either NML or MSL, accounted for a large percentage of the total markers used and MSAP markers were often clustered in each of linkage groups. The results reveal that the hickory genome is highly methylated and DNA methylation might play an important role in this species, which has survived from global cooling in the late Tertiary.

C2p: EUCALYPT PLANTATIONS

Density and stomatal dimensions of contrasting *Eucalyptus* clones of across a climatic gradient

Tatiani Maria Pech¹, Otávio Campoe^{1,2}, Rafaela Carneiro³, Paulo Cesar Poeta Fermino Júnior²

¹Universidade do Estado de Santa Catarina, Lages, Brasil; ²Universidade Federal de Santa Catarina, Curitibaanos, Brasil; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (tatianiamariapech@gmail.com; otavio.campoe@gmail.com; rafaela@ipef.br; paulo.fermino@ufsc.br)

The species of the *Eucalyptus* genus are widely used in forest plantations, representing economic importance for Brazil. However, little is known about the physiological processes that control their growth, and how these processes are governed by genetic and climatic factors. Therefore, the objective of this study is to characterize the density and dimensions of the stomata of different species of the *Eucalyptus* genus, and to evaluate the plasticity of these variables across a strong climatic gradient in Brazil. The experimental sites are part of the TECHS-IPEF Cooperative Research Program, located in SC, PR, SP, MG (from latitude 17° to 27° South). The clones evaluated are pure or hybrid of the following species: *E. urophylla*, *E. grandis*, *E. camaldulensis*, *E. saligna*, *E. benthamii*, *E. dunnii*. Histological blades of abaxial and adaxial leaf surfaces were prepared from leaves of three trees of each clone at each site, and the images analyzed in an optical microscope. The study is under development, and the studied clones have not been evaluated yet at all sites. However, previous results show that the clones differ in the occurrence of stomata in the leaf sides. Among the six clones, three showed stomata at both sides of the leaves, and the other three clones only on the abaxial side. The stomatal density is also different among clones, ranging from approximately 200 to 500 stomata per mm². The stomatal characteristics are important to understand the physiological response of the trees and how they may be related to the adaptation of these clones to different climates.

Coppice potential of 16 different species of *Eucalyptus* after an eight-year rotation.

Marina Sbardella¹, Otávio Campoe¹, Joannès Guillemot^{2,3}, Gueric Le Maire^{2,4}

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²CIRAD, Montpellier, Brasil; ²Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ⁴Universidade E (marina.sba@hotmail.com; otavio.campoe@gmail.com; joannes.guillemot@cirad.fr; gueric.le_maire@cirad.fr)

The adoption of coppice is a commonly used management in different regions of Brazil for plantations of *Eucalyptus*, which requires less investments. However, there are variations in the ability of each genotype to emit sprouts, and higher yields can be obtained by changing the genetic material. The objective of this study was to evaluate the coppice potential of 16 *Eucalyptus* genotypes of different species, (14 clonal and 2 seed origin). The experiment is located in the area of the EUCFLUX-IPEF Cooperative Research Program, in the state of São Paulo, Brazil. The following variables were evaluated at 100 days after harvest of an eight-year rotation of the 16 genotypes: number of shoots per stump, total height, and basal diameter of the three main shoots. Twelve genetic materials showed one or two shoots per stump, and the three clones, with higher development in height and diameter, showed 3 or more shoots per stump. The best shoots of the best clones presented total height of approximately 1 m and average base diameter of 8 cm. The genotypes with the highest number of shoots also presented

better development in height and basal diameter. The 3 less developed genotypes presented mean basal diameter of less than 3 cm and average height of 40 cm for the three main shoots. The results show the clone/species coppice potential, which is important to move forward with coppicing techniques. Future studies will be conducted to evaluate the productivity physiology of these genetic materials.

Changes in biomass production after windstorms in *Eucalyptus grandis* x *Eucalyptus urophylla* hybrids / Alterações na produção de biomassa de híbridos de *Eucalyptus grandis* x *Eucalyptus urophylla* danificados por vendavais

Marco Aurélio Figura¹ , Regiane Abjoud Estopa¹, Mariane Bueno de Camargo¹, James Stahl¹

¹Klabin SA, Telêmaco Borba, PR, Brasil (mafigura@klabin.com.br; restopa@klabin.com.br; maricamargo@klabin.com.br; jstahl@klabin.com.br)

As florestas plantadas do gênero *Eucalyptus* estão expostas à ação dos fatores abióticos do ambiente, que muitas vezes as causam danos e geram reduções em sua produtividade. Nos últimos anos tem-se intensificado as observações de danos por vendavais em plantios clonais de *Eucalyptus*, principalmente em idades mais jovens, preocupando a silvicultura nacional. O presente estudo buscou quantificar as perdas médias na produção de árvores de 7 anos de idade decorrentes de danos anteriores por vento na idade de 2 anos. Foram selecionados 3 talhões de híbridos de *E. grandis* x *E. urophylla* que apresentassem árvores normais (retas e sem danos) próximas a árvores danificadas pelo vento e que permaneceram vivas até a idade final, tipicamente arqueadas e com a presença de brotações ao longo do fuste. Quantificou-se, para cada talhão, um número de 4 árvores médias arqueadas pelo vento e 2 árvores médias normais, medindo-se sua biomassa recém abatida do fuste, separando-a nos sortimentos de celulose (acima de 8 cm de diâmetro com casca), resíduo (entre 2 e 8 cm com casca) e total (somatório dos anteriores). A biomassa média, respectivamente para os sortimentos de celulose, resíduo e total, foi de 411, 19 e 430 kg/árvore para as árvores normais e de 193, 61 e 254 kg/árvore para as árvores arqueadas. Isto corresponde a uma diminuição de 53% na madeira antes destinada a celulose e um aumento de 231% na quantidade de resíduo gerada, ocasionada pelas brotações ao longo dos fustes arqueados. A biomassa fresca total foi reduzida em 41%.

Changes in heartwood/sapwood ratio in *Eucalyptus urophylla* due to soil water deficit

Maria Almeida¹, Graziela Vidaurre¹, José Lousada², Sofia Rocha¹, Rafaela Carneiro³, Otávio Campoe⁴

¹Universidade Federal do Espírito Santo, Jerônimo Monteiro, Brasil; ²Universidade de Trás os Montes e Alto Douro, Vila Real, Portugal; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ⁴Universidade Federal de Santa Catarina, Curitiba, Paraná, Brasil (narunafelix@gmail.com; grazividaurre@gmail.com; jlousada@utad.pt; sofiamaria.r@hotmail.com; rafaela@ipef.br; otavio.campoe@ufsc.br)

Different heartwood/sapwood proportions affect wood use and quality. With forest plantation expansion, clones tend to decrease their ideal phenotypic expression due to the occupation of areas with different edaphoclimatic conditions from locations they were developed. The aim of the study was to compare the heartwood/sapwood ratio (C/A) of eucalyptus wood in contrasting soil water deficit conditions (SWD) across Brazil latitudinal gradient. One wood disc at DBH was sampled from seven *Eucalyptus urophylla* trees at age of 6 years for C/A quantification at 10 sites of the TECHS-IPEF Cooperative Research Program. Heartwood delimitation was visual, by the color difference. The discs were scanned and total heartwood area values were obtained by image analysis system. The sites were separated into 3 groups. Those with the highest latitudes, Botucatu/SP and Buri/SP (SWD: 106 mm year⁻¹) presented the highest C/A values, 2.3 and 1.8, respectively. The sites Estrela do Sul/MG, Guanhães/MG, Rio Verde/GO and Três Lagoas/MS, located at medium latitudes, formed the second group with means of C/A: 1.1 and SWD of 367 mm year⁻¹. The group with the lowest C/A mean (0.6) belonged to sites of the highest values of SWD (534 mm year⁻¹) and lower latitudes, Peixe/TO, Urbano Santos/MA and Eunápolis/BA, and also Belo Oriente/MG. The C/A ration decreased with the increase of the SWD and decrease of the latitude, demonstrating that SWD conditions the response of tree to heartwood production.

Growth and distribution of fine roots in clonal *Eucalyptus* plantations under contrasting climate

Josiana Basilio¹, Otávio Campoe², Rafaela Carneiro³, Túlio Queiroz¹, James Stahl⁴, Marco Aurélio Figura⁴, Rodolfo Costa⁵

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu-SP, Brasil; ²Universidade Federal de Santa Catarina, Curitiba, Brasil; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; (josianajussara@gmail.com; otavio.campoe@gmail.com; rafaela@ipef.br; tulio-bq@hotmail.com; jstahl@klabin.com.br; mafigura@klabin.com.br; rodolfo.costa@vallourec.com)

The main function of fine roots is to provide water and nutrients, therefore, understanding their growth in depth, and distribution over the soil layers is crucial to understand soil water dynamics and nutrients uptake by forest plantations. The objective of this study is to quantify biomass of fine roots (≤ 2 mm) in different species of *Eucalyptus* on contrasting climatic conditions. Fine roots were sampled at the age of 3 years, on four genotypes (*E. urophylla*, *E. urophylla* x *E. grandis*, *E. grandis* x *E. camaldulensis* and *E. urophylla* x *E. brassiana*) at two sites (Bocaiúva-MG and Telêmaco Borba-PR) of the TECHS-IPEF Cooperative Research Program, with deep Oxisols and mean annual precipitation of 850 and 1750 mm, respectively. On the drier site, fine roots were shallower, with the distribution of their biomass on the top 3 meters ranging from 58 to 91% among clones. The wetter site showed deeper fine roots with the distribution of their biomass on the top 3 meters ranging from 60 to 82%. On both sites, the hybrid *E. urophylla* x *E. grandis* showed the shallower fine roots, contrasting with *E. grandis* x *E. camaldulensis* and *E. urophylla* x *E. brassiana*, that showed similarly deeper roots. Studies currently under development are focusing on understanding the relations among fine roots, aboveground growth, wood production, soil water use at different soil layers, and tolerance capacity of these clones to water stress.

Optimal temperatures for growth of contrasting *Eucalyptus* species in Brazil

Túlio Queiroz¹, Otávio Campoe^{1,2}, Clayton Alcarde Alvares³, Rafaela Carneiro⁴, James Stahl⁵, Gabriela Moreira⁶, Marco Aurélio Figura⁵, Helton Lourenço⁷, Helder Andrade⁸, Cristian Montes⁹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil; ²Universidade Federal de Santa Catarina, Curitiba, Brasil; ³Suzano, Imperatriz, Brasil; ⁴Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ⁵Klabin, Telêmaco B (tulio-bq@hotmail.com; otavio.campoe@gmail.com; calcarde@suzano.com.br; rafaela@ipef.br; jstahl@klabin.com.br; gabriela.moreira@paper.com; mafigura@klabin.com.br; helton.lourenco@veracel.com.br; helder.andrade@vallourec.com; crmontes@uga.edu)

The genetic improvement of *eucalyptus* has evolved in the development of genotypes, but we still need more information on the genotype-environment interaction. Understanding the interactions between forest plantation and climate is mandatory for predicting the impacts of climate change on terrestrial ecosystems, and assessing the adaptation and vulnerability of tree species. In this context, potential genotypes were planted at 6 experimental sites, from the South to North of Brazil. We measured the CBH every 15 to 30 days of 9 genotypes (6 trees per genotype) planted in 3 x 3 m spacing, from 2012 to 2018. Finally, two destructive samplings were performed in the middle and at the end of the rotation (2014 and 2018, respectively). Meteorological data of each site was used

to assess the optimal growth temperature. Our results show that optimum temperature for growth depends on the species. The three most planted genotypes in Brazil presented different ideal temperatures for maximum growth: *E. saligna* (17.7 °C), *E. grandis* x *E. camaldulensis* (19.7 °C) and *E. urophyllax* sp. (24.4 °C). Minimum temperatures, ranging from 11.7 - 13.8 °C, and maximum from 31.6 - 32.6 °C were responsible for initiating or stop growth. Understanding the dynamics of tree growth and the relationship with climate is useful to predict productivity in new expanding regions with no previous information, to improve growth predicting models, and to perform zoning of genotypes of Eucalyptus.

Spacing effects on volume of *Eucalyptus* plantations across a climatic gradient in Brazil and Uruguay

Rafaela Pereira Neves¹, Rafaela Carneiro², Renata Aparecida Serio Abranches Junqueira³, Otávio Campoe⁴

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ³Floragro, Itatinga, Brasil; ⁴Universidade Federal de Santa Catarina, Curitiba, Brasil (rafaelapnaves@gmail.com; rafaela@ipef.br; renatabranches@yahoo.com.br; otavio.campoe@gmail.com)

The productivity of commercial forest plantations depends on several variables such as age, genetic material, biotic and abiotic conditions. There are interactions among those variables, e.g., the drier the environment, the higher the competition for water, thereby the area per tree must be larger, without compromise stand level production. The cooperative research program TECHS (Tolerance of *Eucalyptus* clonal to Hydric, Thermal and Biotic Stresses) of the Forestry Science and Research Institute (IPEF) aims to study the biotic and abiotic stresses that affect the productivity of different *Eucalyptus* clones. Our goal in this study is to determine which *Eucalyptus* materials are more efficient for which region in which spacing. We evaluated 34 sites in a wide climatic gradient from northern Brazil to Uruguay (latitudes ranging from 3° to 33° South). In each site, on average, 11 clones were tested in permanent plots where the spacing was increasing from 0.75 m² to 24 m². We evaluated the mean volume per tree and the mean volume per hectare according to the spacing at the end of the rotation (approximately 7 years). The preliminary results indicated that in general, plastic clones had a better performance, although in some extreme conditions site-specific clones performed better. The volume per hectare was greater in smaller spacings but in most cases, the production was unfeasible, due to the high mortality or small dimension of the trees in high stocking. These results contributed to understand how the future productivities will be in relation to the management and climate.

Characteristics of waste from colonies of *Atta colombica* (Hymenoptera: used in dry forest restoration processes / Caracterización del residuo proveniente de colonias de *Atta colombica* (Hymenoptera: Formicidae) utilizado en el proceso de restauración en bosque seco

Alexandra Fonseca Vargas¹, Miguel Eugenio Cadena Romero¹

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (ing.alexandraf@gmail.com; cademiello@hotmail.com)

En el área de compensación del Embalse El Quimbo en el Departamento del Huila Colombia, se utiliza el material residual proveniente de las colonias de hormiga arriera *Atta colombica* en el proceso de restauración, como sustrato en vivero y aporte de materia orgánica. Se caracterizó químicamente el desecho, para la evaluación estructural (mineralización) y composición mineral en sus estados residuales reportados en los montículos "in situ", en tres diferentes coberturas naturales: Bosque (BQ), Herbazal Abierto (HA) y Arbusto Denso (AD), así mismo evaluar la influencia de tres profundidades del montículo (superior, medio e inferior), en época seca y húmeda, la forma de bloqueo correspondió a tres intervalos de tiempo durante el día (Mañana, Mediodía y Tarde). Las variables de respuesta se analizaron mediante un Análisis de Varianza Combinado, para un diseño de Bloques Completos al Azar con arreglo factorial 2 x 3 en serie de experimentos. La relación C:N osciló entre 3.90 y 12.00, mostrando que el valor inferior se obtiene en la interacción de la Época Seca (ES) con Herbazal Abierto (HA) y a la Profundidad Inferior (PI). Así mismo, en la interacción existente de ES x HA x PI, los elementos P (11.29 ppm), Ca (5.43% M.S.), Mg (0.89 %M.S.), B (84.57 ppm) y Cu (17.77 ppm), mostraron sus mayores concentraciones. El K presentó su mayor concentración de 1.90% M.S para la Época Húmeda en un HA y Profundidad Superior, también en Época Seca se presentó la misma concentración, pero en AD y a la misma profundidad

C2q: PHYSIOLOGY AND GENETICS IN PLANTATION SPECIES

RNA interference suppression of DOF transcription factor from *Populus tremula* x *Populus alba*

Laudiane Zanella¹, Juliana Degenhardt-Goldbach², Isabel Gerhardt³, João Carlos Besspalhok Filho¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Embrapa Informática Agropecuária, Campinas, Brasil (laudianezanella@hotmail.com; juliana.degenhardt@embrapa.br; isabel.gerhardt@embrapa.br; joao.bespa@gmail.com)

From the total biomass produced by plants, 70% is represented by cell wall, in which carbon is mainly accumulated in the secondary wall. Therefore, the understanding of the mechanisms that regulate cell wall synthesis and its modification through genetic engineering may lead to the increase of lignocellulosic biomass. Among several functions already attributed to the proteins of the Dof transcription factors, its relation with cell wall formation is one of the most studied. However, the mechanisms involved in this process are not fully elucidated. *Populus* is the most used model plant for studies with forest species, including functional genomics. The objective of this work was to silence one gene of the Dof family by RNAi in plants of *Populus tremula* x *P. alba*, and investigate its function, aiming at the future production of *Eucalyptus* and *Pinus* plants with higher biomass production. For this, a silencing vector was constructed with specific primers of a Dof family gene from *Populus*. To obtain the transgenic plants via *Agrobacterium tumefaciens*, root segments were used as initial explants. Fifteen events were obtained, and in twelve the Dof expression was suppressed at different levels, according to qPCR analyzes. Of these, on five the expression was highly suppressed, indicating that the gene was successfully silenced. In morphological evaluations after 90 days the events did not present phenotypic differences in relation to non transformed plants. Physiological and histochemical analyzes are underway to evaluate lignin and cellulose contents and structural changes in transformed plants.

Cloning optimization of gene encoding trypsin inhibitor in *Falcataria moluccana* Miq.

Ulfah J Siregar^{1,2}, Auraga Dewantoro¹, Nofri Yanti¹

¹Bogor Agricultural University, Bogor, Indonesia; ²SEAMEOBIOTROP, Bogor, Indonesia (siregaruj@gmail.com; auragadewanto@yahoo.com; nofry17@gmail.com)

Sengon (*Falcataria moluccana* Miq.) is a multifunctional and fast growing tree species which has a high economic value. However, the increasing trend of sengon plantation has caused a pest outbreak, especially *Xystrocera festiva* stem borer. Borkor larvae have trypsin enzyme in their gut to hydrolyse stem of sengon. Some sengon resistant accessions showed inhibitory activity of trypsin enzyme, which are important aspect for sengon tree improvement program. The objectives of this research are to optimize preparation of cloning method for the construction of genomic library, especially trypsin inhibitor (TI) gene. This

research used shotgun cloning and specific gene cloning method to establish genomic library. The genomic library was successfully constructed using pGEM-T Easy vector in *E. coli* bacteria strain DH5 α , generating about 9 colonies by shotgun cloning method and sequences of sengon TI genes were obtained with sizes ranging from 107 to 308 bp. The sequences of the colonies had high similarity from nuclear, chloroplast and mitochondrial genomes of various tree species and TI sequences were similar to *Tamarindus indica*, *Glycine max*, *Populus trichocarpa* and *Populus nigra*, however those TI sequences had low E values.

Studying ecophysiological patterns to improve the management of high-productivity *Eucalypt* plantations: the EUCFLUX project

Global climatic changes may deeply affect the functioning of *Eucalyptus* plantations. It is therefore crucial to gain knowledge on the drivers of *Eucalyptus* productivity, carbon (C) allocation and resource-use efficiency in order to ensure a sustained productivity. These data are key to improve the productivity of *Eucalyptus* plantations and reduce their impacts on natural resources towards sustainable management. Building on the innovative results obtained in its first phase (2007-2017), the second phase of the EUCFLUX project, initiated in 2018, aims to enhance our knowledge on eucalypt plantations functioning at various spatiotemporal scales. The EUCFLUX study site is located on a commercial clonal plantation of ca 260 ha in Southern Brazil. The project will specifically 1) quantify the fluxes of energy, C and water along a complete rotation using the Eddy Covariance technique, girth inventories, litter and C content surveys and flux chambers; and assess the effects of forest plantations on soil water availability down to 10m and water table 2) use high-resolution dendrometers and anatomical analyses to study the determinism of growth 3) combine field data, high resolution remote sensing and modelling to upscale our knowledge of eucalypt functioning from site to regional scales and 4) compare the functional responses of more than 16 eucalypt genotypes (clonal and seed-origin) in a common-environment field trial, in order to evaluate the generality of the results obtained on the main clone, but also to evaluate how different are the functional responses of coppice and planted eucalypt trees.

JERFs regulate intracellular K⁺/Na⁺ balance in *Populus alba* × *P. berolinensis* under salt stress

Changjun Ding^{1,2}, Weixi Zhang^{1,2}, Dan Li^{1,2}, Qinjun Huang^{1,2}, Xiaohua Su^{1,2}

¹State Key Laboratory of Tree Genetics and Breeding, Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China; ²Key Laboratory of Tree Breeding and Cultivation of State Forestry Administration, Research Institute of Forestry, Chinese Academy of Forestry Beijing China (changjund@126.com; weixizhang@126.com; changjund@126.com; huangqj@caf.ac.cn; suxh@caf.ac.cn)

Maintaining K⁺/Na⁺ balance in the cytoplasm is important for metabolism as well as salt resistance in plants. In this study, we monitored the growth (height and diameter) of *Populus alba* × *P. berolinensis* genotypes 9# and transgene 9# (ABJ01) carrying the JERF gene over 4 years. Expression of NHX1 and SOS1 which encode Na⁺/H⁺ antiporters in the vacuole and plasma membranes were measured in leaves. Ion flux of Na⁺, K⁺ and H⁺ were measured in the root tip of seedlings stressed by 100 mM NaCl for 7 days, 15 days and 30 days. The results showed that transgenic genotype (ABJ01) grew faster than 9#, and ABJ01 displayed higher NHX1 and SOS1 expression in leaves than 9#. Root ion flux measurement revealed a higher Na⁺ efflux and H⁺ influx in ABJ01 than in 9#, but K⁺ efflux was lower in ABJ01. The results suggest that salt stress induces NHX1 and SOS1 to a greater extent in the ABJ01 genotype, which up-regulate the Na⁺/H⁺ antiporter to better maintain K⁺/Na⁺ balance in the cytoplasm of this more salt resistant variety.

Morphological dissection and cellular and transcriptome characterizations of bamboo pith cavity formation reveal a pivotal role of genes related to programmed cell death

Lin Guo¹, Xuepeng Sun², Zhongru Li¹, Yujun Wang¹, Zhangjun Fei², Chen Jiao², Jianyuan Feng¹, Dingfan Cui¹, Xingyu Feng¹, Yulong Ding¹, Chunxia Zhang¹, Qiang Wei¹ 

¹Nanjing Forestry University, Nanjing, China; ²Cornell University, Ithaca, USA (guolin0915@njfu.edu.cn; xs57@cornell.edu; 840826495@qq.com; 171474787@qq.com; zf25@cornell.edu; cj334@cornell.edu; 274505453@qq.com; 1152319726@qq.com; 921824407@qq.com; ylding@vip.163.com; 550445950@qq.com; weiqiang@njfu.edu.cn)

Pith cavity formation is critical for bamboo to overcome the bending force during fast growth, but the molecular mechanism is largely unknown. Multiple approaches were employed to study the biology of pith cavity formation, including anatomical dissection, mathematical modeling, and transcriptome profiling. We found that the corruption of pith tissue occurred sequentially and asymmetrically from the top-center of the internode down to the bottom, which might be caused by the combined effects of asymmetrical radial and axial tensile forces during shoot-wall cell elongation and spiral growth of bamboo internode. Programmed pith cell death manifested by TUNEL positive nuclei, DNA cleavage and degraded organelles, which was regulated by ethylene and calcium signaling pathway, ROS burst, cell wall modification, proteolysis, and nutrient recycle genes finally might be responsible for pith tissue corruption of *Pseudotsuga japonica*. Although similar physiological changings and transcriptome profiles were found in other randomly selected bamboo species, different forming speed of pith cavity, which might be caused by different pith cells across the internode that negatively correlate with culm diameter was discovered. These findings provided a systematical view on the formation of the bamboo pith cavity and revealed that PCD plays an important role in the bamboo pith cavity formation.

Douglas-fir seedlings in the Pacific Northwest: the genetics of drought adaptation

Erda Celer¹

¹Republic of Turkey Ministry of Agriculture and Forestry General Directorate of Forestry, Ankara, Turkey (celererda@gmail.com)

Douglas-fir (*Pseudotsuga menziesii*) is a widely distributed, ecologically important, and commercially valuable tree species in North America. However, climate change is expected to adversely impact Douglas-fir trees, and assisted migration may become necessary to lessen the effects of climate change. Because

drought stress is one of the projected effects of climate change in the western U.S., it is increasingly important to include drought adaptation traits in breeding programs and in reforestation decisions. In this study, I addressed the following objectives: (1) obtain baseline measurements and climate data to help in the analysis and interpretation of future measurements in the Drought Hardiness Study; (2) characterize the quantitative genetics of drought adaptation traits; and (3) determine whether drought adaptation traits are associated with the climatic origin of Douglas-fir seedlings. To achieve these objectives, data were collected from about 10,000 Douglas-fir seedlings from 429 families from western Oregon and Washington that were planted at two sites (Sprague and Lost Creek) in southern Oregon. Measured variables, which I refer to as drought adaptation traits, included height, second flushing, spring bud flush, damage (foliage, stems, and leaders), and survival. I will discuss the design and results of a study that help increase the understanding about the importance of climatic-driven genetic differences for drought adaptation traits in Douglas-fir. The results of this study will provide useful information for understanding drought, enhancing breeding programs, and potentially adjusting forest management to climate change impacts.

C2r: PHYSIOLOGY AND GENETICS IN PLANTATION

The growing importance of *Eucalyptus* in forest plantations in Chile / Creciente importancia de eucaliptos en plantaciones forestales chilenas

Santiago Barros¹, Roberto Ipinza¹, Maria Paz Molina¹, Braulio Gutiérrez¹, Patricio Rojas¹, Juan Carlos Pinilla¹

¹Instituto Forestal, Santiago, Chile (sbarros@infor.cl; ripinza@infor.cl; mmolina@infor.cl; bgutier@infor.cl; parojas@infor.cl; jpinilla@infor.cl)

Planted forests in Chile cover 2.4 MMha; 1,4 *Pinus radiata*, 0,59 *Eucalyptus globulus*, 0,27 *Eucalyptus nitens* and 0,16 other species, including other Eucalypts like *E. camaldulensis*, *E. cladocalyx*, *E. delegatensis*, *E. regnans*, *E. sideroxyton* and *E. viminalis*. *Pinus radiata* was the main species since the middle of the past century, Eucalypt species were gradually included later. Today eucalypts cover over than 860 Mha, important resource for forest companies and medium and small forest owners. Chilean Forestry Institute (INFOR) has developed research on Eucalypts since the 60s, introducing and breeding Eucalypt species, developing plantation establishment and management techniques, and starting a genetic improvement programme with main focus on *E. globulus* and *E. nitens* and in collaboration with companies and owner associations. Objectives are improving growth, drought or frost tolerance, pulp yield in short turns and solid wood yield in longer turns. Under the climate change scenario challenges seem to be others. Chile's central part, where planted forests are located, face changes like lower medium rainfalls and higher medium temperatures. Changes will involve new threats to planted forests; water scarcity and pest damages, problems that require appropriated genetic material; new species and hybrids. Hybrids and their silviculture, appears as an appropriate way in facing the challenges. INFOR has experience on species introduction and genetic improvement and on hybrids development and management. For instance, *E. tereticornis* x *E. globulus*, as drought tolerant material, and *E. nitens* x *E. globulus*, as frost tolerant material and tolerance to pests.

Kraft pulp production from *Tectona grandis* sawing wood waste

Marina Coelho¹, Eduardo Almeida¹, Caio Almeida¹, Francides Silva Júnior¹, Vanderlei Benedetti¹

¹Universidade de São Paulo, Piracicaba, Brasil (marina.ulian@usp.br; eduardoleitealmeida@usp.br; caio.cfalmeida@usp.br; fjr@usp.br; vabenedetti@gmail.com)

This work aimed to verify the potential use of 14-year-old *Tectona grandis* slab wood for kraft pulp production. *Tectona grandis* wood chips were classified in thickness from 4 to 6 mm and dried outdoors to be used in the kraft pulp productions. The pulping processes were carried out in rotative digester, with 8 individual reactors, which made it possible to obtain delignification curves by applying distinct alkali charges in each reactor, varying from 20 to 27% (NaOH based); 30% of sulphidity and 4:1 liquor-to-wood ratio were used. The heating and cooking times were 60 and 240 minutes, respectively, and the maximum temperature applied was 154° C. The parameters of bulk yield, screened yield, reject content, kappa number and residual alkali charge were analyzed and, later, mathematical models were adjusted by means simple regression in order to estimate the parameters necessary to produce pulp with kappa number 28. The adjusted mathematical models indicated that, to produce pulp with kappa number 28 from *Tectona grandis* wood, it is required alkali charge of 25.5%, resulting in screened yield of 46.4% and residual alkali charge of 23.5%. In conclusion, this preliminary study indicated that it is possible to produce pulp from *Tectona grandis* slab wood. It is highlighted that there is room to optimize the pulping parameters, especially with regards to higher yields, lower kappa number and residual alkali charge.

Genetic variation for heights in progeny of *Eucalyptus tereticornis* in Selvíria, Brazil / Variação genética para altura em progênes de *Eucalyptus tereticornis* em Selvíria, Brasil

Daniele Fernanda Zulian¹, Darlin Ulises González Zaruma², Murilo da Serra Silva¹, Francieli Alves Caldeira Saul¹, José Cambuim¹,

Paulo Henrique Müller da Silva³, Mario Luiz Teixeira de Moraes¹, Ananda Virginia Aguiar⁴

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Engenharia de Ilha Solteira, Ilha Solteira, Brasil; ²Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ³Instituto de Pesqui (danizulian@gmail.com; dgzaruma@gmail.com; mserrasilva@yahoo.com.br; francieli_eng.ambiental@yahoo.com.br; josecambuim@yahoo.com.br; paulohenrique@ipef.br; mario.moraes@unesp.br; ananda.aguiar@embrapa.br)

O *Eucalyptus tereticornis* é uma espécie promissora para regiões tropicais e/ou com déficit hídrico, a espécie apresenta rápido crescimento e madeira apropriada para fins energéticos. Foi avaliado a variabilidade genética em dois testes de progênes de polinização aberta de *E. tereticornis*, instalados na região do Bolsão Sul-mato-grossense – Brasil. Os testes foram instalados em setembro de 2017, na Fazenda de Ensino, Pesquisa e Extensão (FEPE/Unesp), em Selvíria - MS. Em cada teste, foram utilizadas 87 progênes do Programa Cooperativo de Melhoramento Florestal do IPEF. O delineamento experimental foi em blocos casualizados, uma planta por parcela, com 18 e 6 repetições para o teste 1 e 2, respectivamente. Aos 12 meses de idade foram obtidos dados de sobrevivência e altura, os parâmetros genéticos foram obtidos pelo método da máxima verossimilhança restrita e melhor predição linear não viciada (REML/BLUP). A sobrevivência foi alta em ambos os testes (> 80,0%), caracterizando uma boa adaptação da espécie na região. Nos dois testes foram obtidas diferenças significativas entre progênes em nível de 1% de probabilidade pelo teste de qui-quadrado. O coeficiente de herdabilidade em nível de média de progênes foram de 0,62 para o teste 1 e 0,28 para o teste 2. O coeficiente de variação genética em nível de progênes foram de 8,8% e 8,4% para os testes 1 e 2, respectivamente. A interação entre os testes (0,095) não foi significativa pelo teste de qui-quadrado. Os testes apresentam variação genética para o caráter altura na avaliação precoce.

Is it possible to produce forest nursery stock to face droughty periods after transplanting?

Barbara Mariotti¹, Sofia Martini¹, Sabrina Raddi¹, Alberto Maltoni¹, Francesca Ugolini², Juan Oliet³, Douglass F. Jacobs⁴, Andrea Tani¹
¹Università di Firenze, Firenze, Italy; ²Consiglio Nazionale delle Ricerche, Firenze, Italy; ³Universidad Politécnica de Madrid, Madrid, Spain; ⁴Purdue University, West Lafayette, USA (barbara.mariotti@unifi.it, sofia.martini@unifi.it, sabrina.raddi@unifi.it, alberto.maltoni@unifi.it, f.ugolini@ibimet.it, juan.oliet@upm.es; djacobs@purdue.edu; andrea.tani@unifi.it)

Nursery stock with higher tolerance to water stress conditions during the season following transplanting could increase field performance when subjected to seasonally conditions (i.e. Mediterranean climate). This could contribute to the success of forest restoration also in relation to the consequences of climate change. We specifically addressed: (a) the effects of two substrates and three fertilization rates on morphological (root and shoot system) and physiological traits (fluorescence and spectroscopy) after nursery cultivation in three *Quercus* species (18 combinations); (b) the morphological and physiological response of each nursery stock combination to hydric stress test in greenhouse and in the field after transplant. In 2017, *Q. ilex*, *Q. pubescens*, *Q. robur* seedlings were grown in peat and coir (a renewable, sustainable resource). In addition to the nursery-standard fertilization, two other fertilization treatments were tested (enriched in K and in P). In 2018, two parallel performance trials were carried out: a hydric-stress test in controlled conditions (comparing three regimes) and a field planting (central Italy). At the end of nursery cultivation, greater growth, both in shoot and root biomass, was observed in peat-K treatment in all species, followed by the other fertilization treatments within peat substrate. Seedlings in coir showed a general lower development despite a higher shoot/root ratio. Combinations responded differently to the hydric stress test, with generally higher survival and performance for seedlings grown in coir. Results were combined with data collected in the field providing useful information to identify the most promising stock of each species to overcome 'transplant shock'.

In vitro cultivation of *Ilex paraguariensis* A. St. Hil seeds

Maria Cecilia Mireski¹, Elisa Vieira², Antônio Carlos Nogueira¹
¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil (mariacecilia.agro@gmail.com, elisa.vieira@embrapa.br, acnogueira.ufpr@gmail.com)

Ilex paraguariensis seeds are involved in a wood endocarp and the embryos are immature in the ripe fruits. As a consequence the germination is low even after months of adequate conditions. In vitro cultivation in medium supplemented with growth regulators is an alternative for obtaining seedlings from seeds with poor germination. The aim of this work was evaluate the effect of diferent growth regulators in yerba mate seeds cultivated in culture medium. The medium Murashige e Skoog 1/4 was used and supplemented with 3% sucrose, 0.6% phytigel, 4 ml L⁻¹ cercobin; 8 ml L⁻¹ ampicillin and 16 ml L⁻¹ chloramphenicol. The following growth regulators were tested: 0.1 mg L⁻¹ gibberellic acid; 0.2 mg L⁻¹ gibberellic acid; 0.1 mg L⁻¹ NAA and 0.1 mg L⁻¹ gibberellic acid; 0.1 mg L⁻¹ NAA. For each treatment 60 tubes were used containing one seed cut longitudinally and disinfested with 70% alcohol; 0.5% bleach and ultrapure water. The tubes were incubated at 27 ± Celsius degrees with light during 14 hours during 60 days. MS medium supplemented with 0.1 mg L⁻¹ NAA and 0.1 mg L⁻¹ gibberellic acid was efficient with 7% of germination. Nonetheless it was not possible obtain normal seedlings once only the hypocotyl developed radicles with atrophy. New studies are necessary to improve the technic for yerba-mate seed propagation.

Genetic variation among half-sib families of *Tectona grandis* L.f. in Colombia

Ana M. López¹, Alonso Barrios¹, Luis F. Llanos¹
¹Universidad del Tolima, Ibagué, Colombia (amlopeza@ut.edu.co; abarriost@ut.edu.co; lfllanosm@ut.edu.co)

Teak is a high interest commercial tree species, mainly for its outstanding physical and mechanical wood properties, growth rates and adaptability to different site conditions. Superior genetic stocks of teak are required to contribute to the maximization of production in increasingly short periods of time. A study was carried out to evaluate the genetic variation of growth and tree quality traits among 40 half-sib families from 4 provenances from the Atlantic Coast of Colombia. Traits were measured in a 4-year-old progeny test established with a single-tree-plot arrangement in the interior valleys of the country. Variance components were determined using restricted maximum likelihood to calculate narrow-sense heritabilities and genetic gains considering different selection indices. Genetic correlations among traits were computed using multivariate analysis of variance. Additionally, a ranking of families according to total wood volume per hectare was developed. The analysis showed that all the families had a higher survival rate ranging 73-100%. The genetic gains by selecting 30% of the best families were estimated in 2.93, 4.83, 11.97, 6.53, 4.26 and 14.42% for diameter, stem volume, total volume per hectare, crown projection area, branch insertion angle and number of basal sprouts, respectively. Total wood volume per hectare showed significant positive genetic correlations with diameter (rg = 0.72), stem volume (rg = 0.69), crown projection area (rg = 0.66) and stem straightness (rg = 0.31) and a negative correlation with branch diameter (rg = -0.21). The study identified that the best families proceed from municipalities of Canalete and San Antero, Córdoba.

How does water availability and drought sensitivity impact water use and water use efficiency in three fast growing *Eucalyptus* plantations?

Robert Hubbard¹, Otávio Campoe², Rafaela Carneiro³, Marco Aurélio Figura⁴, Gabriela Moreira⁵, Dan Binkley⁶
¹USDA Forest Service, Fort Collins, CO, USA; ²Federal University of Santa Catarina, Santa Catarina, Brasil; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ⁴Klabine, Telemarco Borba, Brasil; ⁵International Paper, Mogi Guacu, Brasil; ⁶Un (rhubbard@fs.fed.us; otavio.campoe@gmail.com; rafaela@ipef.br; marco.figura@klabine.br; gabriela.moreira@internationalpaper.br; dan@cn.colostate.edu)

As climate change continues to drive changes in temperature and precipitation, understanding the trade-offs between wood growth and water use is becoming increasingly important. While a large number of studies have focused on resource use efficiency of stands, less attention has been directed to individual trees. Furthermore, we lack a detailed understanding of how clonal selection and environment impact tree water use in *Eucalyptus* plantations. Our previous work showed that larger, dominant trees had higher rates of wood growth, water use and water use efficiency (WUE) than smaller trees and this pattern persisted with increased water supply in irrigated plots. Here, we expand on this work and examine total water use and WUE for a drought sensitive and drought tolerant *Eucalyptus* clone growing at three climatically different sites within the TECHS research platform in Brazil. At each site, we measured WUE for each clone in control and rainfall reduction treatments. We are testing three hypotheses; 1) water use increases with precipitation inputs and is higher in drought sensitive clones, 2) larger trees use more water and have higher WUE than smaller trees and; 3) this pattern with tree size persists across all treatments and sites regardless of drought sensitivity of the clone. Preliminary data indicates mean annual increment (MAI) was higher in control versus rainfall reduction treatments and dominant trees grew faster than dominated trees. Final results for our hypothesis tests will be available in June 2019 when data analyses are completed.

Reforestation after disturbances in planted Norway spruce stands – influence of silvicultural techniques on seedlings field performanceMartina Dodan², Sanja Perić²²Croatian Forest Research Institute, Jastrebarsko, Croatia (martinat@sumins.hr; sanjap@sumins.hr)

Reforestation after forest decline can be difficult. Selection of silvicultural techniques used during reforestation is crucial for good reforestation outcome, also lowering costs of labour and reproductive material used. Climate change will add to complexity of silvicultural interventions. Present and predicted disturbance regime points to the increase of areas for reforestation in Europe, thus creating the need for update of knowledge on regeneration methods and seedling types used. Newly gained knowledge acts as a background for national forestry and nursery programmes. Study examines area after bark beetles attack and wind throw in planted Norway spruce stand after it was reforested by seeding and planting of European beech and Silver fir at European beech and Silver fir dominated forest area (placed on the crossroads of Central and Southeast Europe). Analysed data track seedlings field performance (height, basal diameter, quality indices and height increment) during three consecutive years (2010–2013) and again eight year after canopy loss (2017). In addition, we discuss the issues of different silvicultural interventions (direct seeding, planting of different type of seedlings, intensities of canopy loss, site preparation techniques) during reforestation of area after disturbances in hilly and mountain areas. Review includes management and legislative legacy as well as state of the art of contemporary silviculture related to reforestation practices of Southeast Europe, with Croatia as a case study.

C2s: PHYSIOLOGY AND GENETICS**Morphological, environmental and genetic attributes of wolf trees' morphological types in Scots pine (*Pinus sylvestris* L.)**Ekaterina Makrickiene¹, Gediminas Brazaitis¹, Darius Danusevičius¹¹Vytautas Magnus University, Kaunas, Lithuania (ekaterina.makrickiene@asu.lt; gediminas.brazaitis@asu.lt; darius.danusevicius@asu.lt)

Wolf trees are super-dominant trees with wide crowns and thick branches. Usually such trees are undesired in the stand due to their odd morphological characteristics; however, such trees can be valuable as habitat, biomass source or for genetic conservation. In our study we approved the existence of two wolf trees' morphological types in Scots pine (*Pinus sylvestris* L.). With the use of environmental and progeny analysis, dendrochronological and genetic methods we assessed the wolf trees in Scots pine from several points of view. This allowed us to find out the differences both between the regular trees and wolf trees and between the two wolf trees' morphological types. Both morphological types were genetically different from the regular Scots pine trees, what resulted in significant differences between the two wolf tree morphological types and the regular trees in their responses to soil fertility and mezo relief. Comparing the annual increments of wolf trees and regular trees, we could observe faster growth of the wolf trees up to the age of 35 years. Sensitivity to the climatic factors strongly depended on the wolf tree morphological type. The second morphological type exhibited a stronger response to precipitation, while the control trees and the first wolf tree morphological type had stronger responses to temperature. Progeny analysis showed that as early as the first year of growth, the wolf tree progenies had longer branches and a higher branch number, while the progenies of the regular trees had bigger height increment.

Research of morphologic features of up to 10-year-old pedunculate oak (*Quercus robur* L.) in the provenance test in Žepče, Bosnia and HerzegovinaMirzeta Memišević¹, Dalibor Ballian^{1,2}, Hojka Kraigher²¹Forest Faculty University of Sarajevo, Sarajevo, Bosnia and Herzegovina; ²Slovenian Forest Institute, 1000 Ljubljana, Slovenia (mirzeta.mh@sfsa.unsa.ba; balliandalibor9@gmail.com; hojka.kraigher@gozdis.si)

Even though remaining populations of pedunculate oak in Bosnia and Herzegovina are small and scattered, their specific genetic structure makes them significant for preserving varieties of pedunculate oak (*Quercus robur* L.) in Bosnia and Herzegovina and Europe. This was the reason for establishing Bosnia and Herzegovina pedunculate oak provenance test in Žepče in 2009. The test material was used in this research. The test includes 28 provenances. The aim of the research is to use morphologic features of height and root collar diameter of plants to determine variability of the remaining pedunculate oak populations in Bosnia and Herzegovina. Average height of one-year-old plants (2009) in all provenances amounts to 36.41 cm, and average root collar diameter to 5.66 mm, while average height of ten-year-old plants reaches 260.0 cm, and average root collar diameter amounts to 67.7 mm. Jelah provenance stood out from the beginning with the above average height of its plants – 30% above total average of all provenances and 25% bigger average root collar diameter compared to total average size in other provenances. After the plants were eight years old, the lowest average height was recorded in Visoko Muhašinovići provenance – 20% lower height compared to total average, 24% smaller diameter in comparison with the total average. The variance analysis has shown statistically significant differences between populations in all tested features, which has been confirmed by Duncan test.

Phenology of *Pentaclethra macroloba* (Willd.) Kuntze (Fabaceae): hyperdominant tree of the Amazonian estuaryAdelson Rocha Dantas¹, Maria Teresa Fernandez Piedade¹, Marcelino Carneiro Guedes², Ana Claudia Lira-Guedes²¹Instituto Nacional de Pesquisas da Amazônia, Manaus, Brasil; ²Programa de Pós-Graduação em Ecologia, Manaus, Brasil; ²Embrapa, Macapá, Brasil (adelson.dantas@yahoo.com.br; maua.manaus@gmail.com; marcelino.guedes@embrapa.br; ana-lira.guedes@embrapa.br)

Pentaclethra macroloba (pracaxizeiro) is a hyperdominant species of the Amazon estuary floodplain. The oil extracted from its seeds has medicinal properties. The effect of the polymodal flood cycle on the phenology of tree, including the pracaxizeiro, from Amazonian estuary is little known. The hypothesis that the flood pulse is the main factor that directs the phenological processes of the pracaxizeiro was tested. Reproductive and vegetative phenophases of 30 pracaxizeiro were monitored fortnight from September/2017 to September/2018, in the Environmental Protection Area of Fazendinha, Macapá, Brazil. Phenophases were correlated with maximum temperature (°C), precipitation (mm) and flood level (cm), using the Spearman correlation. There was positive correlation with temperature between flower buds ($r_s = 0.57$) and flowers in anthesis ($r_s = 0.63$), already with precipitation (buds: $r_s = -0.50$, anthesis: $r_s = -0.53$) and floods (buds: $r_s = -0.65$, anthesis: $r_s = -0.69$) correlations were negative. The correlation was positive between immature fruit with temperature ($r_s = 0.73$) and negative with precipitation ($r_s = -0.64$) and flood ($r_s = -0.57$). Fruit ripening (rainfall: $r_s = 0.38$, flood: $r_s = 0.50$) and seed dispersal (rainfall: $r_s = 0.76$, flood: $r_s = 0.81$) occur in the rainy season and peak flood Amazon river. Leaf production and fall have low correlation with the abiotic variables tested. Flourish in the dry season prevents loss of floral resources due to torrential rains of the Amazon and maximizes pollination by insects. The flood pulse, together with precipitation, acts as a trigger in fruit ripening and seed dispersal.

Difference in leaf $\delta^{15}\text{N}$ among tree species with different type of microbial symbiosis in subtropical, warm-temperate and cool-temperate forests

Shin Ugawa¹, Yoshiyuki Inagaki², Karibu Fukuzawa³, Keisuke Koba⁴, Ryunosuke Tateno⁵, Erik Hobbie⁶

¹Faculty of Agriculture, Kagoshima University, Kagoshima, Japan; ²Shikoku Research Center, Forestry and Forest Products Research Institute, Kochi, Japan; ³Field Science Center for Northern Biosphere, Hokkaido University, Sapporo, Japan; ⁴Center for Ecolo (ushin@agri.kagoshima-u.ac.jp; yinagaki@affrc.go.jp; caribu@fsc.hokudai.ac.jp; keikoba@ecology.kyoto-u.ac.jp; rtateno@kais.kyoto-u.ac.jp; erik.hobbie@unh.edu)

Nutrient acquisition strategies of tree species determine their competitive ability under different nutrient regimes. The process for absorbing soil nitrogen (N) can be estimated by the N stable isotope ratio of leaves ($^{15}\text{N}:$ ^{14}N , expressed as $\delta^{15}\text{N}$), which is determined by different N sources and isotope fractionation in the absorption process. In this study, we examined leaf $\delta^{15}\text{N}$ of 23 tree species which grew in four forests of the subtropical, warm-temperate and cool temperate zones to understand the absorption process of tree species with different types of microbial symbiosis, i.e., ectomycorrhizal (ECM), arbuscular mycorrhizal (AM) and root nodule bacteria (RNB). In contrast to global patterns, where ECM plants averaged 1% lower than AM plants, leaf $\delta^{15}\text{N}$ of tree species forming ECM symbioses averaged 1.7% higher than those forming AM symbioses. Plants with N-fixing symbioses were 0.9% higher than plants with ECM symbioses. However, genus-level variability within AM plants was greater than variability among other plant symbioses. The leaf $\delta^{15}\text{N}$ of these species may be influenced more strongly by the N form acquired or the depth of N acquisition than by ^{15}N fractionation by ECM fungi. The leaf $\delta^{15}\text{N}$ of tree species associated with RNB was closer to zero than other species, but negative. We thus suggest that leaf $\delta^{15}\text{N}$ of tree species with RNB was determined mainly by nitrogen fixation although it may reflect the isotope fractionation by RNB.

Studies on salt-tolerance of Halophyte *Nitraria* L.

Xiuyan Yang¹, Huanyong Li¹, Xiaoqian Tang¹, Ping Huang¹

¹Chinese Academy of Forestry, Beijing, China (sueyxy@126.com; huanyong0913@sina.com; txqcaf@163.com; huangping@caf.ac.cn)

Genus *Nitraria* (about 12 species) are tertiary relict and widespread from Africa, Asia, Europe and Australia. Some 5 species as the primary constructive species distribute in deserts region in northwest of China. As typical halophytes, *Nitraria* have remarkable salt tolerance. In this report, some of our research results were showed: (1) The uptake and accumulation of Na^+ and Cl^- in roots, stems and leaves tended to increase in *N. tangutorum* with the NaCl stress with the K^+ uptake enhanced and the Ca^{2+} uptake decreased. The abilities of ion selective absorption-transportation of *N. tangutorum* were important for maintaining ion homeostasis in leaves under salt stress. (2) Na^+ efflux in *N. sibirica* seedlings increased due to increased plasma membrane H^+ -ATPase and Na^+/H^+ antiporter activity under salt stress. High H^+ pump activity restricts the Na^+ influx through NSCC sandlimits K^+ -leakage through outward-rectifying K^+ channels and NSCCs. (3) Under NaCl concentration of 8% for 40 days, the contents of photosynthetic pigments tended to decrease in *N. sibirica* and *N. tangutorum*. The Pn of *N. tangutorum* was lower and *N. sibirica* was higher than that of the control when the PAR reached about $1000 \mu\text{mol} \cdot \text{m}^{-2} \cdot \text{s}^{-1}$. The activities of Rubisco, PEPC, Ci and Gs decreased in *N. tangutorum* leaves, while Ls increased. The PEPC activity of *N. sibirica* leaves decreased but Rubisco activity, Ci and Gs increased. The $\delta^{13}\text{C}$ value increased in 2 species under the NaCl stress. Salt stress led to the decrease of Rd and LCP for 2 species.

Willow breeding for diversified and sustainable applications in Argentina

Teresa Cerrillo¹, Sabrina Loyal¹, Edgardo Casaubón¹, Esteban Thomas², Jorgelina Grande³, Silvia Monteoliva⁴

¹INTA, Campana, Argentina; ²INTA, Allen, Argentina; ³Papel Prensa SA, San Pedro, Argentina; ⁴CONICET, La Plata, Argentina; ⁵Universidad de La Plata, La Plata, Argentina (cerrillo.teresa@inta.gov.ar; loyal.sabrina@inta.gov.ar; casaubon.edgardo@inta.gov.ar; thomas.esteban@inta.gov.ar; jgrande@papelprensa-sp.com.ar; monteoliva@yahoo.com.ar)

Willow plantations (*Salix* spp) in Argentina are located mainly in Delta of Paraná River and, in a smaller scale, in Northern Patagonia. The old stands are planted with traditional clones, which have low volumetric yield and limited wood quality for paper and sawing industries. In a global context characterized by climate change and by new needs of society and markets, it is essential to improve and adapt clonal availability. Considering these premises, INTA is developing a breeding program. First, more focused on the improvement to achieve clones with high wood production performance; later, the program has been adding objectives that also include other applications (wood and non-wood products). INTA's breeding program, through hybridizations and selection in sequential phases, focuses on obtaining fast growing genotypes, adapted to environmental conditions and suitable for diversified applications. In recent years, seven clones (originated in *Salix matsudana* x *Salix alba*; *Salix matsudana* x *Salix nigra*, and from open pollination on *Salix alba*, *Salix matsudana* and *Salix nigra*) have been released. They show an average volume 45% better than the average of the oldest commercial clones and are suitable for sawing and elaboration of paper pulp for newspapers. The five clones selected for pulp-paper showed good standards also for packing paper. In addition, other seven experimental clones are promising for these integrated applications, including biomass production, silvopastoral systems and experiences in quarries gravel restoration and phytoremediation.

Breeding and clonal selection for basket-making, a strategic activity for smallholders

Teresa Cerrillo¹, Sabrina Loyal¹, Mauro Fernández², Victorio Dieta²

¹INTA, Campana, Argentina; ²INTA, Campana, Argentina; ³INTA, Tigre, Argentina; ⁴INTA, Tigre, Argentina (cerrillo.teresa@inta.gov.ar; loyal.sabrina@inta.gov.ar; fernandez.mauro@inta.gov.ar; dieta.victorio@inta.gov.ar)

Some species of shrubby willows (*Salix* spp) have suitable for basket-making, after applying specific treatment techniques and industrialization methods. In Argentina, these plantations are located in the central-east of the country, with excellent soil and climatic conditions for willow growth. Shrub willows cultivation for basket-making take its biggest expansion in Delta del Paraná between 1930 and 1950 and today represents a strategic activity for smallholders. This small-scale activity provides a sustainable tool to improve the life quality of the families settled in this wetland region. With the aim to obtain a broader and improved offer of clones, INTA is developing a classical breeding program since 2012, by means of controlled crossings and sequential selection phases. After a first selection in 2015, over a seedling bank (originally composed of 200 individuals), 20 pre-selected genotypes were established in a clonal bank and measured between 2016 and 2018. Total plant height, morphological and phenological variables and diseases susceptibility were registered. After that, network of trials was established in six experimental field plots to evaluate the response in different site conditions. Final evaluations showed a group of seven pre-selected genotypes with higher growth and outstanding performance in the other variables, including aptitude to elaborate baskets. These genotypes belong to intraspecific crossings of: *Salix viminalis* and interspecific: *Salix viminalis* x *Salix caprea*. It's expected that these preselected clones will be able to provide, in the short term, a new tool to improve the human well-being and social equity of these smallholders in the territory.

Population structure of *Pentaclethra macroloba* (Willd.) Kuntze in high and low floodplains of the Amazonian estuary

Adelson Rocha Dantas¹, Maria Teresa Fernandez Piedade¹, Marcelino Carneiro Guedes², Ana Claudia Lira-Guedes²

¹Instituto Nacional de Pesquisas da Amazônia, Manaus, Brasil; ²Programa de Pós-Graduação em Ecologia, Manaus, Brasil; ²Embrapa Amapá, Macapá, Brasil (adelson.dantas@yahoo.com.br; maua.manoaus@gmail.com; marcelino.guedes@embrapa.br; ana-lira.guedes@embrapa.br)

The flood cycle of floodplain forests and topographic variations are important factors of diversification and morphological and ecophysiological adaptations of the plant community. *Pentaclethra macroloba* is a hyperdominant species adapted to flood variations. The objective of this study was to characterize the *P. macroloba* population structure between environments with high topography, flooded only during the rainy season and peak flood of the river, (high várzea-HV) and low topography with daily flood (low várzea-LV). The study was carried in the Mazagão Experimental Field, Brazil. Four plots of 1 ha were installed in each environment. All individuals with DBH \geq 5 cm were measured and georeferenced. ANOVA test, 0.05% probability, was applied to verify the structural differences between two environments. The HV had higher population density (51.2 individuals.ha⁻¹) compared to the LV (36.7 individuals.ha⁻¹), although without significance. Basal area was higher in the HV (10.42 m²) in comparison with LV (5.90 m²), with significant difference (F = 7.13, p = 0.00795). The maximum DAP of HV was 67 cm with mean of 24 cm. The LV presented maximum DBH of 42 cm with mean of 21 cm, showing structural difference between the two environments (F = 6.22, p = 0.0131). The aggregation index showed high aggregation in the LV (R = 0.89) than in the HV (R = 0.79), differing significantly between the two environments (F = 11.31, p = 0.0008). Frequency and time of flooding are ecological drives that structure the population of pracaxizeiro causing morphological and ecophysiological adaptations to the individual.

C2t: PHYSIOLOGY AND GENETICS

Environmental interactions and marker assisted selection in a changing world

Luciano Medina-Macedo¹, Jacqueline Grima Pettenati¹, Ana Clara Oliveira Ferraz Barbosa², Juliana Vitoria Messias Bittencourt¹, Ludmila Ferreira Bandeira¹, Alexandre Siqueira Guedes Coelho¹

¹LRSV - Laboratoire de Recherche en Sciences Végétales, Toulouse, France; ²Instituto Florestal Goiano, Urutai, Brasil; ³Universidade Tecnológica Federal do Paraná, Ponta Grossa, Brasil; ⁴Universidade Federal de Goiás, Goiânia, Brasil (medina.ppgabb@gmail.com; grima@lrsv.ups-tlse.fr; bioaco@gmail.com; julianavitoria@utfpr.edu.br; ludmilafb@gmail.com; asgcoelho@gmail.com)

There is evidence that climatic changes can influence genetic interactions among traits as well as the genetic variance themselves. Genetic correlations can shift when populations encounter different environmental conditions, reflecting the fact that genes influencing a trait in one environment may not be important in a different one. Thus, is necessary to understand the forces driving the adaptive ability of forest species. Starting from 300 SSR primers, one hundred without segregation distortion were select to build a genetic map to QTL mapping in a double-hybrid Eucalyptus progeny composed by 200 individuals (select hybrid among *E. dunnii* and *E. grandis* x *E. globulus*). Genetic data, as well as growth and wood properties assessed by NIRS, were gathered in Brazil at field trials located in Minas Gerais and Rio Grande do Sul provinces. An integrated genetic map with 11 linkage groups was built, covering approximately 90% of Eucalyptus genome in a total length of 1420 cM. Applying 99% confidence, a total of seven QTL were associated to growth (diameter, height and to volume), in addition to another twelve QTL related to wood properties (three to density; four to cellulose yielding; three to lignin content; and two QTL to relation siringil/guaiacil). Among these QTL, one QTL related to lignin content and another to cellulose content displayed interactions among environments. These results allow the adoption of breeding strategies as Marker Assisted Selection, taking into account the alleles according to the location and ensuring operational solutions to better adapt forests to climate changes.

Genetic variability among genotypes of paricá (*Schizolobium parahyba* var. *amazonicum*) with regard to initial growth in Sinop, Mato Grosso, Brazil / Variabilidade genética entre genótipos de paricá (*Schizolobium parahyba* var. *amazonicum*) quanto ao crescimento inicial em Sinop - Mato Grosso

¹Embrapa Agrossilvipastoril, Sinop, Brasil; ²Universidade Federal do Mato Grosso, Cuiabá, Brasil; ³Universidade do Estado de Mato Grosso, Cáceres, Brasil (aisy.baldoni@embrapa.br; flavio.tardin@embrapa.br; andreia.botin@yahoo.com.br; jairo—alex@hotmail.com; fabiolinsbinski@hotmail.com; adailthonrodrigues@gmail.com; bruno_spiering@hotmail.com; deparisotto@gmail.com; leonardaneves@unemat.br)

O paricá (*Schizolobium parahyba* var. *amazonicum*) é uma espécie nativa da Amazônia, de rápido crescimento e vem ganhando espaço no cenário nacional dentre as culturas florestais plantadas. Para um plantio bem-sucedido são necessárias plantas de boa qualidade e que apresentem desenvolvimento uniforme. O melhoramento genético pode contribuir para a seleção de genótipos superiores, que manifestem as características desejáveis para a cadeia produtiva, estimulando o plantio. Neste contexto, o objetivo foi avaliar a existência de variabilidade genética entre 58 genótipos e possibilidade de seleção de matrizes superiores, por meio da avaliação do crescimento inicial médio de suas progênes. Para tanto, as progênes foram plantadas na área experimental da Embrapa Agrossilvipastoril, no município de Sinop-MT, num delineamento experimental de blocos casualizados, com 4 repetições e 5 plantas por parcela, nas quais foram mensurados o diâmetro do coleto (mm), altura (m) e número de folhas, 6 meses após o plantio. Os dados coletados foram submetidos a análise de variância, considerando, para cada parcela, a média das cinco plantas. Posteriormente, foi obtida a matriz de distâncias entre genótipos proposta por Mahalanobis e agrupamento dos genótipos pelo método de otimização de Tocher. Os resultados da análise de variância demonstraram diferenças significativas entre genótipos (P < 0,05) para todas as características avaliadas. Pela matriz de distâncias, os genótipos 12 e 42 foram os mais similares e os genótipos 44 e 50 os mais divergentes. Nove grupos de médias foram formados pelo método de Tocher, demonstrando variabilidade genética e possibilidade de seleção de matrizes promissoras para a região.

Simulating environmental changes to evaluate the frost resilience of *Eucalyptus* clones

Luciano Medina-Macedo¹, Jacqueline Grima Pettenati¹, Francisco de Assis Bibeiro², Juliana Vitoria Messias Bittencourt³, Rosana Clara Victoria Higa⁴, Antonio Riioyei Higa⁵

¹Laboratoire de Recherche en Sciences Végétales, LRSV, Toulouse, France; ²Ciliar Mudás, Conchal, Brasil; ³Universidade Tecnológica Federal do Paraná, Ponta Grossa, Brasil; ⁴Embrapa Florestas, Colombo, Brasil; ⁵Universidade Federal do Paraná, Curitiba, Brasil (medina.ppgabb@gmail.com, grima@lrsv.ups-tlse.fr; francisco@ciliarmudas.com.br; julianavitoria@utfpr.edu.br; rosana.higa@embrapa.br; higa@ufpr.br)

The evolving climate is a significant driver of change, reducing forest health and productivity. In spite the Brazilian Forestry be the worldwide leader on Eucalyptus cellulose production and yield, this sector had strong economic losses with low-temperature events at every 20 years since the 1970s. To guarantee

the sustainability of forest production systems under rapid climate change, this study aims to evaluate selected clones to frost survival using chambers with controlled environmental conditions, simulating the Brazilian frost events. The frost damage was estimated to one hundred Eucalyptus clones through evaluation of leaves hurt. Before the frozen, the seedlings were acclimated during 24 hours without, to later be submitted to artificial frozen, where the local temperature decreases as of -1 °C unto -5 °C. The results pointed *E. grandis* as the most susceptible species, followed by hybrids and clones from *E. viminalis*, *E. dunnii* and *E. banjensis*. At -5 °C only clones from *E. dunnii* and *E. banjensis* species were resistant. Moreover, at -1 °C nine hybrids were better than *E. viminalis* clones. The ANOVA claims the existence of high genetic structure related to low-temperature resilience, with heritability around 50% and an environmental coefficient near to 14%. The average frost resilience of fifteen best-scored clones was 25% higher than other ones. Therefore, the controlled environmental chambers are useful to evaluate the resilience of forest species to environmental changes scenarios, allowing the adoption of operational solutions to prepare the forest-based sector to the climatic changes.

Analysis of substrates for transplanting native seedling species cultivated in vitro / Análise de substratos para transplantio de mudas nativas cultivadas in vitro

Fabio Silva¹, Giovani Silva¹, Nadine Desene¹, Natasha Lima¹, Bruno Castilho¹, Berenice Silva¹ 

¹Universidade Federal do Acre, Rio Branco, Brasil (italofabio2011@gmail.com; silva.giovani@gmail.com; nadinezuncke@gmail.com; natashalimadas16@gmail.com; bruno-rnc@hotmail.com; bereniceka@gmail.com)

Dentre os métodos de conservação de florestas nativas, a estratégia ex situ tem sido utilizada de forma complementar às estratégias in situ e on farm, auxiliando na minimização das potenciais perdas de diversidade genética causadas pelos impactos do desmatamento e das mudanças climáticas. Um dos métodos de conservação ex situ é a micropropagação que visa a produção de grandes quantidades de mudas a partir de uma única célula ou tecido vegetal. Para integrar pesquisa e ensino, no presente trabalho, alunos da disciplina de biotecnologia florestal realizaram um experimento de propagação de mudas a partir de plantas nativas da flora brasileira cultivadas in vitro: *Euterpe precatoria* (açai-solteiro); *Ananas comosus* (abacaxizeiro) e *Guadua chacoensis* (bambu). Após a micropropagação, foram testados dois tipos de substratos para a avaliação da sensibilidade/tolerância ao transplantio: 1) substrato comercial (uma mistura 1:1 de casca de coco e húmus de minhoca) e 2) solo argiloso. Copos de plástico transparentes de 300 mL foram preenchidos com os diferentes substratos sendo realizadas duas repetições por tratamento. O substrato e o solo foram encharcados com água (25-50 mL) para o transplantio e estes foram cobertos com o mesmo tipo de copo transparente para simular o ambiente in vitro facilitando a aclimação das mudas. Após 6 dias, foram observados o índice de pegamento que resultou em 100% constatando-se que não houve diferença entre os substratos.

Effect of different methods of pretreatment for dormancy breaking for higher germination of *Leucaena leucocephala* Seeds

Stephen Ndung'u¹, Nancy Mugo²

¹Kenya Forestry Research Institute, Nairobi, Kenya; ²Egerton University, Nakuru, Kenya (stephenmn06@gmail.com; nancymugo65@gmail.com)

The main objective of this study was to determine the effect of different seed dormancy breaking methods and best exposure time regime of *leucaena leucocephala* seeds for mass multiplication. Tree seeds of *Leucaena leucocephala* were sourced from Kenya Forestry Seed Centre stored and subjected to different pretreatment methods ranging from soaking in sulphuric acid at different concentration and time, soaking in hot water at different temperature and time, soaking in cold time and service scarification. Higher germination of 96% was shown by seeds soaked in hot water at 1000 °C for 24 hours followed by those soaked at 100% concentrated sulphuric acid for 3hrs, scarification and cold water in that order for 15 days. Germination percentage declined with increase of both sulphuric acid concentration and soaking time at different constant concentration ranging from 50% to 100%. Equally germination percentage declined with decrease of both water temperature and soaking time at different constant temperature ranging from 1000 °C to 500 °C. The results obtained will be applied in mass germination for mass seedlings production with inform germination at shorter period for increased fodder production.

Effect of indolebutyric acid in treating cuttings of *Bambusa vulgaris* Schrad. ex J.C.Wendl. / Efeitos do ácido indolbutírico no tratamento de Estacas de *Bambusa vulgaris* Schrad. ex J.C.Wendl.

Adalberto Novaes¹, Débora Benedito¹, Kemele Coelho¹, Carlos Sanquetta²

¹Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (adalberto.brito@globo.com; debora_defensor@outlook.com; kemelecrisatina@hotmail.com; carlos_sanquetta@hotmail.com)

A presente pesquisa objetivou-se avaliar os efeitos do Ácido Indolbutírico (AIB) em diferentes concentrações na emissão de brotações, comprimento de ramos e enraizamento de estacas de *Bambusa vulgaris* Schrad. ex J.C.Wendl. O experimento foi conduzido em casa de vegetação na Universidade Estadual do Sudoeste da Bahia-UESB, no município de Vitória da Conquista-BA, Brasil. Para a instalação do experimento, as estacas foram imersas por 10 segundos em solução com ácido indolbutírico (AIB), diluído com hidróxido de sódio em quatro concentrações (0, 1.000, 2.000, e 3.000 mg.L⁻¹) correspondentes aos quatro tratamentos. Usou-se quatro repetições e 10 estacas em cada amostra. As estacas, após tratadas com as respectivas soluções, foram transplantadas para tubetes com capacidade volumétrica de 288 cm³, já preenchidos com o substrato e na posição vertical com o nó basal na profundidade de 5,0 cm. Avaliou-se: a) número de brotações; b) número e comprimento de ramos; c) área foliar; e d) número de raízes. Entre as concentrações de AIB, os efeitos foram similares para número e comprimento de ramos, todavia, para as demais variáveis o AIB usado na concentração 1000 mg.L⁻¹ exerceu efeitos positivos, destacando-se o aumento do número de raízes quatro vezes maior, quando comparado com a concentração Controle, demonstrando portanto, a sua eficiência no enraizamento de estacas dessa espécie.

Beyond restoration success: searching for long term economical sustainability of successional biodiversity-rich agroforestry at the tropical Atlantic rainforest dominion, Brazil

Carlos Eduardo Sicole Seoane¹, Luis Claudio Maranhao Froufe¹, Ocimar Bim², Ronivaldo Moura³, Artur Lima³, Marcelo Francia Arco-Verde¹, Evaldo Muñoz Braz¹, Antônio Nascim Kalil Filho¹, Raul cezar⁴, Sebastian Rech⁵, Pedro Rossi⁴, Jaqueline Cremonese⁴, Pietro Graff⁵

¹Embrapa Florestas, Colombo, Brasil; ²Instituto Florestal de São Paulo, Registro, Brasil; ³Cooperafloresta, Barra do Turvo, Brasil; ⁴Embrapa Florestas, Colombo, Brasil; ⁵Pontifícia Universidade Católica (eduardo.seoane@embrapa.br; luis.froufe@embrapa.br; ocimarbim@gmail.com; lima.adalton@gmail.com; lima.adalton@gmail.com; marcelo.arco-verde@embrapa.br; evaldo.braz@embrapa.br; antonio.kalil@embrapa.br; raulmatiascezar@yahoo.com.br; sebjpv@gmail.com; rossipedrop@gmail.com; jaque.tila@gmail.com; pietrograff77@gmail.com)

On going and past researches demonstrates the positive environmental and social changes brought by agroforest practices adoption and maintenance by peasants at the tropical Atlantic rainforest dominion of the vale do Ribeira region, Brazil. During the succession process at agroflorestas plots, short-lived species are

gradually replaced by long-lived species, aiming to provide continuous food production and to ultimately become a multilayer food production forest system. But one noticeable fact is that once the agroforest plots reaches a forest structure, they do not yield enough marketable products and are cut down or abandoned. This is due to the lack of adequate planning for the latter phases of succession, which is a consequence of planning emphasis on diversity richness and ecological niche filling paradigms. One other aspect on question is that the labor necessary to execute the ongoing management plan is much greater than the labor that the peasants are able or willing to spend. There are some possible alternatives to generate income from the later succession phases of agroforestry, such as agroecotourism structuring, simplification of agroforest design and a shift to productive chains and market analysis paradigms. Our research efforts aims to find and implement mature agroforest planning and management based on focal species that yield an already market consolidated and valuable product, have a relatively low labor demand and establishes viable populations with no need of further reintroduction. Many of the peasants are reluctant to accept the necessary paradigm change, but there are others that are joining us on this effort.

Chemical changes in a series of consecutive rhizome of *Gigantochloa scortechinii* in relation with hydraulic conductance

Hazandy Abdul Hamid^{1,2}, Johar Mohamed¹, Ahmad Ainuddin Nuruddin¹

¹Institute of Tropical Forestry and Forest Products, Serdang, Malaysia; ²Faculty of Forestry, Serdang, Malaysia (hazandy@upm.edu.my; joe5587_jorr@yahoo.com; ainuddin@upm.edu.my)

The aim of this study was to 1) determine the variation of chemical attributes among study sites, 2) define the chemical attributes changes during maturation period of rhizome, and 3) investigate is there any relationship of chemical attributes with hydraulic conductance (Kbg). Bamboo rhizome is important as for storage, translocation and reproduction system. This translocation function is hypothesized to significantly affect by the chemical attributes changes during maturation period of rhizome. Therefore there is an interest to investigate the variation of chemical attributes in a consecutive bamboo rhizome ages. The destructive sampling method was conducted using selective random sampling method on four consecutive rhizomes from healthy *Gigantochloa scortechinii* clumps. Sampling was conducted at two natural forests and one secondary forest (planted). The chemical attributes were examined according to TAPPI standard method except for the holocellulose. Results indicate that the ash content (AC), alcohol-acetone soluble (AAS) and holocellulose (HC) were significant different ($p < 0.01$) among study sites. Furthermore, AC, hot water soluble (HWS), AAS, lignin (L), and HC were found significantly different ($p < 0.01$) with a strong relationship ($r = -0.823, 0.688, 0.986, 0.945, 0.510$ respectively) with rhizome age. The AC showed a significant ($p < 0.01$) positive relationship ($r = 0.747$) with Kbg which depicted that the decreasing of AC in increasing of rhizome age resulted to decreasing of Kbg, but, HWS, AAS, L, and HC showed a significant ($p < 0.01$) negative relationship ($r = -0.706, -0.914, -0.857, -0.567$ respectively) with Kbg which depicted that the increasing of those chemical attributes in increasing of rhizome age resulted to decreasing of Kbg.

C3b: DIGITAL TRANSFORMATION IN WOOD INDUSTRY

X-ray determination of moisture content in wood biofuel assortments for bioenergy plant process control

Henning Horn¹, Janka Dibdiakova², Nils Lindström³

¹Norwegian Institute of Wood Technology, Oslo, Norway; ²Norwegian Institute of Bioeconomy Research (NIBIO), Ås, Norway; ³Mantex AB, Kista, Sweden (henning.horn@treteknisk.no; janka.dibdiakova@nibio.no; nils.lindstrom@mantex.se)

An X-ray measurement method for simultaneous determination of moisture- and ash content, and heating value has been demonstrated at a Norwegian sawmill on a mixture of spruce bark and dry chips. The method is based on combining X-ray transmission imaging and X-ray fluorescence spectroscopy. Bark is normally used to fuel the heat production within the sawmill together with varied portions of chips and/or sawdust. In our study, we use a mix of wet bark and dry chips to increase the overall net heating value of the mix to ensure a stable combustion process. As the biofuel material is usually stored outside without any cover, the moisture content will vary with weather conditions throughout the year. Efficient utilization of the biofuel material to achieve a stable combustion process requires rapid determination of the biofuel moisture content, which is the single most important process parameter of the feed-in material. The method performance has previously been demonstrated with good agreement on other biofuel assortments, but is in this study calibrated for a new mixture of biomass material. The volume of measured samples was approximately 3 litres, with a total analysis time of one minute per sample. By using rapid and accurate X-ray determination of the moisture content, the project aimed to improve the combustion process to ensure more efficient energy use, lower flue gas emissions, and lower maintenance costs at the selected biomass combustion plant. The obtained results from the X-ray measurements showed a good agreement compared to the reference method.

Clear image acquisition: moving board tracking for surface defects identification

Xiao Wang¹, Yucehng Zhou¹

¹Research Institute of Wood Industry, Chinese Academy of Forestry, Beijing, China (wx_dykm@126.com; zhouyc@caf.ac.cn)

Surface quality testing which helps to eliminate the products that contain surface defects is important in wood-based panel production to guarantee the resource efficiency. However, in most industries, such step still depended on manual inspection which is proven to be not efficient enough. In this study, a computer vision based testing system was proposed. To remove the image blur caused by fast moving of the boards on production line, the system used a cam mechanism to drive the camera moving along with the board during exposure time. To examine the tracking performance of the system, the experiment was carried out based on a laboratory scale platform. The result showed that, in each motion period of the cam, the camera velocity would reach board velocity for a certain time which could be used for shooting. Meanwhile, the board could be tracked at any velocity by controlling the cam rotation. The increase in uniform motion angle of the cam would increase the time used for exposure as well as the stability of the mechanism. The images were collected on-line at different board velocities, and it was shown that the board in image was clear while surroundings contained some blurs. Moreover, the blurring length of the image was calculated. It was found that the blurring length was limited to 3 pixels at velocity ranging from 200 to 800 mm/s, which made the image quality high enough for defects identification.

An agent-based model of wood markets

Oliver Thees¹, Stefan Holm¹, Lorenz Hilty²

¹Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, Switzerland; ²University of Zurich, Zürich, Switzerland (oliver.thees@wsl.ch; stefan.holm@wsl.ch; hilty@ifi.uzh.ch)

We present an agent-based model of wood markets. The model covers softwood and hardwood markets for sawlogs, energy wood, and industrial wood. Our study region is a mountainous area in Switzerland. The wood markets in this study region are characterized by many small-scale wood suppliers, and a mix of private and public-owned forests. The model was developed to investigate the availability of wood in the study region under different market conditions. We defined several scenarios that are relevant to policy makers and analyzed them with a focus on the two most important assortments of wood in the study region, namely, sawlogs softwood and energy wood made from softwood. The development of the prices and amounts sold in the scenarios are compared to a business-as-usual scenario. The scenarios were designed to investigate i) the influence of intermediaries, ii) the influence of the profit-orientation of forest owners, iii) the influence of the exchange rate, and iv) the consequences of set-asides in the study region. The presented model has a large potential to support the planning of policy measures as it allows capturing emergent phenomena, and thereby facilitates identifying potential consequences of policy measures planned prior to their implementation. This was demonstrated by discussing the scenario findings with respect to Switzerland's forestry policy objective of increasing the harvested amount of wood to the sustainable potential. We showed that a higher profit-orientation of forest owners would be beneficial for this objective, but also revealed potential conflicts of different economic goals.

Decision support system for the assemble of floorboard top layers

Matthias Kaltenbrunner¹, Maria Anna Huka¹, Manfred Gronalt¹

¹University of Natural Resources and Life Sciences, Vienna, Vienna, Austria (matthias.kaltenbrunner@boku.ac.at; maria.huka@boku.ac.at; manfred.gronalt@boku.ac.at)

The goal of the study is to develop a decision support system for assembling the top layer of floorboards in the parquet industry. The top layer of a floorboard, which has standardized dimensions, is constructed with lamellas of different lengths and grades that are aligned in three lanes. The used grades and the arrangement of the lamellas define the quality of the produced floorboard. This leads to a huge number of possible placement patterns that have to be considered in production planning. Hence, we use a MIP model embedded in the decision support system to optimize the production planning. In detail, the total production costs are minimized, considering the available raw material, the needed amount of different qualities of demanded top layers, and a minimal production quantity per product. First, we present an approach to reduce the number of patterns without constraining the feasible region and second, we investigate numerical experiments where different pattern selection strategies are used. Third, we showcase the decision support system which brings the research to a daily use in the industry. With this talk we want to display how optimization algorithms and tools can improve processes in the wood industry, their development and integration from the problem description to daily use, and their contribution to an ongoing digital transformation.

Performance measurement of industrialized housebuilding on-site activities: a qualitative study to identify improvement potential through digitalization

Wolfgang Grenzfurter¹, Manfred Gronalt¹

¹University of Natural Resources and Life Science Vienna, Vienna, Austria (wolfgang.grenzfurter@boku.ac.at; manfred.gronalt@boku.ac.at)

Industrialized housebuilding (IHB) companies prefabricate wall-, ceiling- and roof elements or modules from forest-based products in plants and assemble them on-site. To collect and analyze data from on-site processes is currently a challenge, as common methods do not provide accurate statements to interventions effects, are not reliable enough or are too cost- or time consuming for periodical performance management. In order to develop an improved performance management for an IHB on-site context and to enable a continual improvement of construction processes and building systems this research aims (1) to investigate current IHB performance measurement and (2) to analyse the needs for improving performance assessment for various production strategies. In this context a pivotal role is given to improvement potentials through the usage of digitalisation concepts. Qualitative interviews with IHB companies from Central Europe are conducted and specific cases are selected to collect insights from various IHB companies' strategies. Further, prevailing concepts for improving IHB performance measurement are developed. Research reveal the need for performance management systems (PMS) to better cope with present real on-site processes and for supporting their controlling. Improvement potentials are identified in the translation of a company's business strategy to critical performance variables for on-site work. A further finding is the need for application scenarios for digital technologies collecting and analysing on-site data. As a results of this work new PMS will be developed according to IHB companies' needs. These may then better support decision in the construction processes and improve overall wood building systems' competitiveness.

Industry 4.0 concepts for the wood industry's digital transformation: three steps to forestry 4.0

Jürgen Rossmann, Michael Schluse¹, Thomas Gerritzen¹, Frank Heinze¹, Martin Hoppen², Oliver Stern¹

RWTH Aachen University, Aachen, Germany; ¹RWTH Aachen University, Aachen, Germany; ¹RIF Institute for Research and Transfer e.V., Dortmund, Germany; ²RWTH Aachen University, Aachen, Germany (rossmann@mmi.rwth-aachen.de; schluse@mmi.rwth-aachen.de; thomas.gerritzen@rt.rif-ev.de; frank.heinze@rt.rif-ev.de; hoppen@mmi.rwth-aachen.de; oliver.stern@rt.rif-ev.de)

Digital transformation is revolutionizing the world and is taking production to a new age. The cornerstone of digital transformation is the real-time availability of all relevant information – in an Internet of Things, Services and Persons (IoTSP). New technologies provide more accurate data of forests than ever before and smart devices are facilitating the daily business. However, due to the heterogeneity of the wood industry, its great number of players with often conflicting objectives, and its decentral structures and processes, the generated data is not used efficiently yet. The new “Center of Excellence for Forestry 4.0” focuses on three major tasks to help the wood industry with digital transformation. (1) Support research and industry to jointly develop concepts and standards to be documented in a “Forestry 4.0 Implementation Strategy”. Like a guideline, this strategy comprises recommendations and hints for the practical implementation of Forestry 4.0. (2) Support the implementation of new technologies by providing knowledge and training programs, provide support for research and implementation projects, and connect interested stakeholders from the industry. (3) Provide so-called Smart Forest Labs as real and virtual environments to develop, test, evaluate and demonstrate new Forestry 4.0 compliant components, systems and processes. The center of excellence provides relevant reference implementations of connected and interactive assets, e.g., digitized forest stands, a smart harvester and skidding machinery, smart chainsaws, a forest sensor network – as physical and as simulated objects.

An expert online information system for industry and forest owners: SEIL / Un sistema experto de información en línea para la industria y los propietarios forestales: SEIL

Carlos Büchner¹, Marjorie Martin¹, Rodrigo Sagardia¹, Eduardo Molina¹, Felipe Guzman¹, Yasna Rojas¹, Carlos Bahamondez¹, Cristian Rojas²
¹Instituto Forestal, Valdivia, Chile; ²Consultor, Los Angeles, Chile (cbuchner@infor.cl; mmartin@infor.cl; rsagardia@infor.cl; emolina@infor.cl; fguzman@infor.cl; yrojas@infor.cl; cbahamon@infor.cl; cristianrojas@gmail.com)

El Instituto Forestal de Chile, en su misión de transferir conocimiento y entregar información oportuna para la toma de decisiones ha desarrollado un Sistema Experto de Información en Línea para la industria y los propietarios forestales con el objetivo central de disponer de información sobre proyecciones del volumen de cosecha madera en pie, proveniente de plantaciones y bosque naturales, disponible durante para un horizonte de 10 años, a nivel de territorios. Información necesaria para el sector privado y público que permite la generación de políticas públicas, su monitoreo, y el desarrollo de nuevas inversiones, entre otros. Las estimaciones de volumen de madera en pie, se basan en la información que entrega el Inventario Forestal Nacional y el Programa de Actualización de Plantaciones de INFOR. Esto alimenta un modelo de programación matemático, que maximiza la oferta física de madera en pie, satisfaciendo una serie de restricciones o parámetros bases, la solución resultante es asignada al territorio utilizando métodos heurísticos (SA), y representando el territorio mediante una grilla, donde cada celda acumula la oferta de madera, diferenciada en productos pulpables y aserrables. SEIL es una plataforma de información web, con un visor de mapas y herramientas de consultas, implementada bajo un modelo de tres niveles que permite flexibilidad y rapidez a las consultas y visualización de datos. Nivel de datos (alfanuméricos como geoespaciales), bajo PostgreSQL y postgres 2.3. Nivel de servicios, publicación de datos web (Geoserver). Nivel de presentación desarrollo en PHP y Laravel (framework).

Data analyses and modelling approaches for log-yard operations using discreet event mathematics

Kalvis Kons¹
¹Swedish University of Agricultural Sciences, Umeå, Sweden (kalvis.kons@slu.se)

Terminals and log-yards play an essential role to secure a raw-material supply to industries. In the Nordic countries, the number of terminals with multiple incoming and outgoing transport methods and storage areas is increasing. An understanding of how to make changes to improve efficiency in existing log-yards is a challenging task. For instance, the simple act of introducing a new storage area at log-yard forces to consider not only construction costs associated with a storage place but also must foresee if there will be the need to modify an existing machine park due to driving distances and storage configuration. In this presentation, the company under study is running a log yard for the pulp mill. The company's log yard is receiving logs from three types of transport methods: trucks, trains and ships. The objective of the presentation is to show how to model such a system using data normalization for different transportations methods and implement them in two modelling approaches ("detailed" and "simplified") of discreet event mathematics, and the considerations required to properly tune these models according to data provided by a company. Possible model application for answering scientific and industry interested questions will be shown such as model suitability for further mathematical optimization and observations of detailed data processing within the log-yard operation to pinpoint possible bottlenecks in the system.

C3c: FOREST OPERATIONS ENGINEERING AND MANAGEMENT INNOVATIONS FOR THE FUTURE

Advances in using robots in forestry operations

Ola Lindroos¹, Omar Mendoza-Trejo¹, Daniel Ortiz Morales^{2,3}, Pedro La Hera¹
¹Swedish University of Agricultural Sciences, Umea, Sweden; ²Cranab, Vindeln, Sweden; ³The Cluster of Forest Technology, Umea, Sweden (ola.lindroos@slu.se; omar.mendoza.trejo@slu.se; daniel.morales@cranab.se; xavier.lahera@slu.se)

Forestry operations have a role to play in the supply of fossil-free raw material to present and future bio-economies. Advances in automation will enable forestry operations to be conducted in a more sustainable way, with better consideration of economic, ecological and ergonomic requirements. In this review, the challenges encountered and the current state-of-the art of the use of robots in the use forestry operations are presented. Current levels of automation are low because of the challenges of operating in unstructured, unknown terrain under extreme conditions. A shortage of data is limiting progress, and there is a strong focus on the integration of sensor technology and development of control systems. There has been some progress in making sensors perceive and understand the structure of the 'natural' forest landscape, the qualitative features of the desired end-products and how to control machine movements efficiently. However, it will still be some decades before fully autonomous forestry machines carry out harvesting and extraction operations.

Automation of harwarder work: evaluation of effects on performance and user experience

Rikard Jonsson¹, Jussi Manner¹, Anders Mörk¹, Martin Englund¹, Hagos Lundström¹
¹Skogforsk, Uppsala, Sweden (rikard.jonsson@skogforsk.se; jussi.manner@skogforsk.se; anders.mork@skogforsk.se; martin.englund@skogforsk.se; hagos.lundstrom@skogforsk.se)

The harvester-forwarder system has dominated the cut-to-length logging operations for about 30 years. The systems productivity stagnated about a decade ago. Consequently, evaluation of alternative logging systems is important. One alternative is the harwarder, a single-machine system that fells, process, cuts and loads the stems directly onto the integrated load-space. The harwarder then transports the stems and unloads them at the landing. So far harwarder has failed to establish a market position, but its cyclic and predictable work is suitable for automation which can improve the harwarders competitiveness. In the study, parts of the harvesting and loading work have been automated on a virtual harwarder in a simulator environment. Three separate tasks have been automated and tuned to work in conjunction. The harvester head rotates to a felling direction that is suitable for the later processing and cutting the stem directly onto the load-space. At the operator's command, the crane follows a path to bring the felled stem to the load-space. The load-space rotates to keep parallel to the stem in the harvester head to facilitate placing the cut logs. We conducted a time study to compare the automated harwarder with an identical but manually operated machine model. We also interviewed the study operators on their attitude towards the automatic functions, real-life relevance and their subjective experience on productivity and workload. Preliminary results will be presented together with a discussion about the consequences of the results and possible next steps for development of the harwarder concept in cut-to-length-operations.

Manual and machine operation team management through IOT for timber harvesting

Toshio Nitami¹

¹University of Tokyo, Tokyo, Japan (nitami@fr.a.u-tokyo.ac.jp)

Manual work often holds important role at a team work in timber harvesting operation. This is usual at the operations on steep hillsides, where are difficult for off-the-road vehicle locomotion. Manual operations are inevitable not only for felling trees but also for choking logs to yarding cable line, and they are needed to be kept synchronized to other operation processes such as hauling, processing and forwarding. IOT method was useful to have operation data at each operation points to know their advancing processes and harmonize them by knowing each other situations in order to make the day work follow well the results by the previous day at the operation site. A Logging Site Management System on IOT was constructed using GPS device and smart phone system. This is constituted with Daily Report, Operation Visualization, Operation Evaluations, Operation Heat Map, Landing Storage Management and their compilation Database. Logging enterprise can manage their logging projects on this computer system based on daily operation achievements at each work points. Daily morning meeting can utilize the processed information to distinguish the location to work advance following the former process by the previous work day. Database of the project is updated daily and updates data for regional forestry supply chain management system, which enables detailed production and purchase matching.

Management automation by maximization of harvesting data utilization

Angelo Conrado de Arruda Moura¹, Elias Chagas Chagas¹, Rafael Aparecido Rodrigues Junior²

¹Suzano, Jacarei, Brasil; ²Suzano, Três Lagoas, Brasil (amoura@fibria.com.br; elias.chagas@fibria.com.br; rafael.rodrigues@fibria.com.br)

In the current days, the advances in Artificial Intelligence developments and its applications are largely known. In addition, that most technology automation relies on a good database. In this way, it is critical to have sensors collecting data in good amount and quality. As different sectors, agricultural and forestry machines are rapidly increasing the utilization of many sensors. The integration of sensors like cameras, Lidar, Sonar, etc., to the deep learning, is allowing the advance of autonomous operation, in proof of concept stage so far. Even considering that autonomous operation must be a reality in the near future, there are opportunities to advance in the utilization of data already available. Thus, the aim of this work was, to maximize the utilization of data generated by harvesting machines. The project consisted in collecting this data for three main purposes: generate productivity maps, create quality reports, and prepare forest productivity data for further studies of silviculture fertilizer application. It was developed machine and web App's, to collect Stanford files from on-board computers (georeferenced information on tree level), a web portal to receive this data, GIS analysis, and finally an user interface, using PowerBI platform, to show maps and reports. Also developed automation for all communication by web services. The project was done on a pilot scale, after validation was approved and defined to implement in all company applications. As main results, we highlight the useful tools to manage the operation, with minimum human interface, and opportunity to automate quality control process.

Frontiers in wood and biomass supply chain optimisation

Mauricio Acuna¹

¹University of the Sunshine Coast, Sippy downs, Australia (macuna@usc.edu.au)

In this presentation, state-of-the-art optimisation techniques and technologies for efficient biomass supply chains are presented. Supply chain optimisation is the application of processes and tools to ensure the optimal operation of a manufacturing and distribution supply chain. In wood and biomass supply chains this includes the optimal placement of inventory within the supply chain, minimising operating costs (including manufacturing costs, transportation costs, and distribution costs). This often involves the application of mathematical modelling techniques using computer software aiming to produce and to deliver the right product at the right time and for the right customer with the goal of maximising revenue and/or product margins. The presentation will also discuss opportunities for improvements in the wood and biomass supply chain including improved characterisation of the resources, log tracking and collaborative planning. In addition, the presentation will expose concepts and technologies around "Industry 4.0", name given to the current trend of automation and data exchange in manufacturing technologies, and the potential use of the technologies to optimise wood and biomass supply chains. Thus, some of the technologies supporting real-time data collection, internet of things, automation and robotics, and data analytics will be presented and discussed. These include mobile technologies, machine to machine technologies, artificial intelligence and big data analytics (deep learning, machine learning), and virtual and augmented reality, among others. The presentation will finalise discussing the challenges and opportunities of state-of-the-art supply chain optimisation for practitioners and researchers, and presenting future initiatives in supply chain optimisation for research and education.

Assessing the Mobile Mapping System applicability for mapping precision forest road networks in Korea

Sungmin Choi¹, Joon-Woo Lee¹, Myeongjun Kim², Hyeongkeun Kweon¹ , Kyo-Won Jung³, Hakjun Rhee¹ 

¹Chungnam National University, Daejeon, Republic of Korea; ²Forest Environment & GeoSpatial Technology Research Institute, Daejeon, Republic of Korea;

³The Korea Forest Engineer Association, Daejeon, Republic of Korea (goodday@cnu.ac.kr; jwlee@cnu.ac.kr; festri.kim@gmail.com;

hkkweon00@gmail.com, jgw@supsansa.net; hakjun.rhee@gmail.com)

This study assessed the applicability of MMS (Mobile Mapping System) to forest road mapping in Korea by applying it to 5 forest road networks in Korea, comparing the accuracy of MMS to total station with Global Navigation Satellite System (GNSS) and as-built drawing using point-comparison and buffering methods, and comparing the effectiveness and economics of the MMS with other mapping techniques. From the point-comparisons, the MMS was 6.8 times more accurate than GNSS and 71.6 times than as-built drawing. With a buffering width of 2 m the forest road networks from the MMS were overlapped with 93.3% of the networks from total station, 96.21% from GNSS, and 50.99% from as-built drawing. The as-built drawing, only available information for current forest road maintenance management, was not accurate, due to frequent design changes during forest road construction and not recording the changes. The MMS processed 11,547,319 data points/km, 46,000 and 401 times more data points than those of total station (251 points/km) and GNSS (28,800 points/km), with less than 16.4% and 17.8% (31.6 min/km) of the surveying time used for the total station (195 min/km) and GNSS (178 min/km). The map-making costs using the MMS, total station, and GNSS were ₩538,182/km, ₩581,125/km, and ₩252,653/km. The high costs from the car-mount MMS equipment rental and operator labor could be offset by high work efficiency. Considering the high accuracy, work efficiency, and economic feasibility, the MMS can be used to map precision forest road networks in Korea.

Model optimization of wood property and quality tracing based on wavelet transform and NIR spectroscopy

Ying Li¹, Yaoxiang Li¹, Wenbin Li², Lichun Jiang¹

¹Northeast Forestry University, Harbin, China; ²Beijing Forestry University, Beijing, China (yingli@nefu.edu.cn; yaoxiangli@nefu.edu.cn; wenbinlin@bjfu.edu.cn; jlchun@nefu.edu.cn)

Wood information intelligent acquiring is the key for timber quality tracing. It is also the prerequisite for timber sorting, processing and fine applications. This study aims to discuss the denoising of aspen wood near infrared spectroscopy (NIRS) with wavelet transform and develop the calibration model for wood density, to analyze the feasibility of NIR-based wood quality tracing. In this study, calibration model was developed for air-dried density of aspen wood based on NIRS and partial least squares (PLS) algorithm. Wavelet transform was used for NIR denoising treatment and model optimization. The best denoising method was determined. Aspen wood density predicted with NIR calibration model together with other wood information (species, locality of growth, measuring unit, ways of data acquisition etc.) was recorded with QR (Quick Response) code for the quick and effective tracing. The readability and effectiveness of the QR code with varied correction levels, number of characters, and pixel sizes were compared. Results showed that: (1) The best model fitting was achieved with the decomposition layer of 5 (db5 wavelet) under the heuristic hard threshold denoising treatment. (2) As the number of coded characters were 217 in this study, the readability of QR code was low with pixel size of 100×100 px while the QR code readability was higher than 90% with pixel size greater than 100×100 px. It can be concluded that QR code could be an effective carrier for timber tracing information acquired with NIRS.

C3d: GLOBAL GREEN SUPPLY CHAINS AS A DRIVER FOR SUSTAINABLE FOREST MANAGEMENT IN THE TROPICS

Green tropical timber supply chains: legality, sustainability, profitability

Gerhard Dieterle¹

¹International Tropical Timber Organization, Yokohama, Japan (dieterle@itto.int)

Major markets for tropical timber and timber products are sending strong signals to importers on the need to demonstrate that forest products are not sourced at the expense of tropical forests. For example, the Lacey Act in the United States of America, the European Union Timber Regulation, Australia's Illegal Logging Prohibition Act and the Japan Clean Wood Act all require evidence of the legality of imported timber. Such initiatives, however, can be confusing for producers, importers and traders, who may be unclear on the documentation they need and the standards to which they must comply; this confusion can diminish market opportunities for tropical timber producers. What is needed is a systems-based approach that ensures legality and aims to achieve sustainability within integrated "green" supply chains. The ultimate aim of green timber supply chains is to ensure stable, reliable supplies of timber from legal and sustainable sources. It is also a pre-condition for advancing towards a bio-based and circular economy because the substitution of non-renewable materials and energy with "green" timber can only be counted if the timber has been produced sustainably (and shown to be so). From the point of view of private operators, green timber supply chains are not just about maintaining or increasing market share, although that is an important outcome. They are also about businesses ensuring efficiency, best practices and transparency at every link in the supply chain — in the forest, on the log truck, in the mill, on the ship and in the showroom. Companies that put in place green supply chains will become streamlined to the extent that they will know exactly where their products are coming from, where those products are in the supply chain at any given time, and how they have been produced. Ultimately, the efficiencies this information will bring will ensure profitability and increase other metrics of healthy businesses. Building green timber supply chains involves various levels of actions and commitments across a wide spectrum of stakeholders, who need to interact in a coordinated manner to ensure sustainable and legal production. Most tropical timber-producing countries lack sufficient infrastructure and technology to establish green supply chains. Public-private partnerships — domestically and with consumer countries — are necessary, therefore, for sharing the incremental costs and ensuring the viability of initiatives to create green supply chains. A long-term task is to reduce the multiplicity and complexity of the green supply-chain requirements applied in different countries. This is necessary to enable small and medium-sized forest producers in tropical countries to become competitive and confident actors in domestic and international markets and to build capacity for sustainable management and production. In many cases, such enterprises will need external assistance and training to prevail in domestic and international markets and to become drivers of sustainable forest management. We see an important role for ITTO and other international organizations as facilitators or "primers" of the shift towards green tropical timber supply chains. We can help build capacities among operators and other stakeholders across supply chains through knowledge-sharing, technical expertise, research, demonstration, the transfer of technology, and access to information and networking.

Making sustainable wood value chains work for sustainable development: unlocking contributions to the SDGs and climate change

Thais Linhares Juvenal¹, Petri Lehtonen¹

¹FAO, ROMA, Italy (thais.linharesjuvenal@fao.org; petri.lehtonen@fao.org)

Forests contribute to the objectives established in the UN 2030 Agenda in manifold ways. Recent assessments identified contributions to poverty alleviation through cash and in-kind income, food security through forest fruits and wood fuel, women employment, provision of ecosystem services, bioenergy, innovation, material efficiency and low carbon products. Reconciling these contributions is fundamental for achieving sustainable rural landscapes and cities. This article proposes the use of the value chain approach to achieve increased forest conservation and contributions to climate change and the SDGs. The article will: i) introduce the "basket of value chains" approach, proposing forests to be considered a basket of value chains (ecosystem services, biodiversity, tourism, wood and non-wood forest products) and their sustainability defined by the existing synergies and trade-offs. In a dynamic system, sustainability is achieved when all potential value chains are developed within its potential and does not prevent the existence of the other; ii) propose a sustainability assessment framework based on the three traditional pillars of sustainability (economic, social and environmental) and an additional one, institutional, to capture governance aspects; iii) discuss the nexus between sustainable forest value chains, sustainable landscapes and sustainable cities; and iv) suggest policies and measures to deliver sustainable jobs and contributions to the bioeconomy while increasing feasibility of sustainable forest management.

BOManejo software - harvest planning and control of the forest production

José Francisco Pereira¹, Fabricio Nascimento Ferreira², Milton Kanashiro²

¹Embrapa Amapá, Macapá, Brasil; ²Embrapa Amazônia Oriental, Belém, Brasil (jose-francisco.pereira@embrapa.br; fabricio.ferreira@embrapa.br; milton.kanashiro@embrapa.br)

BOManejo is a free software developed by Embrapa to assist the elaboration and execution of Sustainable Forest Management Plans (SFMP) in the Amazon. From the information of the forest inventory, together with the definitions of the desired selected criteria and the applicable legal restrictions, through an interactive process of planning and verification of results, this tool allows a more careful tree selection to be harvested and a better control of timber production, therefore improving production and sustainability of the managed forests. The control of the production is a legal and necessary requirement for the authorization of the logs transportation and commercialization, and also can be facilitated by the integration between BOManejo and the electronic control systems of the environmental agencies. A plug-in was developed for the QGIS software to connect to BOManejo, adding features to facilitate the preparation of operational and licensing maps, with the location of trees to be harvested and preserved ones in the forest. It also permits to see the evolution of the harvesting on the map. BOManejo has a licensing module that can be used by environmental licensing agencies to assist in the analysis of the Annual Operational Plans (AOP) prepared with this software tool, in order to streamline and improve the analyzes for its licensing procedures. BOManejo is a platform where new technologies and knowledge can be more easily made available and potentially incorporated into the activities of sustainable forest management throughout the Amazon region.

Rapid screening by fluorescence of finished wood products for targeted sampling

Cady Lancaster¹

¹US Forest Service International Programs, Ashland, OR, USA (cady Lancaster@fs.fed.us)

One of the many considerations for screening timber declarations is determining the presence of a mixture of species in a single shipment. The Wood Identification and Screening Center (WISC) of the US Forest Service International Programs (USFS-IP) has developed a screening protocol for targeted sampling of mixed-wood products. The protocol uses fluorescence to identify probable inconsistencies in species declarations of finished products when multiple species are suspected. Many timber species have a native fluorescence that can be easily observed with exposure to 365 nm light. In traditional wood anatomy, fluorescence of water and ethanol extract of heartwood is used as an indicator in species identification. By using inconsistent fluorescence responses to guide sampling, the shipment can be efficiently targeted for more advanced forensic identification techniques (e.g. anatomy, chemistry). As part of this screening protocol for customs agents, WISC is developing a visual database of wood fluorescence for high and low risk species.

Traceability system improves forest governance in Panama

Felix Magallon¹, Melanio Aguilar¹, Victor Francisco Cadavid¹

¹Ministry of Environment (MiAmbiente), Panama City, Panama (fmagallon@miambiente.gob.pa; vcadavid@miambiente.gob.pa)

A timber traceability system recently put in place in Darien, has already reduced forest illegality, with benefits for forests, managers, companies and Panama's Ministry of Environment. The traceability system enables the tracking of trees using electronic devices — chips — from the moment they are identified to the point at which the timber reaches consumers. In its phase, the system is collecting information on around 700 crop trees per day, and the Ministry of Environment is planning to expand its use to other regions of the country. According to Panama's Ministry of Environment, as reported in the newspaper La Estrella de Panama (6 May 2018), the timber-tracking system has helped reduce illegal logging in the country by 68%. The system is an output of an ITTO-financed project entitled "Strengthening the management capacity of ANAM to reduce illegal timber logging and trade in the East region of Panama (Bayano and Darien) through monitoring and control mechanisms" and is being executed by WWF-Panama in collaboration with the Panama Ministry of Environment.

Technologies to verify the origin and species or genus of wood and wood products

Andrea Olbrich¹, Tereza Cristina Monteiro Pastore²

¹Thünen Institute, Hamburg, Germany; ²Laboratório de Produtos Florestais, Serviço Florestal Brasileiro, Brasília, Brazil (andrea.olbrich@thuenen.de)

For the implementation of national and international legislation that forbids the use of illegally logged or endangered species the identification of timbers in all kind of materials made of timber is becoming increasingly important. The Thünen Centre of Competence on the Origin of Timber is the central contact facility for government agencies, timber trade, consumers and associations to verify the species of wood and/or wood products and its origin. The Centre combines the analytical expertise and competence of the three Thünen institutes of Wood Research, Forest Genetics and International Forestry and Forest Economics responsible for wood identification, proof of origin, certification and timber trade structures. The timber identification in pulp, paper and fiber boards is aggravated since the most of the forensic anatomical characteristics of wood refer on the tissue and nearly all materials of fibers contain a mixture of timbers. Therefore the anatomical identification is the only established method by now. For hardwoods, the characteristics of vessel elements of an unknown sample have to match with the descriptions and high valued micrographs of the vessel elements of known timbers as references. In the past, such references for Asian timbers were missing. The team of authors from the Thünen Institute analyzed 38 species or species groups (including a bamboo and a palm) and published references for them, so now these timbers can be identified in paper and fiber boards as well.

C3e: PRECISION FORESTRY

New generation of forestry based on precision management practices

José Leonardo de Moraes Gonçalves¹, Alexandre de Vicente Ferraz²

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (jlmgonca@usp.br)

The development of improved forest planning and operations can minimize site impacts, increase utilization and minimize or avoid adverse environmental effects. Some principles, aims, strategies and silvicultural practices must be followed for developing sustainable forest plantations based on holistic approach of the productive process. Precision Forestry (PF) is a great tool that aims to provide a silviculture customized for each unit area. It is a new model of forest plantation management. Such tools are becoming more available and applicable to different stages of fast growth forest plantation, and with proven gains in

both the increment of wood, and in reducing the use of inputs. PF may have applications in so much landscape level analyzes including several farms, such as applications within a single stand. Thus, GIS techniques with the use of GNSS, geostatistical and statistics have provided subsidies for the identification and correlation of variables that affect the forest productivity by storing, processing, crossing and overlapping of GIS data. These data are viewed and managed together with digital maps of vegetation, topography, soil, forest sites productive capacity so on, which allows the forest engineer to recognize and visualize in an integrated the distinct characteristics of production and preservation forest areas. The PF has enabled the adoption of some management practices and streamlined other difficult to operationalization through compilation of organized information. There has achieved higher accuracy and technical and financial detail of recommendations silvicultural increasingly specific which has resulted in better adaptation to the plant environment and reducing the occurrence of negative environmental impacts. At the same time, there is the optimization of operating earnings, the rational use of inputs and reduction of production costs. Higher the environmental contrasts, as in most regions of rugged relief, the greater the potential gains of technological capability and productivity. The biggest difficulty to work with this system is related to the large amount of information, usually derived from heterogeneous sources with large spatial and temporal variability, which creates the need for complex information systems to process the data. Moreover, successful cases are going on in many private companies worldwide.

Operational management units for eucalyptus using by the fuzzy logic method / Unidades de manejo operacionais para o eucalipto pelo método da lógica Fuzzy

Itamar Antonio Bognola¹, Lorena Stolle²

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Mato Grosso do Sul, Chapadão do Sul, Brasil (itamar.bognola@embrapa.br; lorena.stolle@ufms.br)

As regiões de cultivos de eucaliptos apresentam uma infinidade de variações ambientais implicando em diferentes produtividades. Uma das explicações para esta variabilidade está relacionada ao meio físico. Desta forma, o entendimento integrado do clima, relevo, geologia e solo é decisivo na transferência dos conhecimentos adquiridos para obtenção de uma silvicultura de maior precisão, visando manter ou aumentar a produtividade da cultura. Para tanto, foi feito um levantamento pedológico detalhado de uma propriedade florestal com 4.660 ha, em Araraquara, SP, a fim de se obter Unidades de Mapeamentos Pedológicas (UMP's), identificando-se ainda as potencialidades e os fatores limitantes das mesmas com relação ao meio físico. Nesse contexto, as práticas de uma silvicultura com maior precisão seria dar tratamento diferenciado a cada uma destas UMP's. No entanto, este detalhamento pedológico por si só tem dificultado o manejo operacional, uma vez que as empresas florestais ainda não estão preparadas para tratar de modo diferenciado cada uma delas. Assim, estas UMP's foram agrupadas em um número bem menor de classes definindo-se as Unidades de Manejos Operacionais (UMO's), para facilitar as práticas silviculturais. A metodologia utilizada foi a da "Lógica Fuzzy" integrada com a extensão EMDS para o ArcGIS e o software livre "NetWeaver" definindo-se as referidas UMO's. Os resultados obtidos por esta metodologia foram semelhantes aos previstos pelo especialista em solo. Verificou-se, portanto, que o método proposto tem grande potencial como ferramenta em ambiente computacional para definir as classes de UMO's.

Assessing automated mechanized irrigation / Avaliação da automação do irrigador mecanizado

Murilo Marques¹, Guilherme Oguri², Thiago Duarte³, Tiago Vasconcelos⁴, Saulo Guerra¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônômicas, Botucatu, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ³Suzano Papel e Celulose S.A., Limeira, Brasil; ⁴Suzano Papel e Celulose S.A (murilocaliente@gmail.com; guilherme@ipef.br; tduarte@suzano.com.br; tvasconcelos@suzano.com.br; saulo.guerra@unesp.br)

O desenvolvimento de máquinas e equipamentos destinado à irrigação de plantios florestais visa o uso consciente do recurso natural, além de melhorar a qualidade e aumentar o rendimento operacional em campo. Este trabalho objetiva avaliar o uso do irrigador óptico automatizado em plantios de *Eucalyptus* spp. O módulo de irrigação automatizado utiliza um trator John Deere 61125J (92 kW) tracionando o conjunto de irrigação, fabricado pela empresa FM Copling, composto por tanque, braços mecânicos, bocais de aplicação de água e sistema de reconhecimento da linha de plantio e das mudas. A avaliação da qualidade da operação foi realizada através da contagem do número de mudas irrigadas e não irrigadas pelo conjunto na operação diurna e noturna. Verificou-se uma assertividade do conjunto de irrigação no modo diurno de 89% e no modo noturno de 94%. A realização da operação durante o período noturno promoveu uma melhor na assertividade da irrigação.

Wood property mapping at the individual tree and landscape level to maximize production and enhance utilization of the forest resource

Mathew Leitch¹, Scott Miller¹

¹Lakehead University, Thunder Bay, Canada (mleitch@lakeheadu.ca; smiller4@lakeheadu.ca)

Major changes in global forest industries has forced Canadian companies to look at how they conduct business with our Northern forests. Vast forest resources found in Canada are utilized and contribute roughly \$20 billion to the GDP every year. In order to remain a significant forest products contributor globally and to increase our production from primarily commodity products to include a larger contribution of value-added or secondary manufacturing, the industry needs to better understand the wood properties of the forest resource and how to best maximize utilization of the resource. In the LUWSTF we have developed methods to map the inherent wood properties of individual standing trees and entire landscapes in order to optimize utilization. We have shown that this type of mapping of properties and utilizing the resource where it best suits products can increase the value of every tree by as much as 30%. Additionally, we have been able to create tree and landscape wood property maps which, display species mixes and wood quality (lumber grades, mechanical properties) across a landscape. This will enable maximum production from each tree, industry to react to market demand quickly, have a better understanding of what is on the landscape and increase investment in primary and secondary industries based on knowledge of the resource and what wood quality an industry requires.

Assessment of automated chemical weeding / Avaliação da capina química automatizada

Augusto Locci¹, Guilherme Oguri², Jeovagno Rangel³, Osmar Menegol³, Marcelo Coutinho³, Saulo Guerra¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônômicas, Botucatu, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ³Fibria Celulose S/A, Aracruz, Brasil (augustodefariolocci@gmail.com; guilherme@ipef.br; jeovagno.rangel@fibria.com.br; omenegol@fibria.com.br; marcelo.coutinho@fibria.com.br; saulo.guerra@unesp.br)

A atividade de capina química de plantas daninhas se faz necessária para garantir um melhor desenvolvimento da cultura de interesse. Atualmente, em todos os sistemas de aplicação de herbicidas pós emergentes ocorre um desperdício de produto, pois é aplicado em faixas ou área total, independente

ou não da presença destas plantas invasoras. A avaliação teve como objetivo analisar a eficiência do sistema de aplicação de herbicida automatizado, utilizando-se o sensor Weedit para identificação das plantas daninhas. Realizou-se um estudo de tempos e movimentos para a determinação dos rendimentos operacionais e, para avaliação da qualidade e do controle das ervas daninhas, foram instaladas aleatoriamente parcelas nos talhões onde houve a aplicação automatizada. Esta aplicação, resultou em uma redução de consumo de herbicida e de água em 53 e 51%, respectivamente quando comparado com a aplicação sem o uso do sensor. Em relação ao rendimento operacional, o conjunto mecânico apresentou uma disponibilidade mecânica de 91% e capacidade de campo efetiva de 1,3 ha h⁻¹. Desta forma, concluiu-se que o uso de sensores pode contribuir para o uso mais sustentável de produtos químicos e água.

The importance of genotyping to specific site in precision silviculture

João Antonio Fowler¹, Itamar Antonio Bognola¹, Antonio Kalil Filho¹, Luis Cláudio Maranhão Froufe¹, Shizuo Maeda¹

¹Embrapa Florestas, Colombo, Brasil (joao-antonio.fowler@embrapa.br; itamar.bognola@embrapa.br; antonio.kalil@embrapa.br; luis.froufe@embrapa.br; shizuo.maeda@embrapa.br)

The term precision silviculture can mean the selection of individuals of a species in a natural population with characteristics suitable for a particular purpose of use. As each individual of the population occupies a specific site, in addition to the soil variables, it is fundamental to identify genotype environment interactions. In this way we are conducting experiments of precision silviculture in specific site in Morretes Paraná State with tree species, *Calophyllum brasiliensis*, *Liquidambar styraciflua* and *Bactris gasipae*, to test influence of specific site on development of plants and future seed production. The variables evaluated in each specific site of each species is soil fertility, soil structure, soil water adsorption curve, resistance of soil penetration, depth of the water table, soil density, diameter at breast height and total height of plants. The same provenance of *Calophyllum brasiliensis* and same clones of *Liquidambar styraciflua* and *Bactris gasipae*. The experimental design is randomized blocks in single three plot with 30 replications / specific sites of each species. The genotyping of each tree of each specific site, combined with variables of soil and climate conditions become possible a much more completely inferences of adequate specific site to each studied species.

Different planting design with the same density yields no difference on the growth of conifer plantations in Sweden

Mostarin Ara¹, Ignacio Barbeito¹, Bjorn Elfving², Ulf Johansson¹, Urban Nilsson¹

¹Swedish University of Agricultural Science, Alnarp, Sweden; ²Swedish University of Agricultural Science, Umea, Sweden (mostarin.ara@slu.se; ignacio.barbeito@slu.se; bjorn.elfving@slu.se; ulf.johansson@slu.se; urban.nilsson@slu.se)

Traditionally, in Swedish forestry, square planting design in a 2 x 2 m arrangement is used for plantation as it is claimed to maximize productivity. With this study based on long-term trials established in mid-1980s, we aimed to test if different planting designs (from square to different rectangular spacings) exert any effect on the growth of three coniferous forest in Sweden: Scots Pine, Lodgepole Pine and Norway Spruce. In these trials, an initial planting density of 2500 seedlings/ha was established using five different planting designs (0.8x5, 2x2, 1x4, 1.33x3 and 1.46x1.46x4 m). DBH, height of the sample trees and damage was recorded from each planting design. Our results show that the volume production, diameter distribution, spatial heterogeneity and damage were not significantly affected by the different spatial designs. This information greatly enhances our knowledge of planted forests, suggesting more flexibility for spatial layout of plantations and consequently for the machinery operations than previously thought when a quadratic planting design was preferred.

A loblolly pine mid-rotation fertilization response model, accounting for response uncertainty

Cristian Montes¹, Henrique Scolforo², Rachel Cook³, Lee Allen⁴, Timothy Albaugh⁵

¹Warnell School of Forestry, University of Georgia, Athens, USA; ²Suzano, Limeira, Brasil; ³North Carolina State University, Raleigh, USA; ⁴Profor Consulting, Raleigh, USA; ⁵Virginita Tech, Blacksburg, USA (crmontes@uga.edu; henriquescolforo@hotmail.com; rcook@ncsu.edu; allen.profo@gmail.com; talbaugh@vt.edu)

Mid-rotation fertilization presents an opportunity to increase the economic return of commercial plantation forests. Since the 1990s, a series of loblolly pine fertilization trials installed in the southeast US have shown responses to nitrogen (N) and phosphorus (P) fertilization, resulting in a sustained increase in stand production at rotation age. Observed fertilization responses had been site-specific, therefore under budgetary constraints, the use of decision tools to appropriately select candidate responsive sites becomes a critical step in the decision framework. There are several models of response to fertilization aiming at productivity gains evaluation. One drawback of such response models stays in their high dependability on empirical relations showing weak biological soundness, constraining use outside the domain of the data used to calibrate them. Mainly, these models are not bounded, failing to limit response rates as fertilizer amount increases plus an incomplete acknowledgment of the uncertainty associated with the predicted process. To bridge this gap, we developed a response model that evaluates the relative response to fertilizer addition, including site index and relative spacing as model parameters as well as to explicitly account for response uncertainty. The new stochastic model is bounded in the magnitude of the response, also allowing practitioners to visualize the areas with the highest chance to increase forest value.

Assessment of the spatial variability in clonal eucalypt stands

Rafael Dias^{1,2}, José Molin¹, Henrique Scolforo², Maurício Simões², Clayton Alvares³

¹Universidade de São Paulo, Piracicaba, Brasil; ²Suzano, Limeira, Brasil; ³Suzano, Itapetininga, Brasil (rafael.donizetti.dias@usp.br; jpmolin@usp.br; hscolor@suzano.com.br; msimoes@suzano.com.br; calcarde@suzano.com.br)

Better site-specific management is possible through spatially explicit site information. Conventionally, spatial information is generated through the interpolation of the inventory plots. The spatial information generates colorful maps, but are these maps useful for providing better site-specific management? The high uncertainty associated with the volume estimates (interpolated) does not ensure the information reliability. Consequently, the understanding of the factors that result in the high volume variation within a stand cannot be assessed. The advance of technology, however, appears as a chance to overcome this drawback. Thus, we propose the use of sensors in operations that are able to measure the volume of each harvested tree. A modeling approach (through kriging) combined to the highly detailed dataset furnishes spatially explicit volume information with great accuracy. The dataset are derived from a stand harvested in 2018. Data was recorded through sensors used in the harvesting operation. At the end, we offer a methodology that provides highly detailed spatial information with high degree of accuracy, while also enabling the assessment of the spatial variability within a stand.

C3f: PROMOTING THE ENVIRONMENTAL, SOCIAL AND ECONOMIC BENEFITS BY MONITORING THE PERFORMANCE OF FOREST MACHINES: NEW APPROACHES IN PRECISION FOREST OPERATIONS

Development of robotics technology for forestry machines

Pedro La Hera^{1,2}

¹Department of Forest Biomaterials and Technology, SLU, Umeå, Sweden; ²Swedish cluster of forest technology, Umeå, Sweden (xavier.lahera@slu.se)

Just like any other industry, forestry continues to be radically altered by technology. To date, two important machines for Scandinavian forestry are the harvester and forwarder. The former cuts trees into round-wood logs of specified lengths, while the latter transports logs out of the harvesting site - a working method known as cut-to-length. To perform this work, these machines use large hydraulic manipulators, known as cranes. To control these cranes, as well as the machine, operators use joysticks sitting inside the cabins. The problem, however, is that a machine operator sitting for an eight-hour shift faces a number of potential productivity-busters. One example is the complex coordination required to seamlessly produce joystick commands to move the crane or the vehicle. Precise control of the crane links usually requires a series of expertly coordinated actions that can prove tiring over time. The control technology commercially available is unintuitive to humans, because it involves multitasking the coordination of each individual cylinder composing the machine. In view of this, machine manufacturers have started leaning towards the idea of smart forestry machines as a technology that can tackle questions about increased productivity and efficiency, and go beyond the limitation of human abilities. However, introducing automation and smart software for forestry machines presents many challenges. This presentation talks about 1) the challenges to bring automation into forestry, 2) the progressive steps to develop automation software, and 3) it will also show results of nearly two decades of research carried out in Sweden.

Process analysis of fully mechanized beech-harvesting - the effect of the piece-volume-law (H. Hilf, 1928)

Fabian Böttcher¹, Bernhard Möhring¹

¹Georg-August-Universität, Göttingen, Germany (fabian.boettcher@uni-goettingen.de; bmoehri@gwdg.de)

Fully mechanized timber harvesting is under a constant technical development. This allows the use of harvesters also in old hardwood stands. Robust studies on the processing times of the individual work steps in these stands are lacking. This study aims at dividing the felling process into relevant sub-processes and analyzing the separate sub-processes to identify the respective time needed. These were separated between tree- and log-based sub-processes. According to the piece-volume-law by Hilf (1928), the relevant cost drivers for fully mechanized harvesting in hardwood stands were identified. To do so, the study analyzed the felling process of a Ponsse-Scorpion-King harvester in old beech-stands (*Fagus sylvatica*). Before harvest, all marked trees in the test area were evaluated according to various attributes (i.e. height, quality). The harvesting process was filmed with a camera from the harvester cockpit and subsequently evaluated according to the defined sub-processes. After the felling, the assimilated assortments were recorded for each sampling tree. The results of this study show the significant effect of single tree volume on the time required for work elements felling, delimiting, regripping and crown placement. A basic time requirement per tree was only found in the moving process. Additionally the influence of re-gripping the tree after a branch on the processing time was analyzed. The likelihood of re-gripping raises with increasing tree-volume: re-gripping was not required at tree-volumes lower than 0.5 m³, but occurred increasingly with volumes above 0.5 m³.

Development of Japanese version of the felling safety game

Yozo Yamada¹, Efi Yulianti Yovi²

¹Ehime University, Matsuyama, Japan; ²Bogor Agricultural University, Bogor, Indonesia (yamada.yozo.fi@ehime-u.ac.jp; eyyovi@ipb.ac.id)

The felling safety game was developed by Dr. Efi Yulianti Yovi to improve safety knowledge of Indonesian forestry workers and supervisors according to the OSH-MS. It is a unique and well-designed board game, and is one of very effective tools to educate novice or ignorant workers in Indonesia. In Japan, all forestry workers should have got safety training, but many working accidents still occur against basic safety operations. Many of skilled workers must forget basic safety knowledge, and might be ignorant about current or new information. The felling safety game is expected for them to awake their basic knowledge about safety felling operation. Each knowledge is appeared at random by a picked card during the progress of the safety game. It causes a positive educational effect on keeping workers' interests without boredom and sleepiness. The prototype of Japanese version was made by direct translation from the Indonesian version, so many problems were found during some trials in Japanese forestry entities. According as those claims and opinions, the revision of Japanese version was performed in the following three steps. First, Japanese version was divided into two versions; a basic version for novices and a management version for owners and supervisors. Second, types of cards were reduced from eight to five to make the safety game simple. Third, number of squares was decreased from 100 to 50 to shorten the playing time. The process of revision and trial results of the revised Japanese version of felling safety game will be introduced.

Spatial interpolation of logging damages through the triangulated irregular network (TIN) method to quantify timber harvesting impacts in secondary Atlantic Forest

Pedro Britto^{1,2}, Dirk Jaeger¹, Stephan Hoffmann², Renato Robert³, Alexander Christian Vibrans⁴, Alfredo Celso Fantini⁵

¹University of Göttingen, Göttingen, Germany; ²University of Freiburg, Freiburg, Germany; ³Universidade Federal do Paraná, Curitiba, Brasil; ⁴Fundação Universidade Regional de Blumenau, Blumenau, Brasil; ⁵Universidade Federal de Santa Catarina, Florianópolis (pcdbritto@hotmail.com; dirk.jaeger@uni-goettingen.de; stephan.hoffmann@uni-goettingen.de; renatorobert@ufpr.br; acv@furb.br; alfredo.fantini@ufsc.br)

The lack of knowledge on potential timber-harvesting impact is one of the constraints causing conflicting goals between conservation and management of the remnant Atlantic Forest biome. In order to contribute to fill these gaps, our research assessed and compared the harvesting impacts of a conventional method (CM) with an alternative and improved method (AM). Permanent sample plots were installed and a full pre-harvesting inventory was performed. Every tree inside plots was tagged and its location (x and y coordinates) was recorded. A post-harvesting inventory was conducted and the timber-harvesting impact on remnant stand was assessed. The positioning of every tree was further georeferenced within ArcGIS software. The geoprocessing methodology "triangulated irregular network" (TIN) was used for generating damage maps with the most affected area per plot. Felling direction and winching line bearings were georeferenced, analysed in ArcGIS and also plotted on these maps. Our results showed that the harvesting affected mainly trees in the lower DBH classes. The felling process in comparison to winching caused most of damage on remnant trees. The winching lines did not follow the shortest extraction distance from the

tree location to the road, nor, were located on the most damaged area inside the plots. Small improvements on AM method allowed a reduction of damaged basal area; a reduction of the “high damaged area” per plot; and a reduction of the winching disturbed ground area. However, the high stand density and heterogeneity of these forests may limit the effectiveness of the efforts to reduce timber-harvesting damage.

Analysis of time and volume variables influencing the grapple saws effective productivity by mathematical models

Lara Tatiane Avelino¹ , Ricardo Hideaki Miyajima¹ , Gislaine Cristina Batistela² , Paulo Torres Fenner¹ , Danilo Simões¹ 

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Campus Experimental de Itapeva, Itapeva, Brasil (laratianeavelino@gmail.com; richidetoshi Miyajima@hotmail.com; gislaine.batistela@unesp.br; fenner@fca.unesp.br; danilo.simo.es@unesp.br)

The productive machine hour (PMH) is influenced by numerous variables present in the field, being that the grapple saws can be affected by the effective time and volume of wood. In this way, mathematical modeling could be used to evidence the correlation degree between these variables. In this perspective, the objective was to analyze, by means of mathematical modeling, the influence of the variables time and volume of eucalyptus wood on the effective productivity of the machine. The grapple saw evaluated was a Caterpillar brand, model 320 DFM, in two operational conditions, where the Condition 1 was an area with terrain declivity of 11.9% uphill; Condition 2: area with 12.0% downhill. The determination of the PMH was obtained by the time and movements methods. In order to express the correlation degree between the variables, Pearson's *r* was used, which showed that the productivity increased as the average timber volume increased, with an inverse relationship with the time variable. For the estimation of productivity in the uphill condition the regression model was adjusted, with coefficient of determination of 0.82. For the downhill condition, the model was adjusted, with coefficient of determination of 0.82, so the two conditions obtained a positive linear relationship. The average PMH in the uphill condition was 120.40m³, while the downhill condition presented an average of 140.92m³, which differed statistically, in other words, the productivity of the grapple saws, on average, differs by terrain slope.

Monte Carlo method applied to the stochastic simulation of technical-economical risk of the forestry plotter

Lara Tatiane Avelino¹ , Ricardo Hideaki Miyajima¹ , Jorge Carvalho Martins¹ , Diego Aparecido Camargo¹ , Danilo Simões¹ 

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil (laratianeavelino@gmail.com; richidetoshi Miyajima@hotmail.com; jorgec.martins@hotmail.com; diegocamargoflorestal@gmail.com; danilo.simo.es@unesp.br)

The forestry grapple saws is an implement that integrates models that act in full-tree harvesting system, and has the function of tracing the stems. Thus, productive machine hour (PMH) is influenced by several technical factors that influence production costs. In this perspective, the objective was to apply the Monte Carlo method for the stochastic analysis of the technical-economical behavior of the eucalyptus tracing under uncertainty conditions. It was evaluated a grapple saws, Caterpillar brand, model 320 DFM, in two operational conditions, where the Condition 1 was an area with terrain declivity of 11.9% uphill; Condition 2: area with 12.0% downhill. Through the study of time and movements, the PMH was determined and the operational cost was obtained using the methodology suggested by FAO. The stochastic simulation generated 100.000 pseudorandom using the Monte Carlo method. Analyzing the operational cost, the distribution that adjusted best was Beta, with average of USD 83.47 h⁻¹, and the fuel presented a strong positive correlation, with 0.91. Considering the PMH and the production cost for both operational conditions, the best model was the Normal distribution. The PMH of Condition 1 presented the average of 130.29 m³ PMH-1 and for Condition 2 the average was 162.33 m³ PMH-1, hence, the production costs were USD 0.96 m³ and USD 0.74 m³, respectively, evidencing that the position of the grapple saws in relation to the terrain declivity influences the PMH.

The application of artificial neural network in wood harvest machines operators learning curve

Millana Pagnussat¹, Eduardo Lopes¹, Izabel Bonete¹

¹Universidade Estadual do Centro-Oeste, Irati, Brasil (millanap@gmail.com; eslopes@unicentro.br; ipbonete@unicentro.br)

Due to the great complexity of wood harvesting machines operation, the great cost and long training period necessary, it is important to find a good way to quantify and compare expenses for a good planning. A computational tool with potential to be applied in the production of natural resources, that makes possible the relation of the database between the field and the operation, are the artificial neural networks (RNAs). The objective of the study was to evaluate the performance of RNAs in the estimation of productive efficiency (PE%), as a function of training time (month), to construct the learning curve of feller-buncher operators. Data from 12 operators were analyzed under different operating conditions. For this purpose, operator's productivity targets (m³/h) were calculated, based on forest quality and species, terrain and machine slope for 12 months. The operator's performance evaluation was calculated by the percentage reached by the target. The RNA was trained in 60% of the data and tested by 40%. Using data from multiple inputs from operating time (month) and target (m³/ha). The results showed that operating time impacted forecasts by 99%. However, the predictions associated with the goal were better, resulting on the productivity increase up to 8 months. The R² was 0.54, showing that the curve had a great correlation with time and showed a learning pattern. Although R² was not ideal, it could be explained by differences in performance between operators about 50%. The neural network was efficient in the estimated operational pattern.

Analyzing a tool for monitoring forest harvesting operations in real time / Análise de ferramenta para monitoramento de operações de colheita florestal em tempo real

Renata Aguayo Lopes da Silva¹, Renato Cesar Goncalves Robert¹

¹Universidade Federal do Paraná, Curitiba, Brasil (renata_aguayo@hotmail.com; renatorbert@hotmail.com)

Os sistemas de gerenciamento das atividades florestais se tornaram ferramentas extremamente importantes para gestão das operações florestais em grandes empresas de base florestal. Especialmente nas operações de colheita florestal, o acompanhamento e monitoramento das operações são muito importantes para a precisa obtenção dos dados de desempenho das operações. Atualmente, esses sistemas de gerenciamento tem seu princípio baseado na comunicação satelital, que facilita o fluxo de informações e permite a obtenção de dados em tempo real. Com base neste cenário, este trabalho objetiva analisar o apontamento eletrônico de determinado sistema implantado em uma empresa florestal localizada no município de Santa Cecília – SC, e suas implicações no controle e monitoramento das atividades. Foram analisados os relatórios de produtividade, paradas operacionais e de manutenção, registros de abastecimento e horímetro das máquinas florestais. Observou-se que com a utilização do apontamento eletrônico e dos relatórios de gerenciamento a gestão das atividades se tornou mais fácil e eficiente. Com este resultado conclui-se que as tecnologias de apontamento eletrônico são ferramentas fundamentais para a gestão das atividades florestais, e nota-se que em pouco tempo se tornarão ferramentas indispensáveis para o bom gerenciamento e ganho de produtividade nas operações de colheita.

Assessing the impacts of forest harvesting and quantifying wood waste in an area of community forest management in the Verde para Sempre Extractivist Reserve in Pará, Brazil / Avaliação dos impactos da colheita florestal e quantificação de resíduos de madeira em uma área de Manejo Florestal Comunitário na RESEX Verde para Sempre-PA

Marlon Costa de Menezes¹, Suzana Ligoski Zeferino¹, Natally Celestino Gama¹, Flávia Ranara da Silva e Silva², Saymon Roberto Pontes da Fonseca³

¹Universidade Federal do Pará, Altamira, Brasil; ²Instituto Floresta Tropical, Porto de Moz, Brasil; ³Comitê de Desenvolvimento Sustentável de Porto de Moz-CDS, Porto de Moz, Brasil (marlon@ufpa.br; suzanaligosk@gmail.com; natallygama28@gmail.com; franarasilva@gmail.com; saymonpontes21@gmail.com)

Os danos ambientais ocasionados durante a colheita florestal estão associados a uma exploração sem planejamento e geram excessiva quantidade de resíduos de madeira, produzindo significativa perda de renda nas comunidades extrativistas. O objetivo deste trabalho foi avaliar os danos ambientais da colheita florestal e quantificar o volume de estoque de resíduos produzidos e desperdiçados em Área de Manejo Florestal (AMF) da comunidade Arimum, na RESEX Verde para Sempre, município de Porto de Moz-PA. O estudo foi realizado na Unidade de Produção Anual (UPA) 06, onde avaliou-se as infraestruturas, danos as árvores remanescentes, abertura de dossel e quantificados (através do método de Huber) os resíduos aproveitáveis. Foram medidas e avaliadas 73 clareiras com dimensões que variavam de 149,00 a 924,00 m², de acordo com as características dendrológicas das espécies abatidas e técnicas de extração de impacto reduzido. A cada árvore explorada foram danificados 7,76 indivíduos, com danos variando de leves a severos distribuídos no fuste e copa. A abertura de dossel para a área foi 25,23 ha, equivalendo a 13,5 % da área da UPA. Mensurou-se amostras de resíduos florestais deixadas após a operação de corte de 57 árvores. A relação percentual encontrada entre volume de tora explorada e resíduos foi 50%. Os danos provocados pela exploração podem ser minimizados com a capacitação, planejamento adequado da rede viária e corte de cipós. A utilização dos resíduos florestais pode constituir uma fonte de renda para as famílias extrativistas, entretanto são necessários estudos que avaliem o custo-benefício da operação de serragem e beneficiamento.

C3g: THE FOREST AND FIRE OPERATIONS NEXUS: SYNTHESSES AND PERSPECTIVES ON INTEGRATING FIRE RISK MANAGEMENT WITH FOREST ENGINEERING AND MANAGEMENT

Effectiveness of firewise approach in controlling forest fire: a case of Uluguru Nature Reserve, Morogoro, Tanzania

Pilly Kagosi¹, Siwa Ernest¹, Innocent Babili²

¹Tanzania Forestry Research Institute, Morogoro, United Republic of Tanzania; ²Sokoine University of Agriculture, Morogoro, United Republic of Tanzania (pjkagosi@yahoo.com; nkyasiwa@gmail.com; babhili@yahoo.com)

Forest fire has received considerable attention in literature because it is considered one of the most common factor causing disturbances in ecosystems and at the same time considered vital in maintaining ecosystems. Firewise approach (FWA) has been proposed and used for controlling forest fire for achieving sustainable forest management. The approach requires involvement of communities in managing forest fire incidences in adjacent reserved forests. Despite considerable period since FWA has been practiced, there is insufficient scholarly knowledge on the effectiveness of the approach in managing the forest fire. This paper examines the effectiveness of FWA in managing forest fires in Uluguru Nature Reserve. The study employed cross-section research designed that involved both quantitative and qualitative data collected from selected villages. Quantitative data were collected using structured questionnaire to 120 respondents selected randomly while qualitative data collected using Focus Group Discussion, observation and key informant interview. Quantitative data were analysed using percentages while qualitative data were analysed using content analysis. The study found alternating periods- firstly the period of overall decrease of wildfire incidences within initial five years of practicing the approach and another period of huge fire occurrence beyond five years. The study conclude that the Firewise-approach is useful in reducing forest fire incidences during early period of practicing the approach. However, the FWA has a challenge of sustaining successes in controlling forest fires including limited fire management training to common community. The study recommends on the need for enhancing and sustaining training of community members on forest fire management.

Drying forest fuels and increasing wildfires in the western United States and adaptation options

Yongqiang Liu¹, Fengjun Zhao²

¹USDA Forest Service, Athens, GA, USA; ²Chinese Academy of Forestry, Beijing, China (yliu99@gmail.com; zhaofengjun1219@163.com)

The western U.S. has suffered prolonged droughts for nearly two decades, leading to drying forest fuels and frequent large wildfires. This study analyzes the historical variability of fuel moisture, drought, and wildfire in the western U.S., project their future trends, and discuss adaptation and mitigation options. Fuel moisture was calculated based on an algorithm from the U.S. National Fire Danger Rating System. Drought and fire potential were estimated using the Keetch-Byram Drought Index. Wildfires were simulated using a model developed based on the extreme value theory. Future trends were projected using dynamically downscaled climate change scenarios. The results show an overall drying trend in the atmosphere and forest fuels in the past three decades. Accordingly, wildfires, especially mega-fires, have increased dramatically. The current trends are projected to continue this century. The drying fuels and increasing wildfires impose a big challenge to fire management and safety. A number of methods could be used to mitigate the impacts. Tree species that can better conserve water and tolerate drought could be planted during vegetation regeneration in the burned area. Prescribed fires could be used more to reduce hazard surface fuels. And urban expansion to forested lands is restrained because urbanization would lead to the heat and dry island effects that could amplify fuel drying in nearby forested lands.

Forest fire fighting: ergonomic and physiological aspects

Elias Apud¹, Felipe Meyer¹

¹University of Concepcion, Concepcion, Chile (eapud@udec.cl; fmeyer@udec.cl)

The present study was carried out with the aim to contribute to the organization of safe and efficient forest fire fighting. For this purpose, studies were carried out in real fires, where the physiological response imposed by the combination of heat exposure and physical work was measured continuously, recording the cardiac frequency. Temperatures were monitored and the slope of the terrain, the characteristics of the fuel and the quality of work were also evaluated in the field. Furthermore, line construction essays were performed to establish, under controlled conditions, the optimum size of crews, working on fuels with different degrees of difficulty and the effect of hydration, rest pauses and time limits for relay of workers. The results showed that forest fire fighting is a very heavy physical activity. The time that a forest fire last and the complexity of environmental conditions, may impose extremely high physiological demands leading to

fatigue, diminishing output and the quality of work. On this basis, the importance of selection, training and alternatives for the organization of fire fighting is discussed, concluding that Ergonomics, with its multidisciplinary approach, is a useful tool to improve the organization of work that can contribute to reduce the risks for workers and the social and economic damage caused by forest fires.

Sustainable forest management under fire risk: ecological options to reduce the fuel loads

Teresa de Jesus Fidalgo Fonseca^{1,2}, Marina Meca Ferreira de Castro^{3,4}, Filipa da Conceição Silva Torres Manso^{1,5}

¹Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal; ²Centro de Estudos Florestais, Universidade de Lisboa, Lisboa, Portugal; ³Instituto Politécnico de Bragança, Bragança, Portugal; ⁴Centro de Investigação de Montanha, Bragança, Portugal; ⁵(tfonseca@utad.pt; marina.castro@ipb.pt; tforres@utad.pt)

Wildfire is a major abiotic disturbance in natural and planted forests, historically affecting large areas of forests all over the world. In forest areas prone to forest fire, such as in the Mediterranean region, the risk of disturbance is continuously present (or recurrent) and need to be considered explicitly by the forest managers. As shown by the dramatic events of October 2017, in Portugal, wildfire suppression response does not guarantee, by itself, to be an adequate procedure to avoid damages caused by this disturbance. It is necessary to begin earlier, at the stand scale level, with preventive forest management procedures. Typical options include the selection of the tree species to plant, promoting the use of the essences most resistant to fire, coupled with their organization in space through compartmentation, and at the stand level, with the reduction of fuel loads of the understory vegetation and downed woody material. For existing forests, reduction of fuel loads can be achieved artificially by a prescribed burn or mechanical removal, or through ecologically based procedures of reducing the understory. This communication brings to analysis, under the umbrella of Project (Forestation of Agricultural Land with More Silviculture, Silvopasture, Innovation and Value), reduction of the understory fuel loads (a) by the management of the average density among trees; (b) by grazing. The effectiveness of the approaches to address the reduction of fuel loads over competing alternatives are evaluated and discussed for real case of studies.

Joint international efforts and challenges for enhancing fire management capabilities in the Chernobyl Exclusion Zone, Ukraine

Sergiy Zibtsev¹, Victor Myroniuk¹, Alan Ager², Richard Lasko³, Joe Reinartz⁴, Johann Georg Goldammer⁵, Vladimir Usenia⁶, Vasyl Gumeniuk¹, Oleksandr Soshenskyi¹

¹Regional Eastern Europe Fire Monitoring Center, National University of Life and Environmental Sciences of Ukraine, Kyiv, Ukraine; ²Rocky Mountain Research Station, US Forest Service, Pendleton, USA; ³US Forest Service, Missoula, MT, USA; ⁴NIMO, United State Forest Service, Lakeview, Oregon, USA; ⁵Global Fire Monitoring Center, Freiburg, Germany; ⁶Institute of Forest, NAS, Gomel, Belarus (sergiy.zibtsev@nubip.edu.ua; victor.myroniuk@nubip.edu.ua; aager@fs.fed.us; rich.lasko920@gmail.com; jreinarz@fs.fed.us; johann.goldammer@fire.uni-freiburg.de; usenyaforinst@gmail.com; vasy.l.gumeniuk@gmail.com; soshenskyi@nubip.edu.ua)

Three major wildfires in Chernobyl Exclusion Zone (CEZ) (2015) burnt 25,000 ha of contaminated lands, contributed to doses of firefighters, regional pollution outside the CEZ by releasing 137Cs, 90Sr, 238Pu, 239-240Pu and 241Am. For preventing future catastrophic fires in CEZ two projects were implemented by U.S. Forest Service (USFS) and the Organization for Security and Cooperation in Europe (OSCE). Within the USFS project (2016-2018), five fire detection cameras installed that increased monitored area from 136,000 to 190,000 ha. Chernobyl firefighters were equipped with fire clothing and breathing-protection means. Improved inter-agency communication were achieved by convening five National Coordination Meetings. Within 12 trainings with USFS instructors firefighters trained with knowledge on fires, safety and incident management. A risk assessed to help manage the long-term effect of re-suspended radionuclides from wildfires. For development of fire management plan spatial dataset was created (fuel loads, contamination, suppression) to develop a cohesive fire management strategy and fire management goals. Within the OSCE project, attention was paid to preparedness of Belorussian and Ukrainian fire services for management of trans-border fires (TBF). Guideline for fire suppression and Belorussian-Ukrainian-English fire terminology were developed for improving coordinated response to TBF, as well as software for predicting doses to firefighters and analysis of legislation of two countries. A table-top exercise for fire command staff was organized by the OSCE, the Global Fire Monitoring Center (GFMC) and the Ukraine-based Regional Eastern Europe Fire Monitoring Center (REEFMC) aimed at strengths of interoperability in addressing radioactive fires.

Sustainable forestry under fire risk: the use of fire operations research to inform forest operations in the interior Western United States

Matthew Thompson¹, Nathaniel Anderson¹

¹US Forest Service, Fort Collins, USA (mthompson02@fs.fed.us; nathaniel.m.anderson@usda.gov)

Forest operations implement treatments that are prescribed to meet landowner and societal objectives, which on federal lands in the western United States continues to emphasize mitigating wildfire risk. The primary objectives of fuel treatments are to reduce the likelihood and intensity of wildfire, and to improve conditions for the control of fire when it occurs. Design principles for fuel treatment operations tend to be well-aligned with fire management objectives, and treatment strategies have been the subject of engineering optimization for at least 15 years. However, for a variety of reasons, on-the-ground implementation rarely aligns with theory, and questions persist regarding treatment return-on-investment (ROI). Although treatment benefits are often estimated by evaluating post-treatment fire behavior, assessing the likelihood of such fire-treatment encounters even occurring is an equally if not more important determinant of ROI. Further, although facilitating fire control operations is often an assumed benefit of treatment, how this could or ought to materialize is not systematically incorporated into treatment design. Arguably what is needed is a treatment prioritization framework that jointly considers fire-treatment encounter likelihood with factors relevant to fire control operations. Recent progress on the latter front includes proactively differentiating landscapes on the basis of suppression difficulty and determining the likely effectiveness of various potential fire control locations, both of which could be ported from the incident response to the fuel treatment prioritization domain. This presentation highlights several ways that fire operations research can be used to inform and enhance the implementation of sustainable forestry under fire risk.

Combating wildfires in South African plantation forests with multi-faceted fuel load reduction measures: Is it working and is it sustainable?

Ben du Toit¹, Christoff Gresse^{1,2}, Angel Goldsmith¹, Paul Viero³, Christopher Pickup^{1,4}, Dean da Costa^{1,3}

¹Stellenbosch University, Stellenbosch, South Africa; ²MTO forestry, Witrivier, South Africa; ⁴SAFCOL, Graskop, South Africa; ³Mondi Limited, Hilton, South Africa (ben@sun.ac.za; christoff@mto.co.za; 22486771@sun.ac.za; paul.viero@mondigroup.com; christopherp@safcol.co.za; dean.dacosta@mondigroup.com)

South African plantation forests have experienced an increase in wildfire damage during the last two decades, attributed to climate change and various socio-political realities. Fuel load reduction is pivotal to successful fire-fighting operations. We used long term experiments and operational case studies to evaluate the efficacy, cost, biotic effects and sustainability of various fuel reduction measures. Repeated under-canopy burning under semi-mature pines can significantly reduce forest floor fuel loads by an average of 6.3 and 12.9 t ha⁻¹ per burning event in in *P. elliotii* and *P. patula* stands, respectively, with apparently no significant reduction in long-term stand productivity. The goal of forest floor reduction to values around 10-15 t ha⁻¹ can be achieved with two to four prescribed burning events, depending on species. Partial incorporation of forest floor and slash residues through disc-harrowing in strips among tree lines has been successfully implemented in eucalypt plantations. Repeated disc-harrowing between tree lines led to significant reduction in forest floor fuel load and to significant changes in root distribution patterns with depth. Surprisingly, these operations only resulted in a non-significant growth reduction (4.5% of basal area) in eucalypt stands tested to date. Biomass collection for energy, slash burning and mulching treatments are implemented by commercial growers to reduce fuel loads, taking soil erodibility and slope conditions into account. Post fire assessment procedures encourages the implementation of low intensity prescribed burning. The effects of various fuel load reduction treatments on soil erosion potential, soil chemical properties, nutrient budgets and long-term sustainability are presented and discussed.

Amazonia sin Fuego, a strategy to reduce forest fires and promote alternatives to burning in the Sierra and coastal regions of Ecuador / "Amazonia sin Fuego", una estrategia para la reducción de incendios forestales y promoción de alternativas al uso del fuego en las regiones Sierra y Costa del Ecuador

Daniel Segura¹, Andrea Bustos¹, Pietro Graziani², Jessica Coronel¹

¹Ministerio del Ambiente del Ecuador, Quito, Ecuador; ² Agencia Italiana para la Cooperación al Desarrollo, Roma, Italy daniel.segura@ambiente.gob.ec; andrea.bustos@ambiente.gob.ec; pietrogra@yahoo.it; jessica.coronel@ambiente.gob.ec)

El fuego ha sido una herramienta de trabajo en todas las culturas del mundo desde hace miles de años. Ha formado parte de la actividad agrícola y ganadera e incluso de fiestas locales, modelando el paisaje en todo el planeta y evolucionando a nuestra especie a través de los años. Por otro lado, el fuego sin control producto de su uso inadecuado, ha creado alarma social, destruyendo bosques y riquezas naturales, poniendo en riesgo a poblaciones enteras y generando pérdidas económicas cuantiosas. En el Ecuador esta problemática no dista del escenario global en materia de incendios forestales. Flagelos de este tipo han ocasionado pérdidas superiores a 200.000 ha en los últimos 10 años, afectando grandes extensiones de bosques naturales y plantados, además de otros tipos de vegetación natural, como los páramos andinos, de gran valor hídrico y abastecedores del recurso agua desde poblaciones pequeñas asentadas en su territorio, hasta las principales ciudades del país de la región sierra e inclusive de la costa. Bajo este escenario desde el 2017 el Programa de Reducción de Incendios Forestales y Alternativas al Uso del Fuego "Amazonia Sin Fuego" (PASF) se implementa en el Ecuador, brindando la oportunidad de continuar las acciones técnicas y tecnologías emprendidas exitosamente en Brasil y Bolivia desde 1999. El PASF Ecuador busca reducir la incidencia de los incendios forestales en la sierra y costa del país, potenciando acciones de prevención, fortaleciendo capacidades técnicas, construyendo política pública y promoviendo prácticas agropecuarias alternativas al uso del fuego en áreas rurales.

Estimating wildland fires economic costs: a proposal

Armando Gonzalez Caban¹, Jose J. Sanchez¹

¹USDA Forest Service, Riverside, USA (agonalezcaban@fs.fed.us; jsanchez@fs.fed.us)

Discussions on the costs of wildfires are generally limited in scope, short-term in nature, and by and large, address mainly suppression expenditures. Recent years have seen improvements on estimating the economic costs of wildland fires, though not to the point of being a common practice. Moreover, scant data is kept on costs of wildfire by federal, state, and local agencies and little research exists on this topic in general (Morton et al; 2003). Up to date few wildland-urban interface (WUI) fires economic costs have been estimated either by public, private and nonprofit sector agencies. Perhaps the reason for this is that the costs of these fires are so large and far reaching that it is a challenging research effort to quantify them. Estimating the economic costs of wildland fires requires accounting for many cost categories including but not limited to direct fire suppression and emergency response expenditures, post fire recovery, water quality mitigation and reimbursement expenditures, and loss of income generating potential or non-market value as a direct or indirect result of wildfire. For each of these categories information must be obtained for public, private and nonprofit organizations involved in the event. Valuation of ecosystem services, particularly those being intangibles or without market values are very difficult to obtain. In this presentation we will introduce a preliminary methodological framework for estimating wildland fires economic costs

C3h: THE ROLE OF FOREST ERGONOMICS IN SUSTAINABLE FOREST MANAGEMENT IN TROPICAL REGIONS

Chilean workforce sustainability

Felipe Meyer¹

¹University of Concepcion, Concepcion, Chile (fmeyer@udec.cl)

Sustainability principles have been acquiring greater significance in the forestry sector. This study deals with the contribution of the human-at-work systems for business sustainability since it is widely conceived that human performance is becoming a critical factor, in improving the sustainability of the organization. In this context, this research aims to contribute to achieving the balance between people capacity and system demand and expects to provide an understanding of these complex interactions and the benefits that this view could bring for the organisations. The forestry sector, this sector is facing a number of challenges that having direct or indirect in the impact the sustainability of the workforce and it's necessary to know it to understand the situation under a holistic point of view.

In that sense, the purpose of this research is to explain, what is happened with the sustainability of the workforce of the forestry sector. To achieve the aim of this research, the author used an ergonomics approach, that has the purpose to identify the elements in the work environment that are affecting that the sustainability of the workforce in the Chilean forestry sector. The results show that the sustainability of the workforce in the Chilean forestry sector is under threatening, since an existing element in the sector that affecting it. The working conditions are a crucial element to improve the sustainability of the workforce.

A sawmill for social inclusion of family farmers in northern Argentina / Una tableadora para la inclusión social de los agricultores familiares del norte argentino

Carlos Alberto Derka^{1,2}, Jorge Kostecki¹, Orlando Jesus Pachinsky¹, German E. Camprubi³

¹INTA, Presidencia Roque Saenz Peña, Argentina; ²Universidad Nacional del Chaco Austral Presidencia Roque Saenz Peña, Argentina; ³Universidad Nacional del Nordeste, Resistencia, Argentina (derka.carlos@inta.gov.ar; kostecki.jorge@inta.gov.ar; pachinsky.orlando@inta.gov.ar; bio-german@hotmail.com)

En la Agricultura Familiar (AF), la sostenibilidad social resulta crucial. El concepto de innovación tecnológica está asociado con dos aspectos clave: su novedad y su adopción social. El objetivo de este trabajo es presentar una tableadora desarrollada en el Instituto Nacional de Tecnología Agropecuaria (INTA) y las posteriores acciones para extender su uso en el norte argentino. Tomando de referencia tecnología extranjera, las adaptaciones realizadas consideraron fundamentalmente la seguridad del operario de la tableadora y sus costos de fabricación. La transferencia de esta tecnología ha tenido dos ejes: los talleres para construir la tableadora y sus accesorios y los de su operación y mantenimiento. Es una herramienta fabricada con hierro y aluminio que mediante elementos de acople a la espada de distintas motosierras de tipo comercial admite el corte de tablas de diferentes espesores que van desde ½ a 10 pulgadas. También se desarrollaron accesorios tendientes a preservar la seguridad de quienes operan la tableadora llegando inclusive a la producción de guantes especiales. El uso de un trípode para elevar el tronco del árbol posibilita que el operario trabaje en forma ergonómica sumando una posición de trabajo más cómoda a la seguridad propia de esta herramienta. Un agricultor puede obtenerla a un valor final al menos un 40% por debajo de las que se ofrecen comercialmente. La tableadora INTA podría ser adaptada a diferentes tipos de bosque y contextos socioeconómicos y servir de referencia para otras iniciativas de inclusión social en el manejo de bosques naturales o plantados.

Aerobic capacity, aerobic threshold, workload and output in forestry workers: an example based on pruning activities

Felipe Meyer¹, Elias Apud¹, Esteban Oñate¹

¹Universidad de Concepcion, Concepcion, Chile (fmeyer@udec.cl; eapud@udec.cl; estebanonate@udec.cl)

The objective of this study is to analyze factors related to the impact of physical fitness of the workers on productivity and work load to determine if this population would be able to respond to the present and future production needs and the ergonomic adaptations required to get closer to the productive goals without undue overload of the workers. Laboratory and field techniques used in this study were described by Apud et al (1999) Results revealed that the aerobic capacity of the pruners (n = 56) was 43 mlO₂ / kg / min, and he body composition of the average group was 20% fat mass. The aerobic threshold was equivalent to 47% of the aerobic capacity. The results of field studies showed that the group has a high dedication to the main activity, close to 80%. The average cardiovascular load was very close to the threshold limit for these workers. In relation to production considering pruned trees per hour, it was found a decreasing trend in productivity as time went on along the shift in all the days evaluated. Consequently, according to the results of this study, ergonomic measures should aim to optimize all those aspects complementary to its main activities, such as clothing, tools, food and organization including the distribution of rest pauses, to mention the most important ones.

Estimation of output in manual forest activities with special reference to pruning

Felipe Meyer¹, Elias Apud¹

¹University of Concepcion, Concepcion, Chile (fmeyer@udec.cl; eapud@udec.cl)

Output depends on the workload that a worker can sustain without fatigue or other risks and on the difficulties to carry out his job, mainly related to the type of trees, climate and ground. In other words, in forestry there is no chance to demand of a worker always the same amount of work. This puts a difficulty to calculate incentives and salaries, especially when workers are paid by piece rate. The objective of this paper is to propose reference tables for calculation of yields in manual forest workers. For the purpose of this presentation, data collected during pruning will be discussed. With respect of methods, work load was estimated from cardiac frequency measured minute by minute during complete shifts together with time studies. Slope of the ground, environmental temperature and characteristics of the trees were also monitored. Statistical procedures were applied to the data and equations were proposed to calculate output. Afterwards, the equations were tested in forests of different degree of difficulty. The equation to estimate pruned trees per hour from the work load and characteristics of the trees was highly significant. When tested afterwards in different conditions, the estimation was within the standard error of the experimental equation. In conclusion, the equation could be transferred to the operation and used for the calculation of expected output and for the calculation of basic salaries or basic salaries plus bonus.

Evolution of the quality of life in Chilean forest camps in the last 40 years

Elias Apud¹, Felipe Meyer¹

¹University of Concepcion, Concepcion, Chile (eapud@udec.cl; fmeyer@udec.cl)

For an effective application of ergonomics in the forest sector, with the aim to improve wellbeing and productivity, there are preconditions, that are determined by the characteristics of the sector itself. In this respect, it is necessary to take into account that work is carried out far from urban areas and workers must remain in camps or travel long distances from home to the forests. Furthermore, in traditional manual forestry work that demands high energy expenditure, the quantity and quality of food is particularly important. The aim of this paper is to present an analysis of the evolution of the forest camps in Chile from the seventies until now, as well as to show the impact of improvements in the diets, not only in terms of quantity of food but also in quality and taste of the workers. Results show that living conditions in camps have improved. The participatory approach started in the early eighties gave the basis for positive changes that are observed at present. Although there is still space for improvements, changes are noticeable and well accepted by the workers. Better living conditions have been favored by a legal decree which establishes minimum hygienic conditions for camps. However, the most important is that companies and most contractors are motivated to innovate, because they are better informed about the importance of the quality of working life to reach good productivity without harmful effects on the workers, topics which will be discussed in the presentation.

Social sustainability: an issue of diversity and forest work

Siegfried Lewark¹, Marion Karmann²

¹University of Freiburg, Freiburg, Germany; ²FSC International, Bonn, Germany (siegfried.lewark@fobawi.uni-freiburg.de; m.karmann@fsc.org)

Social Sustainability is one of the three dimensions of Sustainable Forest Management. This includes Sustainable Livelihood and by definition activities of women and men in forest work. Work in tropical forests is done for earning a livelihood, based on the use of forest resources, timber as well as NTFP. Most of this work is done in the informal sector, where social sustainability is a critical issue. Sustainable forest management in formal economy requires that the operations in the forests are carried out with employees, who know what tools and techniques to use and have the motivation to meet these requirements of the jobs. However, in many tropical countries, the working conditions provided to forest workers are very poor, lacking even the very basic facilities such as proper food and housing. Under such conditions, it must be expected that the work performed in the forest also lacks the quality required for sustainable management.

Safety at forest work – survey and analysis of work accidents in leading state forests in Germany

Udo Hans Sauter¹, Svenja Bonadio¹, Susanne Kaulfuss¹, Stephanie Bethmann¹, Hannes Weinbrenner¹, Alisa Goedecke¹

¹Forest Research Institute Baden-Wuerttemberg, ⁷⁹¹⁰⁰, Germany (udo.sauter@forst.bwl.de; svenja.bonadio@forst.bwl.de; susanne.kaulfuss@forst.bwl.de; stephanie.bethmann@forst.bwl.de; hannes.weinbrenner@forst.bwl.de; alisa.goedecke@googlemail.com)

In the state forest enterprise of Baden-Württemberg, one of the largest forest enterprises in Germany, the number of work accidents increased during last years while the number of work accidents in Germany as a whole showed the opposite trend. This situation gave motivation for a comprehensive analysis of health and safety in the forest working environment, i.e. causes and aspects of work accidents. The survey comprised all obvious work conditions like natural conditions of typical work places in diverse forest types in flat as well in steep terrain, tree dimensions, degree of mechanisation, stage of education of the forest worker, age, fitness and organisational framework. Part one of the study focused on the analysis of recorded work accident cases with respect to the aspects listed above. However, as excellent work related education and high-level personal safety gear are pre-requisites and standard for all forest workers employed by the state forest of Baden-Württemberg emphasis was given to a detailed analysis of the organisation structures, e.i. the relationship between forest workers and management, management routines within the enterprise as well its cooperate culture by methods of social sciences. Numerous guided interviews were realised given deep insights to routines and stress factors during typical work situations. These findings helped to validate, to revise or complement the results of the static accident analysis from part 1 and opened up a dynamic view onto factors for the accidents. Additional aspects like satisfaction on the job and identification with the enterprise can be evaluated.

Concepts of International Forest Ergonomic Textbook for Developing Countries

Yozo Yamada¹, Efi Yuliaty Yovi², Witold Grzywinski³, Amaury De Souza⁴

¹Ehime University, Matsuyama, Japan; ²Bogor Agricultural University, Bogor, Indonesia; ³Poznan University, Poznan, Poland; ⁴Federal University of Viçosa, Viçosa, Brasil (yamada.yozo@ehime-u.ac.jp; eyyovi@ipb.ac.id; witold.grzywinski@up.poznan.pl; amaury paulo@gmail.com)

Forest ergonomic textbooks might be issued in many developed countries. In those countries, students can study forest ergonomics with the native language textbook. However, most of developing and medium countries, including Japan also, don't have own forest ergonomic textbook. Students and researchers in those countries can't study the systematical forest ergonomic, so there are a strong demand to aspire for an international forest ergonomic textbook among them. In those countries, human problems become larger with the economic growth, so ergonomic knowledge will be more significant to solve those problems. Moreover, the evolution of information and robotic technologies is changing the world, and brings sophisticated and complicated problem in each industry. This problem occurs also in developing and medium countries as well as in developed countries. IUFRO RG3.03.00 decided to issue a basic and standard textbook of forest ergonomics including safety management for future new technologies. The main target of this textbook is students and researchers in developing and medium countries, moreover it will be very useful and educational for those of developed countries because it show a future aspect of forest ergonomics. The textbook will consist of nine chapters; 1. History of ergonomics, 2. Worker's burden, 3. Working environment, 4. Work safety, 5. Operational technology, 6. Forestry labor, 7. Owner's responsibility, 8. Regional specific problems, and 9. Future roles of forest ergonomics.

C3i: LPF/SFB - IAWA PANEL DISCUSSION: NEW METHODS AND APPLICATIONS OF TROPICAL TIMBER IDENTIFICATION TO PROMOTE LEGAL LOGGING

New advances of DNA barcoding technology for wood identification in China

Lichao Jiao^{1,2}, Yafang Yin^{1,2}

¹Wood Anatomy and Utilization Department, Research Institute of Wood Industry, Chinese Academy of Forestry, Beijing, China; ²Wood Collections (WOODPEDIA), Chinese Academy of Forestry Beijing China (jiaolichao@126.com; yafang@caf.ac.cn)

Excessive logging and trading in illegal timber are causing deforestation in natural forests, along with a great deal of ecological and economic damage. Wood identification is therefore so crucial and significant that it is a technical prerequisite for monitoring the chain of wood certification. Traditional wood identification relies on diagnostic anatomical features, either macroscopic or microscopic but rarely can provide a precise discrimination of wood at the species level. To overcome such limitations, the newly developed DNA barcoding method may significantly improve the resolution. The paper reviews the new progress of the identification method of wood DNA and its applications of China in recent years. We are establishing the optimized DNA extraction protocol for retrieving good quality and sufficient quantities of DNA from wood tissues, especially for the high-temperature dried wood and long-term stored wood. Besides the wood DNA extraction protocol, a reliable reference DNA barcode library is also one of the main obstacles to the application of DNA barcoding for the next few years. This study also confirmed that xylarium wood specimens are rich sources for reliable DNA sequence data, which will enhance the construction of wood DNA barcode reference libraries. The DNA barcode database of endangered and precious wood species internationally concerned, i.e. *Dalbergia*, *Pterocarpus* and *Santalum*, had been developed so far. Finally, a few cases indicated successful applications of DNA barcoding technology for law enforcement agencies in China. The work will contribute to the conservation of valuable species resources and timber trade monitoring internationally.

Developing high-resolution DNA barcodes for timber species identification based on the complete chloroplast genome

Lichao Jiao^{1,2}, Yafang Yin^{1,2}

¹Chinese Research Institute of Wood Industry, Chinese Academy of Forestry, Beijing, China; ²Wood Collections (WOODPEDIA), Chinese Academy of Forestry Beijing China (jiaolichao@126.com; yafang@caf.ac.cn)

DNA barcoding, an effective tool for wood species identification, mainly focuses on universal barcodes and often lacks high resolution to differentiate species, especially for closely related taxa within the same genus. Therefore, more highly informative DNA barcodes need to be identified. This study is the first to report a strategy for developing specific DNA barcodes of wood tissues. The complete chloroplast genomes of leaf samples of three *Pterocarpus* species, i.e., *P. indicus*, *P. santalinus* and *P. tinctorius*, were sequenced, and thereafter, the most variable DNA regions were identified on the scale of the complete chloroplast genomes. Finally, wood DNA was extracted from wood specimens of the three *Pterocarpus* species, and DNA recovery rates of the selected regions were tested for applicability to verification on the wood specimens studied. The work will offer technical support for curbing illegal timber harvesting activities and for conserving endangered and valuable wood species.

Tropical timber forensics: a multi-methods approach to tracing Bolivian *Cedrela*

Kathelyn Paredes-Villanueva¹ 

¹Universidad Autonoma Gabriel Rene Moreno, Santa Cruz, Plurinational State of Bolivia (kathypavi@gmail.com)

Illegal trade of tropical timber leads to economic and biodiversity losses worldwide. To date, the most common type of fraud concerns false declarations of species and geographic origin, as current legal procedures are generally based on certificates which can be falsified. With concerns about sustainable procurement of tropical timber, there is a need for effective tools to independently verify the source of traded timber. To this end, we applied Direct Analysis in Real Time Time-of-Flight Mass Spectrometry, stable isotopes ($\delta^{13}C/\delta^{18}O$) and microsatellites in *Cedrela* species, one of the major South American timber genera that includes species which are listed in the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES). Heartwood, cambium and leaves from six *Cedrela* species were collected at 11 sites throughout Bolivia. First, DART-TOFMS detected 1062 chemical compounds; Principal Component Analyses (PCA) and Kernel Discriminant Analysis (KDA) of their relative intensities allowed species discrimination with 15-19% mean error and site discrimination with 43-54% mean error for *C. fissilis* and 42-48% for *C. odorata*. Second, stable isotopes signatures were also analysed and it was possible to distinguish species, especially *C. fissilis* with 6.2% mean error. The isotopic site differentiation resulted in low discrimination success: 62.5% mean error for *C. odorata* and 70.5% for *C. fissilis* sites. Third, genetic discrimination assessed by KDA on allele frequency had a 33.7% mean error. Finally, our findings suggest that combining these methods to identify *Cedrela* species and sites could be favorable in some cases but detrimental in others.

Forensic spectra of trees database: case study for rapid database development

Meaghan Parkery-Forney¹, Cady Lancaster², Edgard Espinoza³, Alex Moad²

¹World Resources Institute, Washington D.C., USA; ²US Forest Service International Programs, Ashland, OR, USA; ³National Fish and Wildlife Forensics Laboratory, Ashland, OR, USA (meaghan.parker@wri.org; cady Lancaster@fs.fed.us; ed_espinoza@fws.gov; amoad@fs.fed.us)

The common thread of all species identification techniques is having a sufficiently large database for comparison. The US Fish and Wildlife Forensics Laboratory (NFWFL) developed wood identification protocols using Direct Analysis in Real Time Time-of-Flight Mass Spectrometry (DART TOF MS) in 2011. The immediate benefits of rapid analysis time, no sample preparation, inexpensive materials, and small sample size (slivers) paired with the high species identification resolution of tropical timbers, made the technique a robust tool for forensic identification of wood products. In 2016, NFWFL and World Resources Institute with aid from US Forest Service International Programs began a combined effort to increase the database size for DART TOF MS. In under nine months, collection efforts of a single person increased the database by over 6000 samples, almost doubling the database size, and obtained reference samples of nearly every commercially (in many cases illegally) traded CITES and lookalike timber species. This presentation will summarize the reference collection, partnerships, and emphasize the utility of xylariums in modern timber identification research. Collection efforts established within this project continue with the development of a database for suspected violations of the U.S. Lacey Act.

Wood identification by direct analysis in real time time-of-flight mass spectrometry

Cady Lancaster¹, Edgard Espinoza²

¹US Forest Service International Programs, Ashland, OR, USA; ²National Fish and Wildlife Forensics Laboratory, Ashland, OR, USA (cady Lancaster@fs.fed.us; ed_espinoza@fws.gov)

Wood identification by Direct Analysis in Real Time Time-of-Flight Mass Spectrometry (DART TOF MS) was developed at the National Fish and Wildlife Forensic Laboratory (NFWFL) in 2011 and continues to be used for forensic identification by NFWFL and by US Forest Service International Programs (USFS-IP). In DART TOF MS, a sliver of heartwood is analyzed to generate the small molecule mass spectrum of the wood. Species-specific small molecule (<1000 m/z) mass profiles, or chemotypes, which result from the interaction of the genotype with the environment, are obtained by evaluating multiple spectra from a single species. Combined efforts from the NFWFL and USFS-IP have analyzed over 200 forensic cases and 1000+ wood products ranging from roundwood to essential oils for species-level identification. While already a robust technique, identification capabilities continue to grow with improved reference collection efforts yielding the Forensic Spectra of Trees Database (ForeST©) that holds over 10,000 reference spectra of CITES and commercially significant species. This presentation will cover case studies examining identification of tropical timber and chemotype persistence with time, storage, and geographic variability.

The importance of reference wood collections and complementary forensic species identification techniques for combatting illegal timber trade

Victor Deklerck¹, Ed Espinoza², Jan Van den Bulcke¹, Hans Beeckman³, Joris Van Acker¹

¹Ghent University - Laboratory of Wood Technology, Ghent, Belgium; ²U.S. National Fish and Wildlife Forensic Laboratory, Ashland, USA; ³Royal Museum for Central Africa, Tervuren, Belgium (victor.deklerck@ugent.be; ed_espinoza@fws.gov; jan.vandenbulcke@ugent.be; hans.beeckman@africamuseum.be; joris.vanacker@ugent.be)

With the implementation of FLEGT and EUTR in 2003 and 2013 respectively by the EU and the expansion of the U.S. Lacey Act in 2008 by the USA, there is an increased focus to promote trade in legally produced timber and to put a stop to illegal timber trade. However, this requires complementary forensic timber

identification techniques. Within the Herba Xyla Redd BELSPO– project, which aims at valorizing the *Royal xylarium* and herbarium in Belgium, we have been focussing on combining large wood collections and mass spectrometry for this purpose. The Royal Museum for Central-Africa (Tervuren, Belgium) houses the second largest wood collection in the world and at UGent-Woodlab we have been developing algorithms that are capable of classifying and identifying species based on their chemical fingerprint. The latter mass spectrometry-based technique has been developed at the US Fish and Wildlife Forensic Laboratory (Ashland, Oregon, USA) to identify traded timber or timber products. To obtain a chemical fingerprint, wood slivers are analysed with a DART-TOF Mass Spectrometer (JEOL, USA), leading to ionization and eventually a chemical pattern that is potentially unique per species. The main advantages are its speed, low cost and limited sample size (wood sliver) needed to analyse an unknown wood sample. It is clear that curated, reference, wood collections play a vital role in rapidly expanding this fingerprinting database with samples from all over the world. In this study we present this chemical fingerprinting method and the vital role wood collections play in database-building for timber identification techniques.

Determination of the origin of *Swietenia macrophylla* wood from five Latin American countries and discrimination between *S. macrophylla* and *S. humilis* using portable NIR devices and multivariate analysis

Diego C. Silva^{1,2}, Tereza C. M. Pastore², Liz F. Soares^{1,2}, Filipe A. S. de Barros^{1,2}, Maria C. J. Bergo^{1,2}, Vera T. R. Coradin², Alexandre B. Gontijo², Myrna Herrera Sosa³, César Belletón Chacón⁴, Jez W. B. Braga¹

¹Universidade de Brasília, Brasília, Brasil; ²Serviço Florestal Brasileiro, Brasília, Brasil; ³University of San Carlo, Guatemala City, Guatemala; ⁴Consejo Nacional de Áreas Protegidas, Guatemala City, Guatemala (dcarvalho.silva@hotmail.com; tereza.pastore@gmail.com; liizoares@hotmail.com; filipenesel@gmail.com; mcjbergo@gmail.com; vera.coradin@gmail.com; alexandre.gontijo@florestal.gov.br; myrna_herrera_sosa@yahoo.com; cesarbelte@gmail.com; jezwillian@gmail.com)

The identification of the country of origin of timbers and the differentiation between an endangered very similar wood species are direct forms to combat the illegal logging. To this end, two methods are proposed using NIRS technology. The first one was dedicated to verifying the feasibility of the NIRS technology in determining the origin of the wood of *Swietenia macrophylla* from five Latin American countries - Bolivia, Brazil, Guatemala, Mexico, and Peru. The second one consisted in discriminating two species considered genuine mahogany: *S. macrophylla* and *S. humilis*. The methods were developed using portable NIR spectrometers and chemometrics. Two portable NIR spectrometers were used (MicroNIRTM and MicroPHAZIRTM), and the data analysis was performed using Partial Least Square for Discriminant Analysis (PLS-DA) and SIMCA (Soft Independent Modeling of Class Analogy). The Efficiency Rates (EFRs) showed that the Bolivian model obtained better results with MicroPHAZIR (EFR: 100%) with both PLS-DA and SIMCA. The model for Brazil presented better results with MicroPHAZIR and PLS-DA (EFR: 100%). For Guatemala, Mexico and Peru, the MicroNIR spectrometer with PLS-DA showed slightly better performance, obtaining ERFs equal to 100, 94.9 and 99.4%, respectively, in comparison with the MicroPHAZIR and PLS-DA model. Therefore, the overall results indicated that MicroPHAZIR with PLS-DA was considered the most feasible method. For the analysis of *S. macrophylla* and *S. humilis* species, ERF of 100% was obtained for the PLS-DA model and 98.5% for the SIMCA, indicating the feasibility of the discrimination between these species belonging to the same genus.

M Timbers: Software to assist wood identification of tropical species (android version)

Claudio S. Lisi¹, Christiano S. F. Santana¹, Nayanne A. Menezes¹, Alexandre B. Gontijo², Juliana S. Rodrigues², Vera T. R. Coradin²

¹Universidade Federal de Sergipe, São Cristóvão, Brasil; ²Serviço Florestal Brasileiro, Brasília, Brasil (cleslisi@gmail.com; chris.santana.si@gmail.com; nay_ennes@hotmail.com; alexandre.gontijo@florestal.gov.br; juliana.rodrigues@florestal.gov.br; vera.coradin@gmail.com)

The currently technology, Smartphone's and tablets, portable and practical, enables the development of software with information about the wood anatomy of tropical species. M Timbers, "Madeiras Comerciais do Brasil", is a new version from "Brazilian Commercial Timbers: interactive identification key*". M Timbers, presents the macroscopic description of 157 species, 35 botanic families, being 154 of them tropical species, explored or indicated to commercial timbers. First, this software was designed to studies, but it proved to be very interesting for forest inspection and protection due to its facilities to compare the wood inspected with the database. The user have compare the wood characteristics observed in the wood examined and filter in software by distribution of species, wood color, tree ring, characteristics of vessels and parenchyma, wood macroscopic images and its descriptions. Then only a few species should be compared for identification anatomical comparison. The user can also photograph the wood and send the images and descriptions to specialists in wood identification. With this, we hope to contribute to facilitate studies and improve forest monitoring and conservation. *www.florestal.gov.br/projetos-lpf/85-laboratorio-de-produtos-florestais-lpf/367-madeiras-comerciais-do-brasil-chave-interativa-de-identificacao-baseada-em-caracteres-gerais-e-macroscopicos.

Xylarium bogoriense and development of wood identification system in Indonesia

Ratih Damayanti¹, Krisdianto Sugiyanto¹, Listya Mustika Dewi¹, Andianto Andianto¹, Dwi Sudharto¹, Wening Sri Wulandari¹, Esa Prakasa², Bambang Sugianto², Riyo Wardoyo², Yan Riyanto², Isnaeni Isnaeni³, Maria Margaretha Suliyanti³, Danang Sudarwoko Adi³

¹Forest Products Research and Development Center, Research, Development and Innovation Agency, Indonesian Ministry of Environment and Forestry, Bogor, Indonesia; ²Research Center for Informatics, Indonesian Institute of Sciences, Bandung, Indonesia; ³Res (ratih_turmuzy@yahoo.com; kris.sugiyanto73@gmail.com; lizthya@gmail.com; andiani068@yahoo.co.id; galatan102@gmail.com; weningwulandari@yahoo.com; esa.prakasa@gmail.com; bambangsugianto080373@gmail.com; riyo.war005@gmail.com; yan.rianto@lipi.go.id; isnaeni

Xylarium Bogoriense 1915 is an authentic wood collections located in the Forest Products Research and Development Center, the Ministry of Environment and Forestry, Indonesia. The wood has been collected from most regions in Indonesia since 1914. Nowadays, the Xylarium Bogoriense 1915 wood collection has more than 190,000 thousand specimens consisting of 110 families, 785 generas, and 3,667 authentic wood species. The wood collection has played an important role in wood identification process for research, education, as well as bio-forensic which is involving wood as legal evidence. However, the limitation of existing science, technology, and human resource capacity have caused the process of wood identification to date can only be undertaken by experienced and trained researchers or officers. We are developing methods that can be considered to facilitate the identification of wood species in the field and industry by using computer vision (AIKO). This method is supported by database of macroscopic images of wood cross section namely LignoIndo. The automatic wood identification system is also enhanced to differ of wood origin or geographic location. We are applying some methods for Indonesian tropical timber including bamboo identification by using NIR (Near Infra-red Spectroscopy), Raman Spectroscopy, and Laser Induced Plasma Spectroscopy. The results will be presented.

C3j: METHODS AND MODELS FOR FIRE OCCURRENCE AND DETECTION

Effects of human-related and biotic landscapes features on occurrence and size of modern fires in Sweden.

Guilherme A. S. J. Pinto¹, François Rousseu², Mats Niklasson¹, Igor Drobyshev^{1,3}

¹Southern Swedish Forest Research Centre, Alnarp, Sweden; ²Université de Sherbrooke, Sherbrooke, Canada; ³Centre Université du Québec en Abitibi-Témiscamingue Rouyn-Noranda, Canada (guilherme.pinto@slu.se; francois.rousseau@usherbrooke.ca; mats.niklasson@slu.se; igor.drobyshev@slu.se)

Forest fires are the main disturbance in boreal forests and are mainly controlled by climatic conditions. Additionally, landscape properties may influence fire occurrence and fire size. The role of humans can be influencing fire regimes in two ways, as either a source of ignition or the opposite, by suppressing fires. With this study, we aim to improve knowledge of the relationship and influence of landscape features on occurrence and size of boreal forest fires. We expect to see how our selected landscape variables (road, population density, vegetation zone, tree species, tree's age and firebreak area) and climate data can shed a light on those relationships. With Sweden as our study area we expect to advance fire management strategies regarding the surroundings of large fire events on the boreal region and aim to advance prediction skills of models. We analyzed fire data in Sweden from 1996 until 2012 using Bayesian based models to verify the interactions between those variables with fire events. The preliminary results shows that there is a positive correlation between fire occurrence and road and population density. In fire size, we observed a negative correlation with the same variables. In addition, forest composition and vegetation zones seems to play an important role on both occurrence and size of fires. In a warming and more unpredictable climate, the necessity of improving the knowledge on how the landscape and human-related structures influence large fires is of paramount importance.

An adaptive active fire identification methodology using GF-4 PMI images

Xianlin Qin^{1,2}, Shuchao Liu¹, Xiaotong Li¹, Qian Liu¹

¹Institute of Forest Resources Information Technique, Chinese Academy of Forestry, Beijing, China; ²Forestry Remote Sensing and Information Technology Laboratory of State Forestry Administration, Beijing, China (noaags@ifrit.ac.cn; 83453418@qq.com; girl19950388@qq.com; olivia250864095@163.com)

As part of Chinese Earth Observing System, GF-4 satellite, launched in Xichang Satellite Launch Center on December 29, 2015, is the first geosynchronous orbit remote sensing satellite in China and equipped with one stare camera with spatial resolution of 50m visible/near-infrared channels and a 400m medium wave infrared channel with over 400km swath. To explore the forest fire monitoring method of GF-4 PMI images with multi-channels visible/near-infrared bands and a single medium wave infrared channel, an adapted windows threshold condition for active fire identification methodology has been developed according to the character of GF-4 PMI images. This algorithm has been applied in the forest fire identification in China (such as in the Yulong Naxi autonomous county of Yunan province, the Yajiang county of Sichuan province, the Pingshun county of Shanxi province of China) and the Far East of Russia. And the results of visual interpretation and the relative MODIS fire productions have been used as reference to the detection accuracy assessment. The validation results showed that the commission is more than 80% and the omission is low than 15%. So, the fire identification methodology can be satisfied the need for fire identification operation by using the GF-4 PMI images.

Sustainable forestry under fire risk: synergies between the new bioeconomy and enhancing future fire suppression operations

Nathaniel Anderson¹, Matthew Thompson¹

¹United States Forest Service, Missoula, USA (nathaniel.m.anderson@usda.gov; mpthompson02@fs.fed.us)

Fuel treatments to reduce wildfire risk and improve conditions for fire suppression can be very costly to implement. In the interior western United States, prescribed burning can cost \$300 ha⁻¹ to \$1200 ha⁻¹. However, prescribed burning alone is not a viable option when the risks of crown fire, escaped fire and negative smoke impacts are unacceptable. The cost of mechanized fuel treatments can range from \$2500 ha⁻¹ to \$5000 ha⁻¹. Though they often include the harvest of marketable timber products, the low grade and poor quality of trees and vegetation cut and removed during fuel treatments generally limit value recovery. In most cases, large volumes of unmerchantable logs and biomass are burned for disposal, which has negative air quality and soil impacts. This paper synthesizes the results of multiple research studies focused on understanding the potential for using this biomass as feedstock for the production of advanced biofuels, bioproducts and distributed-scale combined heat and power. Recommendations are made to enhance value recovery from the low grade and low value materials flowing from fuel treatment and forest restoration operations. The goal is to better coordinate the planning and implementation of fuel treatments with harvest operations in ways that encourage efficient links with existing and new biomass end users. Given the vast extent of treatment required in the region under constrained budgets, leveraging the emerging bioeconomy to improve the financial viability of fuel treatment will be critical to treating more acres at lower cost, and improving suppression success in the future.

Modeling annual fire occurrence probability with machine learning algorithms

Gabriel Prata¹, Tiago Conto², Luiz Rodriguez¹

¹Universidade de São Paulo, Piracicaba, Brasil; ²ForLiDAR, Piracicaba, Brasil (gaprata@usp.br; tdc.florestal@gmail.com; lcer@usp.br)

Fire is one of the main causes of forest hazards and its occurrences are often associated to factors like weather and human actions. The aim of this study is to develop a probability model of fire occurrence, based on historical hazard data and a combination of biometric, climatic and socioeconomic variables at stand level. The study was carried out at large area of *Eucalyptus* plantation in the state of Bahia, northeastern Brazil. The biometric variables used to adjust the model considered the assessment of 13,042 forest inventory plots, measured from 2005 to 2017. The fire occurrences were registered from 2010 to 2017, generating 1,840 records. Socioeconomic variables were obtained from official government sources. Random Forest and Logistic Regression models were adjusted with 10-fold cross validation resampling. The accuracy reached up to 95% assertiveness on both algorithms. Both models matched about 95% of unburnt stands. Random Forest proved to be more accurate when dealing specifically with the burned stands, as it correctly assigned 77% of the cases classified as fire occurrences, against 33% from the Logistic Regression. The results showed that the approach tested is capable of assisting forest managers and forest decision makers, reducing the costs of monitoring, firefighting, and potentially increasing revenues by reducing the proportion of burned areas.

Fire risk zones and recommendations for observation towers / Zoneamento de risco de incêndios e recomendação de torres de observação

Brener de Almeida Oliveira¹, Dayane Lopes Pinto¹, Thamires de Souza Carvalho¹, Josué Paoli Reis¹, Cibele Hummel do Amaral¹, Fillipe Tamiozzo Pereira Torres¹, Rodrigo Vieira Leite¹, Lucas Arthur de Almeida Telles¹, Nero Lemos Castro¹, Alexandre Simões Lore

¹Universidade Federal de Viçosa, Viçosa, Brasil (b.oliveiraefl@gmail.com, dayanelopesp@gmail.com; dsc.thamires@gmail.com; josuepaoli@gmail.com; cibelega@gmail.com; tamiozzo@ufv.br; r.vieiraite@gmail.com; lucasarthur36@gmail.com; nerolmcastro@gmail.com; alexandre.

Incêndio florestal é um tema de grande importância no Brasil e no mundo, principalmente pelos danos severos que ele pode causar aos ecossistemas. Para proteger as florestas dos efeitos nocivos dos incêndios são essenciais estratégias e políticas efetivas de prevenção e combate. Uma estratégia eficaz é a utilização de torres de observação para a detecção de focos de incêndios. Esta abordagem reduz o tempo até o primeiro combate. O uso de ferramentas do SIG (Sistema de Informação Geográfica) também tem sido fortemente adotado para previsão de padrões de ocorrências de incêndios a longo prazo em diversos lugares do mundo. Nesse sentido, o presente trabalho teve como objetivo zonar as áreas de risco de incêndios da Reserva Natural Salto Morato - PR e com isso definir áreas prioritárias para implementação de torres de incêndio, a partir do uso de ferramentas de SIG. Para gerar o mapa de risco de incêndio sobrepostos dados de cobertura vegetal, atividades humanas, declividade, altitude, orientação das encostas e exposição das vertentes. Foram identificadas cinco regiões com risco variando de baixo a extremo. Para a alocação das torres foram usados o Modelo Digital de Elevação (MDE) e o limite da área da Reserva Natural, resultando na alocação de duas torres de observação. As duas torres possibilitaram a visualização de 74% da área. Dessa forma, o modelo utilizado para o zoneamento das áreas de risco e alocação das torres de observação atenderam às recomendações para o monitoramento adequado do local.

Forest fire frequency in Brazil / Períodos de maior ocorrência de incêndios florestais no Brasil

Dayane Lopes Pinto¹, Sérgio Guedes Barbosa¹, Aline Gonçalves Spletzer¹, Gumercindo Souza Lima¹, Carlos Elete Torres¹, José Cola Zanuncio¹, Fillipe Tamiozzo Pereira Torres¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (dayanelopesp@gmail.com; sergioflora@hotmail.com; spletzer.algo@gmail.com; glima@ufv.br; carlos.eleto@ufv.br; zanuncio@ufv.br; fillipe.torres@ufv.br)

Incêndios florestais impactam ecossistemas e causam prejuízos. Programas de previsão de incêndios são importantes na formulação de estratégias de prevenção, combate e redução dos danos causados. O objetivo foi determinar os períodos com maior probabilidade de ocorrência de incêndios em vegetação no Brasil, também chamados de Estação Normal do Fogo (ENF). Registros de focos de calor detectados por satélites, entre 1999 e 2014 no Brasil, foram obtidos do Instituto Nacional de Pesquisas Espaciais. As médias mensais foram comparadas e os meses com maior ocorrência de focos de calor foram indicados como a ENF. O número de ocorrências de incêndios e tamanho das áreas queimadas, entre 2006 e 2014, foram obtidos dos Registros de Ocorrências de Incêndios em Unidades de Conservação (UCs) federais do Brasil. As médias mensais foram obtidas e utilizadas para verificar os períodos de ENF indicados. Os registros de focos de calor no Brasil foram maiores no inverno e primavera, com ENF de agosto a novembro. As ocorrências de incêndios em UCs do Brasil foram maiores entre agosto e outubro com maior área queimada (ha) em setembro. Os períodos de maior registro de focos de calor e ocorrência de incêndios variaram entre regiões, porém em todas foram maiores nas estações de seca com baixa pluviosidade e temperaturas mais altas. Características climatológicas e as mudanças no uso da terra influenciam nos períodos de maior ocorrência e nas características dominantes dos incêndios no Brasil, e por isto estratégias de prevenção e combate devem ser intensificadas na estação normal do fogo.

Climate and tropical dry forest fire regime in the Upper Middle Magdalena River Valley, Colombia

Julián Díaz-Timoté¹, Angela Parrado-Rosselli¹

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (jjuliandiazt@hotmail.com; aparrador@udistrital.edu.co)

Causes of wildfires in tropical dry forests have been mainly attributed to land use change, while few information exists on the influence of climate on fire occurrence in these forests. We characterized fire occurrence and extent between 2000 and 2018 in the tropical dry forests of the Upper Magdalena River Valley in Colombia, and analyzed its relationship with annual and supra-annual variability of climatic variables such as precipitation, temperature and evapotranspiration. Using 18 years of high-quality satellite imagery and Moderate Resolution Imaging Spectroradiometer (MODIS) we identified burned area, frequency and spatial pattern of fires, and were associated to temperature, precipitation, and evapotranspiration. Results showed 232 fire events, with no particular pattern of spatial distribution. We found a positive correlation between previous-month's temperature and fire occurrence (number of fires and area), as well as between fire and real evapotranspiration. Major fire years tended to follow the switching from La Niña to El Niño conditions (e.g. 2002-2003, 2006-2007, 2009-2010), probably due to higher fuel produced during the rainy season of La Niña, which when desiccated by the dry El Niño, created conditions for widespread wildfires. Considering the increasing frequency of extreme El Niño events due to climate change, results of this research should be considered in future risk maps and in restoration strategies of tropical dry forests.

Socioeconomic constraints to biomass removal from forest lands for fire risk reduction in the western U.S.

David Nicholls¹, Jeffrey Halbrook², Michelle Benedum³, Han-Sup Han², Eini Lowell⁴, Dennis Becker³, James Barbour⁴

¹USDA Forest Service, Sitka, Alaska, USA; ²Northern Arizona University, Flagstaff, Arizona, USA; ³University of Idaho, Moscow, Idaho, USA; ⁴USDA Forest Service, Portland, Oregon, USA (dlnicholls@fs.fed.us; jeffrey.halbrook@nau.edu; mbenedum@uidaho.edu; han-sup.han@nau.edu; elowell@fs.fed.us; drbecker@uidaho.edu; roy.barbour@usda.gov)

Many socioeconomic constraints exist for biomass removals from federal lands in the western U.S. We examine several issues of importance, including biomass supply chains and harvesting costs, innovative new uses for bioenergy products, and the policy framework in place to provide incentives for biomass use. Western states vary greatly in the extent and utilization of forest resources, the proportion of land under federal ownership, and community and stakeholder structure and dynamics. Our research—which focused on the socioeconomic factors associated with biomass removal, production, and use—identified several important trends. Long-term stewardship projects could play a role in influencing project economics while being conducive to private investment. State policies are likely to help guide the growth of biomass utilization for energy products. New markets and technologies, such as biofuels, for use in the aviation industry, torrefied wood, mobile pyrolysis, and wood coal cofiring could greatly change the landscape of biomass use. Social needs of residents in wildland urban interfaces will play an important role, especially in an era of megafires. All of these trends—including significant unknowns, like the volatile prices of fossil energy—are likely to affect the economics of biomass removal and use in western forests.

C3k: FOREST OPERATIONS ENGINEERING AND MANAGEMENT INNOVATIONS FOR THE FUTURE - 2

Salvage harvesting for bioenergy in Canada: From sustainable and integrated supply chain to climate change mitigation

Nicolas Mansuy¹

¹Canadian Forest Service, Edmonton, Canada (nicolas.mansuy@canada.ca)

The economic and environmental benefits of replacing fossil fuels with wood-based bioenergy are complex, and debates are ongoing on issues such as environmental sustainability of biomass procurement and carbon neutrality. With the greatest biomass per capita in the world, Canada could play an increasing role in the future of global bioenergy and the emerging bioeconomy. Here, we put in perspective the utilization of feedstock salvaged after natural disturbances to supply wood-based bioenergy, by addressing multidisciplinary questions: How much salvaged feedstock is available? How can sustainable practices to support increased removal of biomass be implemented? What are the constraints on development of an integrated supply chain and cost-effective mobilization of the biomass? What is the potential for climate change mitigation? In average, salvaged feedstock could theoretically provide about 100×10^6 oven Dry ton biomass per year, with high variability over time and space. Existing policies and guidelines for harvesting of woody biomass in Canadian jurisdictions could support sustainable biomass removal. However, uncertainties remain as to the development of competitive supply chains, because of the large distances between the locations of this feedstock and available processing sites. Another uncertainty lies in the time needed for a benefit in climate change mitigation to occur. Momentum in the wood-based bioenergy sector will develop only if both the forest industry sector and the energy sector collaborate toward innovative and integrated forest management and procurement solutions, making it possible to extract maximum value from the resource while maintaining its sustainability

Drivers and obstacles for high performances of machine contractors in forest harvesting operations: a qualitative case study on customer and contractor opinions

Malin Johansson¹, Emanuel Erlandsson¹, Ola Lindroos¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden (malin.m.johansson@slu.se; emanuel.erlandsson@slu.se; ola.lindroos@slu.se)

With extensively outsourced forest harvesting operations, the operational performance of contractors is utterly important for the forest industry supply chain, as it affects both cost and availability of raw materials as well as environmental and social impacts of forestry. In this study, we investigate opinions of both key staff at a large forest company (service buyer) and its contractors (service suppliers) concerning what drives and hinders contractors to perform well in different value aspects of the harvesting operation services. By semi-structural interviews with four planning and decision chains constituting all three roles of production managers, production supervisors and contractors, a range of different perceived factors driving and hindering high performance are identified along with opinions of their underlying reasons. The results should be of interest to both researchers and practitioners interested to understand how interactions within business relationships between customers and service suppliers affect both parties' performances. Such knowledge is important for reshaping business practices to better target and use the mechanisms that drive high performance.

Effects of timber extraction operations on soil physical properties and water erosion

Sangjun Im¹, Eunjai Lee², Song Eu¹, Qiwen Li¹

¹Seoul National University, Seoul, Republic of Korea; ²National Institute of Forest Science, Seoul, Republic of Korea (junie@snu.ac.kr; ejay0404@naver.com; dkarj@snu.ac.kr; gimunlee@snu.ac.kr)

In this study, a comparative study was conducted to quantitatively assess detrimental soil disturbance on small harvest sites associated with two timber extraction methods, wood grab and cable yarding operations. A 3.5-ha harvest unit in Korea was selected for study area, where wood grab and cable yarding were separately operated. Soil disturbance class was assessed using the McMahon (1995) visual assessment method. Soil physical properties, such as bulk density, porosity, and saturated conductivity of forest soil, were also measured according to soil disturbance class. The results showed that wood grab operation caused more serious disturbances than cable yarding operation. Deep disturbance accounted for nearly 43% in wood grab operation, where rutting affected 75% of deep disturbance through the heavy machine passes. In contrast, yarding produced about 21% deep disturbed soils with the most comprising undisturbed and shallow disturbance soils (61%). Observations of soil properties in surface layer (0-10 cm) showed that bulk density is 39-54% higher and total porosity is 32-44% lower on the skid trail of wood grab operation compared to the undisturbed site. Soil erosion by water is one of key agents to represent the loss of forest productivity after mechanized timber harvest. Thus, numerical simulation has been operated to evaluate the changes in soil erosion rates on harvest units with different timber extraction techniques. Simulation showed that wood grab operation was estimated to be the most susceptible to water erosion, due to the removal of surface vegetation and increased vehicular traffic and heavy equipment passage

Estimation of wheel ruts and soil compaction with different methods applied in a comparison between skidding and forwarding.

Elena Marra³, Martina Cambi¹, Andrea Laschi¹, Fabio Fabiano¹, Francesco Neri¹, Cristiano Foderi¹, Enrico Marchi¹, Tomas Nordfjell⁴

³University of Florence (DAGRI), Florence, Italy; ⁴Swedish University of Agricultural Sciences (SLU), Umeå, Sweden (elena.marra@unifi.it; martina.cambi@unifi.it; andrea.laschi@unifi.it; fabio.fabiano@unifi.it; francesco.neri@unifi.it; cristiano.foderi@unifi.it; enrico.marchi@unifi.it; tomas.nordfjell@slu.se)

The soil damage extent and severity, caused by wood extraction, are related with soil condition, harvesting system and machine characteristics. Contrasting results have been published about soil damages caused by skidding and forwarding, thus highlighting the needs of further investigations on this topic. In order to analyse the spatial distribution of soil disturbance more accurately, new methods based on the 3D soil reconstruction have been developed. The overall objective of this study was to investigate new methods (portable laser scanner and close-range photogrammetry) and traditional methods (cone penetrometer, manual rut depth measurements, soil bulk density and porosity) for evaluating rutting and soil compaction caused by a loaded forwarder and skidder. Our findings mainly show a relationship between soil compaction (i.e. cone penetration resistance) and rutting (i.e. total reduction of soil volume) in low moisture soil condition. The shortest data acquisition was observed during the portable laser scanning, while in accuracy rutting estimation was higher in close-range photogrammetry. The comparison of photogrammetric and manually-measured profiles confirmed that Structure For Motion photogrammetry can be an accurate instrument for Digital Evolution Model and for morphology description of forest soil disturbance after forest logging. Furthermore, the results showed the effect of harvesting systems and terrain conditions on soil disturbance. In conclusion, soil disturbances were higher for skidder than for forwarder considering the same wood volume extracted.

Effect of soil compaction on tree physiology and growth: a meta-analysis

Barbara Mariotti¹, Martina Cambi¹, Elena Marra¹, Elena Paoletti², Zhaozhong Feng³, Enrico Marchi¹ , Yasutomo Hoshika²

¹Dipartimento di Scienze e Tecnologie Agrarie, Alimentari, Ambientali e Forestali, Università degli Studi di Firenze, Firenze, Italy; ²National Council of Research, Firenze, Italy; ³College of Resources and Environment, University of Chinese Academy of Sciences (barbara.mariotti@unifi.it; martina.cambi@unifi.it; elena.marra@unifi.it; elena.paoletti@cnr.it; fzz@rcees.ac.cn; enrico.marchi@unifi.it; yasutomo.hoshika@cnr.it)

In recent decades, many papers about the effects of forest operation on soil compaction and thus tree growth and regeneration have been published. Most of them examined one or few compaction degrees, tree species, taxonomic groups or soil types, providing interesting result but without interconnections among studies. In order to fill this gap, our study aims to draw general conclusions concerning the impact of mechanized harvesting and soil compaction on tree growth by means of a meta-analysis. We specifically addressed (i) the effects of soil compaction on shoot morphological and physical traits as well as root parameters (ii) the effects of compaction degree according to soil type, taxonomy, age class, and experiment type. The data of several studies were collected taking into consideration peer-reviewed literature indexed in several databases and published between 1948 and 2017. A cross-disciplinary approach was applied including researches under natural environmental conditions and manipulative experiments. The analysis of the collected studies resulted in 56 articles with all the relevant details to be included in the meta-analysis. Our main results suggest that increasing levels of soil compaction affect plant development by an overall decrease of all morphological parameters, more evident in height and root depth; the effect varies according to soil type (generally less strong in arenic soil) and taxonomy, and decreases over time. Compaction significantly reduced net photosynthesis, did not affect leaf nitrogen content (as a proxy of nutrient uptake from roots) but decreased leaf water potential (as a proxy of water uptake from roots).

New design methods to reduce energy consumption of forestry cranes

Omar Mendoza-Trejo^{1,2}, Pedro La Hera¹, Daniel Ortíz Morales³

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²Swedish Cluster of Forest Technology, Umeå, Sweden; ³Cranab, Umeå, Sweden (omar.mendoza.trejo@slu.se; xavier.lahera@slu.se; daniel.morales@cranab.se)

In Nordic countries, logging operations are carried out by the cut-to-length (CTL) method, which considers two forestry machines: a harvester for felling, delimiting, and bucking trees and a forwarder for transporting the logs from the felling to a landing area. Due to the relevance of this method, the scientific and technological development to improve forestry cranes has increased over the past years. Nowadays, forestry cranes are a powerful tool to perform forestry operations. Nevertheless, they are designed with the sole purpose of cutting and collecting logs. However, most of the cranes available in the market do not possess any sensing equipment. Hence, information about forces, positions and velocities of links are unknown. Designing cranes lacking this information leads to oversized designs, high energy consumption, and high vibration levels. One of the methods to modify this scenario is to use mathematical-model-based designs aiming to reduce the energy consumption and the vibration levels. One example is Gravity compensation, which is a well-known technique to design industrial robots, and achieve equilibrium throughout the range of motion. As a result, this reduces the loads on the actuators and the vibration levels. There are different concepts for gravity compensation that can be applied for designing forestry cranes. Among those concepts are the gravity compensation by counterweights, gravity compensation by springs and gravity compensation by using auxiliary actuators. Gravity compensation concepts present advantages and disadvantages, which must be taken into account by the designer in order to reach a successful design.

Productivity analysis of motor manual felling in a yellow pine (*Pinus sylvestris*) stand in Northeast of Turkey

Ebru Bilici¹, Dalia Abbas², Abdullah Emin Akay³, İnanç Taş³

¹Giresun University, Giresun, Turkey; ²American University, Department of Environmental Sciences, Washington, D.C., USA; ³Bursa Technical University, Bursa, Turkey (ebru.bilici@giresun.edu.tr; daliababbas@yahoo.com; abdullah.akay@btu.edu.tr; inanc.tas@btu.edu.tr)

Tree felling is the very first step in producing wood-based forest products. In Turkey, the motor manual method is the most common tree processing operation used for felling, delimiting, and bucking standing trees. In order to ensure the productivity of felling operations, a motor manual method should be well planned and the factors effecting the productivity should be considered. In this study, the productivity of chainsaw felling operation was evaluated using time study analysis. The felling operation was performed using a STIHL MS361 chainsaw in a yellow pine (*Pinus sylvestris*) stand located in the city of Ordu. During the time study, the felling operation was evaluated in four work stages including: moving and preparation, under cut, back cut, and felling. The effects of two stand structures (tree diameter and tree volume) on the felling productivity was analyzed using Pearson correlation coefficient. The average tree diameter and volume were found to be 37.1 cm and 1.09 m³, respectively. It was also found that the average felling productivity was 54.78 m³/hr. The results indicated that the most time-consuming work stage was the undercut stage (37.08%) followed by the back cut stage (27.25%). Statistical analysis revealed that there was a statistically significant ($p = 0.01$) positive relationship between productivity and specific stand structures.

C3p: FOREST OPERATIONS AND THE WORKFORCE

Unsustainable workforce and the consequences over the productivity of the system.

Felipe Meyer¹

¹University of Concepcion, Concepcion, Chile (fmeyer@udec.cl)

The forestry sector is facing a number of challenges that having an impact of the sustainability of the workforce and over the productivity of the system. This study examines the relationship between the working conditions in the forestry sector and the workers. In addition, examines the strategies the Chilean forestry companies are using. Finally, using two examples identify the consequence over the productivity of the system. The overall objective of this study was to investigate the impact of working conditions on the workforce in the Chilean forestry sector and over the productivity of the system. The study involved data collection from 350 forestry workers, both Chilean forest companies and contractors companies along with interviews with managers and experts in the area of forestry, ergonomics, working conditions and health and safety and the study cases. The findings indicate that even though working conditions in the Chilean forestry sector have been improving, they continue to have a negative impact on workers in terms of occupational health, market attractiveness and ageing population. Strategies that forestry organizations have implemented these are not enough to solve the problems mentioned before. The strategies are focused on the prevention of accidents rather the OH problems and none of the strategies pays attention to the wellbeing of the workforce and the development of resources, aspects the workers demand. Finally, due to the problem mentioned above, a negative impact on the productivity of the systems, based on examples related to pruning and harvesting.

Exposure to occupational noise of skidder operators during eucalyptus skidding

Diego Aparecido Camargo¹ , Rafael Almeida Munis¹ , Jorge Carvalho Martins¹ , Emilio José Costa Filho¹ , Danilo Simões¹ 

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil (diegocamargoflorestal@gmail.com; rafaele.munis@gmail.com; jorgec.martins@hotmail.com; ecosta@eucatex.com.br; danilo.simoies@unesp.br)

Occupational noise occupies an important position among the physical agents responsible for health problems for workers; in addition, high levels generated by mechanized forest harvesting operations may characterize jobs as unhealthy. The objective of this study was to evaluate if the noise levels emitted by the skidder during the drag of the eucalyptus wood are in line with the levels established by the Brazilian legislation. The study was developed in a forest area located in the State of São Paulo, Brazil. The skidding operation of entire eucalyptus trees during an eight-hour workday was considered, performed by: skidder 1: John Deere brand, model 948L; skidder 2: Caterpillar brand, model CAT 545D. The data were collected during the total working day by means of a personal dosimeter of Instrutherm brand, following the criteria established by the Occupational Hygiene Standard NHO 01 and by Regulatory Standard 15 adopted for purposes of insalubrity in Brazil. When assessing the noise dose received by the skidder 1 operator, it was verified that the dose was 123.39% and for skidder 2 the dose was 82.83%. Regarding the average noise level (Lavg) for skidder 1 was 86.49 dB (A) and for skidder 2 was 83.64 dB (A). That said, the skidder 1 operator could be exposed without ear protection 390 minutes and the skidder 2 operator 580 minutes. During the evaluations the operators used hearing protectors that allowed the attenuation of 20 dB, ensuring auricular protection for the eight-hour work day.

Evaluation of occupational noise exposure in feller-buncher operators during eucalyptus tree felling

Diego Aparecido Camargo¹ , Rafael Almeida Munis¹ , Jorge Carvalho Martins¹ , Emilio José Costa Filho¹ , Danilo Simões¹ 

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil (diegocamargoflorestal@gmail.com; rafaele.munis@gmail.com; jorgec.martins@hotmail.com; ecosta@eucatex.com.br; danilo.simoies@unesp.br)

A forest machine operator exposed to occupational noise levels above the established limits may have temporary or permanent deafness, as well as sleep disorders, stress, and changes in blood pressure, among other occupational diseases. The objective of this study was to evaluate if the levels of occupational noise emitted by a feller-buncher during the eucalyptus harvesting operation are in compliance with Brazilian legislation in force. The study was conducted in the State of São Paulo, Brazil, during the eucalyptus tree felling operation in the first rotation planting, executed by two fellers-bunchers: feller-buncher 1: Caterpillar brand, model CAT 541, feller-buncher 2: John Deere brand, model 903M. The data were collected during an eight-hour workday by means of a personal integrating meter in accordance with the criteria established by the Occupational Hygiene Standard NHO 01 and by the Regulatory Standard 15 adopted for purposes of insalubrity in Brazil. When measuring the noise dose received by the feller-buncher 1 operator in the workday, the dose was 84.21% and the average noise level (Lavg) was 83.76 dB (A), allowing 570 minutes as the maximum permissible time of exposure in a work day. Whereas, for the feller-buncher 2 the dose was 90.40% and the Lavg was 84.27 dB (A), which allows 531 minutes of exposure without auricular protection. It should be emphasized that the operators were using shell-type ear protectors, which used correctly allows the attenuation of 20 dB. Nevertheless, the values obtained are above the action value, justifying the adoption of preventive actions.

Study of occupational vibration in forest harvesting activity

Jorge Carvalho Martins¹ , Ana Carolina Cazani² , Lara Tatiane Avelino¹ , João Eduardo Guarnetti dos Santos² , Danilo Simões¹ 

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Engenharia, Bauru, Brasil (jorge.martins@unesp.br; carolina.cazani@unesp.br; laratatiavevelino@gmail.com, guarneti@feb.unesp.br; danilo.simoies@unesp.br)

Forest harvesting operations can negatively affect the occupational health of operators, where they are susceptible to several non-ergonomic conditions, among them exposure to vibration levels. The objective of this study was to verify if the whole-body vibration load that the operators of two John Deere feller bunchers, models 903 k (300 HP) and 903 M (300 HP), with 20,688.4 hours of use and 7,803 hours of use respectively, receive in the different directions when operating in an eight-hour work day, are detrimental to the occupational health of the operators. A three-axis accelerometer, model HVM 200 of the Larson Davis brand, was used coupled to the accent of the operators. The results showed an equivalent acceleration for a normalized 8 hour period (A8) of 0.1726 m s⁻² and 0.1153 m s⁻² and a total vibration dose value (VDV) of 8.00 and 5.27 for the model 903 K and 903 M, respectively. The values are below the recommended for the same work day according to ISO 2631-5:2018, where A8 must be in the range of 0.5 m s⁻² to 1.15 m s⁻², and VDV according to the European directive that is 9.1 m/s. Although the usage time of the feller bunchers is unequal, both are in accordance with ISO 2631-5: 2018 and the European directive for the studied parameters of vibration, reflecting that it may not be an aggravating factor of the occupational disorder.

Evaluation of occupational exposure to whole body vibration in forestry tractor skidder operator

Jorge Carvalho Martins¹ , Ana Carolina Cazani² , Diego Aparecido Camargo¹ , João Eduardo Guarnetti dos Santos² , Danilo Simões¹ 

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Engenharia, Bauru, Brasil (jorge.martins@unesp.br; carolina.cazani@unesp.br; diegocamargoflorestal@gmail.com, guarneti@feb.unesp.br; danilo.simoies@unesp.br)

The vibration present in machines employed in the forest harvest, usually by means of the support surfaces, occurs as a result of the oscillation of any movement of these machines around a fixed point; therefore, the vibration is transmitted to the whole body of operators. This physical agent can cause several occupational disorders to the operators, limiting them to the execution of movements or the accomplishment of organic functions. The aim of this study was to evaluate the occupational exposure to the whole body vibration of a skidder operator in three work situation. It was evaluated a John Deere skidder, model 948 L, with tire wheels, motor with nominal power of 281 HP, mass of 22,416 kg, and 7,342 accumulated hours of use. This tractor performed the skidding of full eucalyptus tree, which were planted at the geographical coordinates -22° 96' S and -48° 56' W. For the evaluation, an integrating meter was used in accordance with ISO 8041-1: 2017. The measurements were performed according to the three directions of an orthogonal coordinate system simultaneously, so the accelerometer was fixed to the forest tractor seat. The equivalent acceleration A (8) and the vibration dose value (VDV) were considered. The data were evaluated and compared with ISO 2631-5: 2018. The results showed that the equivalent acceleration values are in compliance with the limits established by ISO 2631-5: 2018, however, the VDV values were higher than the recommended by the European directive, which is 9.1 m/s.

Proposition of an Integrated Ergonomic Indicator (IEI) in the assessment of forest machines

Felipe Oliveira¹, Eduardo Lopes¹, Henrique Koehler², Alexandre Behling²

¹Universidade Estadual do Centro-Oeste, Irati, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (eng.oliveirafm@gmail.com; eslopes@unicentro.br; koehler@ufpr.br; alexandre.behling@ufpr.br)

Ergonomic assessments in forest operations are performed in isolation due by of lack of an adequate methodology that correlates the ergonomic variables simultaneously. The objective this work was to propose new methodology for the ergonomic evaluation of forest machines, by the development of an Integrated Ergonomic Indicator (IEI), useful to relate ergonomic variables. Vibration, noise, heat, luminosity, posture, repeatability, visibility and productivity data were obtained during the day and night periods of the feller buncher, harvester, forwarder, skidder and processor in the Parana State, Brazil. The values, normalized by their deviations from the mean were subjected to factorial multivariate analysis determining the factors that would influence the IEI composition. The factor index was multiplied by the explained variance for each factor and the result was divided by the total variance explained, so that the values remained around 0 and the higher the result, the worse the ergonomic condition. The evaluation presented R^2 of 0.9 and the variables that most influenced were vibration, noise and lateral visibility, relating to each other. The worst machine was the skidder in both work shifts, with IEI of 2.82 for the daytime period and 1.60 for the night, due to impacts and bumps in its displacement added to the high percentage of worker time with the rotated neck. The best machine were harvester B and processor at night with IEI of -1.36 and -0.96, due to low vibration, noise and rotational deviation. The methodology proved to be useful in the integrated ergonomic evaluation

Innovative and adapted harvesting methods for supporting the sustainable management of the southern Brazilian Atlantic Forest

Pedro Britto^{1,2}, Dirk Jaeger¹, Stephan Hoffmann², Renato Robert³, Alexander Christian Vibrans¹, Alfredo Celso Fantini²

¹University of Göttingen, Göttingen, Germany; ²University of Freiburg, Freiburg, Germany; ³Universidade Federal do Paraná, Curitiba, Brasil; ¹Fundação Universidade Regional de Blumenau, Blumenau, Brasil; ²Universidade Federal de Santa Catarina, Florianop (pcdbritto@hotmail.com; dirk.jaeger@uni-goettingen.de; stephan.hoffmann@foresteng.uni-freiburg.de; renatorobert@ufpr.br; acv@furb.br; alfredo.fantini@ufsc.br)

Conservation and management of forest ecosystems are currently conflicting goals in the Brazilian Atlantic Forest biome. At present stage, all forest fragments are protected and commercial logging is highly restricted. This situation generated a lack of willingness of landholders to conserve and possibly even expand native forest areas. A suitable timber harvesting, aiming the sustainable forest management, can provide new income opportunities for landholders and thereby further actively support the process of ecosystem rehabilitation and protection of the Forest. Therefore, our research assessed and compared a conventional timber harvesting method (CM) with an alternative and improved timber harvesting method (AM). Permanent sample plots were installed and a full pre-harvesting inventory was performed. Production rates and associated costs were assessed through a time study analysis. A second inventory, directly after harvesting, was conducted to assess the timber harvesting impact on remnant stand. Our results showed that CM presented a higher productivity and lower cost (3.0 m³ SMH-1 and 12.05 €m-3) compared to AM (1.9 m³ SMH-1 and 20.94 €m-3). The number of damaged trees per harvested trees, for CM, ranged from 0.8 trees ha⁻¹ to 2.5 trees ha⁻¹ and, for AM, from 0.6 trees ha⁻¹ to 2.2 trees ha⁻¹. Improvements on AM method allowed a reduction of damaged basal area and a reduction of the winching disturbed ground area. Nonetheless, a suitable harvesting system should consider further improvements on the felling technique, and additionally, integrate the local knowledge of CM on the forest and tree species with technical improvements of AM.

C3q: MOVING TOWARDS SUSTAINABLE FOREST OPERATION FOR A GREENER FUTURE

Technical and economic evaluation of a forest loader under uncertainty conditions

Ricardo Hideaki Miyajima¹, Lara Tatiane Avelino¹, Rafael Almeida Munis¹, Paulo Torres Fenner¹, Danilo Simões¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade Ciências Agrônômicas, Botucatu, Brasil (richidetoshimiyajima@hotmail.com; laratatiavevelino@gmail.com; rafaela.munis@gmail.com; paulo.fenner@unesp.br; danilo.simoese@unesp.br)

Forest loading is one of the operations subsequent to the forest harvesting. Its operational productivity is influenced by several factors, which means that it is under conditions of uncertainty. In this sense, the objective was to measure the technical-economic risk of loading eucalyptus under conditions of stochastic uncertainty by using Monte Carlo simulation. It was analyzed a Caterpillar forestry loader, model 320D2 FM, equipped with a claw of 0.80 m² capacity. This loader was evaluated in two work situations, by two operators that had different time of professional experience. Operational productivity was determined from the timing and methodology studies. The hourly operating cost was calculated according to FAO (1992). Incorporation of the risk analysis was carried out through the pseudorandom generation of values obtained from the probability distributions. When evaluating the hourly operating cost, the adjustment was for Beta distribution with an average of USD 53.21 h⁻¹. As for the operational productivity, the values adjustment for the operator with the highest experience was Weibull with an average of 207.76 m³ PMH⁻¹. Finally, for the operator with the shortest experience, the adjustment was the Triangular distribution with an average 143.67 m³ PMH⁻¹. Regarding the cost of production for both operators, the adjustment was the Lognormal; and for the operator with highest experience time, an average value of USD 0.31 m³ was obtained. However, for the operator with the shortest experience, the average value was USD 0.50 m³, which evidenced that the time of professional experience influenced the costs of production.

Modeling of the effective productivity of forest loader according to the volume and loading time

Ricardo Hideaki Miyajima¹, Lara Tatiane Avelino¹, Diego Aparecido Camargo¹, Gislaïne Cristina Batistela², Danilo Simões¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade Ciências Agrônômicas, Botucatu, Brasil; ²Universidade Estadual Paulista "Júlio de Mesquita Filho", Campus of Itapeva, Itapeva, Brasil (richidetoshimiyajima@hotmail.com; laratatiavevelino@gmail.com; diegocamargoforestal@gmail.com; gislaïne.batistela@unesp.br; danilo.simoese@unesp.br)

Mathematical modeling is a technique that can be applied in several areas, such as the forest loading, since this last is important from a technical-economic point of view considering that several variables can influence the effective productivity of the machine (PMH). Therefore, the objective of this study was to evaluate the influence of variables loading time and volume of eucalyptus wood on the effective productivity of a forest loader by means of mathematical modeling. The study was carried out in areas of a forest company located in the State of São Paulo, Brazil. It was evaluated the forest load conducted by two operators, with different professional experience times, through the methodology of time and methods considered as a premise for the PMH calculation. The average PMHs of

the operators were significantly different, being 208.85 m³PMH⁻¹ for the operator with the highest operating experience (1) and 114.59 m³PMH⁻¹ for the operator with the shortest experience (2). Pearson's linear correlation showed that as the average volume of wood per cycle increased, productivity also increased, while this ratio was inverse for the loading time. For the estimation of the productivity of operator one, the regression model found was, $\text{prod}=131.98+97.21 \times \text{volume} - 2.89 \times \text{time}$, which presented coefficient of determination 0.73. In addition, for operator two, the model for estimating productivity involving the loading time and average volume of wood per cycle was, $\text{prod}=91.32+70.20 \times \text{volume} - 1.36 \times \text{time}$, with coefficient of determination of 0.72.

Valuation of stands at a standstill in the face of global warming: , sorting of products, analysis of the costs of work from the owner to the economic operator

Henri Husson^{1,2}, Richard Emeyriat³, Riccardo Castellini⁴

¹Centre Régional de la Propriété Forestière, Nouvelle-Aquitaine, Bordeaux, France; ²Centre National de la Propriété Forestière, Paris, France; ³Foret Logistique Conseil, Bordeaux, France; ⁴Cesefor, Soria, Spain (h.husson@cnpf.fr; richard.emeyriat@foretlogistique.eu; riccardo.castellini@cesefor.com)

The valorization of poor or deadlocked forest stands is an important issue in Europe. The initial diagnosis of stands and the sorting of wood products will determine the future of future stands that will be better adapted to global warming. An analysis of 60 sites shows that the analysis of the value of wood and the value of products is often in deficit and leads to additional aid to carry out the work. A decision support guide is being developed as well as a database of tools adapted to the needs of very small forest companies. The European Rosewood programme will be an important element in the communication of the actors. ForLog is a forest site management software linked to a remote database accessible via the web. The software allows structured messages to be sent to field teams (mission orders) and customers (receipts). A mobile application on a smartphone allows you to enter data relating to site activities. The purpose of the study is to study the different operations from producer to operator in order to make an economic, social and environmental assessment. The effects of decisions will be highlighted, the impact on the improvement of global warming will complete the analysis of the economic tools put in place.

Economic consequences of applying accurate bark thickness in mechanised harvesting of Scots pine (*Pinus sylvestris* L.)

Zbigniew Karaszewski¹, Jaroslaw Socha², Mariusz Bembek³, Piotr Mederski³

¹Wood Technology Institute, Poznan, Poland; ²University of Agriculture in Kraków, Kraków, Poland; ³Poznan University of Life Sciences, Poznan, Poland (z_karaszewski@itd.poznan.pl; rsocha@cyf-kr.edu.pl; mariusz.bembek@up.poznan.pl; piotr.mederski@up.poznan.pl)

Different bark thicknesses affect log volume and, consequently, have an impact (multidirectional) on income throughout the whole forest-wood chain, affecting forest owners, forest entrepreneurs, transport companies and customers. For forest owners and entrepreneurs, it may result in a decrease in income if the real roundwood volume is underestimated. An overestimation of the bark content on logs may also affect the weight of transported roundwood. These doubts show complexity of forest management and an unequal position of some actors on the forest-based industries. Proper wood measurement supports the idea of Sustainable Forest Operations in terms of three main principles: economics, quality optimization of products and production and people and society. The volume calculation of roundwood by a harvester is based on the measurements of diameter over bark and log length. To obtain the timber volume only, the bark thickness has to be subtracted by an on-board harvester computer according to the local regulations. These are usually based on the thickness classes of the roundwood or on the percentage of bark content in the roundwood diameter. The aim of the research was to: 1) verify the existing bark allowances with true pine bark thickness values and 2) analyse which factors influence the variation in pine bark thickness. The pine timber selected for the study was harvested by a harvester from trees of different age classes grown in different soil conditions. In this contribution, the final results, including full range variabilities and a statistical evaluation, will be presented in detail.

Medium and long-term investigation on soil degradation after wood extraction operations: comparing skidding and forwarding

Elena Marra¹, Francesco Neri¹, Andrea Laschi¹, Giovanni Mastrodonardo¹

¹Università di Firenze, Firenze, Italy (elena.marra@unifi.it; francesco.neri@unifi.it; andrea.laschi@unifi.it; giovanni.mastrodonardo@gmail.com)

Forest harvesting operations may have a significant impact on soil. The soil disturbance extent and severity are mostly related to soil condition and to the harvesting system. Impacts mainly consists on soil compaction, displacement, and rut formation. Several papers investigated soil damage caused by logging operations on the short-term, but information on the effects of logging on the medium and long-term are still missing. This contribution deals with the effects of wood skidding and forwarding on soil degradation on three sites located in Central Italy. The presented results are related to the medium- as well as the long-term impacts, considering three different periods after forest operations of six months, 1 year and 3 years, respectively. Changes in porosity, bulk density, shear and penetration resistances were investigated on two plots for each wood extraction system adopted, evaluating soil damage. The impact on forest regeneration was also investigated. We found that the restoring time of extraction tracks after logging operations is related to the previous soil compaction level. Skidder did not negatively affect natural regeneration as much as forwarder machine did, while the impact of this latter was lower on sandy soils. In conclusion, the effects on soil of forest machines are still apparent after a long period following forest operations, thus suggesting that the use of previous tracks must be encouraged to avoid the extension of soil disturbance.

Life cycle assessment of carbon footprint of harvested wood products of *Larix kaempferi* in Korea

YoungJin KO¹, Cholho SONG¹, Seulgi LEE¹, Sungeun CHA¹, Hangnan YU¹, Mina HONG¹, Woo-Kyun Lee¹

¹Korea University, Seoul, Republic of Korea; ¹Korea University, Seoul, Republic of Korea (ko871004@gmail.com; cholhosong@gamil.com; cristallize@naver.com; tgy2005@korea.ac.kr; willpower0129@gmail.com; alsdk920902@naver.com; leewk@korea.ac.kr)

This study was focused on harvested wood products (HWPs) of *Larix kaempferi*, the second largest tree species in Korea. In this study, the amount of carbon storage by wood products needs to be quantitative using Life Cycle Assessment (LCA). LCA is a method to evaluate multiple issue environmental impacts attributed to a product of process. In particular, *Larix kaempferi* is with a distribution of 272,000 ha, 11.7 percent, followed by pine trees. In addition, it is used for various purposes, such as building materials, pulp, and particle boards. The use of HWPs in domestic forests is a role of carbon storage in wood products instead of being released back into the atmosphere. Therefore, the specific aim of this study is to estimate carbon storage for the HWPs of *Larix kaempferi* in Korea after pine trees. To estimate the amount of *Larix kaempferi* used in Korea, the total usage of it (413,926 m³) was estimated by checking the purchase amount by domestic product use as of 2016. This resulted in the estimation of the total carbon storage (379,432 ton CO₂) of the *Larix kaempferi* used by multiplying the density of the lumber (0.5 oven-dry ton/m³) and the carbon conversion factor (0.5 ton carbon/oven-dry ton of wood).

Decision criteria for deploying new forest roads / Critérios de decisão para implantação de novas estradas florestais

Felipe Faria¹, Claudio Ortolan¹, Andreia Pimentel¹, Jean Mileski¹, James Stahl¹, Everton Silva¹, Diogo Silva¹, Yasmin Rocini¹

¹Klabin SA, Telêmaco Borba, Brasil (ffaria@klabin.com.br; claudio.ortolan@klabin.com.br; anpimentel@klabin.com.br; jean.mileski@klabin.com.br; jstahl@klabin.com.br; evgsilva@klabin.com.br; diasilva@klabin.com.br; yasmin.rocini@klabin.com.br)

Há que se lembrar que até pouco tempo o manejo incluía madeira para serraria e com a mudança do manejo (madeira para processo) e com novos equipamentos houve a oportunidade de aperfeiçoar o planejamento e as operações florestais, levando em consideração o alto custo de abertura e manutenção de estradas, a relação entre densidade de estrada e o risco de assoreamento dos rios, de erosão e danos nas APPs. Com objetivo de reduzir a abertura de estradas terciárias e aumentar as áreas produtivas, a Klabin S/A estabeleceu critérios e desenvolveu ferramentas para suporte a tomada de decisão de implantação de novas estradas terciárias. Foram levados em consideração os seguintes critérios: densidade de estradas (DE), distância média de extração dos equipamentos (DME), quantidade de madeira disponível em estradas cascalhadas, declividade (Lidar) e tipo de solo. Foram elaboradas duas matrizes de suporte, a primeira através da combinação dos fatores gera uma indicação de recomendação ou não da abertura de uma nova estrada. A partir desta primeira análise e nos casos “recomendados” utiliza-se os dados de solo e declividade, organizados nos mapas de fragilidade para analisar se a recomendação é mantida ou não. Nos casos em que o mapa de fragilidade indica riscos altos ou extremo a estrada não é construída.

Integrating soil characteristics and routine weather data to enhance environment-friendly forest operations

Anton Poje¹, Matevž Mihelič¹, Vasja Leban¹, Janez Krč¹

¹University of Ljubljana, Biotechnical faculty, Department of forestry and renewable forest resources, Ljubljana, Slovenia (anton.poje@bf.uni-lj.si; matevz.mihelic@bf.uni-lj.si; vasja.leban@bf.uni-lj.si; janez.krc@bf.uni-lj.si)

Considering soil types and their characteristics in forest operation is crucial for achieving its environmental viability and sustainable forest management. Soil type and soil water content are the main factors affecting ground bearing capacity and thus determining trafficability and damage to soil, particularly rutting. The aim of this research was to design a decision support system (DSS) prototype based on empirical data. Soil penetration resistance and soil water content were recorded on 4 different soil classes and 6 soil types, which correspond to 60% of Slovenia's soils. The results show that ground bearing capacity significantly depends on water content and soil type. Using limits for soil bearing capacity (i.e. 0.7 and 1.0 MPa), three zones regarding risk for soil damage during CTL harvesting can be determined, namely minimal, medium and high. The water content values between risk zones were estimated at 41% and 55% for cambisol, 22% and 40% for gleysol, 30% and 38% for fluvisol, and 8% in 30% for luvisol. Such simplified DSS is useful to diminish the risk for soil damages on a daily basis. Moreover, inclusion of routine weather data (e.g. forecast) would enlarge the DSS scope to anticipate soil damage risk for the following days. However, the main challenge remains in predicting the soil water content from routine weather data.

C3r: LPF/SFB - IAWA PANEL DISCUSSION: NEW METHODS AND APPLICATIONS OF TROPICAL TIMBER IDENTIFICATION TO PROMOTE LEGAL LOGGING**Building a pedagogical model to identify commercial wood species in post-conflict territories: the case of Colombia / Construcción de un modelo pedagógico para la identificación de maderas comerciales en territorios con pos-conflicto, el caso colombiano**

Juan Francisco Guzman Zabala¹

¹Servicio Nacional de Aprendizaje SENA, Bogotá, Colombia (jfguzmanz@sena.edu.co)

De acuerdo con El Instituto de Hidrología, Meteorología y Estudios Ambientales (IDEAM, 2018) luego del Post-Conflicto generado por la firma del proceso de paz en Colombia con los grupos armados de las Fuerzas Armadas Revolucionarias de Colombia (FARC) y el Ejército de Liberación Nacional (ELN), la deforestación ilegal en Colombia ha ido aumentando constantemente, en 2015 se deforestaron 124 mil hectáreas de bosques, en 2016 se deforestaron 179 mil hectáreas, un 44% más en relación con el año 2015, una cifra que aumentó en 2017 a 219 mil hectáreas deforestadas, 77% más que en año 2015. Amenazando la biodiversidad de un país como Colombia que según Rivers, Oldfield y Smith (2017) posee el 9.6% de todas las especies de árboles en el mundo, alrededor de 5776 especies forestales, convirtiendo a Colombia en el segundo país con la mayor diversidad forestal del planeta. El siguiente artículo presenta el modelo pedagógico diseñado por el Servicio Nacional de Aprendizaje (SENA) para la identificación macroscópica de 29 especies forestales comerciales encontradas en los municipios de Bogotá y Soacha, a través de la construcción de un modelo pedagógico innovador de Xiloteca, que fomenta el aprendizaje intuitivo, con base en la información recolectada en 150 encuestas realizadas a depósitos de madera, integrando las Tecnologías de la Información y la Comunicación (TIC), con el objetivo de capacitar gratuitamente a los actores del Pacto Intersectorial de la Madera Legal en Colombia (PIMLC), como estrategia para la reducción de deforestación ilegal causada por el Post-Conflicto.

Discriminating *Bertholletia excelsa* Bonpl. (Brazilian nut) among similar Brazilian timber by NIRS technology

Carolina C. Vieira¹, Alexandre B. Gontijo², Filipe A. S. Barros¹, Jez W. Braga¹, Tereza M. Pastore², Vera Coradin², Fernanda P. Pieruzzi²

¹Universidade de Brasília, Brasília, Brasil; ²Serviço Florestal Brasileiro, Brasília, Brasil (carolcv1190@gmail.com; gontijoab@gmail.com; filipesnel@gmail.com; jezwillian@gmail.com; tereza.pastore@gmail.com; vera.coradin@gmail.com; fernandapieruzzi@gmail.com)

Bertholletia excelsa Bonpl. is an Amazon native tree endangered with great economic importance. Despite the law protection, its timber have been illegally commercialized as another species from the same family because of their wood anatomy similarities. The aim of this work was the development of prediction models based on Near infrared Spectroscopy (NIRS) in order to improve the *B. excelsa* discrimination among other similar commercial timbers during inspection activities: *Allantoma lineata* (Mart. & O. Berg.) Miers (Seru), *Cariana micranta* Ducke (jequitibá-rosa) e *Lecythis pisonis* Cambess (sapucaia-rosa). The spectra were obtained from Dr. Harry van der Slooten (Forest Product Laboratory - Brazilian Forest Service) wood collection. The NIR spectra (roughly 1595 to 2396 nm) in transversal and longitudinal (radial and tangencial) wood sections were recorded by a handheld spectrometer MicroPHAZIR Analyzer. Discriminant analyzes modelling (PLS-DA) were done in MATLAB R2012 and PLS Toolbox 7.03. The efficiency of predicting species identification models ranged from 61.54% to 100%. A higher efficiency (above 90%) with low number of outliers could be reached for all models that considered the three sectional surfaces of the wood. Then, we could conclude that NIR technology was useful for *B. excelsa* timber discrimination from similar species with anatomic similarities. Besides, models considering both longitudinal and transversal sectional surfaces are more efficiently those considers just the longitudinal sections. The results encourages the use NIRS technology in order to optimize field inspection activities.

Identification of *Dalbergia nigra* and *D. spruceana* by NIR portable spectrometer

Filipe A. Snel^{1,2}, Tereza C. M. Pastore², Vera T. R. Coradin², Jez W. B. Braga¹

¹University of Brasília, Brasília, Brasil; ²Forest Products Laboratory, Brasília, Brasil (filipesnel@gmail.com; tereza.pastore@gmail.com; veracoradin@gmail.com; jezwillian@gmail.com)

The Forest Products Laboratory of the Brazilian Forest Service and the University of Brasília has been studying the NIRS technology, infrared spectroscopy coupled to chemometrics to enable the wood species identification to support law enforcement operations at checkpoints. The method has shown favorable results for mahogany wood identification and has potential to be used in loco. In this work, this methodology was extended for *Dalbergia* species identification. Models were developed to identify two species of *Dalbergia* from Brazil: *D. nigra* and *D. spruceana* among 15 the species. Two chemometrics tools (PLS-DA and SIMCA) and two variable selections (all spectrometer spectral range and a spectral range that includes the main wood compounds bands) were compared aiming the best discriminatory efficiency. PLS-DA is the best potential tool to identify *D. nigra* samples, and this method presented 82.5 % and 81.6 % of efficiency in *D. nigra* discrimination using, respectively, all spectra range and spectra range focused in the main compounds of wood. Even though all spectra range presented better efficiency, it presented three more false positive samples. Therefore, the spectral range focused in the main compounds of wood is recommended for *D. nigra* identification. SIMCA models presented efficiencies lower than 60 % for *D. nigra*. Discrimination of *D. spruceana* was better with PLS-DA than SIMCA but presented lower efficiency with both tools, approximately 60 %. All spectra range showed relatively better discriminatory efficiency in most cases indicating that minority compounds are essential to the identification of species.

Multi-isotope approach to provenancing sandalwood

Ellyse Bunney¹, Francesca McInerney¹, Eleanor Dormontt², Andrew Lowe²

¹The University of Adelaide, Department of Earth Sciences, Adelaide, Australia; ²The University of Adelaide, Department of Biological Sciences, Adelaide, Australia (ellyse.bunney@gmail.com; cesca.mcinerney@adelaide.edu.au; eleanor.dormontt@adelaide.edu.au; andrew.lowe@adelaide.edu.au)

Sandalwood and the oil it produces are highly valuable and widely used forest products. Overharvest and poaching have greatly depleted natural populations of sandalwood resulting in *Santalum album* being listed as a vulnerable species on the International Union for the Conservation of Nature (IUCN) Red List. It is important to be able to distinguish sandalwood that is from sustainable and legal sources and sandalwood that has been poached from the wild. A newly emerging and complementary approach to assessing the origin of timber is isotopic provenancing of wood. Spatial variation of different isotope systems created by factors including differences in hydrology, climate, soil/bedrock type and agricultural practices should result in a unique isotopic signature for different geographical regions when multiple isotope systems are considered. These isotopic signatures are incorporated in to the tissue of organisms grown in that region and may be utilized as a means of identifying where an organic material originated from. This project aims to determine how multi-isotope analysis in sandalwood can be used for provenancing. Carbon, nitrogen, oxygen and strontium isotopic ratios in sandalwood will be measured within individuals, within sites and from different geographic regions to determine if isotopic signatures differ significantly between geographic regions. This project will support the enforcement of illegal logging laws and provide the sandalwood industry with tools to help verify and demonstrate compliance.

Wood anatomy applied as a tool to identify tropical species against illegal wood trade in the state of Sao Paulo, Brazil

Luiz Santini-Júnior¹, Sandra Borges Florsheim², Mario Tomazello-Filho¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ²Instituto Florestal do Estado de São Paulo, São Paulo, Brasil (luizsantini82@gmail.com; sandra.florsheim@gmail.com; mtomazel@usp.br)

The wood exploitation, specially in the Amazon region has increased in the last decades. It is estimated that, annually, 24 million m³ of wood in logs are extracted from the Amazon forest, and approximately 15% is utilized processed on wooden planks in the market of the state of São Paulo. This statistic elevates the state of São Paulo to the position of the world's largest wood consumer from Amazon. The necessity to supervise and regulate the tropical timber trade prompted the São Paulo's government to implement the Project "São Paulo Amigo da Amazônia" (SPAA) in 2007. The inspection provided for the SPAA Project was based on surveys the wood sellers, control the Forest Origin Documents (FOD's) and identification of wood species of wood in their storage yards. In this context, a study was developed in 68 companies from 37 municipalities in the state of São Paulo that operate in the timber segment. Wood samples were collected and 90 tree species were identified through macro and microscopic analysis, and descriptive files and an identification key were elaborated. The results of the tree species identification pointed out 8 clusters of different species, whose timbers were mistakenly marketed by the same popular name. The results also indicated that the species identification through the wood anatomy is of fundamental importance for the success of the programs of inspection and regulation of the commerce of forest products, especially wood, in state of São Paulo and can be applied in other states of the country.

Determining anatomical patterns in wood from mountainous forests tree species in Rio de Janeiro, Brazil / Determinação de padrões anatômicos da madeira em espécies arbóreas de floresta montana, Rio de Janeiro, Brasil

Leonardo Bona do Nascimento¹, Gláucia Crispim Ferreira¹, Pablo José Francisco Pena Rodrigues¹, Arno Fritz das Neves Brandes², Claudia Franca Barros¹

¹Instituto de Pesquisas Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brasil; ²Universidade Federal Fluminense, Niterói, Brasil (bona.nascimento@gmail.com; glaucia.crispim@yahoo.com.br; pablojfrp@hotmail.com; arnofritz@id.uff.br; claudiafrancabarros@gmail.com)

O Rio de Janeiro possui alta diversidade de espécies florestais, o que o torna estratégico para a conservação da Mata Atlântica. A análise das flores do estado por muitas vezes é realizada apenas por estudos fitossociológicos, que deixam algumas lacunas de conhecimento, por exemplo, as características anatômicas das espécies. Após a realização dos levantamentos fitossociológicos realizados pelo Instituto de Pesquisas Jardim Botânico através do projeto PPBio-Mata Atlântica as espécies com os maiores índices de valor de importância foram selecionadas para que sejam descritas a anatomia da madeira. Objetiva-se contribuir para o conhecimento da flora das espécies da Mata Atlântica do estado do Rio de Janeiro, através da realização de descrições anatômicas das madeiras de espécies com maior valor de importância coletadas através dos levantamentos fitossociológicos realizados na Reserva Biológica do Tinguá. O material botânico foi coletado na parcela RAPELD localizada na Floresta Ombrófila Densa Montana da Reserva Biológica (REBIO) do Tinguá, a 900 metros de altitude e processadas de acordo com as técnicas usuais para anatomia da madeira. Foram descritas microscopicamente 13 espécies selecionadas de acordo com as recomendações da IAWA destacando as características diagnósticas. Através deste estudo pode-se verificar convergências anatômicas entre as espécies e descrever o padrão anatômico da madeira para a área. Proporcionando assim esclarecer as estratégias anatômicas das espécies para as condições ambientais no qual estão inseridas. Além disso, tais descrições proporcionarão a realização de uma chave de identificação utilizando o software Xper e permitirão a identificação das espécies arbóreas mesmo sem material reprodutivo.

Anatomical assessment of 50 forest species in southern Ecuador / Evaluación anatómica de 50 especies forestales en el sur del EcuadorAndrés Armijos Montaño¹, Darwin Pucha¹¹Universidad Nacional de Loja, Loja, Ecuador (asarmijos32@gmail.com; darwin.pucha@unl.edu.ec)

La identificación de maderas tropicales a través de sus características anatómicas ha tomado mayor importancia en años recientes. Por ello, este estudio busca realizar la identificación de especies forestales a través de la anatomía de la madera, mediante un análisis estadístico de clasificación no supervisada por medio de clusters, dendrogramas, y heatmaps. Para ello se analizaron 50 especies forestales de la región sur del Ecuador dentro del laboratorio de Anatomía de Maderas Tropicales de la Universidad Nacional de Loja, y se identificaron 50 características anatómicas principales según la normativa IAWA. De éste análisis se encontró que la familia y género no influye directamente en las propiedades anatómicas de la madera, notándose grandes diferencias anatómicas entre las especies. Sin embargo, sólo en casos específicos, especies dentro de una misma familia comparten características comunes, como es el caso de *Anadenanthera colubrina* e *Inga marginata* (Fabaceae) que poseen vasos solitarios en patrones radiales y/o diagonales, y radios agregados con células cuadradas marginales de 2-4 filas; *Cedrela odorata*, *Swietenia macrophylla*, y *Guarea kunthiana* (Meliaceae) poseen en común anillos con poros difusos, vasos solitarios, parénquima axial difuso, radios con ancho de 1 a 3 series con células procumbentes y una sola fila de células verticales. Por todo ello, es necesario realizar un estudio más profundo de la relación entre propiedades anatómicas, clasificación taxonómica, sitio, y condiciones climáticas para lograr una mayor precisión en identificación de maderas tropicales.

Differentiating timber species from the Amazon forest in Paragominas, Pará, Brazil, using near infrared spectroscopy (NIRS) / Discriminação de espécies de madeiras da floresta Amazônica de Paragominas, estado do Pará, Brasil, pela aplicação da espectroscopia no infravermelho próximo (NIRS)Caroline Américo da Silva^{1,2}, Alinne Santos Da Silva¹, Mario Tomazello-Filho¹, Edson Vidal¹, Gilles Chaix^{1,3}¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ²Klabin S.A., São Paulo, Brasil; ³UMR AGAP, CIRAD, Univ Montpellier, Montpellier, France (caroline.silva@klabin.com.br; alinnewood@gmail.com; mtomazel@usp.br; edson.vidal@usp.br; gilles.chaix@cirad.fr)

O trabalho teve como objetivo discriminar 2 espécies florestais tropicais, ocorrentes na Unidade de Manejo Florestal, do município de Paragominas, estado do Pará, Brasil, monitorada há 25 anos pelo IMAZON. Foram selecionadas 41 e 46 árvores de *Copaifera duckei* Dwyer (copaíba) e de *Cordia goeldiana* Huber (freijó), respectivamente, e extraídas amostras do lenho do DAP, pelo método não destrutivo. As amostras do lenho foram fixadas em suportes de madeira, sua seção transversal foi polida, acondicionadas (12% umidade, UR 65%, 20°C) e analisadas (1 cm de distância, direção radial) no espectrômetro NIR MPA Bruker (módulo das sondas de fibra óptica 12800-4000 cm⁻¹, resolução espectral 8 cm⁻¹, dados médios de 32 leituras). Foram obtidos 2.161 espectros, tratados no software The Unscrambler® e simuladas as análises discriminantes com mínimos quadrados parciais (PLS-DA), compostas por 2 classes, (i) *Copaifera duckei*: valor esperado = 0, e (ii) *Cordia goeldiana*: valor esperado = 1, visando distinguir as 2 espécies pela análise quimiométrica das suas madeiras. Os resultados mostraram uma clara separação, com base nos valores esperados, permitindo a discriminação das espécies. A % do erro de classificação foi para a madeira de (i) copaíba [classe = 0, 0,6% (validação cruzada), 0,8% (validação independente)] e (ii) freijó [classe = 1, 0,7% (val. cruzada), 0,2% (val. independente)]. Conclui-se que a metodologia NIRS permite a discriminação de *C. duckei* e *C. goeldiana*, com base nas simulações PLS-DA, utilizando-se amostras não destrutivas de madeira e, se constitui em eficiente ferramenta para a identificação de madeiras e controle da extração ilegal.

C3s: TOOLS AND TECHNIQUES FOR BETTER WILDFIRE MANAGEMENT AND RESPONSE**Flammability of species for use as fuel breaks in forest fires prevention**Bruna Kovalskyki¹, João Francisco Labres dos Santos¹, Andressa Tres¹, Tiago de Souza Ferreira¹, Antonio Carlos Batista¹, Alexandre França Tetto¹¹Universidade Federal do Paraná, Curitiba, Brasil (kovalsyki.b@gmail.com; joaolabres@ufpr.br; tres.andressa@gmail.com; tiagoferreira@florestal.eng.br; batista.ufpr@gmail.com; tetto@ufpr.br)

In general, anthropic action is the main cause of forest fires. When these events occur in the Wildland-Urban Interface (WUI), they become a threat to local communities. One measure of forest fire prevention is the establishment of fuel breaks, which is strips of vegetation with species of lower flammability than those of the main cultivation, with the aim of reducing or avoiding fire spread. One of the characteristics observed for this purpose is the flammability of the combustible material. In this context, the aim of this study was to evaluate the flammability of *Casearia sylvestris* and *Camelia* sp., according to the methodology recommended by Valette (1990) and Petriccione (2006). To evaluate this species, 50 firing repetitions were performed in the epiradiator (250 to 350 °C), each one consisting of 1 ± 0.1 g of fine green combustible material (Ø < 0.7 cm). The following combustion characteristics were analyzed: Ignition Frequency (IF), Ignition Time (IT), Duration of Combustion (DC) and Flame Height (FH). Subsequently, a flammability value was determined, considering the IT and IF of each species. According to the average values found, *Casearia sylvestris* (IF = 96%; IT = 17.5 s; DC = 5.3 s; FH = 13.5 cm) and *Camelia* sp. (IF = 100%; IT = 18.7 s; DC = 14.7 s; FH = 12.2 cm) were classified as flammable species. Therefore, it is recommended that these species are submitted to combustion and calorimetry analyzes in future studies to corroborate with these results.

Colorado homeowners' willingness to pay estimates for reducing wildfire risk: a comparison of survey methodsJose J Sanchez¹, Armando Gonzalez Caban¹, John Loomis², Thomas Holmes³¹USDA Forest Service, Riverside, USA; ²Colorado State University, Ft. Collins, USA; ³USDA Forest Service, Triangle Park, USA (jsanchez@fs.fed.us; agonzalezcaban@fs.fed.us; john.loomis@colostate.edu; tholmes@fs.fed.us)

The loss of life, property, and natural resources has been more devastating in recent years due to the increase in frequency and severity of wildfires. To help reduce risk, the USDA Forest Service (USFS) has promoted private homeowner and public wildfire risk reduction actions. However, these are costly programs to private homeowners and county fire management agencies. To induce participation, cost share programs have been provided. However, there are very limited federal funds and it is important for the USFS to know what geographic areas have the highest economic values for reducing wildfire risk and the relative values of wildfire risk reduction actions to homeowners. In particular, the cost sharing only reduces the cost to the landowner, and if their willingness-to-pay (WTP) falls below their cost share, they will not engage in private actions to reduce wildfire risk on their properties or support homeowner associations' actions. To better understand this issue, a choice experiment survey of Colorado homeowners was conducted to estimate the amount homeowners' would pay for wildfire risk reduction programs in their community and around their home. Colorado homeowners received either an online or mail survey with three choice sets, each

with three alternative programs (public, private, status quo). Using a split sample survey, we estimate Colorado homeowners' WTP for wildfire risk reduction programs and compare them by the survey methods. The results may help fire managers allocate their limited resources to fund public and private actions as well as determine if results vary by survey method.

Modeling the influence of eucalypt plantation on wildfire occurrence in the Brazilian savanna: a comparison of Random Forest, MaxEnt and Logistic Regression

Luiz Felipe de Castro Galizia^{1,2} , Marcos Rodrigues¹

¹University of Lleida, Lleida, Spain; ²University of Eastern Finland, Joensuu, Finland (luizf@uef.fi; rmarcos@eagrof.udl.cat)

Eucalypt plantations are expanding in Brazilian savanna, one of the most frequently burned ecosystems in the world. Wildfires are one of the main threats to forest plantations, causing economic and environmental loss. Modeling wildfire occurrence provides a better understanding of the processes that drive the fire activity. Furthermore, the use of spatially explicit models may promote more effective management strategies and support fire prevention policies. Machine Learning (ML) algorithms have shown their predictive accuracy to model wildfire occurrence. In this context, we implemented and compared Random Forest ML algorithm with Maximum Entropy (MaxEnt) and traditional methods like Logistic Regression (LR) to predict the ignition likelihood across the study area. The models were trained using several explanatory drivers related to fire ignition: accessibility, proximity to agricultural lands or human activities, among others. Specifically, we introduced the progression of eucalypt plantations on two-year basis. Fire occurrences in the period 2010-2016 were retrieved from the Brazilian Institute of Space Research (INPE) database. Results suggest that the use of ML algorithm leads to an improvement in the accuracy in terms of the AUC (area under the curve) of the model when compared to MaxEnt and LR outputs. The ML model denoted fairly good predictive accuracy (AUC \approx 0.72) being useful for evaluating the current occurrence likelihood distribution and unravel fire occurrence driving forces. Results suggested that fire occurrence likelihood was mainly linked to proximity agricultural and urban interfaces. Even though eucalypt plantations were not the main explanatory factor, it contributed to increasing wildfire likelihood.

Use of cultural fire as a tool for territory management and for wildfire prevention

Antonio Casula¹, Gabriella Cuccu¹, Michele Chessa¹, Antonello Cannas¹, Leandro Usai¹, Lino Magari¹, Livo Peluffo¹; Franco Casula¹, Salvatore Cabiddu¹, Giancarlo Muntoni¹

¹Corpo Forestale e di Vigilanza Ambientale della Regione Sardegna, Cagliari, Italy (antcasula@regione.sardegna.it; gcuccu@regione.sardegna.it; michessa@regione.sardegna.it; acannas@regione.sardegna.it; leusai@regione.sardegna.it; lmagari@regione.sardegna.it; lpeluffo@regione.sardegna.it; fcasula@regione.sardegna.it; scabiddu@regione.sardegna.it; gmuntoni@regione.sardegna.it)

During the last 50 years, major socio-economic changes exacerbate fire regime of Sardinia (Italy), the second largest Mediterranean island, resulting into wildfires of unknown speed, intensity and magnitude together with brutal damage to the forests, homes and people lives. During the same period Italian and European culture experienced a diffuse demonization of fire itself and the criminalization of people that was traditionally accustomed to use fire. Sardinian firefight machine greatly increased its efficacy in suppressing fire and in judiciary investigation but despite its efficiency and a continuous growth of economic costs, wildfires continues to create severe damage to the ecosystem. On the contrary, a cultural shift from the paradigm "all fires must be put out" to the one "not all fires are bad fires" is the basis of a project carried out by the Sardinian Forest Service in "Planargia", a specific area located in the NW of the isle where the social conflict between people using fires in their work at the countryside and the firefight apparatus gave way to a collaboration of Forest Service with landowners and local administrations, for a rational use of the ancient cultural fire. The collaboration led to a drastic drop of ignitions and burned areas, to a strong effect of forest fire risk reduction and to a cancellation of the economic costs of wildfire suppression. The project, fully operational since 2012, consisted in an organic fuel load reduction program by the use of prescribed burning conducted by the same land owners, farmers and livestock farmers, assisted by Forest Service crews. The results are exceptionally encouraging not only for the strong reduction of wildfires and suppression costs but also for the proliferation of specific essences of natural fodder crops, for the insect species control (effect offered by the light burn that reduces the need to use pesticide), and, finally, for firefighters' training experience. By working together, forest service, local administrations and landowners developed a collaboration protocol that enhanced the environmental and social control of the whole territory.

Spatio-temporal characterization of tree and stand level canopy structure of fire-tolerant eucalypt forests after wildfires of different severity using Lidar data

Yogendra Karna¹

¹School of Ecosystem and Forest Sciences, The University of Melbourne, Creswick, Australia (ykarna@student.unimelb.edu.au)

Fire-tolerant eucalypt forests are one of the major forest ecosystems of south-eastern Australia and thought to be highly resistant to frequent high severity wildfires. However, the impact of different severity wildfires on the canopy structure of this forest type is under-studied, and there are significant knowledge gaps in relation to the assessment of tree and stand level canopy structural dynamics and recovery after fire. Assessment of canopy structure is a complex task involving accurate measurements of the horizontal and vertical arrangement of the canopy in space and time. This study examined the utility of multitemporal, small-footprint lidar data to describe the changes in the horizontal and vertical canopy structure of fire-tolerant eucalypt forests eight years after wildfire of different severities from the tree- to stand level. Extensive ground measurements were carried out in four severity classes to describe and validate canopy cover and height metrics as they change after wildfire. The preliminary analysis revealed that there is a persistent effect of high severity fire 8 years after both on tree crowns and stand canopy. The tree level analysis results show that high severity fire increased crown depth but decreased the crown projective cover leading to a more open canopy.

Climate change, unsustainable development, outbreaks of heat and forest fires, the real reason why Amazonia "catches fire" / Mudanças climáticas, desenvolvimento insustentável, focos de calor e incêndios florestais, o real motivo da Amazônia "pegar fogo"

Julie Alves da Silva¹, Luiz Joaquim Bacelar de Souza¹, Jakson França Guimarães², Rogério Fonseca¹, Lauana Silva Da Costa¹, José Wilson Pereira Gonçalves², Brenda Corrêa de Castro¹

¹Universidade Federal do Amazonas, Manaus, Brasil; ²Corpo de Bombeiros Militar do Amazonas, Manaus, Brasil (juliealves72@gmail.com; lsouza@ufam.edu.br; obm_franca@yahoo.com.br; rogeriofonseca@ufam.edu.br; lauana.costt@gmail.com; jwillsonbm@yahoo.com.br; bcastrocorrea@gmail.com)

Os efeitos das atividades antrópicas influenciam diretamente na incidência de incêndios florestais, atividades estas que aumentam susceptibilidade das florestas a incêndios. No estado do Amazonas as atividades antrópicas, como agricultura, pecuária e exploração madeireira aumentam a quantidade de materiais

combustíveis disponíveis. Nossos resultados mostram que os meses com maiores incidências de focos de calor no estado ocorrem nos meses de agosto e setembro, concomitantemente são os meses de menor precipitação e maior temperatura média. As mesorregiões Sul e Centro foram as mais afetadas por focos de calor, havendo, nos anos 2000 a 2008, maior concentração dos focos na mesorregião Sul e, de 2009 a 2016, se formou uma “ponte” de focos de calor que acarretaram na maior incidência de focos de calor na mesorregião central, cenário esse que corroborou com o cenário previsto de desmatamento. O município de Lábrea possui a maior média anual de focos de calor, entretanto o município de Boca do Acre foi o município com maior área em quilômetros quadrados afetados por focos de calor. A diminuição dos focos de incêndios neste bioma depende de ações multiagências, muitas delas com suporte logístico insuficiente para um território continental como é o caso do estado do Amazonas. Iniciativas mediadas por técnicos tem auxiliado a melhor gerir o parco capital financeiro disponibilizado pelo estado brasileiro.

C3t: FOREST OPERATIONS ENGINEERING AND MANAGEMENT

Lime and cement use in the chemical and granulometrical stabilization of soil for forest roads

Breno Arrivabeni¹, Carlos Machado¹, Giovani Sant'Anna¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (breno.arrivabeni@hotmail.com; carloscardosomachado@terra.com.br; santannagiovani@yahoo.com.br)

This work aimed to analyze the chemical and granulometric stabilization of a gravel soil for forest roads through the use of lime and cement. The sample was analyzed according to DNIT's different granulometries, related to its natural granulometric characteristics and also when added cement and lime to it as chemical additives, in the proportion of 4% and 8% of the dry soil mass, respectively. The development of this analysis was based on the gravel characterization followed by the compaction tests, California Bearing Ratio (CBR) and Resistance to Simple Compression (RSC). This latter test was based on the norm suggesting a value of 2.17 MPa for a 14 days cure period using lime and 2.1 MPa at 7 days using cement. The results obtained from CBR analysis were superior to the soil without additive, being greater than 300% using cement and greater than 100% using lime. For RCS analysis, the results were below the standards for both additives, but still higher than the natural soil. Therefore, these materials when mixed with lime and cement, have a high bearing capacity and resistance, especially when using cement, which indicates good parameters related to stability, erosion and vehicle traffic.

Strategic investment: real options applied in a forest nursery for production of eucalyptus seedlings

Danilo Simões¹, Douglas Henrique da Fê², Magali Ribeiro da Silva¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Campus of Itapeva, Itapeva, Brasil (danilo.simoies@unesp.br; douglas.fe@unesp.br; magali.ribeiro@unesp.br)

The traditional methods of investment valuation in real assets don't include the uncertainties and strategies, that are inherent to competitive ambiances of the companies of forest base, therefore, can be limit the creation of value for the stakeholders. To mitigate these shortcomings was used the Real Options approach for evaluating an opportunity of investments in real assets to produce eucalyptus seedlings, owing to be a project with features that allow strategic decisions. The project intends to install a forest nursery in of State of São Paulo, Brazil, with the capacity to produce 3.600 million of seedling per year, thus, demanded a CAPEX of USD\$374,399.89. The cash flow was projected for a horizon of 10 years, which was discounted by the CAPM. Owing to the current scenario the investors have how strategies flexibilities the option of wait two years for beginning the activities and more, can expand the operational scale in 30% on the tenth year of the lifespan of the investments project in real assets. Owing to the price evolve over time, the behavior of the price follows the geometric Brownian motion, denoted for movements of up and down, therefore, was make a binomial decision tree in discrete time. In considering that the investments project was implanted after two years and mainly that the probability of 73% of alteration of the operational scale was executed, the results evidenced that there was an increment in the market value, that is the present value expanded was USD1,853,665.11.

Determining the moisture content of pine and eucalyptus logs using radio frequency capacitance / Determinação da umidade de toras de pinus e eucalipto empregando o método da capacitância em radiofrequência

Elisa Pizzaia Goltz¹, André Simon^{1,2}, Pedro Boing^{1,2}

¹Marrari Automação, Curitiba, Brasil; ²Universidade Federal do Paraná Curitiba Brasil (elisa.pizzaia@gmail.com; andre@marrari.com.br; calibracao@marrari.com.br)

O desenvolvimento de modelos matemáticos que correlacionem a permissividade elétrica relativa ϵ' e o fator de perda dielétrica ϵ'' à quantidade de água presente na madeira é um passo fundamental no desenvolvimento de medidores instantâneos de umidade. A correlação entre as variáveis é largamente aplicada na medição de umidade de madeira serrada e, recentemente, de cavacos de madeira, mas não é aplicada ainda na medição da umidade de toras. Este trabalho consistiu na avaliação deste método aplicado também à madeira em toras. Uma vez aprovado, o método pode ser empregado no comércio e na seleção das toras que entram na linha de produção de celulose ou que são alimentação da caldeira de força. No presente trabalho foram utilizadas toras de pinus com umidades entre 12% e 48% e de eucalipto com umidades entre 40% e 60% em base úmida, provenientes de plantios diferentes, todos localizados no Paraná. A avaliação se deu através da correlação entre a leitura crua de um sensor capacitivo quando inserido nas toras e a umidade da madeira obtida pelo método gravimétrico, que forneceu coeficientes de determinação (R^2) de 0,884 para toras de pinus e de 0,6088 para toras de eucalipto. A relação observada entre a leitura do sensor e a umidade das toras permitiu afirmar que o método pode ser aplicado para estimar a umidade dos dois gêneros investigados com o grau de acurácia suficiente para comercializar e classificar matéria-prima antes do processo produtivo de celulose ou a produção de energia a partir da biomassa.

Controlling pine regrowth in Caxambu State Park, in Castro, Paraná, Brazil / Controle de regeneração de pinus no parque estadual Caxambu, Castro, Paraná, Brasil

Luciana Leal¹, Nelson Luiz Cosmo¹, Felipe Fiuza de Lima², Jorge Ricardo Camargo¹, Cristóvam Sabino Queiroz³, Maria do Rocio Lacerda Rocha³

¹Copel Distribuição S.A., Curitiba, Brasil; ²Verdes Lagos, Chopinzinho, Brasil; ³Instituto Ambiental do Paraná, Curitiba, Brasil (lucianaleal.floresta@gmail.com; nelson.cosmo@copel.com; felipe@verdeslagos.com.br; jorge.camargo@copel.com; cristovamsq@iap.pr.gov.br; mrociola@iap.pr.gov.br)

No Estado do Paraná, Brasil, as espécies de *Pinus* spp. são reconhecidas em portaria estadual como exóticas invasoras, sendo previstos o monitoramento, o controle e sua erradicação em unidades de conservação de proteção integral. Em 2015 foram suprimidos os reflorestamentos de *Pinus* spp. existentes no Parque

Estadual Caxambu, município de Castro, Paraná, em região de ocorrência da Floresta Ombrófila Mista. Como condicionante de licenciamento ambiental, o Instituto Ambiental do Paraná (IAP) solicitou à Copel Distribuição S.A. a execução do controle e monitoramento de pinus no parque, pois foi prevista a regeneração de grande número de indivíduos da espécie, devido à presença de banco de sementes no solo, de sua longevidade e da alta taxa de germinação. O controle foi realizado pelo método mecânico e variou em função do porte, com arranquio manual de plântulas e corte de indivíduos jovens, próximo à base do caule. Em aproximadamente 23,5 hectares, em abril de 2018, foram erradicados 13.133 indivíduos de pinus. Repetindo a ação após seis meses, a quantidade removida reduziu para 391 plântulas. Nas áreas que sofreram intervenção observou-se intensa regeneração natural da floresta nativa, promovendo o sombreamento do solo, fator que contribui para a redução de novas infestações de pinus, por ser espécie heliófila. Os resultados mostram a importância do monitoramento e de ações posteriores à supressão de reflorestamentos, para evitar e controlar a reinfestação de espécies exóticas invasoras. Destaca-se a influência da regeneração natural das espécies nativas, em ambiente florestal, na inibição da contaminação biológica por *Pinus* spp.

Integrated management of vegetation in creating power line transmission corridors / Aplicação de manejo integrado de vegetação na abertura de faixas de passagem de linhas de distribuição de energia elétrica

Luciana Leal¹, Robinson Antonio Pitelli²

¹Copel Distribuição S.A., Curitiba, Brasil; ²Centro de Gestão de Tecnologia e Inovação (CGTI), Jaticabal, Brasil (lucianaleal.floresta@gmail.com; rapitelli@ecosafe.agr.br)

O controle de vegetação sob sistemas elétricos nas áreas rurais é realizado pelas concessionárias brasileiras por meio da roçada manual ou mecanizada. Devido a rápida rebrota das plantas, o processo é bastante oneroso e com impactos ambientais. O projeto de pesquisa e desenvolvimento P&D ANEEL 2866-0480/2017 “Manejo Integrado de Vegetação em Abertura de Faixa de Passagem em Linhas de Distribuição de Alta e Média Tensão”, proposto pela Copel Distribuição S.A e o Centro de Gestão de Tecnologia e Inovação (CGTI), com unidades experimentais no estado do Paraná, Brasil, tem como objetivo estudar a viabilidade técnica, ambiental e econômica da abertura de faixa na modalidade de manejo integrado de vegetação, combinando a ceifa inicial com o uso de herbicidas não-agrícolas aplicados de maneira seletiva. Com isto, favorece vegetação cuja característica de crescimento não interfira no desempenho operacional das instalações elétricas ou que demande o mínimo de intervenções, além de prover benefícios como proteção para o solo e ambiente favorável para a fauna. Para viabilizar a operacionalização no setor elétrico, experimentos visam conhecer os efeitos dos tratamentos nas plantas alvo e não-alvo, necessidade de intervenções e magnitude da resiliência da vegetação, bem como impactos ambientais e externalidades da metodologia.

Management of forests under power lines for mitigation of transmission disruptions

Andressa Ribeiro¹, Antonio Carlos Ferraz Filho¹, Mylla Vytória Coutinho Sousa¹, Alessandro Cesar de Sousa Berredo²

¹Universidade Federal do Piauí, Bom Jesus, Brasil; ²Taesa, Rio de Janeiro, Brasil (andressa.florestal@ufpi.edu.br; acferrazfilho@ufpi.edu.br; myvyc@hotmail.com; alessandro.berredo@taesa.com.br)

Brazil has a total of 150,338 MW of installed energy matrix, with many power transmission networks located in forest areas, which are prone to wildfires and responsible for costly power interruptions. Measures taken to reduce fire intensity, and thereby minimize risk of faults, include expansion of vegetation clearance around towers, reduction of vegetation maintenance intervals in high risk locations, management based on vegetation and fuel type, alteration of species composition from high flammability to lower flammability vegetation types, etc. Few studies have been found to date that address the question of what is the appropriate forest management under power lines in the Savannah type (Cerrado and Caatinga) Brazilian biomes. This project is conducted by TAESA in partnership with the Federal University of Piauí, GeoAmbiente and Ekocap, and is divided in five steps to accomplish the goal: 1) GIS mapping of power disruption risk areas evaluating different climate and spatial variables; 2) definition of key forest inventory variables, with specification of the most important tree species; 3) selection and research of the potential species of the region, studying growth cycles and wood properties; 4) seed collection and seedling production analysis and 5) field tests for recovery of degraded areas. *Funded by P&D 2607-0044/2016 “Estudo de ações para mitigação de riscos de desligamentos das linhas de transmissão por queimadas e avaliação de métodos de manutenção de faixas de servidão”.

Assessing impacts from two modes of forest extraction using a tractor-hoist assembly in a mountainous region / Avaliação dos impactos em dois modais de extração florestal com conjunto trator agrícola-guincho em uma região montanhosa

Rafael Oliveira Brown¹, Marcelo Langer¹, Dimas Agostinho Silva¹, Renato Cesar Gonçalves Robert¹

¹Universidade Federal do Paraná, Curitiba, Brasil (brownrafael@gmail.com; marcelolanger@ufpr.br; dimas.agostinho.silva@gmail.com; renatorobert@ufpr.br)

O Brasil possui uma vasta área de plantios florestais, boa parte encontra-se em regiões montanhosas. Nestas regiões de relevo mais acidentado, a mecanização completa da colheita é imprópria. Para estas condições de relevo, o conjunto trator agrícola com guincho arrastador figura como uma alternativa de extração de madeira. O objetivo deste trabalho foi comparar o tempo de ciclo operacional, custo de produção, produtividade e rendimento energético de dois modais de operação na extração de árvores em uma região montanhosa. O estudo foi desenvolvido no Vale do Ribeira, região montanhosa do Paraná em um plantio florestal de Pinus, onde foram analisados os modais, tradicional com um tratorista e um operador de cabo e o modal alternativo com um tratorista e dois operadores de cabo. A metodologia empregada para cálculos de impactos foi a Avaliação do Ciclo de Vida de Produtos, tendo como unidade funcional a quantidade de CO₂eq. emitidas para transportar 1 m³ de madeira em 100 metros de arraste. Os modelos foram ajustados para cada modal e comparados por teste de identidade desses modelos para verificar diferença estatística significativa. Os resultados apontaram para uma melhora de 22,24 % no tempo de ciclo, 14,95% na produtividade e 4,94% no custo de produção e 22,24% no rendimento energético quando se trabalha com o modal alternativo em uma situação com distância de extração de 100 metros. Recomenda-se ainda que outros estudos sobre ergonomia e segurança, além da utilização de dispositivos nos guinchos, sejam desenvolvidos.

Proposed concepts and developments for a forest harvester / Propostas de conceitos e desenvolvimentos voltados a uma colhedora florestal

Rafael Dias^{1,2}, Luis Bernardino¹, Raphael Mialhe¹, José Molin¹, Henrique Scolforo³

¹Universidade de São Paulo, Piracicaba, Brasil; ²Suzano, Limeira, Brasil (rafael.donizetti.dias@usp.br; lgmecanico@hotmail.com; raphael.mialhe@hotmail.com; jpmolin@usp.br; hscoloro@suzano.com.br)

É notável que a indústria florestal busca aumentar a mecanização na colheita de madeira através da inserção de diferentes equipamentos e técnicas, visando sempre à sustentabilidade do negócio florestal, diminuição de custos, aumento da produtividade, melhoria da qualidade da matéria prima e das condições de trabalho e menor impacto ambiental. O objetivo deste trabalho é realizar uma revisão bibliográfica dos desenvolvimentos e pesquisas voltadas a otimização da colhedora florestal e propor possíveis ajustes funcionais dos seus componentes a fim de otimizar quantitativamente e qualitativamente a atividade de colheita

florestal. As propostas de melhorias estão voltadas na otimização e novos desenvolvimentos de sensores, atuadores e proposta de soluções que coletarão dados disponíveis na colhedora possibilitando melhorias no processo. Dentre os desenvolvimentos propostos, destacam-se os novos conceitos de mapeamento de produtividade, o emprego de sensores e atuadores capazes de mensurar fatores de qualidade de uma colheita, a análise preditiva de máquinas a partir de dados de telemetria e a colheita autônoma.

C4a: ADVANCEMENTS IN DIGITAL TECHNOLOGIES FOR DENDROMETRY AND QUALITATIVE INDICATORS OF FORESTS

Augmentation of forest inventory measurements using under-canopy photogrammetry

Demetrios Gatzolis¹

¹USDA Forest Service, Portland, Oregon, USA (dgatzolis@fs.fed.us)

The management of forest resources aiming at addressing diverse challenges while serving the needs of the people requires detailed and frequently updated information on their distribution, status, and trends. Timber-oriented national forest inventories do not always meet these requirements because many measurements on parameters of interest are deemed too costly or difficult to obtain using traditional techniques. Developments in under-canopy photogrammetry, an emerging, computer vision-based technology have the potential to complement inventory surveys. Based on series of images acquired with inexpensive, hand-held cameras, a three-dimensional representation of near-ground vegetation organized as a colored point cloud is obtained. The point density is typically so high that rendered trees or shrubs can be precisely mapped and measured. The survey thus becomes a snapshot in time that can be explored immediately or in the future, if alternative information is needed. Surveys can establish resource baselines for developing countries, support precise estimation of biodiversity, ecological indicators, and local terrain metrics, and where repeated, quantify change in growth rates or occupancy metrics for both trees and understory vegetation. In tests conducted across biomes in the US Pacific Northwest, photogrammetry-derived tree stem diameter measurements at various near-ground heights rivaled in precision those obtained by tape. Under conducive conditions, coarse woody debris volume estimation error was consistently under 2%; elsewhere under 5%. Observed error levels are substantially lower than those obtained using traditional, transect-based field measurements. With camera capabilities continuously improving and prices reducing, under-canopy photogrammetry emerges as an important tool for augmenting forest inventory operations.

Estimation of crown architecture from point clouds

Bogdan Strimbu¹, Rong Fang¹

¹Oregon State University, Corvallis, USA (bogdan.strimbu@oregonstate.edu; rong.fang@oregonstate.edu)

Accurate description of crown architecture is pivotal for understanding physiologic processes and biomass allocation. The most common approach to describe tree crown architecture is by measuring the dimension of trunk and branches, which now can be executed using point clouds. This study compares the accuracy of the measurements executed manually and automatically, by the QSM algorithm, from a terrestrial laser scan of 10 neighboring Douglas-fir trees. The DBH of the sample trees ranged from 49 to 100 cm, and total heights ranged from 38 to 54 m. Diameters along the stem were measured every meter and the branches were measured for insertion angle, diameter at insertion, length, and azimuth. Our results revealed that QSM identified less first-order branches than the manual process. A paired t-test showed that stem diameters are similar for the lower portion of the bole, but QSM supplied significantly smaller values for the upper part. The branch length measured manually was 0.3, and 0.26 m, larger than QSM measurements by insertion height and aspect, respectively. However, the branch diameters were not different between measurements types. Nevertheless the branch insertion angle was 9°, and 10°, larger for manually measurements, by insertion height and aspect, respectively. Our results shows that automatic measurements using QSM for Douglas-fir are reliable for the lower portion of the stem, which is consistent with other studies. However, for heights ≥ 10 m QSM does not provides trustworthy values. The main issue of QSM measurements for Douglas -fir is the significant omission errors in branch identification.

ForeStereo: a cost-effective approach for proximal-sensing field measurement

Forest inventories play a key role as a cost-efficient way to assess forest structure and to monitor forest dynamics. Remote sensing techniques, especially LiDAR, are increasingly used to retrieve some stand features, but ground-based data are still required for area based modelling. New technologies such as Terrestrial Laser Scanner enable data acquisition from ground plots to reconstruct detailed forest structure. However their limited efficiency in field surveys, the lack of standardized methods for estimation of common forest variables and the costly processing of big amounts of data have prevent their use in operational forest planning. ForeStereo, a passive optical sensor based on stereoscopic hemispherical images and developed by INIA-CIFOR, has demonstrated to be an advantageous system for obtaining ground-based information of forest structure. ForeStereo focus on single-scan plots, which simplify and reduce significantly field inventory costs. ForeStereo provides estimates of individual tree variables (DBH, height, volume and crown dimensions) and stand level variables (Leaf Area Index, number of trees, basal area, and volume, which can be summarized for each plot and by species and DBH class). Additionally, the 3D reference of the matched points allows stand structure characterization. These methods have been implemented in dedicated software to attain a cost-effective tool for forest inventories. We present the methodology and critical points of ForeStereo data processing, from the automated image segmentation and matching, to the methods dealing with instrument bias and tree occlusions linked to the single-point surveying. Examples in natural forests and plantations in Spain, Brazil and Chile are shown.

DendroCloud: free terrestrial-based point cloud processing software for forestry

Martin Mokros¹, Milan Koreň²

¹Czech University of Life Sciences Prague, Prague, Czech Republic; ²Technical University in Zvolen, Zvolen, Slovakia (mokros@fld.czu.cz; koren@tuzvo.sk)

The DendroCloud is a free software developed at the Technical University in Zvolen, Slovakia (<http://gis.tuzvo.sk/dendrocloud/> [<http://gis.tuzvo.sk/dendrocloud/>]). The software provides tools for estimation of tree parameters from terrestrial-based point clouds. Point clouds from terrestrial laser scanning

[1] and close-range photogrammetry [2] can be processed in DendroCloud. The main DendroCloud's features include DEM and DSM extraction, point cloud filtering, point cloud segmentation, tree identification, and estimation of tree parameters. The first step for tree diameter and height estimation is a DEM extraction. Then horizontal cross-sections at 1,3 m above the DEM are extracted from the input point cloud. Cross-sections are spatially clustered. The clusters represent cross-sections of individual trees. Clusters can be visually validated and edited before further processing. Positions and diameters of trees can be calculated by several methods [1]. Tree base and tree tip are estimated on the base of point cloud analysis at a tree position. Tree height can be calculated from canopy height model or from tree base and tree tip estimation. Multi-cross sections of trees can be extracted and diameters of trunks at different heights can be calculated. The DendroCloud performance will be presented by two case studies [1-2]; 1. Koreň, M., et. al. (2017). Accuracy of tree diameter estimation from terrestrial laser scanning by circle-fitting methods. *International Journal of Applied Earth Observation and Geoinformation*, 63, 122-128. 2. Mokroš, M., et. al. (2018). Evaluation of close-range photogrammetry image collection methods for estimating tree diameters. *ISPRS International Journal of Geo-Information*, 7(3), 93.

3P sampling with a 360-degree spherical camera

Yung-Han Hsu¹, HaoZhou Wang¹, Ting-Ru Yang¹, John Kershaw¹

¹University of New Brunswick, Fredericton, Canada (yhsu@unb.ca; hwang21@unb.ca; b00605080@gmail.com; kershaw@unb.ca)

An efficient sampling design is required to cost effectively estimate forest conditions. Since the most efficient sampling design is the one with selection probabilities proportional to the parameter of interest (Basu 1969, *Ind J Stats* 31:441), sampling with probability proportion to prediction (3P sampling) is potentially one of the most efficient sampling designs. To obtain the "prediction" for each sample point consistently and rapidly, remote sensing techniques, such as spherical cameras and airborne light detection and ranging (LiDAR) could be used to assist. In this study, plant fraction (PF), the proportion of area covered by vegetation, is estimated using a Ricoh 360° spherical photo and is used as our prediction in 3P sampling. At each sample point a spherical photo is obtained near breast height (1.3m), downloaded to a smartphone, and a custom app is used to derive PF. PF is compared to a random number drawn from a design-specific range to determine if detailed measurements are collected at the sample point. The plant fraction is converted to volume using ratio estimation. Results of the accuracy of the volume estimates and sample efficiencies were evaluated and compared with results using raw LiDAR metrics (quantile 45th LiDAR height, Q45) and LiDAR-derived volume estimates as predictors. Although Q45 was the most efficient covariate at the prediction phase, plant fraction performs as well as LiDAR-derived volume. Since a Ricoh 360° spherical camera is relatively inexpensive, it has the potential to be an alternative selection criterion in areas without LiDAR scanning.

Use of consumer 360-degree cameras to capture hemispherical photos for canopy structure analysis.

Alexander Bilyk¹, Reino Pulkki¹, Guy LaRocque², Chander Shahi¹

¹Lakehead University, Thunder Bay, Canada; ²Canadian Forest Service, Quebec City, Canada (ambilyk@lakeheadu.ca; rpulkki@lakeheadu.ca; guy.larocque@canada.ca; cshahi@lakeheadu.ca)

While the use of hemispherical photos has been studied extensively, it is still challenging to capture images suitable for analysis. The systems used currently rely on a full size, digital SLR camera, gyro and fisheye lens. This presents challenges for use in the field, as the equipment is heavy and can be quite expensive. In this study we compared the use of the Ricoh Theta to the GoPro Fusion for the ability to capture under canopy 360-degree images for processing in gap light analyzer and WinSCANOPY. The images were captured across a variety of forest conditions, but all plots are part of the provincial forest plot network and have been extensively measured. A total of 50 plots were measured and the results are presented here. The cameras chosen represent a range in consumer 360-degree cameras, with the Ricoh Theta being more affordable and the GoPro fusion being at the higher end of the spectrum. The total data management workflow as well as the results from Gap Light Analyzer and WinSCANOPY will be presented.

Remote tree diameter measurement through digital dendrometers

José Scolforo¹, Samuel Campos¹, Ivonise Andrade², Arthur Neto¹, Danilo Lima¹, Sérgio Teixeira¹, Thiza Altoé¹, Vitor Ferreira¹, Pedro Bouzon¹, Leandro Silva¹, Rafael Ribeiro¹

¹Federal University of Lavras, Lavras, Brasil; ²Inventar GMB, Lavras, Brasil; ¹Universidade Federal de Lavras, Lavras, Brasil (hscolfo@ncsu.edu; samuelcampos@lemaf.ufla.br; ivonise@inventargmb.com.br; arthur.miranda.neto@gmail.com; danilo.delima@deg.ufla.br; sergio.teixeira@deg.ufla.br; thizafaltoe@gmail.com; vhg_ferreira@hotmail.com; peubouzon@gmail.com; leandrobsilva@gmail.com; rafa.ribeiro.bq@hotmail.com)

Accurate information on the present and future forest stock is desired. There are well developed sensors to measure forest surface through airborne laser scanning as well as to measure tree volume and stem form through terrestrial laser scanning. Although the use of these technologies has been increasing in forestry, there is still lack of tools to continuously measure tree and forest growth. To overcome this drawback, we offer a newly developed sensor that allows for real time forest monitoring. The sensor measures tree diameter in a daily basis or even in a shorter time step as well as it has the capability to record climate data, such as temperature and throughfall. We will demonstrate the sensor properties and a set of measurements under a variety of forest conditions and types for over 3 month-period.

C4b: ADVANCES IN REMOTE SENSING OF VEGETATION: SENSORS, METHODOLOGIES AND APPLICATIONS

ALOS-2 PALSAR-2 L-band cross-polarized data analysis for the assessment of carbon sequestration of Tropical Rainforest, Berkelah, Malaysia

Robert Masole¹, Yousif Hussin¹, Henk Kloosterman¹, Zulkiflee Abd Latif

¹ITC, University of Twente, Enschede, Netherlands; ²Universiti Teknologi MARA (UiTM), Shah Alam, Malaysia (robertnag@yahoo.com; y.a.hussin@utwente.nl; e.h.kloosterman@utwente.nl; zabdlatif@gmail.com)

In this thesis research, we examined the application of L-band ALOS-2 PALSAR-2 SAR data to model the Above Ground Biomass AGB/carbon stock and carbon sequestration of the tropical rainforest. The SAR parameters were evaluated on the basis of the single SAR backscatter image and time series analysis

of combined HV and HH polarizations. Also, the saturation effect of radar backscatter for AGB estimation was established by determining the saturation level at which AGB prediction tend to level off. The satellite SAR data used for this study were representing a time series of SAR images acquired in two dates: September 2016 and September 2017 by the ALOS-2 PALSAR-2 sensor. A relationship between forest AGB and L-band SAR backscatter were established using the linear, logarithmic, and multiple regression approaches. For a single scene, the best results were observed with HV-polarized backscatter ($R^2 \approx 0.82$, $RMSE \approx 79\text{tons ha}^{-1}$) and ($R^2 \approx 0.87$, $RMSE \approx 68\text{tons ha}^{-1}$) using logarithmic regression for scenes acquired in September - 2016 and September - 2017 conditions respectively. SAR backscatter saturation was estimated at 270tons ha^{-1} , the point at which SAR backscatter response to AGB started to decrease by 0.02dB. The stronger achievement was observed in the estimation of the amount of carbon sequestration between September 2016 to September 2017. An estimated total of 3.62tons/ha of carbon was sequestered in Berkelah forest in one year. This study proved that combining temporal series of SAR scenes could be a better estimator of carbon sequestration.

High-resolution oil palm detection across South-East Asia

Olha Danylo¹, Johannes Pirker¹, Guido Lemoine³, Guido Ceccerini³, Linda See¹, Inian Moorthy¹, Neha Joshi¹, Ian McCallum¹, Florian Kraxner¹, Steffen Fritz¹

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²KU Leuven, Catholic University of Leuven, Leuven, Belgium; ³European Commission, Joint Research Centre, Ispra, Italy (*danylo@iiasa.ac.at; pirker@iiasa.ac.at; guido.lemoine@ec.europa.eu; guido.ceccerini@ec.europa.eu; see@iiasa.ac.at; moorthy@iiasa.ac.at; joshin@iiasa.ac.at; mccallum@iiasa.ac.at; kraxner@iiasa.ac.at; fritz@iiasa.ac.at*)

Palm oil production has increased substantially over the last decade, from 10 to 21 Million hectares between 2000 and 2017, almost 90% of which is located in South-East Asia. Several studies have applied remote sensing techniques to estimate the extent of oil palm plantations in South-East Asia on a national scale or above. Most have deployed visual, expert-based interpretation methods or semi-automatic approaches with extensive field information. These approaches are very labor intensive, thereby limiting their utility for upscaling towards the development of a close to near real-time monitoring system. The availability of radar imagery has given rise to a new generation of remote sensing studies that benefit from robustness to cloud coverage and high revisiting frequency. Recent experimental studies have demonstrated the usability of free and open data from the Sentinel 1 mission for oil palm detection, particularly for detecting smallholder plantations and features such as plantation age. Against this backdrop, we present the first fully-automated remotely sensed oil palm map of South-East Asia based on free and open radar data processed using Google Earth Engine. Furthermore, using very high resolution imagery for independent validation, we will demonstrate the accuracy of our product and compare it to other existing remote sensing products. This new radar-based approach could be used to develop a close to near real-time oil palm monitoring system at a national scale or above, thereby bridging the gap between detection of land cover and land use.

Applicability of SAR Sentinel-1 data to distinguish drivers of deforestation in the Amazon

Andrea Puzzi Nicolau^{1,2}, Africa Flores-Anderson^{1,2}, Robert Griffin^{1,2}, Kelsey Herndon^{1,2}

¹University of Alabama in Huntsville, Huntsville, USA; ²NASA-SERVIR SCO, Huntsville, USA (*an0052@uah.edu; africaixmucane.florescordova@nasa.gov; robert.griffin@nssc.uah.edu; kelsey.e.herndon@nasa.gov*)

The Amazon is the largest expanse of tropical rainforest globally and deforestation resulting from land use changes poses a major concern for sustainable resource management. Synthetic Aperture Radar (SAR) data have all-weather and all-day capability, and thus are well-suited for mapping land cover and land use (LCLU) in tropical regions, which are seasonally influenced by cloud cover. Understanding drivers of deforestation is fundamental for the development of policies and measures to reduce emissions and for developing forest reference levels. Sentinel-1 data present unprecedented potential since the observations are free and openly available, providing for the first time dense and regular SAR data. This study analyzes the applicability of Sentinel-1 data to differentiate deforestation drivers, identified as a current need for early-warning deforestation systems. The study area covers a deforestation frontier in the Amazon where the landscape is characterized by a mosaic of LCLU. Collect Earth Online is used for reference LCLU data collection, and five classes are defined for this study: Forest, Secondary Vegetation, Agriculture, Pasture, Urban/Artificial, Mining, Water. Amplitude gamma-0 time-series spanning 2017-2019 are analyzed along with statistical metrics for each class, and a classification decision tree is developed in a cloud-based platform. Preliminary results show that water and artificial areas are easily distinguishable from other classes. The use of the polarization ratio VV/VH is suggested to be useful to distinguish agriculture from pasture. It is expected that these analysis' results will complement the current forest and land cover monitoring systems by providing additional actionable information for decision-making.

Forest growth dynamics of managed forests in the Southwestern Brazilian Amazon

Marcus d'Oliveira¹, Luis Oliveira¹, Mario Acuña²

¹Embrapa Acre, Rio Branco, Brasil; ²IFAC, Rio Branco, Brasil (*marcus.oliveira@embrapa.br; luis.oliveira@embrapa.br; mhacuna@gmail.com*)

The objective of this work was to present the growth forest dynamics results obtained in two sites located in Acre and Amazonas states in the southwestern Brazilian Amazon. Both areas were submitted to selective logging following RIL technics. The harvesting intensity was low (around $10\text{ m}^3\text{ ha}^{-1}$) and the cycles length varied from 20 to 25 years. The results showed individual trees growth rates (annual mean DBH increment) similar to the observed in other studied managed forest sites with low species composition and none timber specific weight variation along the monitoring time. Annual ingrowth and mortality rates were always high and, as a consequence, turnover rates (estimated as the necessary time to observe the mortality of half of the original population) very fast. The peaks observed in the mortality rates were not always associated with forest logging and shall compromise the biomass and commercial timber stocks recovery on the prescribed cycle. Several studies on forest dynamics indicate that turnover rates are accelerating since the 50' and that this acceleration increased during the 80' in pantropical forests. The values we found for turnover in the studied sites (below 30 years) indicate a still greater turnover acceleration in the first decade of the 21st century in the region. These results indicate that forest management alone can not entirely explain the observed changes in the forest dynamics parameters and special care must be taken to the management and conservation of these forests.

The potential of both SAR and optical data for mapping purposes in Southern Brazil

Aline Delfino Germano^{1,2}, Veraldo Liesenberg², João Vitor Frigeri², Mariane Moura Andrade², Marcos Benedito Schimalski²

¹Universidade Federal de São Carlos, Sorocaba, Brasil; ²Universidade do Estado de Santa Catarina, Lages, Brasil (germanoad@outlook.com.br; veraldo.liesenberg@udesc.br; joaovfrigeri@hotmail.com; enairamma@hotmail.com; marcos.schimalski@udesc.br)

The study aimed at evaluating the performance of optical (Landsat-5/TM) and full polarimetric SAR data (ALOS/PALSAR), alone and combined, for mapping purposes of a rural area in Southern Brazil. A total of 13 classification scenarios using both Support Vector Machine (SVM) and Random Forest (RF) were used. Results showed that the maximum Kappa index from the SAR dataset alone was 86%; on the other hand, the value for optical sensor alone was 95%. The integration of the two sensors achieved 97%, showing that the combination of optical data with SAR data improves the supervised classification. Both RF and SVM methods have similarities in Kappa indexes for different scenarios. Z-test showed significance at five scenarios, including the combination of both optical and SAR data. Therefore, SAR data are recommended for mapping purposes at places that confer difficulty in obtaining images from optical sensors free of clouds. Sponsored by FAPESC, CNPq, CAPES.

The importance of multifrequency SAR on successional forest stage mapping procedures

Veraldo Liesenberg¹

¹Universidade do Estado de Santa Catarina, Lages, Brasil (veraldo.liesenberg@udesc.br)

Multi-frequency SAR scenes were evaluated for classification of successional forest stages and land use classes in Eastern Amazon. Advanced Land-Observing Satellite (ALOS) Phased Array L-band Synthetic Aperture Radar (PALSAR) data, RADARSAT-2 (C-Band), and TERRASAR-X (X-Band) data were used independently and combined in a dual SAR system approach. ALI/EO-1 image acquired at the same period was used as additional ground reference and input dataset. We evaluated backscattering intensity, polarimetric features, interferometric coherence and texture parameters for classification purposes using random forest (RF) classification. Results showed that L-band data alone performed better than C- and X- bands alone but overall accuracies remain low. The combination of two SAR datasets showed similarity at the 5% significance level when considering L-band with either C- or X- band. We show that in absence of optical data, polarimetric features and texture extracted at any frequency increase classification accuracies when compared to backscattering data alone.

Evaluation of digital elevation models for drainage network extraction in a tropical forest area in Central Amazon

Raildo Torquato Souza¹, Veraldo Liesenberg², Tiago Nunes Silva¹, Louri Klemann Junior¹, Luís Antônio de Araújo Pinto¹, Ítala Lorena de Lima Ferreira¹, Marcos Benedito Schimalski², Emanuel Arnoni Costa²

¹Universidade do Estado do Amazonas, Itacoatiara, Brasil; ²Universidade do Estado de Santa Catarina, Lages, Brasil (torquatto.92@gmail.com; veraldo.liesenberg@udesc.br; tgnunesfal@gmail.com; klemannjr@yahoo.com.br; lpinto@uea.edu.br; lorena.uea@hotmail.com; marcos.schimalski@udesc.br; emanuelarnonicost@hotmail.com)

This study aims to compare the drainage network elaborated through fieldwork and GPS measurements with those extracted from four freely available DEMs such as ALOS/PALSAR (Advanced Land Observing Satellite / Phased Array type L-band Synthetic Aperture Radar), ASTER/GDEM (Advanced Spaceborne Thermal Emission and Reflection Radiometer / Global Digital Elevation Map), SRTM (Shuttle Radar Topography Mission) and TOPODATA (Brazilian Full Coverage Refinement of SRTM Data). First, the drainage vector was vectorized manually taking into account trees whose diameter at the breast height (DBH) was ≥ 40 cm, which were identified in the field as permanent presentation areas (PPAs). In addition, a drainage contribution area ranging from 10 to 150 was applied for each of the aforementioned DEM data sources. Afterward, comparisons between each generated drainage network with the ground reference was compared to each other using the Kappa index and Z-test (Global Accuracy). Results showed that the drainage network generated from the four DEM performed well in shape but had overestimation in total length. However, the drainage network extracted from both the SRTM and ASTER were the most similar to those obtained from the field network (9.65 km). They had 13.56 km and 12.97 km, respectively. Statistically, the DEMs showed an overall accuracy higher than 94%. It is recommended to evaluate other environmental conditions as well as high spatial resolution DEMs generated by airborne LiDAR data.

C4c: BENCHMARKING IN FORESTRY – CHALLENGES AND SOLUTIONS FOR ESTABLISHING BENCHMARKING SYSTEMS

Benchmarking of forest operations productivity and costs in industrial forest plantations in Uruguay

Alejandro Olivera Farias¹, Pablo Santini², Carlos Perdomo¹, Mauricio Gervaz²

¹Centro Universitario de Tacuarembó - Universidad de la República, Tacuarembó, Uruguay; ²MBOPU Servicios Forestales, Paysandu, Uruguay (alejandro.olivera@cut.edu.uy; pablo.santini.consult@gmail.com; cperdomo@fagro.edu.uy; mauricio.gervaz@gmail.com)

Industrial forests plantations in Uruguay have increased rapidly in the last decades, from less than 100,000 hectares in 1990 to 1,100,000 in 2015. To accomplish this, forest service providers were developed, first for Silviculture, and later for harvesting operations. The production of more than 16 million m³ of round wood annually is export oriented; the majority of the production is pulpwood for local industries that export Celulose. Forest operation costs account for up to 80% of wood production costs. Comparing costs internationally is crucial for Uruguayan forest companies, because, to remain competitive companies need to improve continuously its operations, increase productivity, improve quality and reduce costs. Likewise, it is important to benchmark costs and productivity indicators locally as a tool to compare contractors' costs and productivity. Moreover, for contractors a benchmarking would be a tool to evaluate their costs and productivity to remain competitive within the local market, identify improvement opportunities, and develop improvement strategies. Furthermore, a benchmark managed by an independent organization (university) would give support for forest practitioners to cooperate in improving the sector competitiveness. The project aims to establish a benchmarking in Uruguay –updated annually— collecting data from companies and contractors on productivity and costs for a list of forest operations (Silviculture and harvesting) identifying the conditions of each operation. The data will be collected annually between January and March via an anonymous online questionnaire, and a report with the results will be released in April. The results may be used for international benchmarking.

Benchmarking in Austrian forestry - supporting management by means of Forest Accountancy Data Networks

Philipp Toscani¹, Walter Sekot¹

¹University of Natural Resources and Life Sciences, Vienna; Institute of Agricultural and Forestry Economics, Vienna, Austria (philipp.toscani@boku.ac.at; walter.sekot@boku.ac.at)

A Forest Accountancy Data Network (FAN) is a special infrastructure for the systematic and continuous collecting of socio-economic information of forest enterprises. Austria has a long tradition in operating FANs, dating back to the 1960ies. There is one network addressing larger holdings and one focusing on small-scale farm forestry. Although an FAN is usually established for policy purposes, the collected data is also of great scientific interest. Furthermore, the standardized accounting scheme proved to be a most suitable basis for ratio analysis and interfirm comparisons. Starting from a sampling design, the expansion of the network of bigger forest enterprises has in fact been driven by the interest of forest owners and managers to participate and several benchmarking circles have been established in terms of a bottom-up approach. The individual reports have been adopted repeatedly to the requests of such 'pressure groups' and the set of ratios has been amended accordingly, thereby improving also the scientific significance of the database. Thus, this specific FAN turned into a transdisciplinary exercise. The latest developments in the FAN of farm forests were inspired by these experiences. A top-down initiative has been launched in order to enhance the significance of the results for the management of the participating farms. The individual reports were considerably improved and additional information for benchmarking is provided. The framework may well serve as a blueprint for related activities e.g. on behalf of extension services.

The German forest accountancy data network - concept, application and harmonization to other networks

Matthias Dieter¹, Lydia Rosenkranz¹, Hermann Englert¹, Walter Sekot², Philipp Toscani², Bernhard Pauli³, Patric Bürgi³, Nils Ermisch⁴, Bernhard Möhring⁵
¹Thünen Institute of International Forestry and Forest Economics, Hamburg, Germany; ²Institute of Agricultural and Forestry Economics, Vienna, Austria; ³Bern University of Applied Sciences, Zollikofen, Switzerland; ⁴Landwirtschaftskammer Niedersachsen, Neuenkirchen, Germany; ⁵Georg-August Universität Göttingen Abteilung Forstökonomie, Göttingen, Germany (matthias.dieter@thuenen.de; lydia.rosenkranz@thuenen.de; hermann.englert@thuenen.de; walter.sekot@boku.ac.at; philipp.toscani@boku.ac.at; bernhard.pauli@bfh.ch; patric.buergi@bfh.ch; nils.ermisch@lwk-niedersachsen.de; bmoehri@gwdg.de)

The German Forest Accountancy Data Network (FADN) of the Federal Ministry of Food and Agriculture (BMEL) was established over 40 years ago. It comprises roughly 350 private, communal and state forest enterprises with a forest area above 200 ha and is based on a uniform product plan of the booking system, developed by the German Forestry Council (DFWR). Its participating forest enterprises provide about 650 natural and economic key figures every year. The FADN provides invaluable data on the economic situation of forest enterprises and is therefore an important data base for the analysis of numerous forest policy issues like the financial burdens from nature protection measures in forests, as well as for Germany's reporting obligations like the European Forest Accounts or the National Accounting. Austria and Switzerland have comparable accountancy schemes in place, though they do not yet allow a direct comparison of key-figures across countries. Hence, in 2004 a data network cooperation of Germany, Austria and Switzerland was launched, the so called DACH-initiative, with the aim of harmonizing forest accountancy data across borders and comparatively analyse the economic situation of middle-European forestry. This presentation aims to show the concept, the range of uses and challenges of the German FADN. Moreover the establishment of the DACH-data network will be outlined with some results of the data harmonization and finally some considerations of the use of the DACH-network as a blueprint for a worldwide network on forest accountancy data will be presented.

Possible explaining variables for the share of fully mechanized cut-to-length harvesting globally

Mikael Lundbäck¹, Carola Häggström¹, Tomas Nordfjell¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden (mikael.lundback@slu.se; carola.haggstrom@slu.se; tomas.nordfjell@slu.se)

Within an earlier part of this study, data on the share of fully mechanized cut-to-length (CTL) harvesting method of the annual harvested volume of industrial roundwood was obtained for 29 countries. To quantify the effect of some possible explaining variables a linear regression analysis based on ordinary least squares parameter estimation was done. For this the open source statistical software R (version 3.5.1) was used. The data for the studied variables was gathered based on hypothetical cause-effect relations with CTL. Initially 11 possible variables were compiled, out of these, 8 variables were included in the regression analysis, the others did not have data for all countries, however the final model include only three variables – diesel price, share of steep slope and gross domestic product per capita (GDP). All three variables as well as the full model have significant p-values at the 5 % level and an adjusted R² value of 0.57. There are several imaginable variables that might improve the model but for which data does not exist currently, for example average tree volume. The model can be used for two purposes, first to predict the share of CTL in a country, compare the result of the model to what is known and try explaining the difference – no obvious explanation might imply market opportunities for manufacturers of CTL equipment. Second, the model explains the relations between some surrounding variables, and the share of CTL – higher diesel price and GDP favor CTL while higher share of steep slope does the opposite.

Benchmarking harvesting systems costs in industrial forest plantations across different global regions

Fulvio Di Fulvio¹, Mauricio Acuna², Pierre Ackerman³, Dalia Abbas⁴, Raffaele Spinelli⁵, Alejandro Olivera⁶, Sandra Sanchez⁷, Nopparat Kaakkurivaara⁸
¹IIASA, Laxenburg, Austria; ²University of the Sunshine Coast, Sippy Downs, Australia; ³Stellenbosch University, Stellenbosch, South Africa; ⁴American University, Washington DC, USA; ⁵CNR, IVALSÀ, Sesto Fiorentino, Italy; ⁶Universidad de la República de (difulvi@iiasa.ac.at; macuna@usc.edu.au; packer@sun.ac.za; daliaabbas@yahoo.com; spinelli@ivalsa.cnr.it; alejandro.olivera@cut.edu.uy; ssanchez@cetemas.es; nopparat.manavakun@gmail.com)

In the global market, there is an increasing demand for wood products, which represents a challenge for the efficient supply of woody biomass resources and the protection of natural forest ecosystems. Within this context, industrial forest plantations, already account for one-third of the global roundwood supply, and they are expected to significantly increase their contribution in the future, due also to the rapidly increasing demand for bioenergy. Harvesting operations represent up to fifty percent of the total biomass supply cost from industrial forest plantations. Therefore, the future competitiveness of woody biomass supply from plantations in different global regions will depend on improving the financial performances of harvesting systems. Modeling the future competitiveness of woody biomass supply requires a better understanding of the adaptations of harvesting systems to plantation modules in different geographical regions and to their own unique economic situations, as well as understanding the factors explaining efficiencies and costs in the different regions. Accordingly, this study aims to compile and benchmark the many case studies appeared in the recent literature in order to summarize, describe and examine the major drivers affecting the efficiencies and costs of different harvesting systems used in industrial forest plantations across the globe. The knowledge gathered in this study will provide the opportunity for improved modeling of wood supply systems which in turn will provide useful insights to practitioners for designing future cost effective systems tailored to the needs of different regions of the World.

Characterization and comparison of forest productivity across countries and forest types

Jianbang Gan¹, JinHan Park¹

¹Texas A&M University, College Station, USA (j-gan@tamu.edu; cupidjh@gmail.com)

Forest productivity is fundamental to the provisions of timber and ecosystem services. It varies with or is influenced by natural and human factors including climatic and soil conditions, disturbances (e.g., diseases, pest infestations, wildfire, storms, etc.), silvicultural practices, and forest age and structure, among others. We identify and characterize global forest productivity patterns and compare forest productivity in different countries and forest types in the world. We also estimate statistical associations between forest productivity and biophysical and socioeconomic factors. This study sheds new light on differences and similarities in forest productivity across countries and forest types and the reasons behind them. Our results also provide a benchmark of global forest productivity and are of value for improving global forest productivity and sustainability.

Global timber investments, 2017

Frederick Cabbage¹, Rafael Rubilar¹, Bruno Kanieski¹

¹Department of Forestry and Environmental Resources, NC State University, Raleigh, NC, USA (fredcabbage@yahoo.com; rafaelrubilar@udec.cl; bkanies2@ncsu.edu)

We estimated timber investment returns for 22 countries and 54 species/management regimes in 2017, for a range of global timber plantation species and countries at the stand level, using capital budgeting criteria, without land costs, at a real discount rate of 8%. Returns were estimated for most years for the principal plantation countries in the Americas—Brazil, Argentina, Uruguay, Chile, Colombia, Venezuela, Paraguay, Mexico, and the United States—as well as New Zealand, Australia, China, Vietnam, Laos, Spain, Finland, and Poland. South American plantation growth rates and their concomitant returns were generally greater, at more than 12% IRRs, as were those in China and Vietnam. These rates of return followed by returns to plantations in southern hemisphere countries of Australia and New Zealand and in Mexico, with IRRs around 8%. Temperate forest plantations in the U.S. and Europe returned less, from 4% to 8%, but those countries had better risk ratings, timber markets, and infrastructure. Returns to most planted species and countries have decreased from 2005 to 2017.

SilviBenchmark: Benchmarking forest production data based on “typical enterprises”

Lydia Rosenkranz¹, Bjoern Seintsch¹, Sven Günter¹, Walter Sekot², Philipp Toscani², Bernhard Pauli³, Patric Buerger³, Fulvio Di Fulvio⁴, Yelto Zimmer⁵

¹Thuenen Institute of International Forestry and Forest Economics, Hamburg, Germany; ²BOKU, Institute of Agricultural and Forestry Economics, Vienna, Austria; ³Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences, Zollikofen, Switzerland; ⁴ILASA International Institute of Applied Systems Analysis, Laxenburg, Austria; ⁵Global Networks GUG, Braunschweig, Germany (lydia.rosenkranz@thuenen.de; bjoern.seintsch@thuenen.de; sven.guenter@thuenen.de; walter.sekot@boku.ac.at; philipp.toscani@boku.ac.at; bernhard.pauli@bfh.ch; patric.buerger@bfh.ch; difulvi@iiasa.ac.at; yelto.zimmer@agribenchmark.net)

The forest industry faces the challenges of globalization, e.g. rising demands for timber and price competitions of raw wood production. Also, increasing demands for forest ecosystem services can be leading to restrictions for forest production. The cost-effectiveness of forestry around the world is influenced by the respective regulatory policy frameworks, the choice of forest management type and the choice of harvesting and timber-transport system which lead to diverse factor costs or revenues for forest production. In a globalized world, in-depth knowledge of the different country-specific framework conditions, the resulting operations and management strategies of forestry and logging and finally the economics of these different systems is of great importance. In order to obtain comparable data across countries, a global network of experts as well as a harmonized approach of data collection for all participating countries is essential. So far, there is a lack of internationally comparable forest production data and no respective forum to develop and discuss concepts and methods for an international forest production database. Against this backdrop, we wish to establish a lasting international network for benchmarking forest production data using the “typical forest enterprise” approach, aiming to provide strategic insights to stakeholders from forestry, logging and timber industry, policy and development agencies. The presentation shall introduce our idea of establishing SilviBenchmark to potential partners from other countries and provide a systematic overview of the concept. Here, the long-term experience with Central European forest accountancy data networks and global agricultural benchmarking networks (agri benchmark) will be incorporated.

C4d: CROWN STRUCTURE AND DYNAMICS AS CAUSE AND EFFECT IN MODELLING TREE GROWTH, FORM, AND WOOD QUALITY

Long-term dynamics of loblolly pine crown structure as affected by planting density and cultural intensity

Dehai Zhao¹, Bronson Bullock¹, Cristian Montes¹

¹University of Georgia, Athens, USA; ¹University of Georgia, Athens, USA (zhaod@uga.edu; bronsonbullock@uga.edu; crmontes@uga.edu)

Loblolly pine (*Pinus taeda* L.) is an important timber species in the southeastern US. A better understanding of loblolly pine crown relationships with growth will help improve productivity estimates and optimize management regimes. Loblolly pine culture/density study was initiated in 1995/96 with 40 installations across the southern US. Each installation contains 12 plots planted at six levels of planting density (740 – 4448 trees/ha) in combination with two levels of cultural intensity (operational vs. intensive). With data from this study, we will report long-term effects of planting density, cultural intensity and site quality on loblolly pine growth and crown attributes. Destructive biomass sampling was also conducted and vertical distribution of foliage biomass were assessed. Lower planting density or more intensive treatment increased average crown length. Crown ratios declined over time, and the decrease rate increased with increasing initial density and cultural intensity. Foliage to branch biomass ratio decreased over time, and was not significantly affected by cultural intensity or planting density. Stem to crown biomass ratio was significantly affected by planting density but not by cultural intensity. More intensive stands or stands on more productive sites raised to a maximum foliage biomass at earlier ages, then flattened. Planting density significantly affected foliage biomass in early development stage, then this effect was no longer significant. However, vertical distribution of foliage biomass was still affected by planting density and cultural intensity.

Consequences of and factors that may affect coordinated growth between the live crown and the stem in populations of trees

Thomas Dean¹

¹Louisiana State University, Baton Rouge, LA, USA (fwdean@lsu.edu)

Foliage expires; consequently, in order to live, trees must continually replace it. In forests, new foliage emerges from buds exposed to sufficient light while shaded buds die, cycling foliage to the top of the trees. Foliage on a branch terminated with a dead bud will eventually die as will the branch, causing the bottom of the crown to lift. The proximity and size of neighboring trees, which can be expressed in terms of stand density, determines the rate in which buds die, and together with height growth sets the length of the live crown. Trees are self-designing structures that manage strain due to water and mechanical stress. As the dimensions of the live crown change due to height growth and increasing stand density, stem cross-sectional area size and taper follows suit in a predictable manner to maintain efficient water conduction to existing and new foliage and to physically support the increasing gravitational and lateral forces created by crown growth. Trees are constrained however in their response by genetic rules governing physiology and by developmental history. For instance, some species cannot respond to disturbances that allow light to impinge on the bottom of a mature stem. The presentation will discuss the coordinated growth that occurs with crown expansion, how silviculture practices affect crown growth and ultimately stem growth, and to what degree biotic and abiotic factors can affect the coordination between crown and stem morphology.

Crown structure and foliage distribution are influenced by site, genotype and planting density but may not explain differences in growth for native and exotic *Pinus taeda*

Timothy Albaugh¹, Chris Maier², Otávio Campoe³, Rachel Cook⁴, Rafael Rubilar⁵, David Carter¹, Thomas Fox⁶

¹Virginia Tech, Blacksburg, USA; ²USDA Forest Service, Research Triangle Park, USA; ³Universidade Federal de Lavras, Lavras, Brasil; ⁴North Carolina State University, Raleigh, USA; ⁵Universidad de Concepcion, Concepcion, Chile; ⁶Rayonier, Yulee, USA (tim_albaugh@vt.edu; cmaier@fs.fed.us; otavio.campoe@gmail.com; rcook@ncsu.edu; rafaelrubilar@udec.cl; davidcarter@vt.edu; tom.fox@rayonier.com)

Pinus taeda L., a native in the southeastern United States, grows considerably faster when planted outside of its native range. Explanations for this phenomenon include differences in crown structure, foliage distribution and specific leaf area (SLA). To examine these factors, we destructively sampled 72 trees where all branch diameters and their distances from the tree top were measured. Foliage mass and SLA were determined for a representative subset. Trees were selected from three sites: North Carolina (NC; native range), Virginia and Brazil (BR; exotic locations). The same two genotypes were planted at 618 and 1853 trees ha⁻¹ across sites under two levels of silviculture (operational and no nutrient limitation). We examined how site, genotype, planting density and resource availability influenced crown structure (branch number, size, and within crown position), foliage distribution and SLA. In general, branch diameter and within crown position were similar among sites, yet significant differences were observed due to all factors for branch number, branch diameter, foliage distribution and SLA. However, the observed differences did not necessarily explain greater growth in BR. For example, in some treatment combinations, BR trees had fewer, smaller diameter branches than trees from the US sites but the BR trees still grew faster. There was more foliage on the BR trees but the distribution of the foliage for the NC and BR sites was similar. Apparently, additional hypotheses need testing to identify the cause of greater growth of *P. taeda* in exotic locations.

Exploring the impact of spacing and silvicultural management on crown structure, light use efficiency and wood production of *Pinus taeda* varieties

Otávio Campoe¹  Timothy Albaugh², Rachel Cook³, Rafael Rubilar⁴, David Carter², Thomas Fox⁵

¹Federal University of Lavras, Lavras, Brasil; ²Virginia Tech, Blacksburg, USA; ³North Carolina State University, Raleigh, USA; ⁴Universidad de Concepción, Concepción, Chile; ⁵Virginia Tech, Blacksburg, USA; ⁶Rayonier, Yulee, USA (otavio.campoe@gmail.com; tim_albaugh@vt.edu; rcook@ncsu.edu; rafaelrubilar@udec.cl; davidcarter@vt.edu; tom.fox@rayonier.com)

Canopy structure and dynamics, a key information to understand wood production in forest plantations, is highly influenced by genetic variability, silvicultural practices, and management. However, precise quantification of their specific impact, and potential interaction, on efficiency of wood production is lacking. To address this topic, we are using a group of three experiments, installed at Virginia-USA, North Carolina-USA, and Paraná-Brazil, six genetic entries of *P. taeda* (four clonal, one open pollinated, and one control mass pollinated), planted at three densities (618, 1235, and 1853 stems ha⁻¹), with two levels of silviculture (operational and intensive). The objective of this study is to assess the effects of these different treatments on tree crown structure, light absorption and light use efficiency for wood production. To calculate light absorption (LA), we use MAESTRA, a process-based model parameterized for each individual tree within the plots. The model considers crown dimensions and leaf area of each tree, and how the neighbouring trees interact for light absorption. Light use efficiency (LUE) of wood production is calculated as the ratio between wood growth and absorbed light. Current results show that intensive silviculture increase crown volume, LA and also LUE. Wider spacings increase light absorption but not LUE. Different crown ideotypes from varieties, affects both LA and LUE. The tree-level approach allows analyses and simulations related to the impact of fertilization on leaf area, different varieties on crown ideotype, competition for light absorption at different spacings and thinning intensities, responses of leaf area reduction by pruning.

Light interception and light use efficiency following thinning and fertilization in intensively managed Douglas-fir stands

Douglas B. Mainwaring¹, Douglas A. Maguire¹, Jacob D. Putney¹

¹Oregon State University, Corvallis, USA (doug.mainwaring@oregonstate.edu; doug.maguire@oregonstate.edu; jacob.putney@oregonstate.edu)

Silviculture of Douglas-fir in western North America has become increasingly intensive, with focus changing from maximizing yield to maximizing return on investment. Accordingly, managers are seeking ever more efficient means of production, with yield gains from silvicultural treatments scrutinized ever more closely under economic criteria. Achievement of greater management precision in Douglas-fir plantations will rely in part on quantification and modeling of mechanisms represented by production, distribution, and photosynthetic efficiency of foliage within individual trees and across the entire stand canopy. Branch and foliage sampling has therefore become increasingly common in operational and experimental stands monitored simultaneously for biomass production and response of foliage spatial distribution and needle age class structure to silvicultural manipulation. In the synthesis described here, foliar N, specific leaf area, and vertical foliage distribution were estimated from multiple studies in intensively managed Douglas-fir plantations. These attributes and conventional tree measurements were used to simulate canopy light absorption, photosynthesis, and water balance with the model MAESPA to test the effects of fertilization and thinning on tree-level PAR absorption and subsequent light use efficiency. Results from MAESPA simulations indicated that non-dominant trees received the greatest benefit from thinning and dominant trees the greatest benefit from fertilization. This response is consistent with empirical tree-level modifiers

representing direct thinning and fertilization effects measured in experimental and operational Douglas-fir plantations. Stands can be prioritized for treatment by characterization of site and stand conditions coupled with mechanistic insights provided by hybrid models of forest production.

Advances in crown and tree growth modelling in the tree and stand simulator (TASS)

Catherine Bealle Statland¹, Ian R. Cameron², James W. Goudie¹

¹British Columbia Ministry of Forests, Lands, Natural Resource Operations and Rural Development, Victoria, Canada; ²Azura Formetrics Ltd., Kamloops, Canada; ¹British Columbia Ministry of Forests, Lands, Natural Resource Operations and Rural Development (catherine.beallestatland@gov.bc.ca; ian.cameron@azura.ca; jimgoudie@shaw.ca)

The Tree and Stand Simulator (TASS) is the primary growth and yield model used to project the growth and value of managed forests in British Columbia, Canada, for timber supply analysis and silviculture decision support. As a complex, individual-tree model that tracks the dynamics of tree crowns in three spatial dimensions, TASS has a flexible structure that can accommodate structurally and compositionally diverse stands. Growth, yield and wood quality predictions dynamically respond to silvicultural manipulations through treatment effects on crowns and their competitive environments. A long history of research into crown and stem morphology supports this functionality, involving detailed destructive analyses of stem, branch and foliage of many sample trees, and construction of sub-models that predict crown profiles, foliage density and biomass, tree bole increment and increment distribution. In-depth study of silvicultural field experiments and permanent sample plots is necessary to both understand the mechanisms of managed stand development and to test and calibrate the simulations. Ongoing experimentation with different degrees of abstraction strives to achieve performance that balances biological fidelity with a level of model complexity appropriate for operational needs. This presentation will briefly review the rationale behind and structure of crown-based modelling in TASS, then focus on the latest research into such things as crown profile representation, new formulations for bole increment and increment distribution models, and individual tree response to fertilization.

Branch longevity in Scots pine: Does latitude matter?

Olav Høibo¹, Geir I Vestøl¹, Douglas Maguire², Urban Bergsten³

¹Faculty of Environmental Sciences and Natural Resource Management, Norwegian University of Life Sciences, Aas, Norway; ²Department of Forest Engineering, Resources and Management, Oregon State University, Corvallis, USA; ³Forest Biomaterials and Technol (olav.hoibo@nmbu.no; geir.vestol@nmbu.no; doug.maguire@oregonstate.edu; urban.bergsten@slu.se)

Crown recession results from mortality of branches near crown base due to low light intensity. Light conditions vary greatly with latitude and stand structure, but simulations have demonstrated that at high latitudes longer crowns are more efficient. Few empirical studies have verified this apparent response to sun angle. We hypothesize that empirical testing of latitudinal effects on crown length will verify this theoretical effect of lower sun angle and more uniform vertical distribution of light intensity on increased branch longevity. Forty-two Scots pine trees were sampled from seven Swedish thinning trials managed by the Swedish University of Agricultural Sciences. Latitude ranged from 59° to 67° north. Branch whorls were sampled from stump height to first living branch. Branch longevity of the 1225 knots in these whorls was analysed with mixed models containing covariates for stand, tree and whorl fixed effects and stand- and tree-level random effects. Latitude had a positive parameter estimate of 1.07, meaning that branch longevity increased by approximately one year per degree northern latitude. Other fixed-effect variables were positively correlated with branch longevity, including relative whorl height, knot diameter and mean annual ring width for ring interval 21 to 39 years at breast height, but the reverse was true of average height increment. Negative interaction effects between relative whorl height and knot diameter and between average height increment and knot diameter complicated interpretation of the results, but supported the hypothesized relationship between sun angle and branch longevity.

Wood and fiber property variation within plantation-grown conifers and its relationship to crown structure and dynamics

Laurence Schimleck¹, Joe Dahlen², Douglas B. Mainwaring¹

¹Oregon State University, Corvallis, USA; ²University of Georgia, Athens, USA (laurence.schimleck@oregonstate.edu; jdahlen@ug.edu; doug.mainwaring@oregonstate.edu)

An understanding of the effect of silvicultural practices on wood property variation within-trees is critical. Wood properties exhibit large variability at multiple scales - within an annual ring, within-tree, among trees in a stand, and across regions (the phenotype) and all are the consequence of a complex interaction of genetic and environmental components. In terms of wood properties within-trees patterns of variation typical of common plantation conifers largely reflect growth trajectories determined by genetics. Environmental (silvicultural) factors cause these general patterns to vary, for example as reflected by changes to earlywood and latewood proportions within rings or the rate of change of properties across multiple rings. For a given species how properties vary will depend on silvicultural decisions regarding a plantation - location, planting density, fertilization and thinning - all influence crown structure and dynamics which ultimately impact the wood property variation observed. In this paper we will describe patterns of wood property variation within common conifer plantation species and explore how crown structure and crown dynamics can cause these patterns to vary

Relationship between leaf area index and yield in commercial plantations of *Eucalyptus pellita* using different measurement methods and fertilizer treatments in the Colombian Orinoco region / Relación entre el índice de área foliar y el rendimiento en plantaciones comerciales de *Eucalyptus pellita* bajo diferentes métodos de medición y tratamientos de fertilización en la Orinoquia Colombiana

Luz Adriana Molina García^{1,2}, Pedro Emilio Martínez Ospina²

¹Pontificia Universidad Javeriana, Bogotá, Colombia; ²Universidad Distrital Francisco Jose de Caldas, Bogotá, Colombia (adrianamoliga7@gmail.com; pemartinezos@gmail.com)

La productividad de plantaciones comerciales está dada por condiciones climáticas y productivas del sitio, las cuales se ven expresadas en el comportamiento de variables fisiológicas. Los múltiples esfuerzos por lograr un aumento de la productividad de las plantaciones muchas veces no resultan exitosos por diversas razones, como la falta de información relacionada al comportamiento fisiológico de las especies, calidad del sitio, entre otros. Por estas razones, se buscó integrar nuevos parámetros con el propósito de generar pautas de diagnóstico del crecimiento de plantaciones forestales relacionada con el indicador ecofisiológico índice de área foliar (IAF) para la especie *Eucalyptus pellita* en la Orinoquia, como un mecanismo de apoyo al modelamiento del crecimiento forestal. Se usaron y compararon tres métodos indirectos de medición del índice de área foliar. El resultado de esta investigación genero un coeficiente de correlación

y comparación entre los métodos de medición empleados y un indicador general de cómo está cambiando el IAF de acuerdo a las diferentes condiciones ambientales y a la fertilización. Se encontró que la altura está en función del IAF y la humedad relativa y que fue significativo integrar a los modelos de regresión lineal variables ambientales como la humedad volumétrica de los suelos y la luz que ingresa bajo el dosel. Mediante el análisis de correlación se mostró que la variable IAF está fuertemente relacionada con variables dasométricas como la altura y el diámetro, y por tanto, con el volumen, siendo este un paso para integrar la variable IAF a los procesos de simulación

Characterization of canopy structure, leaf area index and light interception of *Eucalyptus* clones

Eduardo More de Mattos¹, Dan Binkley², José Luiz Stape³, Otávio Campoe⁴, Clayton Alcarde Alvares⁵

¹Geplanta Tecnologia Florestal, Piracicaba, Brasil; ²Northern Arizona University, Flagstaff, USA; ³Departamento de Ciências Florestais, Universidade de São Paulo, Piracicaba, Brasil; ⁴Universidade Federal de Santa Catarina, Curitiba, Brasil; ⁵Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (eduardo@geplanta.com.br; dan.binkley@alumni.unc.edu; stape@suzano.com.br; otavio.campoe@ufsc.br; calcarde@suzano.com.br)

The production of forests depends on the interception of light for photosynthesis, and light interception depends on the area of leaves and how they are arranged within canopies. This study examined these aspects using 18 *Eucalyptus* clones, covering the most representative species and hybrids planted in Brazil, such as *E. grandis*, *E. urophylla*, *E. benthamii*, *E. dunnii* and others, showing a broad variety of canopy structure, leaf area, crown shape and size. The experimental site is located at 23° 51' 10.8" S, 48° 42' 3.6" W, 685 m above sea level, in Buri-SP, southeast of Brazil, where the plots were planted in December 31st, 2011 at 3 m x 3 m spacing (1111 stems ha⁻¹) following standard management practices. Destructive sampling was conducted in 12 representative clones, along with optical assessment of canopies from 18 to 32 months after planting, during canopy closure period. Leaf area index, or LAI, ranged from 2.9 to 5.9, while optical methods ranged from 1.8 to 4.6. Self-shading of leaves was evident, as optical methods could not fully capture total leaf area, the clumping index varied from 0.5 to 0.9 and were highly correlated with crown surface area and crown volume. Average leaf inclination angle ranged from 32 to 70 degrees, with higher inclination angles genotypes correlated to lower average LAI. These traits reveal the tremendous variability within *Eucalyptus* genera and points to strategies that can be taken to match genotypes to environmental conditions, as well as helping breeding programs.

Carbon fluxes and partitioning of different varieties of *Pinus taeda* with contrasting crown ideotypes

Gerardo Rojas¹, Otávio Campoe^{1,2}, Timothy Albaugh³, Rachel Cook⁴, Rafael Rubilar⁵, David Carter³

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brasil; ²Universidade Federal de Lavras, Lavras, Brasil; ³Virginia Tech, Blacksburg, USA; ⁴North Carolina State University, Raleigh, USA; ⁵Universidad de Concepción, Concepción, Chile (gerardo.forestal03@gmail.com; otavio.campoe@gmail.com; tim_albaugh@vt.edu; rcook@ncsu.edu; rafaelrubilar@udec.cl; davidcarter@vt.edu)

The growth of planted forests can be described in terms of the supply of ecosystem resources where they are established, the proportion of these resources that trees can actually absorb, and the efficiency with which they use the resources to convert CO₂ from the atmosphere into above and belowground biomass. Patterns of carbon fluxes and partitioning to different components can significantly vary among varieties, depending on breeding strategy, history and objectives. To address this issue, we are measuring all the components of the aboveground net primary production (production of stems, leaves and branches) and total belowground carbon fluxes (the sum of root production, respiration and mycorrhizal production), and their partitioning on five different varieties of a 7-year-old of *Pinus taeda* (one open-pollinated, one mass control pollinated and three clones) planted in the south of Brazil. Additionally, leaf area index measurements are performed at peak and off-peak periods during the year. These varieties show contrasting crown ideotypes, from narrow to broad crown, and a consistent variation of leaf area index, leading to significant differences in productivity. Evaluating these patterns will increase our ability to understand how different varieties, with different crown ideotypes invest the absorbed carbon into wood production. The study is under development, and will be completed by July 2019.

C4e: DECISION SUPPORT APPROACHES FOR FORESTRY OF THE 21TH CENTURY

Recent advances in EMDS version 7 enhance decision support for adaptive forest management in the 21st century

Keith Reynolds¹

¹USDA Forest Service Research, Corvallis, USA (kreynolds@fs.fed.us)

The Ecosystem Management Decision Support (EMDS) system is a spatially enabled system for environmental analysis and strategic and tactical planning that was originally released by the Pacific Northwest Research Station in 1997. There have been major advances in system functionality in the past few years, and three new areas of advancement are coming in the next two years. Building on its core functionality of logic processing and multi-criteria decision modeling, which has been available as an ArcMap component since 2002, recent advances in version 7.0 include speed and capacity enhancements to geodatabase processing, release of EMDS as an extension to three open-source geographic information systems, implementation of two new analytical engines for Bayesian reasoning and Prolog-based decision trees, and integration of R, Python, and Java scripting tools to support advanced geoprocessing needs of EMDS developers. In addition, tutorials for all analytical engines are provided online, and demonstrations are now available on an EMDS YouTube channel. New advances coming in the next two years include implementation of a graphical workflow environment for advanced customization, and introduction of a cloud-based collaboration manager that allows teams of resource managers to collaborate synchronously and asynchronously on EMDS applications that have been exported from the desktop environments.

Spatial pattern of climate change effects on Lithuanian forestry

Gintautas Mozgeris¹, Vilis Brukas², Ekaterina Makrickiene¹, Nerijus Pivorius¹, Algirdas Augustaitis¹, Marius Mikalajunas¹, Gintaras Kulbokas¹

¹Vytautas Magnus University, Kaunas, Lithuania; ²Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Alnarp, Sweden (gintautas.mozgeris@vdu.lt; vilis.brukas@slu.se; ekaterina.makrickiene@vdu.lt; npivorius@gmail.com; algirdas.augustaitis@vdu.lt; marius.mikalajunas1990@gmail.com; gintaraskulbokas@gmail.com)

The sensitivity of forests and forestry to climate change is widely reported. In Lithuania, the increase in air temperature, precipitation, nitrogen depositions during the vegetative period and reductions in SO₂ concentrations and sulphur deposition during last 3-4 decades are associated with increased growth intensity of coniferous tree species and neutral reactions of deciduous. This presentation investigates how sensitive is the provision of ecosystem services to forest management, and to what extent may climate change influence the provision. We specified several alternative future scenarios with varying extent of efforts to mitigate the climate change, under differing assumptions for future forest yield, timber demand and price trends. Then we simulated forest resource development

and forest use under conditions of alternative climate mitigation scenarios using decision support system and assuming that current forest management practices are continued. We analysed spatial and temporal patterns of ecosystem service provision at the level of regional branches of State forest enterprise. The main finding is that the increased efforts for climate change mitigation correlate positively with profits from forestry activities. Reduction of biodiversity values is lesser, despite increasing growth intensity. The study was conducted within the frames of H2020 project ALTERFOR and National research program FOREstRESS.

Computer based decision support system for optimization of farm forestry land uses in kenya

Jonah Kiprop¹, Joshua Cheboiwo¹

¹Kenya Forestry Research Institute, Nairobi, Kenya (jonahkipsat@gmail.com; jkchemangare@yahoo.com)

In Kenya primary forest production takes place in four forest categories namely; public plantations, farm forests, community forests and private forests. In the last decades farm and private forests have high registered growth driven largely by high demand for forest products and returns to investment for the sector to leverage on operational efficiency to maximize profits. The sector will remain an important component of the forestry sector in the country in the future. However, the smallholder farm forest sector is faced with many challenges key being inadequate information on management operations, valuation techniques and markets and market specifications that results in low productivity and low quality trees hence low forest incomes. This Project entailed development of a web based decision support system (DSS) to enable individuals/investors make well informed decisions regarding investment in the forestry sector in Kenya. This project was developed by a team from Kenya Forestry Research Institute (KEFRI) and other experts in forestry and ICT. The main features of the interactive DSS are provision of information on forest management and operations (planting, spacing, silvi-cultural operations); Financial analysis-Cost benefit analysis of key forest enterprises (costs, yields, benefits, prices), Forestry land use comparative analysis (alternative forest enterprises, competing agricultural crops), markets and marketing analysis (list of products market, prices, market value chains, marketing efficiency). Users who include smallholder farmers, investors with interest in forestry can interact with the system through a portal and access information necessary for promoting investments and optimization of farm forestry farm uses in Kenya

Claim your seat at the table: adaptive governance toolkit to bring in community voices into catchment and community regeneration

Sandra J. Velarde¹, Tim Barnard¹, Tui Warmenhoven², Pia Pohatu², Lisa Sharma-Wallace³, Peter Edwards⁴, Lania Holt¹, Andrew Dunningham¹, Barbara King⁵, Jeff Coutts⁶

¹Scion, Rotorua, New Zealand; ²He Oranga mo Nga Uri Tuku Iho Trust, Ruatorea, New Zealand; ³Independent, Cincinnati, USA; ⁴Manaaki Whenua, Wellington, New Zealand; ⁵Barbara King Ltd., Taupo, New Zealand; ⁶Coutts J&R, Toowoomba, Australia (sandra.velarde@scionresearch.com; tim.barnard@scionresearch.com; tuiaroaha@gmail.com; pia@uritukuiho.org.nz; lisa.jean.wallace@gmail.com; edwardsp@landcareresearch.co.nz; Flania.holt@scionresearch.com; andrew.dunningham@scionresearch.com; barbkinganz@gmail)

We reflect on lessons learnt from a 3 year action-research programme undertaken in one of the most environmentally degraded and socio-economic deprived areas of New Zealand. In partnership with indigenous researchers and the local community, we designed and tested an adaptive governance toolkit to bring community voices into catchment restoration, where forestry plays a key role in addressing a landscape-scale erosion problem. Adaptive governance approaches are a family of methods that facilitate multi-party dialogue that underpins sharing power and resources. Adaptive governance has been used to address a number of environmental problems around the world. The concept is founded on recognising the complexity of social-ecological problems and advocating for a flexible and collaborative approach to help solve them based on local context and livelihoods. Our toolkit combines social network analysis to identify and capitalise on community, government and business leadership, role-playing games to better understand complexity and to provide a safe space for experimentation and a monitoring and evaluation framework to document progress. We note the potential of our toolkit on several fronts: identifying unexpected consequences of forestry, building empathy between stakeholders, generating creative ideas, and increasing participants' awareness of the complex web of relationships, priorities, barriers, resources (people, time, financial) and enablers which sets the context for forestry in the 21st century

Threatened Plant Adviser: a decision support system for managing threatened flora species within the Tasmanian forest practices system

Anne Chuter¹, Mark Wapstra², Angela Gardner¹

¹Forest Practices Authority, Hobart, Australia; ²ECOTas, Hobart, Australia (anne.chuter@fpa.tas.gov.au; mark@ecotas.com.au; angela.gardner@fpa.tas.gov.au)

Tasmania is an Island State of Australia and is home to approximately 500 threatened flora species. Many of these species occur in areas that may be subject to forest practices, including forestry operations. Management actions for threatened flora species have traditionally been applied on a case by case basis taking into consideration the local conditions at the time. This has led to fine scale, short term approaches that can be expensive and inappropriate for some species and some forest communities. On recent years we have been working on a decision support system that delivers management advice and actions for threatened flora species. The decision support system is titled the Threatened Plant Adviser, and integrates information from species modelling, as well as research and monitoring to deliver on-ground management actions that are consistent and adaptable as new information becomes available. The Threatened Plant Adviser is a web based program that is designed to be accessible to all users. Here we present information on the development of this system from the initial species prioritisation process, species predictive habitat modelling, and implementation and effectiveness monitoring of the management actions.

Tactical harvest planning of fast-growing forest plantations using heuristic optimization techniques

Pedro Belavenutti^{1,2}, Woodam Chung¹, Luis Diaz-Balteiro²

¹Department of Forest Engineering, Resource and Management, Oregon State University, Madrid, Spain; ²Departamento de Ingeniería y Gestión Forestal, Universidad Politécnica de Madrid, Madrid, Spain (inv.florestal@gmail.com; woodam.chung@oregonstate.edu; luis.diaz.balteiro@upm.es)

Tactical harvest scheduling is a challenging problem in the management of industrial forest plantations. The problem consists of achieving strategic production targets by making spatial and temporal forest operations decisions, such as timber harvesting, road maintenance and log transportation. To solve the spatially explicit planning problem, we applied a GIS forest planning tool developed using an iterative heuristic optimization method. The tool integrates harvest scheduling and road network problems and minimizes both fixed and variable costs. Any quantifiable environmental costs of management actions can be also integrated and considered for multiple objective minimization problem and solving. In this presentation, we present the GIS tool and its applications developed for an industrial forest plantation located in Brazil. The usefulness, limitations and future improvement of the tool are also discussed.

Integrating ecosystem services research in forest planning using simulation models and open source tools

Louise Sing^{1,2} ; Stephen Bathgate¹, Marc J Metzger², Duncan Ray¹, Christina Tracey³

¹Forest Research, Roslin, United Kingdom; ²University of Edinburgh, Edinburgh, United Kingdom; ³Forestry and Land Scotland, Torlundy, United Kingdom (louise.sing@forestryresearch.gov.uk; stephen.bathgate@forestryresearch.gov.uk; marc.metzger@ed.ac.uk; duncan.ray@forestryresearch.gov.uk; christina.tracey@forestryandland.gov.scot)

Publicly owned forests have a special role in delivering multiple ecosystem services (ES) that society demands. Management decisions affect the supply of these benefits, which vary both spatially and temporally, creating a complex context for forest management decision making. For example, how much change in the forest is required to maintain or increase benefits? How much change can be made without affecting current benefits? We describe a simulation approach using dynamically coupled models to explore the effect of alternative forest management approaches on a range of ES using a case study in northwest Scotland. By simulating forest growth under climate change we explore the effects of decisions on ES indicators. We present our decision support tool developed using R Shiny, a free open source visualisation package, for disseminating the results to the forest planning manager, as well as lessons learnt from the case study and its wider applicability for supporting forest planning. In particular, we show how management decisions are limited by constraints imposed by existing forest stock, requiring a simulation of multiple rotations for changes to become apparent. Zoning for particular objectives allows the forest planning team to estimate the impact of long-term change in provision on overall ES outputs from the forest. This work helps our understanding of the trade-offs of changing management relative to 'business as usual' approaches. The project has shown the importance of collaboration between researchers and practitioners, as their involvement at each stage of the process increased decision support system uptake in decision making.

Large-scale forest simulations for the prediction of bird diversity in Central Europe

This talk will focus on the results of the interdisciplinary BiodivERsA GreenFutureForest project, which has as main objective to investigate how to modify current forestry to secure both high future (sustainable) timber yield, and viable biodiversity based on simulations of landscape scenarios. As a key organism group in the context of biodiversity, this presentation focuses on forest bird species. Nowadays, the need of adapting forest management to fulfill the demands of a society that requires multifunctional forestry arises as one of the current challenges to forest modelling. Thus, tests and optimization techniques for different alternatives and over the territory are particularly relevant. This is especially important for decision support in large administrative regions, under high population pressure, like in Central Europe. Spatial models that connect forest structures with the occurrence of a large number of forest bird species were coupled with the forest simulator SILVA. The resulting tool allows assessing how different forest bird species may be affected by different forest management strategies. Five management scenarios, spanning 100 years, were simulated for two large regions, the Swiss Canton of Zürich and the entire federal state of Bavaria in Southern Germany. These scenarios cover a broad range of management options, from monofunctional to explicitly multifunctional forestry. The novel coupled model will allow tuning timber production and bird diversity by iterative scenario modifications according to the goals of different stakeholders. The experiences made so far suggest, that the approach of model coupling for large area forest simulations significantly increases decision relevant information.

C4f: FOREST ASSESSMENT, MODELLING AND MANAGEMENT FOR NONWOOD FOREST PRODUCTS

Ecological services of forest ecosystems in islands: production forest, exotic woodland and natural forest

Lurdes Da Conceição Borges Silva¹, Rui Elias², Diogo Pavao¹, Mónica Moura¹, João Porteiro¹, Anunciação Ventura¹, Fernando Lopes³, Francisco Silva³, Francisco Moreira⁴, Ana Moniz³, Luís Silva¹

¹CIBIO, Centro de Investigação em Biodiversidade e Recursos Genéticos, InBIO Laboratório Associado, Pólo dos Açores – Faculdade de Ciências e Tecnologia da Universidade dos Açores, 9501-801 Ponta Delgada, Portugal., Ponta Delgada, Portugal; ²cE3c/ABG – Centre for Ecology, Evolution and Environmental Changes/Azorean Biodiversity Group & University of the Azores, 9700-042 Angra do Heroísmo, Azores, Portugal., Angra do Heroísmo, Portugal; ³Business and Economics Department, University of the Azores, Rua da Mãe de Deus, 9501-801, Ponta Delgada, Portugal., Ponta Delgada, Portugal; ⁴Institute of Agronomy, Centre for Applied Ecology, University of Lisbon, Portugal., Lisboa, Portugal (lurdes.cb.silva@uac.pt; rui.mp.elias@uac.pt; diogo.c.pavao@uac.pt; monica.mt.moura@uac.pt; joao.jm.porteiro@uac.pt; maria.am.ventura@uac.pt; fernando.rr.lopes@uac.pt; francisco.jf.silva@uac.pt; fmoreira@isa.utl.pt; ana.id.moniz@uac.pt; luis.fd.silva@uac.pt)

Forests provide a broad range of ecosystem services, but their contribution is not homogeneous. Due to land changes associated with anthropogenic activity, primordial forests have been replaced by production and secondary forest, often constituted by exotic woodland, particularly in islands. This research addresses ecological and economic valorisation of forests in the Azores, an interesting model region in studies devoted to biodiversity pattern changes, associated with anthropogenic activity. We assessed biodiversity, structure and carbon accumulation in a gradient of forest types in three islands, including 30 stands for each type (production forest - PF, exotic woodland - EW, and natural forest - NF). Regarding taxonomic diversity, there was ample evidence that NF harbored the highest biodiversity levels and PF the lowest. Dendrometric analysis of almost 3000 trees revealed the dominant tree species in each forest type: PF – *Cryptomeria japonica* used for timber production; EW - the invasive tree *Pittosporum undulatum*; NF - the endemic trees *Juniperus brevifolia* and *Laurus azorica*. Diversity levels were generally lower for structural than for taxonomic data, particularly for PF. Regarding carbon accumulation, although differences between soils were small, aboveground carbon stocks were much higher in PF. As a whole, we concluded that NF play an important role as native biodiversity hotspots, PF provides economic assets and could play a major role as carbon sink, while EW presently has a marginal role, for instance in honey and compost production, while its biomass has potential for energetic valorization. Other services, such as tourism and recreation are also discussed.

Success of artificial inoculation of *Inonotus obliquus* on living birches (*Betula* spp.)

Henri Vanhanen¹, Rainer Peltola², Pyry Veteli³, Riikka Linnakoski³, Marta Cortina Escribano⁴, Juho Haveri-Heikkilä², Pirjo Mattila⁴, Pertti Marnila⁵, Juha-Matti Pihlava⁵, Jarkko Hellström⁵, Tytti Sarjala⁶, Niko Silvan⁶, Mikko Kurttila¹, Jari Miina¹

¹Natural Resources Institute Finland (Luke), Joensuu, Finland; ²Natural Resources Institute Finland (Luke), Rovaniemi, Finland; ³Natural Resources Institute Finland (Luke), Helsinki, Finland; ⁴Natural Resources Institute Finland (Luke), Turku, Finland; ⁵ Natural Resources Institute Finland (Luke), Jokiainen, Finland; ⁶Natural Resources Institute Finland (Luke), Parkano, Finland (henri.vanhanen@luke.fi; rainer.peltola@luke.fi; pyry.veteli@luke.fi; riikka.linnakoski@luke.fi; marta.cortina.escribano@luke.fi; juho.haveri-heikkila@luke.fi; pirjo.mattila@luke.fi; pertti.marnila@luke.fi; juha-matti.pihlava@luke.fi; jarkko.hellstrom@luke.fi)

Inonotus obliquus is a pathogenic fungus growing on broadleaves. Its sterile conks, also known as chaga in Asia and Russia or Pakuri in Finland, are considered as functional food. Due to a higher value of Pakuri compared to the wood of the tree which it is growing on, the cultivation of *I. obliquus* on living trees is expected to generate new income opportunities for forest owners. A total of 679 living birch trees (*Betula pendula* and *B. pubescens*) in 24 stands growing under different conditions throughout Finland were inoculated with two strains of *I. obliquus* and re-examined after 4–5 years. Our aim was to examine the success of fungus inoculation and the appearance of sterile conks on birches, and to investigate factors that affect the success of inoculation. The average proportion of birches infected per stand was, $79 \pm 13\%$ whereas $6 \pm 15\%$ of birches per stand were bearing one or more conks. A part of infected trees (13% of all trees studied) showed also a sign of bulged and/or cracked bark. Therefore, most birches were successfully inoculated, but so far only a few sterile conks were formed during 4–5 post-inoculation years. Due to slow formation of conks, the cultivation of *I. obliquus* may be difficult to integrate into the management of commercial forests, but set-aside, low-productive birch, especially *B. pubescens* stands are recommended to be utilized in for cultivation.

An X-ray based method to estimate pine nuts weight/cone weight ratio as a basis to increase cones price negotiation transparency

Conceição Santos Silva^{1,2}, Isabel Carrasquinho³, Margarida Tomé⁴

¹APFC, Coruche, Portugal; ²UNAC, Lisboa, Portugal; ³INIAV, Oeiras, Portugal; ⁴CEF/ISA, Lisboa, Portugal (css@apfc.pt; isabel.carrasquinho@iniav.pt; magatome@isa.ulisboa.pt)

A large percentage of Portuguese forests in the Mediterranean region are managed with a strong focus on NWFP, with particular emphasis on cork and pine nuts. These NWFP are an important source of income for the landowners, therefore the negotiation of price is of utmost importance. In the case of pine nuts, price strongly depends on the ratio pine nuts weight/ cones weight, from now on designated by pine nuts yield. The traditional way to estimate the pine nuts yield requires the sampling of some cones for further processing (sampling design not covered here): 1) elimination of wide pine nuts through water immersion; 2) opening the cones for shelled pine nuts extraction; 3) manual opening of the shelled pine nuts for the extraction and weighting of the edible part. This last step is very time consuming and reduces the possibility to increase sample within a reasonable cost. This presentation describes the research undertaken to define a methodology for determination of pine nuts weight without the manual opening. For this purpose, the shelled pine nuts were disposed and glued in a paper sheet and X-rayed. The X-rayed shelled pine nuts were 1) visually assessed for identification of damaged pine nuts; 2) several variables measured in each shelled pine nut with the software SmartGrain v1.2 with the objective to develop a model to estimate pine nuts weight from the variables available from the SmartGrain software. The study shows that using X-ray is a good methodology to estimate the pine nuts yield.

Mapping cork caliper in Portugal using percentile regression

Joana Paulo¹, Paulo Firmino¹, Sónia Faias¹, Margarida Tomé¹

¹Instituto Superior de Agronomia, Lisboa, Portugal (joanaap@isa.ulisboa.pt; pnfirmino@isa.ulisboa.pt; sonia@isa.ulisboa.pt; magatome@isa.ulisboa.pt)

The ‘montado’ is an oak-dominated woodland ecosystem, distributed along the Iberian Peninsula. It is dominated by the cork oak (*Quercus suber* L.), the species responsible for the production of the cork. Maps concerning the species potential distribution in Portugal have been based on climate and soil thresholds. However, these maps do not express the potential cork production, which is essential for the farms economic sustainability and for defining regional policy measures. Using a quantile regression methodologic approach, the current work aimed to research the relationship of a set of variables with cork caliper, which is assessed by the value of the cork growth index (accumulated value of the eight first complete growth years). The dataset used includes 1339 cork samples. The developed models were used for mapping map, at the national scale, the potential cork calliper growth, considering the thresholds defined by the cork stoppers industry. Results showed a parabolic effect of annual precipitation in cork calliper, with an optimum value varying from more than 1000 mm for the lower percentiles to 500 mm in higher percentiles. A negative effect of maximum annual temperature and a positive effect of tree diameter for all percentiles were observed. A negative effect of the number of debarked branches was only significant at the percentiles equal or higher than 50. The potential cork calliper map obtained, shows a high variability within the percentage range of extracted cork usable for cork stoppers applied by the industry, with higher values at North of the Tagus river.

Legal barriers to the use of non-timber forest products from the Atlantic Forest in Paraná, Brazil / Entraves legais para a utilização de produtos florestais não madeireiros da Mata Atlântica Paranaense

Jaqueline de Paula Heimann¹, Vitor Afonso Hoeflich¹

¹Universidade Federal do Paraná, Curitiba, Brasil (jaquelineheimann@yahoo.com.br; vitor.ufpr@gmail.com)

A FAO define os Produtos Florestais Não Madeireiros como “Todos os bens de origem biológica, assim como os serviços derivados da floresta e terra sob uso similar e exclui a madeira em todas as suas formas” (FAO, 1995). Os principais PFNM do estado do Paraná, segundo dados do IBGE, são: erva-mate, palmito, pinhão, e nó de pinho. De acordo com a Lei Florestal Nacional, a coleta de PFNM como atividade eventual ou de baixo impacto é permitida, inclusive em áreas de Reserva Legal, desde que: para fins de subsistência e produção de mudas; ou exploração agroflorestal e manejo florestal sustentável, comunitário e familiar, desde que não descaracterizem a cobertura vegetal. Porém, o estado do Paraná, possui 99% de seu território enquadrado como área do Bioma Mata Atlântica, que possui regulamentação própria, conhecida como Lei da Mata Atlântica, segundo a qual “A exploração eventual, sem propósito comercial direto ou indireto, de espécies da flora nativa, para consumo nas propriedades ou posses das populações tradicionais ou de pequenos produtores rurais, independe de autorização dos órgãos competentes, conforme regulamento”. Ou seja, a exploração de PFNM da floresta nativa no Paraná, mesmo que praticada por populações tradicionais, quando possui propósito comercial, depende de autorização do órgão ambiental (BRASIL, 2006). Conclui-se com isso que, a falta de comunicação existente entre duas normas federais, impede a livre comercialização dos PFNM paranaenses, com isso cria-se um embaraço ao desenvolvimento da atividade extrativista.

Sustainable models for collecting, processing, and marketing non-timber forest products in Chile / Modelos sustentables de recolección, procesamiento y comercialización de productos forestales no madereros (PFNM) en Chile

Gerardo Valdebenito Rebolledo^{1,2} 

¹Instituto Forestal, Santiago, Chile; ²Universidad Mayor Santiago Chile (gvaldebe@infor.cl)

La dinámica económica y social de los PFNM en Chile ha experimentado un crecimiento relevante y sostenido en los últimos 20 años. Las Exportaciones al año 2017 registran montos por sobre los 93 MMUS\$, representando una cartera de 90 productos, los cuales se envían a más de 50 países. El mercado interno genera ingresos anuales a 200.000 personas del mundo rural, posee fuerte connotación de género y es factor determinante del ingreso familiar. Los productos recolectados y consumidos en Chile mueven un mercado de 370 MMUS\$ anuales, en base a 480 productos, de los cuales el 90% provienen del bosque nativo. El estudio identifica, caracteriza y prioriza los modelos de negocios sustentables vinculados a la recolección, procesamiento y comercialización de PFNM en Chile, desarrollados por agricultores, campesinos y comunidades del mundo rural y extrae a partir del rescate de esas experiencias empíricas, los factores de sostenibilidad de mayor relevancia en la dimensión silvícola (bosque), de agregación de valor (procesos) y comercial (negocios). Los resultados obtenidos identificaron tres modelos, de Menor a Mayor nivel de sostenibilidad: Tradicional, Colaborativo y Asociativo, donde los factores relevantes de sostenibilidad fueron el conocimiento empírico y cultural de las comunidades, los procesos de innovación que agregan valor, el endemismo, la condición de productos orgánicos y los productos vinculados a mercados de nicho. Respectos de los factores limitantes destacan la ausencia de información de mercados, catastro, inventario y cuantificación de los recursos disponibles, técnicas de manejo, recolección sustentable y la alta fragmentación de las cadenas de comercialización.

Constructing an agenda for managing non-timber forest products in Colombia / Hacia la construcción de una Agenda para la gestión de los Productos Forestales no Maderables en Colombia

Ren e Lopez Camacho¹, Guillermo Orlando Murcia Ojeda², Felipe Barney Arango³

¹Universidad Distrital Francisco José de Caldas, Bogotá. D.C., Colombia; ²Ministerio de Ambiente y Desarrollo Sostenible, Bogotá. D.C., Colombia; ³WWF, Cali, Colombia (rlopezc@udistrital.edu.co; gomurcia@minambiente.gov.co; fbarney@wwf.org.co)

Se reconoce a nivel mundial que los productos forestales no maderables -PFNM- proporcionan múltiples beneficios de subsistencia a las comunidades locales y a las economías regionales y nacionales. Estudios recientes han demostrado que se requiere de la vinculación comercialización-conservación y desarrollo para avanzar en la integración de los PFNM en las economías nacionales. Sin embargo, aún se desconoce la incorporación de estos productos en el diseño de políticas y como estrategia para lograr proyectos que permitan la mitigación de la pobreza, reducir la deforestación y el desarrollo de acciones en procesos de post-conflicto como es el caso de Colombia. Analizamos las políticas, legislación y potencialidades actualmente existentes frente a los Productos Forestales no maderables en Colombia, lo que nos permitió establecer 12 puntos claves que permiten facilitar la integración de los PFNMs en una agenda de desarrollo para Colombia permitiendo el beneficio de las comunidades locales. Estos puntos se basan en aspectos de inventario, aspectos ecológicos, directrices para el aprovechamiento de estos productos en distintos ecosistemas, decisiones de gestión de la tierra y el comercio, así como la incorporación de inclusión de los PFNM en el uso y manejo de la tierra y en medidas de compensación y restauración dentro de las licencias ambientales. Para cada uno de los puntos clave en el desarrollo de la agenda se presenta el estado actual de conocimiento y algunas propuestas para avanzar en su desarrollo.

Integrating non-timber forest products into forest assessments and management

James Chamberlain¹, Gregory Frey², Christine Small³, John Munsell⁴

¹US Forest Service, Blacksburg, USA; ²US Forest Service, Research Triangle Park, USA; ³Radford University, Radford, USA; ⁴VirginiaTech, Blacksburg, USA (jchamberlain@fs.fed.us; gregoryfrey@fs.fed.us; cjsmall@radford.edu; jfmunsel@vt.edu)

The plants and fungi harvested for non-wood products are critical to the health and resilience of forest ecosystems. Furthermore, the products derived from these species are essential to human sustenance, livelihoods, and security, and contribute significantly to local and national economies. And yet, these products rarely are managed as natural resources, integrated into forest assessments or management, or included in forest valuations or inventories. The findings and knowledge presented in a recent national assessment of nontimber forest products in the US are the foundation for this insightful presentation that examines efforts in the US to value the provisioning ecosystem services, estimate growth and yield, undertake product inventories, and monitor and track production of raw materials of non-timber forest products (NTFPs). An approach to compute a conservative and defensible estimate of the provisioning of marginal values of NTFPs is discussed. The presentation also explores a method developed to inventory NTFPs from plant roots based on modelling of below-ground biomass using above-ground metrics. Examples of tree-based NTFPs are presented to illustrate use of existing forest inventory data. Efforts to develop systems for tracking the harvest of medicinal forest products, which are needed to estimate volumes and values, are presented. The challenges that may impede efforts to undertake these essential activities are explored. Although this presentation focuses on research in the United States, these approaches and findings are applicable to countries and ecosystems around the world and should benefit every country that harvests NTFPs for sustenance, livelihoods, or economic gains.

C4g: FOREST INVENTORY AND MODELING: PAST SUCCESSES, CURRENT CHALLENGES AND FUTURE PROSPECTS

The effect of natural and anthropogenic disturbances on the uncertainty of large-area forest growth forecasts

Lara Climaco de Melo¹, Mathieu Fortin², Robert Schneider¹

¹UQAR, Rimouski, Canada; ²AgroParisTech, Nancy, France (laracmelo@gmail.com; mathieu.fortin.re@gmail.com; robert_schneider@uqar.ca)

The uncertainty that disturbances induces in large-area growth forecasts has not been fully addressed. Thus, this study aimed to estimate the contribution of disturbances to the uncertainty of large-area forest growth forecasts. The case of study was the Bas-Saint-Laurent region, in Quebec, Canada. We focused on two major disturbances affecting that region: spruce budworm (SBW) outbreaks and harvest activities. Growth forecasts were carried out for a period of 100 years (2003-2103) using ARTEMIS-2009, a stochastic individual-based model. Using the Monte Carlo technique, we simulated four scenarios: a baseline; a harvest scenario; a SBW scenario; and a scenario including both harvest and SBW. Uncertainty estimation was performed using a bootstrap variance estimator that applies to the context of hybrid inference. In the Bas-Saint-Laurent region, omitting SBW outbreaks caused an overestimation of 7.4% in volume at the end of the 21st century. The results revealed that the total variances increased over time. For the scenarios including SBW, the variances were three to six times

greater than those in the scenarios without outbreaks. Harvesting did not greatly contribute to the total variance. We conclude that to reduce the uncertainty of large-area growth forecasts in the Bas-Saint-Laurent, considering SBW dynamics is a crucial issue.

Integrating canopy structure measurements in national inventories: challenges and opportunities

Daniel Augusto da Silva¹, Heitor Felipe Uller², Murilo Schramm da Silva², Adilson Luiz Nicolletti³, Aline Klitzke², Janine K. Likoski¹, Alexander Christian Vibrans²

¹Fundação Universidade Regional de Blumenau, Programa de Pós-Graduação em Engenharia Ambiental, Blumenau, Brasil; ²Fundação Universidade Regional de Blumenau, Pós-Graduação em Engenharia Florestal, Brasil; ³Fundação Universidade Regional de Blumenau, Blumenau, Brasil (danielaugusto@furb.br; heitor.ullerflorestal@gmail.com; murilo.sch.silva@gmail.com; adilson.ln@gmail.com; klitzkealine@gmail.com; janinelikoski@hotmail.com; acv@furb.br)

Forest canopies are the main interface between forests and the atmosphere influencing climate at all levels, from local to global. The canopy of tropical forests is particularly complex, studying it can improve our understanding of the forest ecology, functioning and interaction with climate. Nevertheless, studies involving tropical forest canopies are rare and punctual, limiting the satellite estimates and climate models accuracy assessments, as well as our understanding of forest ecology and physiology. Digital Hemispherical Photographs (DHP) are a cheap, operationally simple and reliable way to estimate stand-level canopy structure parameters like Leaf Area Index, Canopy Opening and Radiation Absorption. However, accurate canopy estimations from DHP depend on clear overcast conditions to distinguish vegetation from sky, imposing an operational and financial limitation to large scale DHP-exclusive surveys. Integrating DHP surveys to national forest inventories can be a workaround to these limitations. The experience at the Forest and Floristic Inventory of Santa Catarina (IFFSC) demonstrated that the DHP survey can be done with almost no time penalty by the field team, overcoming the financial limitation. Even with an estimated data loss (~31%) due to non-ideal sky conditions under operational constraints, we are still able to generate a comprehensive estimation of the canopy structure, by means of 280 out of 418 units, with 20 DHPs each. Furthermore, improvements in image processing and classification can considerably lower data loss. This approach can drastically improve the ground data of canopy parameters in the tropics, crucial for global coupled atmosphere-biosphere models used in climate change assessments.

Distance-dependent competition indices – when are they really needed?

Margarida Tomé¹

¹Universidade de Lisboa, Instituto Superior de Agronomia, Centro de Estudos Florestais, Lisboa, Portugal (magatome@isa.ulisboa.pt)

Inter-tree competition is a fundamental process in plant communities and has gained importance in recent research on forest ecosystem modeling. The effect of local neighbors on tree growth has been expressed by foresters using some mathematical formulation – commonly referred to as a “competition index” – representing how much each tree is affected by its neighbors. Functions used to quantify competition range from simple formulations expressing the hierarchical position of the tree within the stand to more complex indices that express the size of, distance to, and number of local neighbors. Foresters have designated the last as distance-dependent, to express the need to register tree coordinates, but more recently ecologists have used the term spatially explicit individual-based models. There has been considerable debate in the literature as to whether tree spatial information improves prediction of individual tree growth. Conceptually, one would expect some improvement in precision when going from distance-independent to distance-dependent indices; however, most of the comparisons of competition do not report large differences. In this presentation, we analyzed some case studies for comparison of individual tree models using or not distance-dependent competition indices. The case studies focus the use of distance-dependent competition indices as regressor in individual tree dbh increment models but also in thinning algorithms. The analysis includes the visual assessment of the long term resulting stand structure, both spatial distribution of the trees and diameter distributions.

A Bayesian Model Averaging approach for modelling tree mortality in relation to site, competition and climatic factors for Chinese fir plantations

Lele Lu¹, Hanchen Wang¹, Sophan Chhin², Aiguo Duan¹, Jianguo Zhang¹, Xiongqing Zhang¹

¹Research Institute of Forestry, Chinese Academy of Forestry, 100091, China; ²Division of Forestry and Natural Resources, West Virginia University, Morgantown, USA (18553439861@163.com; xqzhang85@caf.ac.cn; xqzhang85@caf.ac.cn; xqzhang85@caf.ac.cn; xqzhang85@caf.ac.cn; xqzhang85@caf.ac.cn)

Relationships between tree mortality and endogenous factors and climate factors have emerged as important concerns, and logistic stepwise regression is widely used for modeling the relationships. However, this method subsequently ignores both the variables not selected because of insignificance, and the model uncertainty due to the variable selection process. Bayesian Model Averaging (BMA) selects all possible models, and uses the posterior probabilities of these models to perform all inferences and predictions. In this study, Bayesian Model Averaging (BMA) and logistic stepwise regression were used to analyze tree mortality in relation to competition, site index, and climatic factors in Chinese fir (*Cunninghamia lanceolata* (Lamb.) plantations established at five initial planting densities (A:1667, B: 3333, C: 5000, D: 6667, and E: 10 000 trees/ha). Results showed that the posterior probability of the best model acquired by stepwise regression was less than that of the best model (highest posterior probability) acquired by BMA for pooling the data and density level D. Especially in the other planting densities, the model selected by stepwise regression was not in the BMA models. It indicates that the BMA method performed better than logistic stepwise regression, because BMA gave accurate posterior probability by taking into account the uncertainty of the model. In addition, the mortality increased with high competition and decreased with increasing temperature. The research has important implications for managing Chinese fir plantations under climate change.

Forest inventory in changing landscape, going towards integrated multipurpose surveys

Marco Marchetti¹, Lorenzo Sallustio¹

¹University of Molise, Campobasso, Italy (marchettimarco@unimol.it; lorenzo.sallustio@unimol.it)

The strong interconnection among different land use and land cover change (LUC) dynamics such as land abandonment, forest regrowth and urban growth as well as their cumulative effects on ecosystems' structure and functionality, clearly underline the strategic role of land use inventory to support land management and planning while offering room for further analysis dealing with specific sectorial needs (i.e., forest inventory to support sustainable forest management, urban forestry, urban planning). This work aims to summarize recent outcomes and methodological remarks obtained by testing the Italian Land Use Inventory (IUTI)

to support land policy and planning in Italy. Three main and interlinked LUC emerged in Italy since 1990: (i) the increase in forest lands (+ 1.7% of the Italian territory); (ii) the loss of arable lands (-4.2% of the Italian territory) due to both urban growth, shift to permanent crops, and natural reforestation particularly in mountain areas; (iii) the increase in built-up areas (+1.6% of the Italian territory). The in-depth analysis highlighted the spatial distribution and polarization of such phenomena and their ecological, economic and social impacts as well as the extension and characteristics of particularly important features such as urban forests, trees outside forests and clearings. Acting as a multipurpose land use inventory system, IUTI was proved to be effective in offering a comprehensive set of information not limited to forests ecosystems but enlarged to their relation with adjacent landscapes (e.g., urban and agricultural), thus setting the scene for a better operationalization of ecological principle into decision making contexts.

Developing site-index equation for loblolly pine using climatic water balance components

Anil Koirala¹, Cristian R. Montes¹, Bronson P. Bullock¹

¹Warnell School of Forestry and Natural Resources, University of Georgia, Athens, USA (anilk@uga.edu; crmontes@uga.edu; bronsonbullock@uga.edu)

Site-index models based on dominant height and age of trees are commonly accepted measures of site productivity in forest plantations. Therefore, reliable estimates of dominant height over time are critical, as they provide the foundations for site productivity estimates used in growth and yield models. Forest site productivity depends on the combination of many environmental factors, where as tree height is only a general proxy indicator of these factors interacting over time, and as such, subject to large errors. Hence, selection of appropriate environmental variables along with field-based data is expected to result in more consistent estimates. Although numerous studies have incorporated climatic variables in their site-index models, there is still lack of understanding among the research community with respect to the selection of suitable climatic variables. Models including the climatic water balance components such as water-deficit, excess water, and effective temperature are scarce. These components are especially important to address the influence of drought on plant growth. Therefore, the main question of interest for this study is to evaluate the change in dominant height estimates of forest stands with respect to changes in water balance components. High-resolution actual evapotranspiration (AET) and potential evapotranspiration (PET) were combined to determine water access/deficit of sites. These were incorporated into a loblolly pine site index model using generalized algebraic approach and maximum likelihood calibration methods that accounted for long-term uncertainty in the results. Our model is a step further to improve precision in dominant height estimates of loblolly pine in the southeast US.

Diameter distribution of six clones of *Eucalyptus* under different ages and spacing

Silvio Henrique Menezes Gomes¹, João Luís Ferreira Batista¹, Kátia Luis Soares¹, Luciana Duque Silva¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (silviogomes@usp.br; batista.jlf@usp.br; kalitasoares@usp.br; lucianaduques@usp.br)

Diameter distribution studies are an important tool for forest management planning and practice, particularly for stand growth and yield prediction models. In these studies, the stochastic distributions frequently fitted to data are beta, Johnson's SB, log-normal, Weibull and gamma; the last two more often show best fit and are applied to several forest management conditions. The goal of this study was to evaluate the change in the diameter distribution of six eucalyptus clones under three different planting spacing that were remeasured along six ages. The two stochastic models were applied to the diameter distributions in each specific condition. For each eucalyptus clone, the effect of age and planting spacing on the diameter distribution was investigated through seven models: 1) null model, there is no effect of age and spacing; 2) full model, for each combination of age and spacing; 3) age model, a distribution for each age; 4) spacing model, a distribution for each spacing; 5) age-function model, distribution parameters are linear function of age; 6) spacing-function model, distribution parameters are linear function of spacing; and 7) age-spacing-function model, distribution parameters are linear function of age and spacing. The models were fitted by maximum likelihood methods and were compared using Akaike Information Criterion (AIC). The full model (2) with Weibull distribution was the best model for all clones, but the age-spacing function model (7) was consistently the second best model. The likelihood profiles of scale and shape parameter estimates revealed that for some clones the age effect might be irrelevant.

Development of a volume equation virtually invariant to location, age, and genetic material

John Paul McTague¹, Henrique Scolforo², Jose Roberto Scolforo¹

¹Universidade Federal de Lavras, Lavras, Brasil; ²Suzano, Limeira, Brasil (forestbiometrician@yahoo.com; henriquescolforo@hotmail.com; jscolforo@dcf.ufla.br)

There exists an overreliance on the construction of new volume equations in Brazil. Equations are, of course, species-specific. Many times, however, separate equations are constructed for each farm (forest tract), and age class. The equations are developed with destructive sampling techniques. Quite frequently the constructed volume equations are of the form: $V = (ff) D2H$, where ff is the form factor. New model construction is expensive, and the models suffer from low sample sizes. An appealing alternative in Brazil, therefore, is the development of generalized tree volume equations. To calibrate a volume equation virtually invariant to location, age and genetic material, we offer the development of a new modeling framework for clonal eucalypt plantations. The dataset originates from inventory information of sites located in northern Minas Gerais State, Brazil. A total of 48 plots were selected and following the inventory measurements, all trees were bucked and scaled; 1844 trees compose the destructive sample. The combination of upper stem diameters and pre-defined stem heights in a taper equation, allowed for the development of a powerful modeling approach that displays higher accuracy when compared to conventional volume equations.

C4h: FROM LONG-TERM MONITORING AND TIME SERIES TO FORESIGHT ANALYSES AND PROJECTIONS

Large trees have increased greatly in Finland during 1921-2013, old trees have not

Helena M. Henttonen¹, Pekka Nöjd², Susanne Suvanto¹, Juha Heikkinen¹, Harri Mäkinen²

¹Natural Resources Institute Finland, Helsinki, Finland; ²Natural Resources Institute Finland, Espoo, Finland (helena.henttonen@luke.fi; pekka.nojd@luke.fi; susanne.suvanto@luke.fi; juha.heikkinen@luke.fi; harri.makinen@luke.fi)

Large and old trees have a vital role in preserving biodiversity in forest ecosystems. Forest inventories provide detailed information about size distribution of trees, but long time series on the age distribution of individual trees are rarely available. The first sample-based National Forest Inventories (NFI) were established in the Nordic countries in the 1920s. We used Finnish NFI data for studying changes in the densities of large trees (diameter ≥ 40 cm) over a time span of almost 100 years. The frequencies of old trees (age ≥ 150 years) were studied for 1971-2013. Large trees have increased as much as 325%, mainly since the 1970s. Old trees have become slightly less common (-4%) since the 1970s. The large majority of old trees in Finland were quite small. Trees that are both large and old showed a

notable increase during 1971-2013. High densities of large and/or old trees were observed in areas with restrictions on wood production emphasizing their role in maintaining biodiversity. The results reflect the destructive effects of former land use and the transition from dimensional cuttings to clear cuts and thinning from below after the 1940s. Proportionally larger changes were observed for southern Finland, where a higher population density has resulted in more intensive land use. As the densities of large trees and old trees have developed in completely different manner, our results suggest that monitoring only the size distribution of trees will not sufficiently describe the role of old trees as constituents of biodiversity.

Growth pattern of timber species in an ecotone among amazon forest types

Aline Canetti¹, Patrícia Póvoa de Mattos², Evaldo Muñoz Braz², Afonso Figueiredo Filho³

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Universidade Estadual do Centro-Oeste do Paraná, Irati, Brasil (alinecanetti@gmail.com; patricia.mattos@embrapa.br; evaldo.braz@embrapa.br; afigfilho@gmail.com)

This work aimed to describe the individual growth of *Apuleia leiocarpa* (Vogel) J.F. Macbr., *Erisma uncinatum* Warm., *Hymenolobium excelsum* Ducke and *Trattinnickia burserifolia* Willd. in Mato Grosso State, Brazil. Growth analyzes were carried out using dendrochronology. We calculated mean increments and passage time between diameter classes, adjusted growth equations in diameter and derived volume increment curves at an individual tree level. The four species showed annual growth rings. Gompertz model showed better adjust to explain *A. leiocarpa* and *H. excelsum* growth and Johnson-Schumacher to *E. uncinatum* and *T. burserifolia*. The differences between diameter class increments, passage time and growth pattern over each species life span were related to their ecological groups. The diameter growth culmination and the maximum annual growth volume of *A. leiocarpa* occurred in smaller diameters and at younger ages when compared to the other species, which characterizes it as an early secondary species. *E. uncinatum* and *T. burserifolia* presented typical late secondary species characteristics, inverse to *A. leiocarpa*. *H. excelsum* is probably indifferent to light incidence, as trees presented constant increment during their lifetime. Our analyzes will be the basis of growth simulations at species population level, to be used in the elaboration of guidelines aiming at sustainable forest management.

Applying tree rings and population models to improve future timber yield projections of *Hymenaea courbaril* (Jatobá) in the Eastern Amazon

Isabela Marques¹, Edson Vidal², Mario Tomazello-Filho³, Peter Groenendijk⁴

¹Departamento de Biologia Vegetal, Instituto de Biologia, UNICAMP, Campinas, Brasil; ²Laboratório de Silvicultura Tropical, Esalq, USP, Piracicaba, Brasil; ³Laboratório de Anatomia e Identificação de Madeiras, Esalq, USP, Piracicaba, Brasil; ⁴Departament (isabela.marques.bio@gmail.com; edson.vidal@usp.br; mtomazel@usp.br; pterg@unicamp.br)

To ensure sustainable timber productivity in polycyclic logging systems and to conserve forest function and services, it is crucial to adopt species-specific adaptive forest management systems. Yet, management plans are usually based on models that simulate future timber yields using limited, short-term growth, reproduction, and survival data, and that only poorly incorporate within-species variations in these vital rates. For growth data, tree-ring analyses allow for obtaining such long-term data that includes within-species growth differences. Here we combine 25 years of vital-rate data from experimental forest plots with different past exploitation (control, conventional exploitation and Reduced-Impact Logging (RIL)) with tree-ring analysis and state-of-the-art demographic models (Integral Projection Models) to simulate future timber yields of the tropical species *Hymenaea courbaril*. We simulated yields under conventional and RIL scenarios and assessed how using tree-ring data and including persistent growth differences between individuals affect timber yield projections. Future yields were below 100% of the initial exploited volume in all simulations. However, long-term yield recuperation was higher under RIL than under conventional exploitation. Using tree-ring based models and incorporating persistent growth differences lead to higher future yields. Our results suggest that timber volumes accumulated over many decades cannot grow back within current logging-cycle lengths (the “primary-forest premium”), but also that RIL practices are an important step to reach sustainable timber productivity. As more and more plot and tree-ring data comes available, approaches like ours - incorporating population dynamics and long-term vital rates - can be used to orient decision making to attain sustainable management of tropical forests.

Analysis of the diametric structure of the Amazonian forests from the point of view of forest management

Evaldo Muñoz Braz¹, Aline Canetti², Patrícia Póvoa de Mattos¹

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (evaldo.braz@embrapa.br; alinecanetti@gmail.com; patricia.mattos@embrapa.br)

Natural forest management is currently the only land use activity that maintains approximately 88% of the number of initial trees. Nevertheless, the amazon forest management continues to be criticized. It is always questioned about its effectiveness as an environmental tool that guarantees the sustainability of natural forests. The reason for this criticism is a number of mistakes and misunderstandings about the analysis of monitoring results or simulations of natural forest management. The goal of this work was to enrich the understanding of Amazon Forest productivity when under management rules. This work also intended to analyze the misunderstandings about natural forests management. We analyzed the general diametric structure of the Amazon forest, identifying key points of transition to old forest, points of growth reduction, accumulation in basal area and decrease in timber volume production. The analysis of the species growth pattern, evolution of the individual species community over time and volumetric production help to explain the interruption of the structural balance of the Amazon forest after diameter class of 75 cm. This imbalance limits the cutting cycles that must be estimated for management, since it shows that the forest is finishing its most productive phase. We can also conclude that pursuing the original structures of an Amazon natural forest after extraction is incompatible with forest management as senescent and stagnated trees (all pristine forest structure) represent an accumulated stock, but do not represent the productive capacity of the trees in a production forest.

Forest responses to environmental perturbations in Central Europe: from permanent research plots to model projections

Katarina Merganicova¹, Jan Merganic², Zuzana Sitkova³, Daniel Kurjak², Zoltan Barcza^{4,5}, Martin Mokros¹, Peter Fleischer², Hrvoje Marjanovic⁴, Dora Hidy⁵, Katarina Strelcova², Tomas Hlasny¹

¹Czech University of Life Sciences Prague, Faculty of Forestry and Wood Sciences, Prague, Czech Republic; ²Technical University Zvolen, Faculty of Forestry, Zvolen, Slovakia; ³National Forest Centre - Forest Research Institute Zvolen, Zvolen, Slovakia; ⁴Croatian Forests Research Institute, Zagreb, Croatia; ⁵Eötvös Loránd University, Budapest, Hungary (k.merganicova@forim.sk; merganic@tuzvo.sk; sitkova@nlcsk.org; kurjakd@gmail.com; zoltan.barcza@ttk.elte.hu; martin.mokros@gmail.com; p.fleischersr@gmail.com; hrvojem@sumins.hr; dori.hidy@gmail.com; katarina.strelcova@tuzvo.sk; tomas.hlasny@gmail.com)

The knowledge of driving forces of forest growth helps foresters to assess the production potential of their forests, and supports their management decisions. Here we present a novel framework for the assessment of forest productivity drivers and responses along an extended environmental gradient across Central Europe. The framework consists of selected monitoring plots established within the European forest monitoring programme ICP Forests and highly-equipped intensively monitored plots situated in five European countries (Croatia, Hungary, Slovakia, Poland and the Czech Republic), and the regionally adapted biogeochemical process-based model Biome-BGCMuSo (Hidy et al; 2016). We describe the overall concept of this framework and recent advances in the development of the applied ecosystem model, including its parameterisation for common forest tree species of the region. Finally, we exemplify the application of the framework for the assessment of forest productivity responses to selected perturbations. We highlight how linking of long-term monitoring data and ecosystem models can increase our capacity to simulate forest ecosystem dynamics and to address main challenges faced by the contemporary forestry with respect to ongoing global and regional environmental changes.

Applying empirical data of a forest accountancy network to show the effects of tree species diversity on financial risk and economic return in private forest enterprises

Johannes Wildberg¹, Bernhard Möhring¹

¹University of Göttingen, Faculty of Forest Sciences and Forest Ecology, Department of Forest Economics, Göttingen, Germany (jwildbe@gwdg.de; bmoehri@gwdg.de)

The selection of tree species for the establishment of forest stands can be regarded as a financial investment with long-lasting economic consequences concerning entire rotation periods. An investment's success depends on the expected returns and volatility thereof. In finance theory the so called diversification effect reduces the risk of volatile returns. This study combines finance theory with empirical accounting data to support the hypothesis of reducing the risk of volatile return in forest enterprises through tree species diversification. Based on the data of a forest accountancy network in Germany, the effect of tree species diversity on risk and return was analyzed. We used economic parameters of 37 private forest enterprises in Western Germany documented over more than 45 years to calculate historic returns and volatility. The data revolves around the most relevant tree species in Germany including spruce, beech, oak and pine. The data demonstrated a positive diversification effect as species diversity in forest enterprises was negatively correlated with the volatility of return. While the economic return of all forest enterprises was equal to sum of the returns of the underlying tree species, the enterprises' volatility was lower than the summed volatility of the individual tree species. In summary, forest enterprises with a diversified tree species composition will not yield the highest returns possible, but are able to reduce risk for a given level of return. However, the non-stationary development of tree-species-assets as well as risk preferences need to be considered in management decisions.

An imputation/copula approach to modeling long-term species dynamics in the Acadian Forest of northeastern North America

John Kershaw¹, Yung-Han Hsu¹, Ting-Ru Yang¹, Elizabeth McGarrigle²

¹University of New Brunswick, Fredericton, Canada; ²Nova Scotia Department of Natural Resources, Truro, Canada (kershaw@unb.ca; yhsu@unb.ca; tyang1@unb.ca; emcgarrigle@gmail.com)

Copulas are a special class of multivariate distributions whose marginals are all uniform. Through the process of translation, the marginal distributions can be transformed into any parametric or empirical distribution. Copulas have been widely applied in many fields for time series analyses. In medicine and economics, copulas have been used to model long-term dynamics of very complex systems with very good results. However, only recently have copula applications been developed in forestry. We propose a model that uses an iterative system of imputation and copula sampling to explore long-term dynamics in mixed species stands in the Acadian Forest in northeastern North America. The imputation step identifies nearest neighbors to subject trees or plots and copulas are built from this set of nearest neighbors. Random samples from the copula are then used to define the dynamic step. Long-term dynamics from a variety of different forest types are simulated and compared to expected dynamics based on successional theory. Copulas offer an alternative to parametric modeling and time series analyses. The imputation/copula model proposed here provides an approach for separating signal from noise in long-term forest dynamics data from multiple sources. The system is modular and can be easily expanded to include climatic and regional site factors enabling exploration of climate change effects on forest dynamics.

C4i: INNOVATIVE APPLICATIONS OF UNMANNED AERIAL VEHICLES (UAVS) IN FOREST SCIENCE AND MANAGEMENT

Evaluation of three point cloud generation platforms used in forest inventory

Cory Garms¹, Chase Simpson¹, Chris Parrish¹, Michael Wing¹, Bogdan Strimbu¹

¹Oregon State University, Corvallis, USA (cory.garms@oregonstate.edu; chase.simpson@oregonstate.edu; chris.parrish@oregonstate.edu; michael.wing@oregonstate.edu; bogdan.strimbu@oregonstate.edu)

Light detection and ranging (lidar) and structure from motion (SfM) are relatively new methods of describing terrestrial systems with 3D point clouds. The objective of the present study is to assess the effectiveness, measured as the cost/results quality, of three sensors producing point clouds. The sensors were mounted on three different platforms: 1) the multispectral sensor, mounted on an unmanned aerial vehicle (UAV-MS); 2) the Velodyne Puck lidar sensor, installed on an octocopter UAV (UAV-P); and 3) the Velodyne HDL-32E lidar sensor, mounted on a truck, for a mobile terrestrial lidar scanner (MLS). The platforms scanned a 2.0 ha Douglas fir stand near Corvallis, Oregon, USA. The least expensive platform, UAV-MS, requires the least expertise, but also produces the lowest resolution point clouds (14 cm average point spacing versus 5cm and 3cm for UAV-P and MLS, respectively). The MLS platform is the most expensive but provides a profile perspective that allows tree stem delineation 50 meters into the stand. All platforms predicted the total height of individual trees with an $r^2 > 0.83$, but the MLS supplied also diameters along the stem. Our study suggests that for annual inventory a UAV-MS based approach is satisfactory, but for thinning or regeneration harvests a combination of UAV-MS with MLS is the best approach for areas with a well-developed road network, even that edge effects are present. A double sampling strategy removed the edge effect and provided unbiased estimates for volume.

Comparative analysis of canopy heights estimated using UAV LIDAR and photogrammetry

Qingwang Liu¹, Liyong Fu¹, Shiming Li¹, Zengyuan Li¹, Mei Li¹, Mengxi Wang¹

¹Research Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing, China (liuqw@ifrit.ac.cn; fuliyong840909@163.com; lism@ifrit.ac.cn; lizengyuan@ifrit.ac.cn; limei@ifrit.ac.cn; 15501130818@163.com)

The forest structure and under-story terrain could be finely measured using Unmanned Aerial Vehicle (UAV) based Light Detecting and Ranging (LIDAR) and photogrammetry. Laser pulses has the ability of penetrating forest canopy and describe the vertical profile of vegetation. The stereo reconstruction of high-overlapped images can be used to generate dense point cloud finely reflecting the variation of canopy surface. The LIDAR-based Canopy Height Model (CHM) was generated using LIDAR point cloud subtracted by LIDAR-based Digital Terrain Model (DTM). The photogrammetry-based CHM was generated using photogrammetry point cloud subtracted by LIDAR-based Digital Terrain Model (DTM). This study compared the canopy heights between LIDAR and photogrammetry-based CHMs. The study area was located in Jigongshan National Nature Reserve, China. The result showed that there was high correlation between heights of LIDAR and photogrammetry. The LIDAR-based heights were slightly higher than that of photogrammetry. The overall mean of differences between canopy heights was 0.1 m. The photogrammetry-based CHM has a decreased trend as the values of LIDAR-based CHM increased. The values of differences changed from negative to positive when the LIDAR-based CHM was higher than 16 m. It indicates that photogrammetry will overestimate lower part of forest canopy and underestimate upper part of canopy to some degree.

Innovative data capture and algorithms for improving outcomes from UAV image-based point clouds of forests

Luke Wallace¹, Simon Jones¹, Chris Bellman¹, Mark Shortis¹, Arko Lucieer², Bryan Hally¹, Darren Turner², Samuel Hillman¹, Jaime Hernandez³

¹RMIT University, Melbourne, Australia; ²University of Tasmania, Hobart, Australia; ³Universidad de Chile, Santiago, Chile (luke.wallace2@rmit.edu.au; simon.jones@rmit.edu.au; chris.bellman@rmit.edu.au; mark.shortis@rmit.edu.au; arko.lucieer@utas.edu.au; bryan.hally@rmit.edu.au; darren.turner@utas.edu.au; s3482969@student.rmit.edu.au; jhernand@uchile.cl)

Increasingly UAVs equipped with imaging sensors are being used to observe forest structure. In order to characterize forests accurately a core set of reliable information is required that describes the terrain surface and the upper parts of canopy. Several studies have demonstrated vulnerabilities in the workflow (camera quality and settings, flight parameters and weather conditions) used to reconstruct 3D forest descriptions that can result in inconsistent results. A method and a consistent set of guidelines for producing reliable and repeatable characterizations across a range of forest types is yet to be developed. This project investigates the pathologies within image-based point clouds and assesses novel strategies for ensuring reliable information describing the terrain and canopy from UAV data capture. In order to achieve this vulnerabilities at each step of the workflow are identified and novel approaches to overcome the resultant point cloud pathologies are developed. These approaches include ensuring camera quality and calibration are sufficient, choosing algorithms within the approach that best match the environment and novel multistage data capture methods. All approaches are tested in a series of real and simulated case studies with varying weather, canopy and terrain conditions. The outcome of this study is a matrix outlining the capture and processing requirements for the optimum outcome in different forest types for target metrics. For example, improved terrain and forest description in high canopy cover environments can be achieved through the inclusion of off-nadir imagery to ensure small canopy gaps are exploited in the image matching process.

The Potential of UAV Images in the Classification of Successional Forest Stages in Mixed Ombrophilous Forest Environments

Felipe Matheus Pinto¹, Marcos Benedito Schimalski¹, Adelar Mantovani¹, Veraldo Liesenberg¹

¹Universidade do Estado de Santa Catarina, Lages, Brasil (felipe_matheus.p@hotmail.com; marcos.schimalski@udesc.br; adelar.mantovani@udesc.br; veraldo.liesenberg@udesc.br)

Due to the higher spatial resolution of images obtained by Unmanned Aerial Vehicles (UAV), pixel-to-pixel classification methodologies do not present good results. In addition, the cameras used for these vehicles usually record only the visible band, which impairs the identification of the vegetal cover. Therefore, new methodologies must be designed to obtain appropriate classifications using the visible information only. Regarding the spatial resolution, object-oriented classification methodologies tend to present more satisfactory results. Vegetation indices with visible bands, such as the Triangular Greenness Index (TGI), tend to improve results. The main objective of this study is to define a methodology for classifying images obtained by UAV with ultra-high spatial resolution and distinguish succession stages from forest fragments. The study was conducted in the municipality of Curitibaanos, Santa Catarina, Brazil. Aerial mosaics were generated in the Agisoft Photoscan® software. The Segmentation and Classification toolset was employed for the object-oriented classification of regions. In addition, TGI was used coupled with the spectral bands. A confusion matrix was generated for the evaluation of partial results. The Kappa Index was calculated. Results showed 0.62 and 0.85 Kappa Index accuracy, which represents results considered to be "Very good" or "Excellent". The study found that satisfactory results were obtained for the classification even with bands only in the visible range, showing the potential of this methodology in the classification of ultra-high spatial resolution images.

Predicting habitat suitability for greater glider (*Petauroides volans*) using remote sensing: implications for conservation planning

Benjamin Wagner¹ , Patrick Baker¹, Craig Nitschke¹

¹The University of Melbourne, Melbourne, Australia (bwagner@student.unimelb.edu.au; patrick.baker@unimelb.edu.au; craign@unimelb.edu.au)

The greater glider (*Petauroides volans*) is Australia's largest gliding possum. Although distributed along the entire eastern coast, local populations are in decline and modelling predicts contractions of their habitat in the future. The species is now considered threatened in certain regions. Population declines have commonly been attributed to logging and burning activities, resulting in conservation measures emplaced accordingly. Other research indicates that the decline might be related to factors like forest nutrition, changes in foraging quality or climate, but are often not considered in conservation planning. Our project seeks to address interactions between these factors at a landscape-scale using a combination of UAV based remote-sensing, field validation and landscape modelling to answer the questions: 1) what are the main determinants of habitat suitability of greater gliders in southeastern Australia? and 2) what role does forest nutrition and climate have on glider occurrence and abundance? Using both fixed-wing and multirotor UAVs equipped with multi-spectral sensors over our study sites, we collected high-resolution imagery to correlate to tree nutrition and stand structure. While a multirotor device is used to cover small areas where ground surveys of forest structure, leaf and soil sample collection has taken place, the fixed wing system will be used to capture imagery of unsurveyed larger areas. These >100ha areas are used to test our models of forest nutrition, derived from the plot level UAV data. Our aim is to identify glider habitat using high spatial and detailed nutrition models to improve reserve design and forest management.

What UAV remote sensing can tell us about sustainability of forest management at operational level: lessons learned from the EU-funded FRESHLIFE project

Anna Barbati¹, Marco Balsi², Francesca Giannetti³, Diego Giuliarelli¹, Bruno Lasserre⁴, Davide Travaglini³, Gherardo Chirici³

¹Università degli Studi della Tuscia, Viterbo, Italy; ²OBEN s.r.l., Sassari, Italy; ³Università degli Studi di Firenze, Firenze, Italy; ⁴Università degli Studi del Molise, Isernia, Italy (barbati.sisfor@unitus.it; marco.balsi@gmail.com; francesca.giannetti@unifi.it; dgiuliarelli@unitus.it; lasserre@unimol.it; davide.travaglini@unifi.it; gherardo.chirici@unifi.it)

Experiences from the EU LIFE project “FRESHLIFE-Demonstrating Remote Sensing integration in sustainable forest management” are presented to discuss opportunities offered by UAV remote for monitoring sustainable forest management (SFM). The technical feasibility of mapping some Forest Europe’s SFM indicators at the forest compartment level was evaluated. UAV data collection under leaf-on canopy conditions (RGB imagery and LIDAR) was combined with field sampling (150 plots, size= 530 m²) in temperate forests of Central Italy (3 sites, size 200-250 ha). Orthomosaic images from UAV imagery (pixel 10 cm), were classified by visual interpretation to identify forest canopy species and tree defoliation. Compositionally distinct forest types were accurately mapped (per class accuracy>70%). Defoliation was detected on upper canopy trees, but only at its highest level (> 70% of leaf loss). Combination of field and LIDAR-derived height metrics allowed the spatial estimation of growing stock and aboveground biomass by linear regression, at the plot size resolution (R² from 0.25 to 0.80). The variable performances of the predictive models can be related to different canopy penetration of the LIDAR, which affected the amount of ground returns and, accordingly, the DTM quality. LIDAR data acquisition also under leaf-off canopy conditions could address this limitation. Lessons learned ultimately highlight that traditional forest inventory can be efficiently complemented by UAV remote sensing to map the examined SFM indicators at operational scale. But planning of flight missions should be properly considered to optimize and standardize UAV data collection by different sensors (flight parameters, timing), so to generate high-quality data.

C4j: REGIONAL FOREST OBSERVATIONS FOR SUSTAINABLE FOREST MANAGEMENT

Regional forest observations for annual change detection

Yong Pang¹, Zengyuan Li¹

¹Chinese Academy of Forestry, Beijing, China (pangy@ifrit.ac.cn; lizy@caf.ac.cn)

With rapid development of social and economic, forests face an increasing number of threats and pressures. How to effectively evaluate and assess the forest resource in large scale has become a common concern of many economies especially developing economies. Multi-temporal earth observation data characterize the forest gain and loss activities spatially and timely. This provides a good way to map the active forest gain and loss regions. With constant updating and developments of earth observation technologies, more and more medium-high spatial resolution remote sensing data are available free of charge or at a reasonably low cost. In this study, time series of optical remote sensing data from multiple satellites were used, including Landsat-5/7/8, Sentinel-2A/B, GaoFen-1/2/6 (GF-1/2/6) and Beijing-2 (BJ-2). These satellites provide repeat observations on a week to month cycle with spatial resolutions ranging from 4 m to 30 m. We developed an algorithm for composition of cloud-free optical remote sensing imagery using weights for collection date, cloud contaminated extent and opaque degree calculated at pixel level. The weighted mean value was calculated for each pixel in the composition image, then time-series of forest cover indices were calculated to detect changes. Results from test sites in Guangxi (China), Laos, Malaysia and Thailand were analyzed. Field GPS points and screen interpreted changes were used for evaluation. Overall, the annual change accuracy using the annual composition images is about 82%. The annual change accuracy using quarterly composition images increased to approximately 92%.

Monitoring of Alpine forests combining LiDAR and Sentinel 2 data

Mathias Schardt¹, Janik Deutscher¹, Manuela Hirschmugl¹

¹Joanneum Research Forschungsgesellschaft mbH, Graz, Austria (mathias.schardt@joanneum.at; janik.deutscher@joanneum.at; manuela.hirschmugl@joanneum.at)

The international convention on the protection of the Alps (short: Alpine Convention) concludes that climatic change, catastrophic storm events and bark beetle calamities pose a growing threat to our Alpine forests. Forest administrations and forest owners undertake great planning efforts and mitigation measures to prevent forest degradation. To do so, these forest entities depend on the availability of relevant and timely information on the status of Alpine forests. Satellite remote sensing data in combination with LiDAR data are used to derive reliable information on forest status and forest change that forest owners and forest administration require to better manage and protect our Alpine forests. Two different types of services will be introduced: A near real-time alert system based on time series analyses of multi-temporal satellite images to rapidly and continuously map forest changes resulting from storm damage and insect calamities, and an inventory service that provides improved and updated information on selected forest parameters including timber volume, forest density, tree height and 3D structural characteristics on stand level. The method presented build on the one hand on Sentinel 2 data which forms an ideal basis for the establishment of a large-scale monitoring system. On the other hand full-waveform LiDAR data is used to assess the relevant inventory data mentioned above. The real time alert service developed is integrated and run in the EODC cloud processing environment that provides ample resources for timely production and delivery of information. The users will access the services through a conventional web browser.

Influence of sample selection method and estimation technique on sample size requirements for wall-to-wall estimation using airborne LiDAR

Ting-Ru Yang¹, John A. Kershaw¹, Aaron R. Weiskittel², Tzeng Yih Lam³, Elizabeth McGarrigle⁴

¹University of New Brunswick, Fredericton, Canada; ²University of Maine, Orono, USA; ³National Taiwan University, Taipei, Taiwan; ⁴Nova Scotia Department of Lands and Forestry, Truro, Canada (tyang1@unb.ca; kershaw@unb.ca; aaron.weiskittel@maine.edu; tylam.forest@gmail.com; emcgarrigle@gmail.com)

Understanding how forests in response to climate change is important for designing and planning forest management and policy. However, due to the complex stand structure and forest dynamic, more detailed inventory information is required to have better predictive capability for a variety of forest inventory attributes over a range of forest ecosystems and geographic regions. Ground-based plots and various statistical modeling techniques are used to develop relationships between a desired forest attribute and a range of derived LiDAR metrics. The current modeling approaches are only as strong as the field data from which the LiDAR relationships are developed, and, unfortunately, some of the primary tenets of forest inventory design have been minimized or ignored. To improve our

ability to predict future forest productivity under climate change, the sample design used to collect the necessary calibration data should be considered firstly over the calibration modeling approach. No analysis has systematically explored the influence of different selection methods on the efficiency of estimators of forest attributes using LiDAR-assisted estimation. To fill this knowledge gap, the influences of different sample selection methods, estimation techniques, and sample sizes on wall-to-wall LiDAR-derived inventory predictions are explored. Equal and variable probability selection designs are examined and model-assisted versus design-based estimators compared. Recommendations and considerations for efficient sample designs for future LiDAR inventories are presented.

Spatio-temporal synergistic analysis and modeling of forest above-ground biomass dynamic information

Xin Tian¹, Zengyuan Li¹, Erxue Chen¹, Min Yan², Chengyan Gu³

¹Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing, China; ²Aerospace Information Research Institute, Chinese Academy of Sciences, Beijing, China; ³Forestry Planning and Design Academy of Forest Products Industry, (tianxin@caf.ac.cn; zy@caf.ac.cn; chenerx@caf.ac.cn; yanmin@aircas.ac.cn; gudove3608@gmail.com)

Forest dominates the terrestrial carbon cycle and forest above-ground biomass (AGB) has been the critical index for carbon sequestration capacity. However, any individual method, such as ground-measurement-based method, remote-sensing-based method, and ecological model-based model, cannot efficiently describe the changing processes and driven mechanisms of forest AGB dynamics. Based on multi-mode remote sensing, time-space dynamic knowledge of forest ecological process, and continuous multi-disciplinary ground observation data, this project is planning to model spatial-temporal continuous, physical quantity-synergy forest AGB dynamics. Firstly, a highly accurate regional forest AGB product obtained by applying multi-mode remote sensing and scaling connection, is used as the AGB basis. Then, the uncertainties of simulation of forest growth processes are alleviated by use of model-model and model-data fusion strategies. Finally, modeling of forest AGB dynamics is accomplished by combining forest AGB basis with succeeding dynamic forest growth processes, which taking the effects of tree mortality, forest disturbance into account. The methodology of spatio-temporal synergistic modeling of Forest AGB dynamic information proposed by this project, can explore the eco-physiological mechanisms of spatio-temporal pattern of forest AGB dynamics and the driven forces of natural and anthropogenic disturbances. Moreover, this methodology can extend the spatial and temporal dimensions of forest AGB dynamics and in order to precisely improve forest quality and promote the national ecological civilization.

Understanding stand characteristics of natural forest using airborne laser scanner data for sustainable forest management

Yasumasa Hirata¹, Naoyuki Furuya¹, Toshiaki Owari², Daisuke Sakaue³

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²The University of Tokyo, Kamogawa, Japan; ³The University of Tokyo, Furano, Japan (hirat09@affrc.go.jp; nfuruya@affrc.go.jp; owari@uf.a.u-tokyo.ac.jp; sakaue@uf.a.u-tokyo.ac.jp)

Natural forests are expected to demonstrate multifaceted functions such as biodiversity preservation function and environment conservation function. On the other hand, accurate information on natural forest resources necessary for sustainable management is largely insufficient compared to artificial forests. In order to manage natural forests continuously, it is important to grasp information such as resource amount and growth amount at stand or landscape level. In this study, we aim to develop a method to grasp the stand characteristics of natural forest from tree height of forest stands and forest canopy transmittance of laser from data obtained by airborne laser scanner (ALS) measurement. The study area is the natural forest of the University of Tokyo Hokkaido exercise forest. First, DSM (digital surface model) and DEM (digital elevation model) were prepared from ALS data, and DCM (digital canopy height model) was created from the difference between them. The canopy transmittance of the laser beam irradiated from the aircraft was calculated by setting a grid of 5 m × 5 m. Using these data as explanatory variables, we created a model for grasping stand characteristics based on the sum total of breast height cross section and forest material volume as objective variables. In addition, the degree of openness was calculated with a 5 m mesh and compared with the elapsed years after selective logging in units of stands. It was clarified that information on forest canopy transmittance of laser light is important in grasping stand characteristics using ALS data.

Planted forests exhibit longer spring phenology duration than natural forests in sub-alpine area of Southwest China

Pengsen Sun¹, Ning Liu², Zhen Yu³, Lei Zhang⁴, Jingxin Wang⁵, Shirong Liu⁶

¹Research Institute of Forest Ecology, Environment and Protection, Chinese Academy of Forestry, Beijing, China; ²Department of Forest Resources, University of Minnesota, Otto, USA; ³Department of Ecology, Evolution, and Organismal Biology, Iowa State University, Ames, USA; ⁴Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China; ⁵Division of Forestry and Natural Resources, West Virginia University, Morgantown, USA; ⁶Chinese Academy of Forestry, Beijing, China (sunpsen@caf.ac.cn; liun@um.edu; zyu@iastate.edu; zhangthunder@163.com; jxwang@wvu.edu; liusr@caf.ac.cn)

The Southwest China sub-alpine forests are composed large scale of planted forests, which are recently found to be prone to browning as a result of early spring water shortage. Spring phenology duration is strongly linked to subalpine eco-hydrological processes and thus the key to understand forest growing trends. However, spring phenology difference among planted (PF), natural (NF) and mixed forests (MF) under seasonal and inter-annual climate variation is poorly understood. The traditional and model-based phenology representations fail to capture the process and pattern of spring phenology. In this paper, we used a combination of surface meteorological data, forest inventory maps, 250 m resolution MODIS data, the spatial statistic histogram (SSH) method to analyze the spring phenological responses of PF, NF and MF. Our results demonstrate browning trend in planted forests and significantly greening trends in natural forests during the study period of 2001-2015. Advanced onset date of spring green up (SOS) in planted forests (DOY 148) than natural ones (DOY 156). SOS of planted forests exhibit high elevation sensitivity than natural forests. Mixed forest showed a decline in elevation sensitivity at 3500 m higher. All forests in subalpine area showed higher sensitivity to precipitation than to air temperature. The spring phenological duration (SOSd) of planted forests (47 days) was longer than natural ones (41 days), moreover, SOSd became variable and tend to be upward in all forests in most recent years, which indicates a sufficient sub-alpine water supply during spring and is likely a result of earlier snow melting.

PROTEST project: towards a multidisciplinary methodology for forest territorial analysis

Raphaël Aussenac¹, Jean-Mathieu Monnet¹, Thomas Carrette², Sylvie Durrieu³, Pierre Paccard⁴, Catherine Riond⁵, Arnaud Sergent⁶, Patrick Vallet¹

¹Univ. Grenoble Alpes, Irstea, LESSEM, Grenoble, France; ²FCBA, Saint Martin d'Hères, France; ³TETIS, Univ Montpellier, AgroParisTech, Cirad, CNRS, Irstea, Montpellier, France; ⁴Geopark Massif des Bauges, Le Chatelard, France; ⁵ONF R&DI, Chambéry, France (raphael.aussenac@irstea.fr; jean-mathieu.monnet@irstea.fr; thomas.carrette@fcba.fr; sylvie.durrieu@irstea.fr; p.paccard@parcdesbauges.com; catherine.riond@onf.fr; arnaud.sergent@irstea.fr; patrick.vallet@irstea.fr)

In French mountain areas, the heterogeneity of forests, the fragmentation of ownership and accessibility constraints hamper inventory and management actions. To ensure the sustainability of ecosystem services provided by forests, it is necessary to evaluate them while taking into account the local and global socio-

economic context. The PROTEST project aims to build a methodology for territorial analysis of forest resources, based on advances in remote sensing, GIS, forest dynamics modelling and territorial foresight. The study area of the project is the Geopark Massif des Bauges (France) that contains 50000 ha of forests. The first task is to produce a map of forest resources, based on airborne lidar remote sensing, and of its accessibility, based on the Sylvaccess model. The second task is to implement a territorial foresight work and define forest management scenarios that combine environmental and societal determinants. Societal factors and their possible evolutions will be defined on the basis of field surveys and expert opinions. Depending on these factors and on a typology of parcels, scenarios of forest management will be proposed to simulate the behavior of owners. In the third task, these scenarios will be integrated into a spatialized model of forest dynamics, in order to simulate the evolution of the forest mosaic at the parcel level. Linker functions will be integrated to evaluate ecosystem services (wood production, biodiversity, carbon stock...) from simulated forest characteristics. The results will be used to support participatory workshops that will aim to define a forest management strategy supporting the territorial development.

Technological innovations for monitoring the impact of forest management in forestry dynamics and carbon flows in Latin America */ Innovaciones tecnológicas para el monitoreo del impacto del manejo forestal en las dinámicas silviculturales y los flujos de carbono en Latinoamérica*

Natalia Ruiz-Guevara¹, Diego Delgado¹, Fernando Carrera¹, Mario Chacon¹, Miguel Cifuentes Jara¹

¹Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba, Costa Rica (natalia.ruiz@catie.ac.cr; ddelgado@catie.ac.cr; fcarrera@catie.ac.cr; mario.chacon@catie.ac.cr; miguel.cifuentes@catie.ac.cr)

Las innovaciones tecnológicas para el monitoreo de bosques en Latinoamérica se enfocan a medir el cambio de uso de tierras a gran y mediana escala, mientras que el monitoreo de unidades de manejo forestal no se realiza de manera regular o tecnificada. Se sistematizaron experiencias en países latinoamericanos para analizar el potencial de tecnologías disponibles para evaluar el impacto del manejo forestal, sobre la dinámica silvicultural y flujos de carbono. Estas, van desde imágenes de sensores remotos de distintas resoluciones, plataformas virtuales, drones para la teledetección forestal, dispositivos móviles y aplicaciones para el registro de inventarios en campo. Para la medición de flujos de carbono se identificó a las torres de medición de gases, plataformas virtuales colaborativas y calculadoras de carbono de uso forestal. El uso de dispositivos móviles y aplicaciones destacan por su bajo costo, facilidad de difusión, compatibilidad con diversas funciones y sencillez de uso. Se recomienda desarrollar aplicaciones con funciones múltiples, para el registro geográfico de árboles y parcelas de corta; cálculo de volúmenes de aprovechamiento e indicadores económicos; registro de indicadores de impacto como área de claros, afectación a vegetación circundante y regeneración natural; y estimación de emisiones de gases de efecto invernadero. A nivel nacional, se resaltan las experiencias de Brasil, Guatemala, Panamá y Surinam. Además, se recomienda realizar investigaciones comparativas respecto del costo y precisión entre información proporcionada por sensores remotos y el monitoreo directo en campo en áreas bajo manejo forestal, a fin de tener certeza sobre su potencial para la toma de decisiones silviculturales.

C4k: REMOTE SENSING AND GEOGRAPHIC INFORMATION SYSTEM FOR FOREST MONITORING AND MANAGEMENT

Forests in a changing planet: challenges for the sustainable development of tropical countries

Luiz Aragão¹

¹Tropical Ecosystems and Environmental Sciences, National Institute for Space Research, São José dos Campos, Brasil (laragao@exeter.ac.uk)

Fully functional tropical forests are critical for maintaining the eco-climatic stability of the Earth system and for providing ecosystem services crucial for social and economic development of tropical nations. Using the Amazon as a study case, this presentation will focus on the concept of sustainable development to discuss how remote sensing of tropical forests can support nations to achieve this new global paradigm. The interaction between climate and natural forests is the first step to understand the functioning of this ecosystems and how they store carbon, cycle water and maintain their diversity. These forests, however, are constantly threatened by human-climate interactions, which push these systems beyond their natural boundaries. Direct and indirect impacts of deforestation and fires are two of the most pressing issues in tropical countries, with consequences for the maintenance of the functioning of forests and their capacity to provide essential services for the development of these nations. Several studies using multiple spectral and spatial resolutions from passive and active remote sensors for Earth observation and climate are being developed to provide information on the extent of these forests, how they interact with climate and human-induced changes and what are the consequences of these interactions. From this understanding, I conclude by offering insights on to use this tool to generate fundamental information for supporting the long-term planning of the sustainable development of tropical nations.

Detection of early stage bark beetle infestations in spruce stands using multitemporal low cost hyperspectral imaging

Donatas Jonikavicius¹, Gintautas Mozgeris¹, Vytaute Juodkiene², Henrikas Stravinskas³, Albinas Tebera³

¹Vytautas Magnus university, Kaunas, Lithuania; ²University of Applied Sciences, Kaunas, Lithuania; ³Kaunas Forestry and Environmental Engineering University of Applied Sciences, Girionys, Lithuania (donatas.jonikavicius@vdu.lt; gintautas.mozgeris@vdu.lt; vytautejuodkiene@yahoo.com; h.stravinskas@kmaik.lm.lt; a.tebera@kmaik.lm.lt)

The insect outbreaks and resulting forest damages are becoming more intense nowadays. One of preconditions for successful control and fighting the insect attacks is early detection of the outbreaks. Recent advance of low-cost but effective remote sensing solutions offers new opportunities in monitoring forest conditions. The objective of this study was to develop operationalization proposals for using low-cost hyperspectral imaging technology for the identification of early stage bark beetle infestations in spruce stands. The study was carried out in Dubrava forest located in central part of Lithuania. Four imaging flights were conducted in summer seasons of 2017 and 2018, aiming to capture images after the infestation of spruce trees by bark beetle. Imaging system built on simultaneous use of a hyperspectral camera based on a tunable Fabry-Pérot interferometer and colour-near infrared (CIR) camera, installed on ultra-light type aircraft was used for data acquisition. Attacked trees were field identified and mapped, together with sample of not-infested trees. Images were processed to get image mosaics with ground sample distance (GSD) 15-20 cm for CIR images and GSD 40-60 cm for the hyperspectral images. The spectral characteristics of images were used to classify the crowns into two categories – infested and not-infested. The overall accuracy of classification was reached for the best case 77 % (Cohen's kappa: 0.54). Classification accuracies using hyperspectral data were up to 20% better than using the CIR data. The results suggested that novel remote sensing techniques could offer great potential for assessment of the health condition of spruce stands.

Mapping deforestation and forest degradation in Mato Grosso, in the Brazilian Amazon region, using fraction imagery derived from LANDSAT-8 OLI images / Mapeamento do desmatamento e degradação florestal no estado do mato grosso, amazônia brasileira, utilizando imagens fração derivadas das imagens oli do Landsat-8

Yosio Edemir Shimabukuro¹, Andeise Cerqueira Dutra¹, Egidio Arai¹, Valdete Duarte¹

¹Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil (yosio.shimabukuro@inpe.br; andeise.dutra@inpe.br; egidio.arai@inpe.br; valdete.duarte@inpe.br)

Desmatamento é a substituição da floresta por outra cobertura da terra enquanto a degradação é uma modificação da cobertura florestal a longo prazo. Na Amazônia brasileira a degradação florestal é causada principalmente pelas atividades de exploração seletiva da madeira e queimadas descontroladas, e a sua contribuição para o cálculo da emissão de carbono continua a ser um desafio. A discriminação entre áreas afetadas por corte seletivo e fogo é importante para o programa do REDD+ (redução de emissões por desmatamento e degradação florestal) da UNFCCC (Convenção-quadro das Nações Unidas sobre mudança climática). Neste contexto, este trabalho apresenta um procedimento semi-automático para monitoramento da degradação florestal na Amazônia brasileira utilizando imagens fração derivadas do Modelo Linear de Mistura Espectral (MLMS). Imagens OLI (Operational Land Imager) do Landsat-8 obtidas de 2015 cobrindo o estado do Mato Grosso na Amazônia brasileira foram utilizadas no método proposto. Primeiramente, a abordagem consiste em mapear áreas de desmatamento e áreas de florestas degradadas pelo fogo utilizando segmentação das imagens fração. Em seguida, as áreas degradadas por exploração seletiva da madeira foram mapeadas usando um classificador baseado em pixel. Os resultados mostraram que as imagens fração são adequadas para mapear as áreas desmatadas e as áreas degradadas causadas por fogo e corte seletivo. Conclui-se que a resolução espacial desempenha um papel importante para o mapeamento de áreas de exploração seletiva da madeira, já que o tamanho dos píxeis e carregadores utilizados para o arraste das árvores cortadas são menores do que a resolução espacial das imagens OLI.

Assessing longitudinal variability in phenological characteristics of Shorea robusta forest in Nepal using remotely sensed data

Sanyog Basnet^{1,2}, Anil Koirala², Damodar Gaire¹, Cristian R. Montes³

¹Institute of Forestry, Tribhuvan University, Hetauda, Nepal; ²Ministry of Forest and Environment, Government of Nepal, Kathmandu, Nepal; ³Warnell School of Forestry and Natural Resources, University of Georgia, Athens, USA (fr.sanyogbasnet@gmail.com; anilk@uga.edu; d.gaire@forestrynepal.org; crmontes@uga.edu)

Shorea robusta is the most valuable timber species of Nepal in terms of distribution, utilization and financial gain. Despite its wide environmental distribution range and its phenological behavior across the country, silvicultural operations for this species are based only on a single operational calendar developed by government. The research on phenological characteristics of this species is very scarce. Thus, the aim of this study was to address the knowledge gap on phenological characteristics of *Shorea robusta* forests from different longitudinal ranges, which can eventually improve their overall management in the country. The study retrieved the seasonality parameters of four different *Shorea robusta* forest blocks in a longitudinal range within the time frame of 2012 to 2017 by analyzing the MODIS NDVI data layer with the spatial resolution of 250m of 16-day composite. For the selected time period, the phenological parameters of *Shorea robusta* forest were extracted using the TIMESAT program and mapped out the change in NDVI. The study revealed uneven start in growth initiation, ranging between 12 to 45 days for the study areas. Phenological start and ending times were found to be earlier in eastern Nepal as compared to the western part of the country. The length of growing season was highest in Middle Nepal while the peak NDVI found to be highest in western Nepal. Our study suggested the need for the appropriate adjustment in the schedule and annual calendar of silvicultural and forest management activities for *Shorea robusta* forest in order to achieve optimum financial return.

Annual (2000-2016) maps of forest aboveground biomass in the Northwestern USA

Andrew Hudak¹, Patrick Fekety², Steven Filippelli², Michael Falkowski², Robert Kennedy³, Van Kane⁴, Grant Domke⁵

¹USDA Forest Service, Moscow, USA; ²Colorado State University, Fort Collins, USA; ³Oregon State University, Corvallis, USA; ⁴University of Washington, Seattle, USA; ⁵USDA Forest Service, St. Paul, USA (andy.hudak@gmail.com; patrick.fekety@colostate.edu; steven.filippelli@colostate.edu; michael.falkowski@colostate.edu; rkennedy@coas.oregonstate.edu; vkane@uw.edu; gmdomke@fs.fed.us)

Airborne lidar collections were associated with project-level field plots (N=3,805) to predict forest aboveground biomass (AGB) with high confidence where lidar data were available. The plot and lidar reference data were contributed by 29 different stakeholders representing different forest types and conditions from across the northwestern USA, but nevertheless constituting a biased sample of the region. In this project, multiple project-level AGB maps served as training areas for predicting forest AGB synthetically; predicted AGB pixels were randomly drawn from the landscape-level forest AGB maps following post-stratification. Predictor variables in the regional model included annual tasseled cap indices (and annual delta indices) derived from LandTrendr (a Landsat image time series algorithm), the global forest canopy height product, a digital elevation model, and 30-year (1960-1990) climate normals produced for North America. At both the landscape and regional modeling scales, we used Random Forests (RF) as our predictive modeling tool. The regional model produced annual AGB maps at 30m resolution from 2000 through 2016 for the study region. Our verification approach was to compare the mapped annual biomass predictions to AGB estimated by the US Forest Inventory and Analysis (FIA) Program nationally at FIA plots coincident in space and time, and calculate a simple linear model bias correction to bring our AGB estimates in line with unbiased FIA estimates. National-scale forest cover maps generated independently from PALSAR data at 25-m resolution were used to mask non-forested areas from the final AGB maps prior to public archival and for monitoring, reporting, and verification (MRV).

The moja global open-source software library for integration of land sector data in support of climate change mitigation and other land management objectives

Robert Waterworth¹, Werner Kurz², Robert de Ligt¹, Marcela Olguin³, Guy Janssen⁴

¹Mullion Group, Canberra, Australia; ²Natural Resources Canada, Canadian Forest Service, Victoria, Canada; ³Mullion Group, Mexico City, Mexico; ⁴moja global, Brussels, Belgium (robert.waterworth@mulliongroup.com; werner.kurz@canada.ca; robert.deligt@mulliongroup.com; marcela.olguin@mulliongroup.com; guyjanssen@june@gmail.com)

The land sector is expected to contribute to greenhouse gas emissions reductions and sinks at global, national and local levels. Policy instruments including Nationally Determined Contributions, Reducing Emissions from Deforestation and Forest Degradation, and carbon markets all require land sector greenhouse gas monitoring systems to advance rapidly if countries are to use the land sector to help meet emission reduction goals. Improving the

spatial and temporal resolution of emissions estimates can inform policy development and verify that emissions mitigation activities are real. Access to remote sensing data that help inform land management has greatly increased in recent years, but tools to convert such data into emissions and removals estimates are still limited. Here we show the importance of spatially and temporally resolved emissions estimation methods using the Full Lands Integration Tool (FLINT), an open-source platform developed specifically to take advantage of the fine spatial and dense temporal activity data from remote sensing to produce spatially and temporally resolved emissions and removals estimates. FLINT is a modular platform that does not lock users to any specific data product, emissions estimation method or modelling approach. This allows users to start with basic methods such as global emission factors and progress to advanced models and add improved data over time within a single framework. To date, FLINT combined with scientific modules configured to country-specific needs has been applied in over 10 countries, helping build an open-source community (moja global) that ensures reduced development costs and long-term benefits for all users.

Estimating revenue and cost as well as profitability and availability of forest resources in the whole of Japan

Kazuhiro Aruga¹, Takahisa Yamamoto¹, Yusuke Matsuoka¹, Battuvshin Biligt², Hiroaki Shirasawa³

¹Utsunomiya University, Utsunomiya, Japan; ²Tokyo University of Agriculture and Technology, Tokyo, Japan; ³Forestry and Forest Products Research Institute, Tsukuba, Japan (aruga@cc.utsunomiya-u.ac.jp, ma178506@cc.utsunomiya-u.ac.jp; mc196952@cc.utsunomiya-u.ac.jp; biligt.blizz@gmail.com; shirasawa@ffpri.affrc.go.jp)

We developed the model to estimate revenue and cost as well as profitability and availability of forest resources from each forestry operation site with appropriate forest operation system according to road networks and geography using GIS data processed by MATLAB in Tochigi prefecture, Japan (Yamamoto et al. online first, IJFE). We are expanding the model to the whole of Japan by obtaining GIS data for private and communal forests from other 46 prefectures and for national forests from the Japan Forestry Agency. The estimated revenue and cost as well as profitability and availability will be verified with the statistical data compiled by the Japan Forestry Agency obtained from each prefecture. Then, the model will be used to project those future values of each forestry operation site for sustainable forest management. Forest GIS data were developed separately for national forests by the Forestry Agency, and for private and communal forests by each prefecture. This is the first study of this kind combining private and communal forests with national forests, in the whole of Japan. Furthermore, existing studies developed similar models, but their units of forests were defined using 1 km² mesh or municipality. MATLAB could be used to make estimations for the whole of Japan, within a reasonable timeframe, defining units as forestry operation sites.

Multicollinearity effect on aboveground biomass estimation efficiency using spaceborne multispectral and full-waveform laser ranging data collected by the Landsat 7 ETM+ and the Global Ecosystem Dynamics Investigation (GEDI) missions

Svetlana Saarela¹, Sören Holm¹, Paul P. Patterson², Magnus Ekström¹, Laura I. Duncanson³, John Armston³, James R. Kellner⁴, Sean P. Healey⁵, Göran Ståhl¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²USDA Forest Service, Fort Collins, USA; ³University of Maryland, College Park, MD, USA; ⁴Brown University, Providence, USA; ⁵USDA Forest Service, Ogden, USA (svetlana.saarela@slu.se; soren.holm@gronsteden.se; plpatterson@fs.fed.us; magnus.ekstrom@slu.se; lduncans@umd.edu; armston@umd.edu; james_r_kellner@brown.edu; seanhealey@fs.fed.us; goran.stahl@slu.se)

Forests play a vital role in forming the environment as a habitat for multitude species influencing climate change largely by affecting the amount of carbon dioxide in the atmosphere. A need of information on state of forest attributes such as growing stock volume and aboveground biomass (AGB) is demand-driven by a number of international organizations. Typically, national forest inventory systems provide the information based on field measurements. However, the fieldwork is costly and for remote areas inefficient. With increased availability of remotely sensed (RS) data, opportunities to improve the information efficiency become noticeable. Recent developments of statistical methods within model-based inference allow to combine RS data with field measurements to obtain accurate estimates of AGB with corresponding estimated uncertainties. The two most popular estimation modes are (i) the conventional model-based, and (ii) hybrid estimator. The latter one utilizes sampled RS data. Although, the methods were proven efficient, their performances are largely dependent on the parameters of the regression models involved. In regression analysis, multicollinearity is often treated as a problem to be fixed. It is known to inflate the variance of estimated model parameters, which might lead to misjudged significant predictor variables. However, for prediction purposes, it is not clear whether multicollinearity leads to overestimation of prediction variance. This study analyzes an effect of multicollinearity on AGB estimation efficiency within model-based inference using wall-to-wall Landsat 7 ETM+ data and sampled GEDI data. Our results show that multicollinearity lead to almost negligible effect on the AGB estimation efficiency.

C4I: FOREST INVENTORY AND MODELING: PAST SUCCESSES, CURRENT CHALLENGES AND FUTURE PROSPECTS - 2

Local and regional patterns of stand development of *Populus tremuloides* in the southwestern United States

Warren Moser¹

¹US Forest Service, Rocky Mountain Research Station, Flagstaff, AZ, USA (warren.k.moser@usda.gov)

Populus species exist across the northern hemisphere either as standalone forests or mixed with other tree species, particularly conifers. Quaking aspen (*P. tremuloides* Michx.) occurs in montane and high plateau environments across the Southwestern United States. Over the past several decades, reports of regional aspen decline have stimulated interest in the long-term health and viability of aspen. The U.S. Forest Service's Forest Inventory and Analysis (FIA) program has been collecting and analyzing data on aspen extent, growth and mortality since the 1990s. This paper analyzes seral and stable stands, based on patterns of disturbance, proportion of site occupancy by aspen and presence of adequate regeneration, on a national forest in Utah. The structure and dynamics of these stands are then compared with similar stands in the FIA database to evaluate trends in growth, regeneration and mortality. Of the 94 plots measured on the national forest, only 50 % contained aspen trees in the understory plot and only 16 % contained understory trees at least 1.9 m in height (20 trees in total). These results illustrate the challenge of appropriate aspen stand management: Will there be aspen trees in the future? Management actions geared to the successional state of aspen will be suggested. The patterns of dependence upon disturbance, vulnerability to successional pressures and management challenges in the face of herbivory and climate influences are common throughout the *Populus* genus and our results should interest anyone who manages this forest type.

A method to reduce inventory cost and projection uncertainty using a state space modeling with explicit uncertainty drivers

Cristian Montes¹, Bronson Bullock¹

¹Warnell School of Forestry, University of Georgia, Athens, USA (crmontes@uga.edu; bronson.bullock@uga.edu)

Under a continuing low-interest rate environment, volatile debt and equity markets, sustained yield with low uncertainty result in a very attractive incentive for timberland investors. However, in spite of the attractiveness of the investments, forest yield is also subject to volatility. Forest yield, being a function of available resources, such as nutrients, water and, temperature, is subject to variations that will depend on the inherent climatic variability at any given site. Forecasting climatic variability has become mainstream science over the last three decades, with variable rates of success; therefore, it is hard to suggest the use of climatic variables in forest applications without inducing bias in forest projections. To bridge the gap between state of the art in climate forecasting and the need to make better management decisions, we developed a framework to account for climatic uncertainty as part of the decision process, explicitly quantifying between-site differences in climatic variation and using the expected variation as part of the uncertainty term in a growth and yield model. We parametrized a loblolly pine state-space growth and yield model using the variation in climatic variables such as water deficit, excess water, and temperature as part of the uncertainty term. Our results show clear differences among areas where loblolly pine is planted in the southeast US, suggesting a potential path to include climate information as part of the decision-making framework. When combined with spatially explicit inventory data, our framework allows for a reduction in inventory costs and uncertainty projections on even-aged plantations.

Comparing the form of different genetic materials of *Eucalyptus* using model fit and selection for taper equation

Rafaela Pereira Neves¹, Rildo Moreira e Moreira¹, João Luís Ferreira Batista¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (rafaelapnaves@gmail.com; rmoreira@usp.br; batista.jlf@usp.br)

When the objective of commercial forest plantations is for the nobler uses of wood, there is the interest in genetic materials that have better forms, not only for those that produce more volume, because it is desirable trees with larger dimensions. There are several approaches to express the form of trees, simple approaches such as form factor and complex approaches such as the modeling of trunk profile through taper equations. Our objective is to identify genetic materials of *Eucalyptus* that have better form and search for alternatives that better express the form of trees. The experiment was performed in Itatinga, São Paulo, Brazil. We used data from 417 trees cubed from 18 genetic materials at 11 years old. Using model fit and selection, we describe the taper of trees (DBH² as a function of height) through a linear heteroscedastic model using a trigonometric function with four parameters. The best model was the one that considered each material has its own parameters, i.e., the form of the trunk differs among them. It would not be efficient comparing the four parameters of the model among the 18 materials. We used the fitted trigonometric function to find the form factor and the Pressler Height (at which point the diameter is equal to half of the DBH). The difference in trunk profile of the genetic materials was better expressed by the Pressler height than by the form factor. We conclude that different genetic materials under the same condition may have different forms.

Modelling the effects of pruning and thinning on tree- and stand-level growth for intensively-managed radiata pine plantations

Guillermo Trincado^{1,2}, Roland Peters², Luis Letelier²

¹Universidad Austral de Chile, Valdivia, Chile; ²Modelo Nacional de Simulación (MNS), Concepción, Chile (gtrincad@uach.cl; rpeters@udec.cl; lletelier@udec.cl)

Radiata pine (*Pinus radiata* D. Don) is the most important commercial tree species in Chile for producing pulp and solid wood products. These fast-grown plantations are intensively managed covering about 1.48 million hectares under a wide range of soils and climate conditions. For producing clear wood silvicultural interventions of thinning and pruning are applied on highly productive sites. The main goal of this research is to evaluate diverse approaches for modelling the short- and long-term response to pruning and thinning at individual tree- and stand-level to be incorporated into the growth and yield simulator INSIGNE. Data for this study will be obtained from long-term pruning and thinning experiments established by the MNS forest research center between 1987-1990 in eight locations. These experiments cover a wide range of thinning and pruning treatments (with three-repetitions) allowing for analysing long-term growth responses. Thinning and pruning response functions will be included at the stand-level basal area and at the tree-level diameter growth models. Using an independent dataset a comparison of predictive capabilities will be performed between the models including the thinning and pruning response functions over the baseline models. Furthermore, the best strategy for incorporating these response functions into the baseline models (e.g. additive or multiplicative) will be also explored.

How well can we predict tree recruitment in the Acadian forest in New Brunswick using mathematical models?

Marie-Andrée Giroux¹, Ines Khedhri^{1,2}, Fidele Bognounou^{1,2}, Gaétan Pelletier², Stéphanie Landry², Chris Hennigar³

¹K.-C.-Irving Research Chair in Environmental Sciences and Sustainable Development, Université de Moncton, Moncton, Canada; ²Northern Hardwood Research Institute Inc., Edmundston, Canada; ³New Brunswick Department of Energy and Resource Development, Fredericton, Canada (marie-andree.giroux@umoncton.ca; ines.khedhri@umoncton.ca; fidele.bognounou@gmail.com; gaetan.pelletier@hardwoodsnsb.ca; stephanie.landry@hardwoodsnsb.ca; chris.hennigar@gnb.ca)

Natural forest regeneration is a highly variable and largely stochastic process. The patterns of forest regeneration are not well known with regards to the establishment, survival, and growth of commercial northern hardwoods species in the Acadian Forest Region. This represents an important research gap because with current global pressures such as climate change, there is a critical need to predict how commercial species will regenerate under various environmental and silvicultural scenarios. One approach to contribute filling this gap is to develop models to predict various characteristics of forest regeneration, and determine whether the predicted characteristics are correlated with observed values from field data. The main objective of this project is to compare the observed and predicted recruitment or ingrowth for different hardwood species found in the Acadian forest in New Brunswick using simulation models. Ingrowth corresponds to the number of trees in a sample plot that have grown into a required threshold size (diameter at breast height; 5 cm in our study) over a certain period. We used a tree list model to predict the ingrowth of sugar maple, American beech, black spruce, and balsam fir, and compared the predictions with observed values of ingrowth. The adjusted coefficients of determination (adjusted-R²) between the observed and predicted values varied between 0.06 and 0.4. These results indicate that there is a need to adjust the model parameters in order to improve its prediction ability. This ongoing work will contribute producing critical modeling tools for managers, companies, and scientists from the forest sector.

Improving spatial distribution of growing stock volume (GSV) estimation using convolutional neural networks (CNNs)

Sungeun Cha¹, Hyun-Woo Jo¹, Moonil Kim¹, Cholho Song¹, Woo-Kyun Lee¹

¹Korea University, Seoul, Republic of Korea (tgy2005@korea.ac.kr; endeavor4_a1@naver.com; windy7up@gmail.com; cholhosong@gmail.com; leewk@korea.ac.kr)

In South Korea, where more than 63% of the country covered by forest, an accurate estimation of carbon stock is essential to understand the carbon cycle. However, current estimates of Korean growing stock volume (GSV) are mostly derived from expensive field data. Any techniques, which allows reducing amount of ground data with reliable accuracy, would save cost and time. The goal of this research is to test the Convolutional Neural Networks (CNNs) algorithm fed with a portion of the national forest inventory (NFI) data in order to predict the carbon stock for entire country using satellite imagery and auxiliary information. Spatial distribution of growing stock volume (GSV) of South Korean forests was predicted by CNNs algorithm, which is a sort of deep learning. NFI data was randomly sampled for the training from 90% to 10% in 10% increments. As a result of the analysis, more than 98% accuracy (Total GSV 713.25 Mm³) of the total GSV of the NFI data was obtained when training over 20%. However, when using 10% as training and 90% as validating, the estimated total GSV was 563.44 Mm³, and the accuracy was definitely reduced. Consequently, we found that the error rate of total GSV was less than 5% when using over 17% of NFI data as training. In this study, spatial distribution of growing stock volume of forests in South Korea was predicted by CNNs model based on satellite imagery, auxiliary information, and portions of NFI data.

Internet of trees: forest inventory in the internet of things age, the potential of using electronic sensors for asset monitoring and forest experiments

Esthevan Augusto Goes Gasparoto¹, Maycow Berbert¹, Mateus Yamoto¹, Marcos Isaac Junior¹, Emily Shinzato¹

¹Treovia Forest Technologies, São José dos Campos, Brasil (esthevan@treovia.com.br; maycow.berbert@treovia.com.br; mateus.yamoto@treovia.com.br; isaac.junior@treovia.com.br; emily@treovia.com.br)

The continuous forest inventory is one of the main support tools for proper management of forest assets. In order to estimate tree volume and forest growth rates, it is necessary to measure tree diameters. In spite of their extreme importance, within the forest science, the methodologies and tools to obtain and collect diameter over time, have undergone little technological evolution. Therefore, the present study aims to demonstrate the potential of using new technologies, which involve the application of IoT sensors and cloud computing, to obtain automated forest information. Electronic wireless dendrometers (IoT sensors), focused on industrial applications and fast-growing forests, have been developed and patented by the authors. Several IoT sensors were installed, along with partner companies, in commercial plantations of *Pinus* spp. and *Eucalyptus* spp. in 7 Brazilian states. The adoption of the technology has allowed to obtain data with very high precision and at submillimetric resolutions. In addition, it was possible to obtain real-time online information, eliminating expenses with displacement and mainly with the incidence of errors inherent to the human factor in the data collection. In addition, the technology allows the production of 600 times more information than the traditional methodologies used, helping forest researchers better understanding the interrelations of climate, site, management and forest growth.

Challenging the Peruvian government in leading the National Inventory of Forests and Wildlife: challenges and opportunities for Decision-Making / “Reto del Estado peruano en liderar el Inventario Nacional Forestal y de fauna silvestre: desafíos y oportunidades para tomar decisiones”

Aurea Erica Castro Aponte¹

¹SERFOR, LIMA, Peru (acastro@serfor.gob.pe)

El Perú, con 68,733,265 hectáreas en 2016, es uno de los 10 países con mayor cobertura forestal en el mundo y el segundo en Latinoamérica después de Brasil. En sus bosques habita gran diversidad biológica y su territorio es origen y fuente de suministro de ingentes cantidades de agua dulce proveniente de la gran cuenca amazónica. Sin embargo, estos bosques se talan anualmente a una tasa que supera las 120 mil hectáreas, tanto por acción de la agricultura migratoria y la ganadería, como por iniciativas privadas empresariales y por actividades mineras. Existe la necesidad de priorizar en la Política de Estado la generación de información actual del bosque. En este contexto, el Estado peruano implementó el Inventario Nacional Forestal y Fauna Silvestre-INFFS el año 2012 como un esfuerzo conjunto del gobierno a través del Ministerio de Agricultura y Riego y el Ministerio del Ambiente, y del Programa Forestal Global FAO-Finlandia. El INFFS su objetivo es “proveer en forma continua información actualizada y confiable para la planificación del manejo sostenible de los recursos forestales de las regiones Selva, Sierra y Costa peruanas, colectando, procesando y reportando datos sobre la biomasa, reservas de carbono, deforestación, biodiversidad de árboles y fauna silvestre e información socioeconómica de las poblaciones rurales asentadas en su entorno”. Finalmente, los inventarios son esenciales para la gestión forestal y como herramienta clave para los tomadores de decisión, posibilitando una gestión sostenible del recurso forestal para los privados (productores y empresas) y Administraciones públicas (ministerios y secretarías del Estado/Gobierno).

C4m: DECISION SUPPORT APPROACHES FOR FORESTRY OF THE 21TH CENTURY - 2

Simulating impacts of local forest policies on forest ecosystem functions

Yusuke Yamada¹ ; Yuichi Yamaura¹, Masayoshi Takahashi¹, Kazuki Nanko¹, Toshiya Matsuura¹, Shoji Hashimoto¹, Norimasa Takayama¹, Kenichiro Toda², Tamotsu Sato¹

¹Forestry and Forest Products Research Institute, Tsukuba, Ibaraki, Japan; ²Forestry and Forest Products Research Institute, Tsukuba, Ibaraki, Japan;

²Nagano Prefecture Forestry Research Center, Shiojiri, Nagano, Japan (yamayu@ffpri.affrc.go.jp; yamaura@ffpri.affrc.go.jp; martaka@ffpri.affrc.go.jp; knanko@ffpri.affrc.go.jp; matsuu50@ffpri.affrc.go.jp; shojih@ffpri.affrc.go.jp; hanri@ffpri.affrc.go.jp; toda-kenichiro@pref.nagano.lg.j)

Forest policies are designed to achieve desirable forests, however, the policies might not produce the intended results due to multiple decision makers of forestry activities. Simulating influences of policies on forest functions are vital to support policymaking. This research aims to estimate impacts of local forest policies on forest ecosystem functions in Japan. The impacts of policies are estimated by comparing current and future situations. To predict the future forest conditions, forestry harvesting by decision makers in the region is simulated. The simulation specifies the location of forestry harvesting according to probabilities that are defined by analysis of past harvesting location. The past harvested forests are identified with Hansen's forest loss data (<http://earthenginepartners.appspot.com/science-2013-global-forest>). The probabilities of harvesting are modified in each simulation according to forest policies. This research predicts future forest conditions under policies to promote wood

production and/or to alleviate the impacts of forestry harvesting. Then, forest ecosystem functions including wood production, biodiversity, soil conservation, carbon retention, protection from landslides, and recreation functions are evaluated for the current and simulated forests. The evaluation models are developed with national forest inventory data. Results of the simulation indicated that the increase in wood production impaired the future forest ecosystem functions, but not to the point where the local forest was harmed disastrously. The simulation also suggested that the regulation on harvesting in the appropriate area could alleviate the impacts. These results can support establishing policies to manage local forest sustainably.

Mechanistic forest growth simulation versus empirical growth tables in spatio-temporal decision support for forest management

Ilië Storms¹, Bruno Verbist¹, Jos Van Orshoven¹, Christopher Reyer², Bart Muys¹

¹KU Leuven Division Forest, Nature and Landscape, Faculty of Bioscience Engineering, Leuven, Belgium; ²Potsdam Institute for Climate Impact Research, Potsdam, Germany (ilie.storms@kuleuven.be; bruno.verbist@kuleuven.be; jos.vanorshoven@kuleuven.be; reyer@pik-potsdam.de; bart.muys@kuleuven.be)

Decision support systems (DSS) are becoming more widespread in forest management, helping to shape the forests of the future. These systems allow foresters to simulate future forest performances under expected or hypothetical conditions and select the most optimal forest management strategy based on the simulations results and stakeholders' preferences. To increase forest managers' awareness about the long-term effects of their management, a DSS called Sim4Tree was developed for Flanders, Belgium and has been operational for almost a decade. Sim4Tree is a strategic and tactical planning tool that performs simulations of forest development based on traditional empirical growth curves, which, thanks to the flexible Sim4Tree structure, can be easily replaced by other growth models. Unfortunately, empirical growth curves do not allow easily taking into account dynamic processes such as those related to changing management practices and climate change. By plugging in the mechanistic forest growth model '4C (FORESEE)' these changing conditions can be accounted for, allowing to predict future biomass standing stock under different management and climate scenarios in Flanders. Our research shows the possibility of using national forest inventory (NFI) data to parameterize mechanistic models and illustrates the importance of mechanistic models in DSS by evaluating different management (business as usual, production oriented and recreation oriented) and climate scenarios and how these compare to the results from the empirical growth tables and the NFI. The results will improve the performance of Sim4Tree to support the choice for optimal future-oriented forest management scenarios.

Harvest schedule under price endogeneity: linking field operations to market decisions

Bruno Kanieski da Silva¹, Frederick W. Cabbage¹, Robert C. Abt¹, Karen L. Abt²

¹North Carolina State University (NCSU), Raleigh, USA; ²U.S. Forest Service, Southern Research Station, RTP, USA (bkanies2@ncsu.edu; cabbage@ncsu.edu; bob_abt@ncsu.edu; kabt@fs.fed.us)

Harvest schedule models are a common decision-making system used by forest planners and practitioners. These models assume timber prices are exogenous to timber supply and use operational and biological constraints to decide the optimal silvicultural prescriptions. However, this assumption does not necessarily hold since few landowners might have a large share of timberland in a market, and therefore their harvest decision might substantially affect the market supply and prices. We built a decision support system where timber prices are endogenous to timber suppliers; the silviculture operations are therefore a function of common production restrictions and also from the interaction with other market agents. Users have the option to estimate the optimum allocation of a resource based on other landowners' decision in a game theory set up. Initial results demonstrated a more realistic representation of business strategy in concentrated markets. In addition, the approach presented complements the partial equilibrium models by linking decision in the field and market shocks.

FORSITE - a dynamic forest site classification to support adaptive forest management

Harald Vacik¹, Herbert Formayer¹, Klaus Katzensteiner¹, Michael Grabner¹, Marcus Wilhelmy², Michael Englisch³, Klaus Klebinder⁴, Herwig Prose⁵, Walter Poltnig⁶, Gerfried Winkler⁷, Ralf Klosterhuber⁸, Alexander Podesser⁹

For the selection of appropriate tree species mixtures forest management asks for a sound database on forest site information especially under the consideration of climate change. Adaptive forest management takes into account the likely effects of climate change and innovative decision support approaches can help to increase the resistance and resilience of forest ecosystems. The lack of forest site information in large parts of Austria asks for a new approach in forest site classification and mapping. Climate change will affect the classification of forest sites and the future choice of tree species. Theoretical concepts for a "dynamic site classification" exist, but its large scale implementation as an integrated site and forest classification is a scientific challenge. In this contribution we present the approach based on a GIS-based geo-ecological stratification model. The database is based on a digital elevation model, a geological base map, digitally available site and climate data as well as empirical site parameters. A map of forest types will be derived based on thematic maps, including information about energy, water and nutrient balance. Those parameters will be modelled on the basis of point and area related data, which are combined to forest types with a uniform combination of site factors. The model allows a dynamic stratification of the forest types based on a logical combination of the geo-ecological parameters. In addition to the ecological facts, each forest type is characterized by silvicultural guidelines containing information on the choice of tree species, potential hazards and adaptive forest management practices.

Managing forests for water harvesting under changing future climate in Korea using the WEPP model

Hakjun Rhee¹, Hung Tae Choi², Dong-Geun Kim³, Anurag Srivastava⁴, Hyun Seok Kim⁵

¹Chungnam National University, Daejeon, Republic of Korea; ²National Institute of Forest Science, Seoul, Republic of Korea; ³Kyungpook National University, Sangju, Republic of Korea; ⁴Purdue University, West Lafayette, USA; ⁵Seoul National University, Se (hakjun.rhee@gmail.com; choiht@korea.kr; dgkim96@knu.ac.kr; srivas42@purdue.edu; cameroncrazies@snu.ac.kr)

Forest provides various ecosystem services, and can be managed for water resources. This study accesses the effects of forest management on water harvesting by applying the Water Erosion Prediction Project (WEPP) model to unit area (1 hectare) of different forest stands (coniferous, deciduous, and mixed) and management activities (control, 30%, 50% thinning) under current and future climates at three locations in Gwangneung and Yangju, Korea. The modeling

results from no management activities were compared to stream runoff monitoring data from 2003 to 2017, which showed the Nash-Sutcliffe efficiency of 0.700, 0.660, and 0.557. The WEPP predicted the average runoff of 813, 813, and 736 mm/m²/year, compared to the monitored average runoff of 797, 1011, and 724 mm/m²/year for coniferous, deciduous, and mixed forests. The WEPP also predicted the runoff increase of 75.2 and 84.2 mm/m²/year from 30% and 50% thinning for coniferous, 74.9 and 83.7 mm/m²/year for deciduous, and 59.5 and 67.5 mm/m²/year for mixed forest. These runoff increases were not enough to warrant thinning operations economically under current climate in Korea. The study finds that the WEPP can be used to assess the effects of forest management on water harvesting. The WEPP will be further applied to the three forests under future climates, and up-to-date assessment on the modeling will be presented. The modeling approach from this study will be used to develop online WEPP interface for water harvesting that is later incorporated into multi-objective forest management decision support system in preparation for new climate era.

Biodiversity assessment in plantation forests of Northern Portugal with fuzzy-logic approach

Marija Cosovic¹, Peter Biber², Brigite Botequim¹, Miguel Bugalho³, José Guilherme Borges¹

¹Forest Research Centre, School of Agriculture, University of Lisbon, Lisbon, Portugal; ²Center of Life and Food Sciences Weihenstephan, Technical University of Munich, Freising, Germany; ³Center for Applied Ecology "Prof. Baeta Neves", School of Agric (cosovicmaja@gmail.com; peter.biber@lrz.tu-muenchen.de; bbotequim@isa.ulisboa.pt; migbugalho@isa.ulisboa.pt; joseborges@isa.ulisboa.pt)

Biodiversity in forest management planning recently became a necessity for ensuring regular ecosystem functioning, resilience and sustainability. The specific objective of this research was to examine biodiversity at the stand-level in plantation forests. The case study area in Vale de Sousa, the North of Portugal, (14.773 ha) is mainly taken by plantation forests of maritime pine and blue gum in pure and mixed stands. Fuzzy logic for evaluating biodiversity and other ecosystem services was recently proposed and demonstrated by P. Biber in the context of the EU project ALTERFOR. In this study, we applied a fuzzy-logic approach for testing three biodiversity indicators: tree species composition, tree mortality and shrub biomass (Mgha⁻¹). This approach gives values between 0 (very low) and 1 (very high) provision of biodiversity categories and allows qualitative value-rules in relation to these four indicators. The value-rules are established according to stakeholder's knowledge and validated by experts. The values of each indicator are expressed in a form of colored matrices and a final fuzzy output of biodiversity is expressed as a continuous score between 0 and 1. The results demonstrate that monoculture stands have the lowest score for biodiversity due to the zero level of each indicator after the clearcut. Mixed stands have different periods of clearcut and this contributes to a higher score for biodiversity in general (fuzzy-output). The fuzzy-logic approach is a very useful tool as it provides powerful reasoning resources for decision support, capturing the qualitative assessment given by stakeholders and subsequently enabling quantitative results.

A multi-criteria decision support system for industrial forest plantations interactive management groups based on compromise programming

Silvana Nobre¹, Luis Diaz-Balteiro¹, Luiz Carlos Rodriguez², Luiz Felipe Arcalá³

¹Universidad Politécnica de Madrid – ETSI de Montes, Forestal y del Medio Natural, Madrid, Spain; ²Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Departamento de Ciências Florestais, Piracicaba, Brasil; ³Innovatech, Consultin (silvana.nobre@gmail.com; luis.diaz.balteiro@upm.es; lcer@usp.br; larcala@innovatech.com.br)

Forest plantation managers face many conflicts as they continuously seek higher productivity levels at lower costs and higher profits with minimum social and environmental impacts. Leading countries on timber, pulp, and fiberboard have their managers constantly interacting to fine-tune industrial and forest demands. The decision process needs a compromise solution to accommodate antagonisms. The multicriteria approach may be applied since it sustains that decision makers seek to find a balance between objectives usually in conflict. Decision Support Systems (DSS) employ computer-assisted optimization approaches, which have been used since the early 1960s. Nowadays, multi-objective Group Decision Making (GDM) techniques rely on new coming technology platforms that have empowered models and software developers. We present a DSS that overcomes the challenges brought by the real-life mix of goals confronted by the managers. We have applied the MCDM (Multi-Criteria Decision Making) approach to Forest Strategic Planning using a generalizable MOLP (Multi-Objective Linear Programming) and Compromise Programming embedded in a DSS that offers an interactive GDM (Group Decision Making) interface. It was tested on a Brazilian case to assess the capability of supporting decisions of stakeholders representing industrial, forest, social and environmental interests. The decisions concerned the management of 20 thousand hectares of eucalyptus plantations to supply a wood panel plant in the State of Mato Grosso do Sul, Brazil. As a result, the proposed DSS mapped the consequences to the future of the plantations as changes in macro-economic context, investors' strategies and climate interacted, creating challenging and conflictive situations.

Achieving dynamic treatment units in forest planning using pixel proximity

Pär Wilhelmsson¹, André Wästlund¹, Karin Öhman¹

¹Department of Forest Resource Management, SLU, Umeå, Sweden (par.wilhelmsson@slu.se; andre.wastlund@slu.se; karin.ohman@slu.se)

Conventional forest planning today is based on the stand approach. The forest is divided into stands, homogeneous in aspects relevant to the upcoming forestry and fixed over time. Most often treatments are applied the entire stand. Past studies have reasoned that this limits flexibility when striving for goal achievement and they have also shown that this is not the only approach possible. Another is the dynamic treatment unit approach. Here the concept of the stands is neglected. The forest data consists of small pixels which is made possible by advances in remote sensing. The treatment units exist only momentarily and are formed by clustering treatments in space and time. The objective of this study is to present a model for conducting forest planning by the dynamic treatment unit approach where the planning problem could be solved with an exact solution method. The spatial aspect of the model is represented by a metric which takes into account treatments of neighboring pixels within a radius from a given pixel. The presented model is in a case study included in a forest planning problem including the net present value, the spatial metric and harvest flow constraints. The data consists of 3587 pixels of 12,5x12,5 m corresponding to 56 ha of forest land in the southwest of Sweden. The results proved the model to be successful in achieving the DTUs and solved the problem within reasonable time. This study adds a method to achieve dynamic treatment units in forest planning.

C4n: INNOVATIVE APPLICATIONS OF UNMANNED AERIAL VEHICLES (UAVS) IN FOREST SCIENCE AND MANAGEMENT - 2

Use of unmanned aerial vehicles in forest consulting: opportunities and barriers

Patrícia Nazário¹

¹*Ekoflow Soluções Ambientais, União da Vitória, Brasil (pattyinpa78@gmail.com)*

Unmanned aerial vehicles (UAVs), also known as Drones or RPAS, have been increasingly used in precision forestry, because allows the generation of images with a level of detail higher than traditional satellites. The use of UAVs in the forestry sector is broad, been possible to replace traditional methods of plant survival evaluations, with advantages in terms of accuracy and cost. Using a laser active sensor (LiDAR) platforms, data such tree height can be obtained directly and volume and basal area are obtained indirectly. From images captured by RGB sensors, it is possible to estimate the wood stock in the field by applications for mobile. Yet, the application still restricted, with great potential for growth as result of advances in scientific research, with about 3000 articles published on applications of UAVs in forests in 2018. Furthermore, the offer of UAVs with good cost and performance for different jobs in the forest area been increasing, some manufactured by DJI may be highlighted: Phantom and Mavic. However, it is necessary to invest in training and instruments, to offer good services and products, leveraging market. Although the cost of acquiring a UAV has become more affordable, equipment for image processing (hardware and software) are costly, and it is necessary investment in good processors, GPUs, RAM and devices with high storage capacity, the acquisition of a software license stay expensive. If the service is volume calculation of forest assets, may be necessary to invest more in the UAV acquisition and the LiDAR system.

Unmanned Aerial System LiDAR data as basis for in-situ forest inventories

Markus Hollaus¹, Wilfried Karel¹, Norbert Pfeifer¹, Moritz Bruggisser¹, Martin Wieser¹, Magnus Bremer^{2,3}, Martin Rutzinger³, Di Wang⁴, Guenther Bronner⁵

¹*Department of Geodesy and Geoinformation, TU Wien, Vienna, Austria;* ²*Institute of Geography, University of Innsbruck, Innsbruck, Austria;* ³*Institute of Interdisciplinary Mountain Research (IGF), Austrian Academy of Sciences (ÖAW), Innsbruck, Austria;* ⁴*Department of Built Environment, Aalto University, Helsinki, Finland;* ⁵*Umweltdata GmbH, Wolfsgraben, Austria (markus.hollaus@geo.tuwien.ac.at; wilfried.karel@geo.tuwien.ac.at; norbert.pfeifer@geo.tuwien.ac.at; moritz.bruggisser@geo.tuwien.ac.at; martin.wieser@geo.tuwien.ac.at; magnus.bremer@uibk.ac.at; martin.rutzinger@oeaw.ac.at; di.wang@aalto.fi; g.bronner@umweltdata.at)*

The investigation of new acquisition methods for acquiring in-situ forest inventories (FI) is an active research field today. The fast technological development of terrestrial laser scanner (TLS) during the last years allows the 3D reconstruction of entire forest scenes with cm-accuracy. Even though the estimation of tree position and diameter at breast height (DBH) is possible with precisions that are comparable with traditional in-situ measurements, the tree height estimation is often hampered due to occlusions of the tree tops. In the last years several lightweight, survey-grade LiDAR sensors mounted on unmanned aerial systems (UAS) were developed and are available on the commercial market. These so-called UAS-LiDAR devices open up new possibilities for FIs. The acquired 3D point clouds enable the 3D modeling of individual trees up to branch level and thus tree position, tree height, taper function, DBH and forest structure can be derived with different levels of detail. The advantage of UAS-LiDAR is the estimation of tree heights with very high precision especially for the dominant and codominant trees. In the opposite suppressed trees are often not represented in the derived 3D point cloud and consequently their tree position and height can not be assessed. Within this contribution data sets from different survey-grade UAS-LiDAR systems will be shown. The accuracy and completeness of the derived forest attributes for several coniferous and deciduous forest sites in Austria will be presented. Finally, a framework of integrating this type of data into operational FIs will be discussed.

Comparison of above canopy and below canopy laser scans using UAV and mobile laser scanning method

Peter Surovy¹, Karel Kuželka¹, Martin Slavík¹, Lukáš Bilek¹

¹*Czech University of Life Sciences Prague, Prague, Czech Republic (surovy@fd.czu.cz; kuzelka@fd.czu.cz; mslavik@fd.czu.cz; bilek@fd.czu.cz)*

Laser scanning from UAV based platforms is recently becoming innovative way to obtain data from forests ecosystems. It provides detailed 3D point clouds with accuracy within centimeters. In contrast to UAV photogrammetry the movement of sensor can be faster, and it also improve reconstruction of the ground and the partially shaded area. In this work we present a comparison of the same laser scanner type (Riegl VUX 1) deployed in the first case on the UAV platform Riegl Ricopter and in the second one on the ground using backpack career for acquisition of the data from the same forest stand. The aerial scanning is faster and more comfortable, on the other hand the terrestrial mobile scanning does not require flight permission and highly trained personnel. In terms of time consumption the ground acquisition takes more time, on the other hand flying requires pre- and post- flying procedures which makes the overall time requirements comparable for both scenarios. Studied stand is 60 year old pine forest (*Pinus sylvestris*) of 0.8 stocking density. By both methods the tree amount recovered was 100%, the ground based method has higher error in terms of height and diameter at breast height mostly due to the misalignment of individual walks (scans), the aerial method provides more accurate and precise measurement of both of these two variables. The ground method, though provides higher density of points on the stems and bottom part of crowns and the stem cleanness and taper can be more precisely estimated from these data.

Inter-comparison of UAV SfM and UAV LiDAR to capture understorey structural characteristics

Samuel Hillman¹, Luke Wallace¹, Arko Lucieer², Karin Reinke¹, Darren Turner², Simon Jones¹, Bryan Hally¹

¹*RMIT University, Melbourne, Australia;* ²*University of Tasmania, Hobart, Australia (samuel.hillman@student.rmit.edu.au; luke.wallace2@rmit.edu.au; arko.lucieer@utas.edu.au; karin.reinke@rmit.edu.au; darren.turner@utas.edu.au; simon.jones@rmit.edu.au; bryan.hally@rmit.edu.au)*

Estimates of below canopy vegetation have been identified as an important variable for wildlife habitat diversity, precision forestry, fuel hazard modelling and understorey forest competition dynamics. While Unmanned Aerial Vehicles (UAV) equipped with digital cameras and laser scanners are being increasingly used to measure overstorey canopy metrics variables, less emphasis has been placed on their ability to characterise the below canopy vegetation. The paper explores 3D information collected using UAV platforms for describing structural properties. Sensors including the Reigl mini-VUX, Velodyne Puck, Sony Alpha 6000 and DJI Phantom pro-4 were deployed in a range of common forest types in Australia to capture 3D information for comparison. Sub-canopy metrics including height and cover were derived and compared to reference data collected using a Terrestrial Laser Scanner. Results suggest that changes in canopy characteristics of density and height along with below-canopy characteristics of near-surface and surface cover and height can be resolved to varying degrees using both sensors. The image based approach is able to characterise the understorey of sparse cover environments with acceptable accuracy (cover +/- 10% and height < 0.5m). However in higher cover, multi-storey environments this technology is not accurate. The LiDAR scanners perform better in these environments with the

multiple returns offered by the mini-VUX scanner offering the greatest opportunity to observe below canopy structure. The relative low-cost in combination with accurate assessments of forest structure, UAV approaches represent a viable technique to provide forest policy makers with the information required to make informed decisions for implementing management strategies.

Regeneration behaviour of Okoumé *Aucoumea klaineana* in canopy gaps of a forest concession in Gabon

Christian Aeschlimann¹

¹Bern University of Applied Science, Bern, Switzerland (christian.aeschli@gmail.com)

From an economic perspective, Okoumé is the most important tree species of Gabon. However, since it is considered as a long living pioneer species regeneration under selective harvesting management is insufficient. In a first step, the current state was analysed based on intense literature review and conduction of expert knowledge. In addition, an inventory as a chrono sequence was performed on two sites where selective harvesting interventions took place in 2017, 2016, 2015, 2014 and 2010. In total 46 plots were installed in logging gaps in order to assess the regeneration dynamic of Okoumé. One site is embossed by aged Okoumé forest, while the other one is of very young Okoumé forest type. Even though regeneration in the logging gaps with an average size of 470 m² was not sufficient, regeneration in the very young Okoumé forest type was significantly higher than in the aged Okoumé forest type. A correlation between average distance of seed trees to the logging gap could be observed. Additionally, a low-budget drone was used to surveying the area of inventory plots whereof orthomosaics were generated and an automatic model for detecting logging gaps was performed. As was already well known that regeneration of Okoumé in gaps smaller 0,25 ha is almost not possible, the study confirms these observations and concludes, that silvicultural treatments need to be adapted to the species requirements in order to guarantee sustained yield in the long run.

Use of UAS thermal imagery to identify dead standing timber as part of forest mortality monitoring

Alexander Bilyk¹, Reino Pulkki¹, Guy LaRocque², Chander Shahi¹

¹Lakehead University, Thunder Bay, Canada; ²Canadian Forest Service, Quebec City, Canada (ambilyk@lakeheadu.ca; rpulkki@lakeheadu.ca; guy.larocque@canada.ca; cshahi@lakeheadu.ca)

The use of FLIR thermal cameras has risen with drones, especially in the search and rescue and fire-fighting fields. This has caused the price of these sensors to become more affordable and allow new and novel research ideas to be explored. In this study we flew over 50 forest research plots, capturing 6400 m². The purpose of this flight was to identify the location of all dead-standing timber as part of the permanent growth and yield monitoring program. The current field method requires field staff to walk the entire area and attempt to identify all dead trees from the ground. This is both time-consuming and can lead to errors with trees being missed. The FLIR thermal images allow for the rapid identification of dead standing timber, as dead trees glow in the thermal spectrum. This information was compared to the mortality counts conducted by ground crews and a comparison was completed to look at the effectiveness of this technology in augmenting the field crew measurements. By making the identification of mortality trees an automated process, the ground crew was able to focus on collecting relevant information without walking aimlessly in the field. The images also act as a permanent record, allowing for scientists to look at how these plots are changing over time as trees mature and die out of the canopy.

C40: REGIONAL FOREST OBSERVATIONS FOR SUSTAINABLE FOREST MANAGEMENT - II

High-resolution spatial imagery for demarcating the forest in Galilea, Colombia: towards declaring protected areas / Imágenes de alta resolución espacial para la delimitación del bosque de Galilea, Colombia: hacia la declaratoria de áreas protegidas

Uriel Pérez Gómez¹ ; Luis Pérez Vasquez¹ ; Miguel Ángel Quimbayo Cardona¹ 

¹Universidad del Tolima, Ibagué, Colombia (uperez@ut.edu.co; laperezv@ut.edu.co; miguelq@ut.edu.co)

Actualmente en el bosque de Galilea, localizado en el departamento del Tolima-Colombia, se realizan actividades de exploración petrolera. Hoy en el mundo una alternativa a esta situación es la declaratoria de área protegida. El objetivo de la investigación es proporcionar un área límite, como línea base para la definición de la protección del bosque de Galilea, a escala 1:25000. La metodología utilizada considera el uso de nueve imágenes de alta resolución espacial del sensor PlanetScope tomadas el 16 de mayo de 2017, con cobertura de nubes inferior al 10 %, correcciones radiométricas y geométricas, y ortorectificadas. Las imágenes fueron interpretadas en pantalla con el fin de delimitar la categoría Bosque y otras zonas naturales tomadas del sistema de clasificación Corine Land Cover adaptado para Colombia. El proceso consideró la actualización del límite del área de Bosque existente de otra fecha, y obtenido bajo el mismo sistema de clasificación. Para el trabajo de verificación en campo se utilizó un muestreo estratificado con afijación proporcional, y se analizó una matriz de confusión para determinar tanto la fiabilidad global como la del usuario y del productor. Finalmente, el límite del área propuesta se ajustó, apoyado en el análisis de otra información geográfica disponible y a los lineamientos proporcionados por el Ministerio de Ambiente y Desarrollo Sostenible para la declaratoria de área protegida. Se construye un sistema de información geográfico bajo el sistema de coordenadas EPS:3116 y documentado de acuerdo a las normas establecidas por el grupo de trabajo 28 del Instituto Colombiano de Normas Técnicas

Spatial patterns of logging-related disturbance events: preliminary results from a multi-scale analysis on forest management units located in the Central Brazilian Amazon

Thais Almeida Lima¹, René Beuchle², Astrid Verhegghen², Verena C. Griess¹, Peter Vogt²

¹University of British Columbia, Vancouver, Canada; ²European Commission, Joint Research Centre, Ispra, Italy (tha.almeida.lima@gmail.com; rene.beuchle@ec.europa.eu; astrid.verhegghen@ec.europa.eu; verena.griess@ubc.ca; peter.vogt@ec.europa.eu)

In the Brazilian Amazon selective logging can reach an area as big as that reported as deforested. Medium resolution satellites, such as Landsat, have long been used to assess the extent of selectively logged forests in the region. However, studies addressing the spatial pattern of logging are rare. In addition, the use of input data sets with less than 30 m spatial resolution are still scarce. The present study describes the spatial patterns of selective logging in 12 forest management units (FMU), located near the village of Santo Antônio do Matupi, State of Amazonas, Brazil. Selective logging was mapped for the years 2016-2017, using 10 m spatial resolution Sentinel-2 imagery. The input data for the spatial pattern analysis was a binary map of disturbed undisturbed forests produced using the Delta rNBR approach. Two pattern metrics (proportion and contagion) were extracted from square moving windows with different sizes. These two metrics were

used to classify the disturbed areas in five classes of disturbance, ranging from very low to very high. These classes were compared with different categories of logging infrastructure mapped in the field. They were also linked with forest recovery by post-harvest values of the rNBR index. Log landings and logging roads were associated with high disturbance intensity classes, whereas very low disturbance intensity was linked with isolated disturbance types. Post-harvest values of rNBR showed different degrees of forest recovery for patches with different disturbance intensities, indicating that the five classes of disturbance can be linked with actual disturbance types.

Using satellite imagery components in spatial modeling of volume in stands of *Eucalyptus* sp. / Uso de componentes de imagens de satélites na modelagem espacial do volume em povoamentos de *Eucalyptus* sp.

²Universidade Federal de São Carlos, Sorocaba, Brasil; ⁴Embrapa Gestão Territorial, Campinas, Brasil (livialanzi@yahoo.com.br; crthiersch@ufscar.br; amartins@sorocaba.unesp.br; monicathiersch@ufscar.br; rafael.mingoti@embrapa.br; jrpassos@ibb.unesp.br; rafamic_10@hotmail.com)

Uma maneira de conhecer o comportamento espacial de um plantio e aumentar a precisão das estimativas de volume seria utilizar interpoladores geoestatísticos, como a krigagem ordinária (KO) e a krigagem deriva externa (KDE), esta última utiliza, além da variável espacial, variáveis auxiliares. As imagens de satélites possuem diferentes componentes que se correlacionam com as variáveis dendrométricas podendo ser usados como variáveis auxiliares. O objetivo foi avaliar o desempenho da KDE na estimativa do volume de um povoamento de *Eucalyptus* sp., utilizando componentes de imagens como variáveis auxiliares e compará-la com a KO. Estimou-se o volume por parcela partir de um inventário de 210 parcelas. Foram extraídos das imagens (SPOT-6) obtidas da área, o nível de cinza das bandas, a razão entre as bandas, índices de vegetação, medidas de textura e índices gerados a partir das texturas. Para KDE, ajustou-se o modelo de covariância através do método Stepwise e a seleção pelo método AIC (Critério de Informação de Akaike). Os semivariogramas KDE e KO foram ajustados por diferentes modelos teóricos e a escolha do modelo se deu pelo menor valor do erro padrão residual. O modelo de covariância selecionado explicou 91% do volume foi composto por banda verde, textura de correlação da banda verde, índice de textura de correlação multiplicado pela banda azul e pela idade. Nos dois semivariogramas, o modelo que melhor se ajustou foi o exponencial. As estimativas de volume geradas pela KDE produziram melhores resultados que as estimativas da KO, obtendo o menor valor de erro padrão residual.

Rapid, automated tree coverage measurement using a convolutional neural network

Tess Russo¹, Courosh Mehanian², Shawn McGuire², James Daniel³, Ben Wilson², Marie Connett¹

¹Global Good, Bellevue, USA; ²Intellectual Ventures Laboratory, Bellevue, USA; ³Consultant, Nairobi, Kenya; ²Intellectual Ventures Laboratory, Bellevue, USA (trusso@intven.com; cmehanian@intven.com; smcguire@intven.com; jd4consulting@gmail.com; bwilson@intven.com; mconnett@intven.com)

In the Bonn Challenge, multiple companies, NGOs, and governments committed to restoring nearly 350 million hectares of degraded lands by 2030. Data on land cover contributions to carbon fixation are needed by governments to comply with climate change treaties and can be critical to guide economic incentives for farmers. Current monitoring methods employed by the World Agroforestry Centre (ICRAF) and the US Geological Survey require individuals to view imagery and manually enter observations. At rates suggested, it would take nearly 730 FTE years to evaluate just 10% of the Bonn Challenge land restoration commitment, which almost certainly precludes ideal rates of monitoring to evaluate and refine the process of implementation. A rapid, automated, and easily implemented algorithm is required to inform sustainable forest management and land restoration with accuracy suitable for local scales and robustness required by broader regional geographies. We are developing a tool to evaluate percentage of tree cover from remote sensing imagery. The automated algorithm employs convolutional neural networks and is trained using observations from approximately 2000 high resolution 1-ha images with tree densities ranging between 0 and 98%, making the method appropriate for regional assessments with a variety of land conditions. Accuracy of the algorithm is assessed against the dot-grid method, which varies as a function of tree coverage. Though intended for application on degraded, reforested, and mixed-use agroforestry land types, the method can be applied in other environments and for other purposes, e.g. quantifying tree coverage as input to tree carbon or soil-water-ecosystem restoration models.

Product recovery predictions combining tree lists from a harvester stem database and estimated diameter distributions provided by a mobile laser scanner system

Liviu Theodor Ene¹, Johan Holmgren², Jon Söderberg¹, Erik Willén¹

¹Skogforsk, Uppsala, Sweden; ²Swedish University of Agricultural Sciences, Umeå, Sweden (liviu.ene@skogforsk.se; johan.holmgren@slu.se; jon.soderberg@skogforsk.se; erik.willen@skogforsk.se)

Accurate product recovery predictions are necessary for supporting an effective planning of harvesting operations and optimization of the wood flow. To meet this requirement, Swedish forest companies Skogforsk and Forbis have developed an extensive database infrastructure containing compiled CTL- harvester production files. The system allows imputing tree lists retrieved from the harvester data to stands scheduled to harvest in the operational planning. The potential yield on such areas can be estimated using bucking simulations on the imputed tree lists, hence it is important that the imputed DBH distributions match the true DBH distributions as close as possible. Currently, the DBH distributions are not provided in the forest registers, this information being coarsely estimated by low intensity preharvest inventories. A backpack-mounted system integrating a NovAtel SPAN-IGM-S1 INS and a Velodyne VLP-16 scanner was used for stem positioning and DBH measurements in preharvest inventories on 5 experimental blocks of 0.16 to 0.32 ha containing mixed coniferous forest, located in Northeast Sweden. The estimated DBH distributions were matching well the ground true distributions from the harvester production files after the final cut. Tree lists from the harvester database were imputed to each block using DBH-related auxiliaries and nearest neighbor imputations. The imputation accuracies and the product recovery results remained relatively stable after thinning down the estimated diameter distributions about four times (50 trees per block), which translates into lower inventory costs and may recommend the mobile lasers as a feasible preharvest inventory method in boreal forests with relatively simple structures.

Sample size reduction in forest inventories using importance indexes / Redução do tamanho amostral em inventário florestal através de índices de importância

Lucas Arthur de Almeida Telles¹, Helio Garcia Leite¹, Gustavo Eduardo Marcatti¹, Liniker Fernandes da Silva², Carlos Pedro Boechat Soares¹, Rodrigo Vieira Leite¹

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Universidade Federal do Recôncavo da Bahia, Cruz das Almas, Brasil; (lucasarthur36@gmail.com; hgleite@gmail.com; gustavomarcatti@ufsj.edu.br; linikerfs@gmail.com; csoares@ufv.br; rvieiraite@gmail.com)

Continuamente novos métodos são propostos para reduzir o tamanho amostral de inventários florestais sem comprometer sua acurácia. Neste sentido, o objetivo do trabalho é propor uma metodologia para redução amostral de inventários baseada na representatividade de parcelas. A metodologia consiste em: Etapa 1 – seleção de parcelas, onde são propostos índices de importância (Delaunay, Variância e Combinado) e seleção aleatória (Aleatório) para identificar parcelas a constituir amostragens alternativas; Etapa 2 – avaliação dos critérios de seleção, onde estimativas de índice de local e volume geradas por krigagem de amostragens alternativas são comparadas com a original. Foram utilizadas reduções de 15, 30, 45 e 60% em relação as 152 parcelas existentes no inventário original. O índice Delaunay prioriza parcelas espaçadas com maior número de vizinhas. Já o índice Variância prioriza parcelas com maiores variâncias da krigagem, assegurando maior ou menor intensidade amostral de acordo com a heterogeneidade da área. O combinado é a junção dos dois anteriores com um fator de ponderação de 0,5. A utilização dos índices de importância se mostrou mais eficiente em relação a seleção aleatória para índice de sítio (respectivamente, $R^2_{min} = 0,94$ e $R^2_{min} = 0,89$) e volume (respectivamente, $R^2_{min} = 0,96$ e $R^2_{min} = 0,70$), sobretudo em reduções superiores a 30%. O índice Delaunay pode ser facilmente aplicado pois utiliza apenas as coordenadas das parcelas como input. Já o índice Variância pode viabilizar reduções a partir do inventário piloto. Neste trabalho, os três índices se mostraram eficientes, mas os resultados podem variar conforme características da área.

Deforestation from gold mining in the Madre de Dios region of Peru (2000-2017) / Deforestación por minería aurífera en madre de dios – Perú (2000 – 2017)

Lasmit Cerón Cancharis¹, Natalia Miranda Samame¹, Ethel Rubin de Celis Llanos¹

¹Universidad Nacional Agraria La Molina, Lima, Peru (20091044@lamolina.edu.pe; 20110152@lamolina.edu.pe; erubin@lamolina.edu.pe)

La investigación se desarrolló en el departamento de Madre de Dios – Perú con el objetivo de cuantificar la deforestación causada por actividad minera para los años 2000 y 2017 mediante imágenes satelitales LANDSAT 5 y LANDSAT 8, se realizó una clasificación supervisada mediante el algoritmo de árboles de decisión; proceso directo, rápido y con resultados a usar de forma individual o grupal. Los resultados muestran que entre los años 2000 y 2017 hubo una diferencia de 47 657.43 ha con actividad minera. Se detectaron 1 139.77 ha de actividad minera en el año 2000 recuperándose en el 2017. Se obtuvo un índice Kappa de 93% de acierto, con validación de juicio de expertos. La pérdida de cobertura causada por la minería en Madre de Dios fue analizada en las categorías territoriales, donde se observó un incremento en 42.52% (35 183.45 ha), siendo las más afectadas las comunidades nativas, concesiones para reforestación y zonas de amortiguamiento de Áreas Naturales Protegidas.

C4p: FOREST ASSESSMENT**Prompt mapping of forest stand damages after windthrow event using unmanned aerial vehicle**

Martin Mokroš¹, Julián Tomaščík², Alžbeta Grznárová², Jozef Vyboštok², Ján Merganič³

¹Czech University of Life Sciences Prague, Prague, Czech Republic; ²Technical University in Zvolen, Zvolen, Slovakia; ³Technical University in Zvolen, Zvolen, Slovakia; (mokros@fd.czu.cz; tomascik@tuzvo.sk; grznarova@tuzvo.sk; vybostok@tuzvo.sk; merganic@tuzvo.sk)

In our research, we have focused on two important issues. Firstly, we have investigated the usage of fixed-wing UAV with real-time kinematic (RTK) which can offer the possibility to eliminate the usage of ground control points. In areas with complicated accessibility (especially forests), this can be highly beneficial. The eBee Plus was used; 43 check points have been placed in the area (300 ha) for evaluation of RTK accuracy. Processing of images was done in Agisoft Photoscan Professional. The positional accuracy was calculated based on check points. RMSE of X, Y and Z axis was as follows: X=2.2 cm, Y=2.3 cm, Z=4.9 cm. Secondly, we have investigated the possibility of windthrow areas mapping within forest stands and the volume estimation of salvage logging. The windthrow areas were measured by multiple GNSS devices in the field and salvage logging volume from whole target area was measured by local foresters. Processing of images was done in Agisoft Photoscan Professional and windthrow areas identification was completed in ArcGIS for Desktop. Five windthrow areas were identified during the field campaign with the total area of 25.39 ha. The same areas were identified from UAS data with a total acreage of 25.09 ha (0.3 ha difference). The difference between the volume of salvage logging measured in the field and derived from UAV data and forest plan was only 5% (525 m³). The results are proving great potential for prompt forest land mapping. Additionally, the RTK accuracy meets the requirements for forestry purposes.

Monitoring tropical forest disturbance using repeatedly acquired digital aerial photography from unmanned aerial vehicle

Tetsuji Ota¹, Sie Thu Minn¹, Tual Cin Khai¹, Nobuya Mizoue¹, Shigejiro Yoshida¹

¹Kyushu university, Fukuoka, Japan (ota.tetsuji.887@m.kyushu-u.ac.jp; sithumin.tn@gmail.com; tualcinkhai@gmail.com; mizoue@agr.kyushu-u.ac.jp; gm.syoshida@gmail.com)

Small scale disturbance such as selective logging is one of the factors causing forest degradation in tropical forests. Here, we evaluate the utility of repeatedly acquired digital aerial photographs (DAPs) from a lightweight unmanned aerial vehicle (UAV) to monitor small scale disturbance in tropical forest. We constructed two 9-ha plots in Myanmar and partitioned two plots into subplots of size 0.25 ha. DAPs from a lightweight UAV were acquired three times, which were immediately before selective logging, immediately after selective logging and 1.5 year after selective logging. A photogrammetric point cloud (PPC) was created from DAPs. The aboveground biomass (AGB) changes due to small scale disturbance at subplot scale were regressed against metrics expressing forest changes calculated from PPC. This study demonstrates that repeatedly acquired DAPs from a lightweight UAV can be used to monitor small scale disturbance in tropical forests.

Using hemispherical photographs to evaluate the impacts of selective logging

Daniel Augusto da Silva¹, Janine K. Likoski¹, Heitor Felipe Uller², Aline Renata Klitzke², Alfredo Celso Fantini³, Alexander Christian Vibrans²
¹Fundação Universidade Regional de Blumenau, Programa de Pós-Graduação em Engenharia Ambiental, Blumenau, Brasil; ²Fundação Universidade Regional de Blumenau, Programa de Pós-Graduação em Engenharia Florestal, Blumenau, Brasil; ³Universidade Federal de Santa Catarina, Programa de Pós-graduação em Agroecossistemas, Florianópolis, Brasil (danielaugusto@furb.br; janinelikoski@hotmail.com; heitor.uller.florestal@gmail.com; arklitzke@furb.br; alfredo.fantini@ufsc.br; acv@furb.br)

Sustainable management of native forests can be an important conservation strategy, discouraging the conversion to other land uses. When applied to secondary forests, it takes out pressure on pristine primary stands, while giving revenue to the landowner and maintaining most of the environmental services and biodiversity. The canopy structure influences the climate inside and outside the forest, thus, interfering in environmental services (weather regulation) and understory biodiversity. We conduct a pilot management project in a 40-year-old secondary Atlantic Rainforest in Santa Catarina where we evaluated the canopy structure, and trees regeneration at nine 1600 m² sample plots before and after various intensities of selective logging. Hemispherical photographs were processed in the CAN_EYE software to provide the canopy information, the logging intensity was determined by the percentage of tree basal-area harvested (ΔG) and we determined the density of pioneer species regeneration six months after logging. Linear regression determined the relation between the variables. The results show that the ΔG influenced in the canopy opening ($R^2 = 0.41$, $p < 0.05$), but not on the leaf area index ($R^2 = 0.16$, $p > 0.05$); and that the canopy opening influenced the regeneration density of pioneer species ($R^2 = 0.25$, $p > 0.05$). This suggests that ΔG has a relevant influence on the forest regeneration composition, but limited influence in processes linked to leaf area, such as photosynthesis, evapotranspiration and CO₂ absorption. The monitoring of the area will provide an insight of the long-term consequences of the logging intensities on a secondary forest.

Estimation of stand heights with Unmanned Aerial Vehicle (UAV) photographic image

Shang-Chuan Huang¹, Chaur-Tzuhn Chen¹, Mu-Yu Huang¹, Jan-Chang Chen¹
¹National Pingtung University of Science and Technology, Pingtung, Taiwan (j69212002@gmail.com; cct@gisfore.npust.edu.tw; b10312023@gmail.com; zzzjohn@mail.npust.edu.tw)

Forest resource inventory provides essential information for forest management, where the stand height is an important variable for estimating the stock volume of large-scale forests. Unmanned Aerial Vehicle (UAV) aerial photography has the advantages of quickly acquiring the large-scale surface information, high-resolution image, and low flight cost. Nowadays, high-density stereo point cloud data can be obtained through image-matching, which is suitable for stand height extraction. The purpose of this study was to extract the stand height using the UAV aerial imagery produced a canopy height model (CHM) and to verify the tree height of each tree inventory data in the ground plots. The results indicate that aerial photogrammetry extracted by UAV should be used for generating digital elevation model (DEM) and a digital surface model (DSM). By integrating DEM and DSM, CHM information can be established based on UAV aerial photography, and no significant difference between the UAV stand height and the ground data was found. The spatial variability of the stand height generated by UAV could be used as forest resource monitoring tools which provides important information for decision makers in terms of forest management. However, further research on the application of forest resources inventory, the estimation of stocks and the application of forest management plans is necessary.

Landscape patterns associated with extraction in the Amazon: characteristics and mapping of potential areas of açai palms in Northeastern Pará, Brazil / Padrões da paisagem associados ao extrativismo na Amazônia: caracterização e mapeamento de áreas potenciais de ocorrência de açai no nordeste Paraense

Anielli Rosane de Souza¹, Maria Isabel Sobral Escada¹, Gabriela Veneziani de Souza Santos², Antônio Miguel Vieira Monteiro¹
¹Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil; ²Universidade Estadual Paulista, Rio Claro, Brasil (anielli.souza@inpe.br; isabel.escada@inpe.br; ga.veneziani@gmail.com; miguel.monteiro@inpe.br)

A Amazônia legal brasileira apresenta diferentes padrões de paisagem relacionados com fatores naturais e antrópicos, gerados por múltiplos agentes, históricos de ocupação e por atividades econômicas como o extrativismo e a agropecuária. Os diferentes tipos de ocupação geram padrões de paisagem que podem ser observados a partir de dados de sensoriamento remoto. Na Amazônia, o extrativismo do açai (*Euterpe oleracea*) é de suma importância para a economia local. Embora importante, esta atividade não é mapeada e nem contemplada nos sistemas existentes de monitoramento de uso e cobertura da terra da Amazônia (TerraClass, MapBiomas e IBGE), devido às limitações técnicas operacionais, gerando lacunas de conhecimento e dificuldades na elaboração de políticas que visem a estruturação de cadeias produtivas e a inserção das populações extrativistas nos arranjos produtivos locais (APL). As atividades de extração do açai podem ser representadas por áreas de cobertura florestal, entretanto, essa informação é insuficiente para seu mapeamento, pois nem toda área de floresta apresenta ocorrência dessa palmeira. O objetivo deste trabalho é mapear as áreas potenciais de ocorrência de açai combinando dados refinados de uso e cobertura da terra do TerraClass de 2014 com dados extraídos do Shuttle Radar Topography Mission (SRTM) e o uso do algoritmo Height Above the Nearest Drainage (HAND) que possibilita mapear áreas de várzea, ambiente natural de ocorrência de açai. Como resultado obteve-se um mapa cuja classe de alto potencial de ocorrência de açai representou 43% da área de estudo. Esse resultado indica o grande potencial econômico da região analisada.

A common problem: how to make the NFI data being used (and shared)

Alexander Christian Vibrans¹, Laio Zimmermann Oliveira¹
¹Fundação Universidade Regional de Blumenau, Blumenau, SC, Brasil (acv@furb.br; laiozoliveira@gmail.com)

NFI are designed to collect, process and disclose forest resource data. NFI networks should attend a critical issue that is the challenge to get the generated information effectively used. Failure of communication with the general public and with decision-makers, in particular may be the background of this situation. While the initial question "why" (we need reliable data) is simply to respond, the following "who and how" (data will be used and shared) is decisive specially in countries where NFI are not deep-rooted and institutionalized. We discuss the matter within the context of the Brazilian NFI, about Santa Catarina state (95,000 km²). We discuss how multiple involvements with stakeholders at local, regional and international level may increase public awareness on NFI outcomes and, last but not least, may assure long-term financial support. As soon as first cycle was performed, we started an disclosure campaign targeting schoolchildren and the rural population; we reported results to environment agencies and councils; a multi-institucional working group prepared guidelines for a new, inventory data based forest policy; we designed an action plan to achieve the forest policy defined goals regarding forest land use and resource management rules, secondary forest restoration, rare and endangered species protection. We published scientific studies on biomass and carbon stock, on forest ecology and dynamics, on human impacts at different scales. Data-sharing with global research groups and databases like GFBI and sPlot/iDIV, cooperations with space agencies for sensor calibration and validation, among others, increased the inventory's credibility.

Growth pattern of *Couratari stellata* in a Tropical Rain Forest in the Southwestern Amazon

Caroline Gaspar¹ ; Evaldo Muñoz Braz² ; Patricia Povia de Mattos² ; Luciano Watzlawick¹, Andreia Taborda dos Santos³ 

¹Universidade Estadual do Centro-Oeste, Irati, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Universidade Federal do Paraná, Curitiba, Brasil (gaspar.caroline@yahoo.com; evaldo.braz@embrapa.br; patricia.mattos@embrapa.br; farinha@unicentro.br; andreiatabordayahoo.com.br)

The natural forest management, especially from the Amazon rainforest, is an important source of income and employment generation. However, there gaps information about species that are managed, such as the growth pattern of commercial species, an important factor to ensure sustainable management. The aim was to describe the individual growth of *Couratari stellata* in the Jamari National Forest, Rondônia State, Brazil. Dendrochronology was used for growth analysis, for this, 12 stem discs were collected. The growth rings were marked and measured with the LINTAB, with 0.01 mm accuracy. Confirmation of the annual growth layer was performed by cross-dating. Six mixed models were tested to determine the growth pattern of *C. stellata*, and the best choice was based on statistical results and graphical analysis of residues and the adherence to real data. The Lundqvist model showed satisfactory statistical parameters for the growth (Syx = 18.30%, AICC = 1.07E+06 and BIC = 1.07E+06). The trees had 143 years old (mean) and presented DBH (mean) = 65 cm, ranging from 46.5 to 83.4 cm. The diameter class that presented the largest average increment in diameter was 65 cm center class, with approximately 0.52 cm.year⁻¹, with the average annual increment = 0.45 cm. There are indications that the cutting diameter for *C. stellata* is from 75 cm in diameter, ensuring the wood quantity for the next cycle, if it is considered a cut rate compatible with the diameter structure of the stand.

Growth performance of *Macaranga tanarius* from 4 provenances in Peninsular Malaysia

Rosdi bin Koter¹, Moha Zaki bin Hamzah², Noraini Abd Shukor², Hazandy Hamid², A. K. Wan Rasidah¹, Patahayah Binti Mansor¹

¹Forest Research Institute Malaysia (FRIM), Kepong, Malaysia; ²Faculty of Forestry, University Putra Malaysia, Selangor, Malaysia (rosdi@frim.gov.my; rosdi@frim.gov.my; rosdi@frim.gov.my; rosdi@frim.gov.my; patahayah@frim.gov.my)

This study was initiated after recognizing the importance of growth and yield studies of plantation-grown pioneer fast growing species for future forest management decisions, coupled with a general paucity of knowledge on the growth and potential yield of the species planted under plantation condition. The species of *Macaranga tanarius* is regarded among the most promising *Macaranga* genus because of the seed availability throughout the year and potentially seed germinated after probing trial established compared with other species. The studies will provide an opportunity to generate baseline information for future planting of *M. tanarius* under plantation condition. Information on growth and potential yield of the species can be used in the planning for future establishment and management planning for future *M. tanarius* plantations. Growth performance from each provenance were collected and planted in four established plantation plots in SPF Jeli, SPF Maya Ayer, SPF Selandar, Melaka and Field 52 Bukit Hari, FRIM HQ. The trial was laid out in a randomized complete block design with three replications. Generally all provenances were well adapted and performed well in their growth and significantly differ between genotip and environment. Variation exist in height, root collar, survival and biomass. North provenance planted at SPF Jeli showed the highest survival and height increment value followed by Mata Ayer; Selandar and FRIM HQ. Based on the results of this study, *M. tanarius* is a promising species but further study need to be further explored on the genetic studies.

C4q: FOREST ASSESSMENT

Changes in aflatoxin standards: implications for EU border controls of nut imports

Ibtissem Taghouti¹, José Maria Garcia-Alvarez-Coque², Victor Martinez-Gomez²

¹National Research Institute for Rural Engineering Water and Forestry, Ariana, Tunisia; ²Universitat Politècnica de València, Valencia, Spain (ibtissem.taghouti@gmail.com; jmgarcia@upv.es; vicmargo@esp.upv.es)

Food safety concerns about the risk of aflatoxin (AF) contamination have been growing in many regions, particularly in the EU. To protect consumers from health risks, the EU has established strict standards for maximum acceptable AF levels in food products. The EU's AF standards have changed several times. This article examines the Rapid Alert System for Food and Feed (RASFF) database, which contains notifications on border controls on AF levels in tree nuts and peanuts. A count data model was used to analyze the impact of political economy considerations, past alerts and path-dependence effects on RASFF border controls. Policy changes, including the harmonization and relaxing of EU's AF standards, significantly affected the frequency of border controls, with diverse effects among exporting countries. It is believed that the present study provides some insights to the modeling of food standards for explanation or forecasting purposes.

Quassia amara L. growth under different shading conditions: implications for the management of Costa Rica natural and planted forests

Joana Paulo¹ ; Villalobos Roger²

¹Instituto Superior de Agronomia, Lisbon, Portugal; ²Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba, Costa Rica (joanaap@isa.ulisboa.pt; rvillalo@catie.ac.cr)

The overall objective of the present work is to research the impact of light conditions on the *Quassia amara* L. growth, both in young plantations and natural forests, discussing implications for the sustainable management and production of the species in Costa Rica. Illumination conditions are characterized, at the tree level, by the crown illumination index (cii). The working hypothesis is that the tree crown illumination index can help to determine the best illumination conditions to promote tree diameter growth. Results show that for young trees, growing in young forest plantations (pure, mixed or agroforestry stands), best illumination conditions for diameter growth are characterized by a cii value of 2.5, corresponding to high lateral light interception and under 10% of the vertical projection of the crown exposed to vertical light. These conditions characterize mixed plantation or agroforestry stands, with adult trees presenting developed crowns that reduce vertical light exposure to the *Quassia amara* L. growing bellow. For trees growing in natural forests, presumably older due to the traditional management strategies of these areas, best illumination conditions are characterized by a cii value of 4.5, corresponding almost to between full overhead light (more than 90% of the crown area exposed to vertical light and partial lateral light blocked) to a completely exposed to overhead and lateral light. Management of natural forests where *Quassia amara* L. is present should stand upon for later light conditions, in order to guarantee suitable illumination conditions for the natural regeneration and growth of the young trees.

Evaluating introduction and productivity of Vietnam *Acacia* hybrid in South China

Yichen Zong¹, Yongqi Zheng¹, Furong Lin¹, Ping Huang¹, Wenying Guo¹, Chengrong Xu², Xiufang Yin³

¹Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China; ²Hepu Forest Research Institute, Hepu, China; ³Jiangmen Forest Research Institute, Jiangmen, China (zongyc@caf.ac.cn; zhengyq@caf.ac.cn; linfr888@163.com; pippin09@163.com; 13801288911@139.com; hepulks@163.com; 2667701329@qq.com)

Vietnam *Acacia* hybrid was selected by *Acacia mangium* across *A. auriculiformis*. Five clones were introduced from Vietnam by exchange forest seeds. Four test plantation was built in South China including Jiangmen(JM), Hepu(HP), Zhangzhou(ZZ) and Chuxiong(CX). *Acacia* hybrid could grow, flower and fruit at the four sites and productivity were all higher than CK after two years. Five hybrid *Acacia* clones were all higher than CK on high growth character, and were ranked as ZZ>JM>HP>CX. The height of clone No. 73 was 5.2 m and more 24% than CK. There were significant difference on diameter of breast height(DBH) between clones and CK at the four sites. Clones DBH were all bigger than CK and ranked as HP>ZZ=JM>CX. The DBH of clone No. 73 was 5.0 cm and more 35% than CK. The individual volume of clone No. 73 was 0.0042 m³ at HP site. The wind-fall rate of *Acacia* hybrid clones were 35% , CK was 67% after typhoon Rammasun 2014 at HP site. The wind folding resistance of each clone of typhoon Rammasun was in order No.73= No.75>No.10>No.71>No.16>CK. It was short-term snowed at CX site December 2013. The cold resistance which was evaluated by survival rate were No. 10>No. 73>No. 16= No. 75>CK>No. 71. According to the comprehensive evaluation of different weight of volume (60%), stem shape (20%), survival rate (10%) and stress resistance (10%), clone No.73 was the best one, followed by No.71 and No.16.

DBH and basal area growth by thinning intensity of major coniferous plantations in the Republic of Korea

Yeongwan Seo¹, Daesung Lee¹, Jungkee Choi¹

¹Kangwon National University, Chuncheon ²⁴³⁴¹, Republic of Korea (ywseo@kangwon.ac.kr; daesung@kangwon.ac.kr; jungkee@kangwon.ac.kr)

The effect of thinning intensity was analyzed on the DBH growth of major coniferous plantations, which are *Pinus densiflora* (Pd), *Pinus koraiensis* (Pk), and *Larix kaempferi* (Lk) in the Republic of Korea. For the study permanent monitoring plots were installed in 37 sites, 45 sites and 45 sites of Pk, Pk, and Lk respectively from 2012~2015 with each plot consisting of non-thinning (C), light thinning (L) and high thinning(H) plots. They were inventoried again during 2015~2018. The thinning ratio ranged in 0~5% for non-thinning, 10~28% for low thinning, and 30~50% for high thinning based on basal area. Thinning intensity was found to have an effect on the DBH increment and growth rate of the three species (C0.5) the thinning effect was found to be significant among the control, light thinning and heavy thinning plot. Unlike DBH increment total basal area increment per hectare were found to be C>L>H, but the growth rate was C<L<H.

Assessing periodic increment and mean annual increment in African mahogany (*Khaya ivorensis* Chev.) / Avaliação do incremento periódico e incremento médio anual do Mogno Africano (*Khaya ivorensis* Chev.)

Camilla de Almeida¹, Sybelle Barreira¹

¹Universidade Federal de Goiás, Goiânia, Brasil (camilla_paulino@outlook.com; sybelle.barreira@gmail.com)

O mogno é apreciado por suas características madeireiras, que é muito utilizada para construção civil e movelaria. Possui densidade moderada, espécie de madeira com boa trabalhabilidade. Dessa forma, seu valor agregado é elevado no mercado de produtos nacionais e internacionais. Apresenta características semelhantes às do mogno brasileiro (*Swietenia macrophylla* King), além de boa adaptação às condições edafoclimáticas brasileiras. Para melhor compreender o desenvolvimento da espécie, o trabalho tem como objetivo analisar o incremento periódico (IP) e o incremento médio anual (IMA) de uma população de *Khaya ivorensis* Chev. localizada na região de Brasília, DF. A área possui 17,92 ha com 4.000 indivíduos em um espaçamento de 5,5 m x 5,5 m, e a cada 4 linha de plantio há um espaço de 26 m onde, atualmente, há pasto com braquiária. Foram amostradas 8 parcelas, entre 2015 a 2018, totalizando 416 indivíduos. Para cálculo do IP e IMA, utilizaram-se os dados de DAP dos três anos. O incremento periódico mínimo foi de 2,5 cm e o máximo foi de 19,4 cm. O IMA foi de 8,04 cm. Esses resultados mostram que a espécie apresentou boa adaptação com crescimento satisfatório. Porém, o Mogno Africano apresenta sensibilidade à deficiência hídrica, decorrente da distribuição irregular de chuvas que ocorrem na região, tendendo a ter o crescimento em diâmetro limitado.

Modeling through dynamic systems for the main silvicultural operations at a Colombian forestry company / Modelamiento vía dinámica de sistemas para las principales operaciones silviculturales en una empresa reforestadora colombiana

Wendy Katherin Lorenzana Velosa¹, Valentina Montaña¹

¹Universidad distrital Francisco José de Caldas, Bogotá, Colombia (wklorenzav@correo.udistrital.edu.co; valentina²⁵montano@gmail.com)

La siguiente investigación presenta el diseño de cuatro modelos basados en dinámica de sistemas para cada una de las operaciones principales de una empresa reforestadora en Colombia (Elaboración de casillas, fertilización, plantación y replantación). A través del análisis cuantitativo y cualitativo del estudio de métodos y tiempos con el cual se identificaron las variables críticas de cada proceso, las interacciones entre estas y la influencia del método usado por cada contratista sobre la calidad y los rendimientos, lo que permitió consolidar la estructura de cada operación mediante diagramas de Forrester individualizados. Dentro de los resultados se destaca la identificación de personal sobrecargado lo que generó reducciones en la eficiencia de la operación para la cuadrilla en conjunto, adicionalmente a través de análisis de correlación se encontró que una unidad de tiempo muerto (específicamente en la operación de plantación) presenta relación inversa con la productividad de forma exponencial de modo tal que se evidenció la necesidad de incluir personal de apoyo para reducir los tiempos empleados en desplazamientos y descanso a la vez que la productividad general de la cuadrilla se incrementa. Los resultados totales junto con los modelos establecidos se proyectan como insumo para la implementación de experimentos de simulación que garanticen la toma de decisiones eficientes con el uso de escenarios estadísticamente confiables y que le brinden al sector forestal un referente para minimizar la variación en sus procesos y productos a pesar de ser una industria donde no es posible controlar numerosas variables que la influyen.

Dominant height model for *Gmelina arborea* incorporating stand and environmental variables

Alonso Barrios¹, Ana M. López¹

¹Universidad del Tolima, Ibagué, Colombia (abarriost@ut.edu.co; amlopeza@ut.edu.co)

The aim of this research is to develop a site index model for *Gmelina arborea* plantations incorporating stand and environmental modifiers in its structure to increase its flexibility to the climatic changes that are beginning to be experienced. A total of 160 stands from 1 to 16 years-old, located in the Andean Region and

the Atlantic Coast were used. At each stand, between 1 and 38 temporary sampling plots were established. At each plot, the dominant height was calculated as the average height of the 100 trees with the largest diameter per hectare and competition measures such as Reineke's Stand Density Index and Relative Spacing were determined. The study allowed to identify the growth function of Chapman-Richards as a base model for the projection of the dominant height and the determination of the site index of each plot. A correlation analysis allowed to identify elevation, annual precipitation and relative spacing as environmental and stand covariates associated with the productivity of these plantations. The incorporation of these covariates in the base model of dominant height allowed to increase by 30% and reduce by 43% and 40% the fit index, the absolute bias, and the root mean square error, respectively. The developed model will allow foresters to have a greater certainty in their projections, improving forestry planning, since changes in the productivity of the site will have an effect on the volumes of wood produced and this will be reflected in changes in the optimal rotation age and the profitability of plantations.

Estimating forest biomass using the multi-sensor approach and multi-stage sampling in the Brazilian Amazon / Estimativa de biomassa florestal por abordagem multi-sensor e amostragem em multiestágios na Amazônia Brasileira

Andeise Cerqueira Dutra¹, Egídio Arai¹, Valdete Duarte¹, Yosio Edemir Shimabukuro¹

¹Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil (andeise.dutra@inpe.br; egidio.arai@inpe.br; valdete.duarte@inpe.br; yosio.shimabukuro@inpe.br)

A escassez de informações espaciais e temporais sistematizadas para quantificação da biomassa florestal tem se tornado uma limitação para o desenvolvimento de políticas públicas para conservação das florestas. Tais informações subsidiam o entendimento sobre a dinâmica florestal, o ciclo de carbono no planeta e quais os impactos ocasionados por mudanças no clima e no uso e cobertura da terra. O uso de tecnologias para a aquisição de dados remotamente coletados, como oLight Detection and Ranging(LiDAR), permitem coletar medições da estrutura vertical da floresta. No entanto, o custo elevado e a menor disponibilidade de dados LiDAR sobre grandes extensões ainda é um desafio. Neste contexto, este trabalho apresenta um método de integração de dados de sensoriamento remoto óptico em diferentes resoluções espaciais, dados LiDAR e de campo, para a geração de um mapa de biomassa florestal aérea na Amazônia Brasileira. Imagens dos sensores Moderate Resolution Imaging Spectroradiometer(MODIS)/Terra e Operational Land Imager(OLI)/Landsat foram adquiridas cobrindo o estado do Mato Grosso em 2015. A integração dos dados foi realizada por amostragem baseada em multiestágios, no qual cada estágio foi representado como: primário (MODIS), secundário (OLI) e terciário (LiDAR e campo). Em seguida, os dados LiDAR foram utilizados para a calibração do modelo de biomassa e, então, a biomassa foi estimada nos estágios posteriores. Por fim, os resultados obtidos pelo método proposto foram comparados com dados de biomassa disponíveis na literatura. Conclui-se que a utilização integrada dos produtos apresentou resultados satisfatórios para a estimativa de biomassa em escala regional.

C4r: MULTI-CRITERIA DECISION ANALYSIS FOR MULTIFUNCTIONAL FORESTS

Utilizing multi-criteria decision analysis to assess tradeoffs between ecosystem services: alternative approaches and potential contributions

Donald Hodges¹, Lidija Zadnik Stirn²

¹University of Tennessee, Knoxville, TN, USA; ²University of Ljubljana, Ljubljana, Slovenia (dhodges2@utk.edu; lidija.zadnik@bf.uni-lj.si)

Individual forests provide a wide range of ecosystem services that can often be managed simultaneously. As our ability to identify and measure these services increases, however, management decisions will become more difficult since we must determine which services to emphasize and how those actions affect other ecosystem services. These decisions will be based not only on biophysical factors, but must also weigh social, economic, and political implications. Consequently, planning becomes much more complex as we must include a variety of stakeholders who are not familiar formal decision making approaches, yet their participation is critical for achieving the required consensus in group decision making. Multi-criteria decision analysis (MCDA) and Group decision making methods (GDM) offer a number of techniques that will be critical for assessing the biophysical, social, and economic tradeoffs and identifying the optimal management decisions for managing multiple ecosystem services under several decision makers. This presentation will review the issues related to management planning for ecosystem services, identify MCDA and GDM techniques best suited for these management conditions, review advantages and disadvantages of each, and offer some conclusions as to what approaches hold the most promise.

The regional forest management scenarios for the sustainable carbon neutrality in Finland

Kalle Karttunen¹, Soili Kojola², Saija Huuskonen², Anssi Ahtikoski³, Hannu Salminen⁴, Jari Hynynen², Susanna Kujala⁵, Outi Hakala⁵, Hannu Törmä⁵, Jouko Kinnunen⁶, Antti Karhunen⁷, Mika Laihanen⁷, Raghu K.C⁷, Tapio Ranta⁷

¹LUT University, Mikkeli, Finland; ²Natural resources institute Finland, Vantaa, Finland; ³Natural resources institute Finland, Oulu, Finland; ⁴Natural resources institute Finland, Rovaniemi, Finland; ⁵University of Helsinki, Seinäjoki, Finland; ⁶Statistics and Research Åland, Mariehamn, Finland; ⁷LUT University, Mikkeli, Finland (kalle.karttunen@lut.fi; soili.kojola@luke.fi; saija.huuskonen@luke.fi; anssi.ahtikoski@luke.fi; hannu.salminen@luke.fi; jari.hynynen@luke.fi; susanna.kujala@helsinki.fi; outi.hakala@helsinki.fi; hannu.torma@helsinki.fi; jouko.kinnunen@asub.ax; antti.karhunen@lut.fi; mika.laihanen@lut.fi; raghu.kc@lut.fi; tapio.ranta@lut.fi)

The aim of the study is to promote ways to reach the goals of the carbon neutrality at the South Savo region in eastern Finland by examining the solutions for emission reductions and forest use. The study has taken the first step for reaching the carbon neutrality at the regional level in Finland considering also the regional economic effects. The carbon dioxide neutral region means that the region's internal activity does not change the carbon content of the atmosphere. The study has started by updating the regional energy balance and its carbon influence. Second, the carbon impact on forest use will be measured. Finally, the regional economic effects of alternative carbon neutrality solutions will be estimated. The study method has been developed by combining alternative forest management simulations with computable general equilibrium (CGE) modelling. Permanent National Forest Inventory plots has been used as an input of forest management simulation. Then, applying a modified CGE model (RegFinDyn), the socio-economic solutions will be assessed at the regional level. The aim is to include the carbon solutions to the CGE model as well. Earlier results have shown that a more intensive use of forest decreases the carbon sequestration potential but increases the regional socio-economic benefits. The carbon balance should be compensated either for emission reduction solutions or by controlling the use of forest. It is important to choose the solutions which are not only emission efficient but also economically sustainable at the regional level.

Benchmarking Brazilian State Forest Institutions: implementation of policy goals evaluated by the 3L Model

Juliana da Motta Bustamante¹, Mirjana Stevanov², Max Krott¹, Edson Ferreira de Carvalho³

¹Göttingen University, Göttingen, Germany; ²University of Novi Sad, Novi Sad, Serbia; ³Universidade de Viçosa, Viçosa, Brasil (jumotta85@gmail.com; mzavodj@gwdg.de; mkrott@gwdg.de; edsonf@ufv.br)

Worldwide, sustainable forest management became the most relevant forest policy goal. At the same time, it is brightly ambiguous goal as well. The challenge is to structure benchmarking approach in a way that all diverse aspects of this policy goal are covered and simultaneously the requirements of sharp scientific evaluation are satisfied. Differently from other approaches, the 3L-Model establishes a link between the Layer of politically relevant goals and the Layer of empirically feasible measurements through the Layer of theoretical frameworks. The vague policy formulations get more precise that way, resulting in the set of eight benchmarking criteria and 20 indicators, able to capture comprehensive performance of state forest institutions by using selected indicators on the empirical level. We apply the 3L- Model on the Brazilian state forest institutions and take the Forest Service (forest concessions) and the Ministry of Agriculture (plantation forestry) as examples. While doing that were on participatory observation, survey and documents for empirical evidence. The results show that Brazilian forest policy strives toward sustainable forest management, as an overall goal. In more particular, the performance of both examined institutions is more market than public demand oriented. At the same time, there are constrains in keeping forest stands sustained. Even both institutions are recognized as strong representatives of sustained wood yield coalition, the Brazilian land use conflicts ask more for a facilitator of all diverse interests in forests. Our study confirmed that the 3L-Model can well be applied also to the non-European countries after indicators are slightly adapted.

Research on key technology and auxiliary design system for multi-functional forest management plan

Yangsheng Xie¹, Yuanchang Lu¹, Xiangdong Lei¹, Xianzhao Liu¹, Xiaoming Wang¹, Daoxiong Cai², Hong Guo¹

¹Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing, China; ²Experimental Center of Tropical Forestry, Chinese Academy of Forestry, Pingxiang, China (xieys@ifrit.ac.cn; ylu@ifrit.ac.cn; xdlei@ifrit.ac.cn; liuxianzhao@ifrit.ac.cn; wxming35@163.com; rlxcdx@126.com; hongguo@ifrit.ac.cn)

As China's forest management gradually enters the stage of multi-functional forest management, the task of compiling multi-functional forest management plans is becoming more and more urgent. The multi-functional forest management plan preparation technology is the basis and key for the formulation of multi-functional forest management plan, and has not yet formed a complete system. This paper starts with the multi-functional forest management plan technical system, and studies the theory and key technologies of multi-functional sustainable forest management plan, including multi-functional forest management zoning, silvicultural system design, sustainable harvest calculation, and the input-output of multi-functional forest management. This study puts forward the key technologies for the preparation of multi-functional forest management plans, sorts out the technical system, and completes the auxiliary design system. The results of the study provide technical specifications and auxiliary tools for the preparation of multi-functional forest management plans, and are a useful attempt to integrate technical development of multi-functional forest management plans. At the same time, it is of great significance to support the sustainable management of forest ecosystems, promote the preparation and implementation of forest management plan, and ensure the scientific and practical results of the preparation.

Potential of system of intensive forestation

Pasuta Sunthornhao¹, Kosum Mekmongkolchai², Napak Karnasuta²

¹Kasetsart University, Bangkok, Thailand; ²PTT Reforestation and Ecosystem Institute, Bangkok, Thailand (fforpts@ku.ac.th; kosum.m@ptplc.com; napak.k@ptplc.com)

The system of Intensive Forestation (SIF) define as an innovating technique of afforestation which first founded at Wangchan Forest Project, Rayong Province, Eastern region of Thailand under collaborating research programmed between Kasetsart University (KU) and Reforestation and Ecosystem Institute, Petroleum Authority of Thailand (PTT) since 2014. The different between SIF and national regular reforestation e.g. undertake on agriculture land, planted by over 50 native tree species, planting of 2,500-3,125 seedling/hectare with ratio between hard and soft wood species of 80:20, have no exactly spacing of planting, and intensive handle tender maintenance of weeding, fertilizing, water system, etc. The goal of SIF was rapidly generating artificial natural forest which it has to consist multi crown cover level and high potential of carbon dioxide sequestration through generate source of biodiversity and non-timber forest products (NTFPs). The finding of 4 years monitoring and evaluation stage by permanence plots based on 2.25% of sampling size in demonstrating area of 21.27 hectares, found density 1,960 tree/hectare, survival rate 68%, average total height and diameter at breast height of 3.30 meter and 5.40 centimeter respectively, which rosewood species (*Dalbergia cochinchinesis*) was highest dominant species. Moreover, the biomass was 15.46 ton/hectare, and carbon sink of 26.64. Anyway, above finding presented several parameter higher doubles when compare with regular reforestation. Nowadays, we found some of natural enable mushroom and vegetable in the demonstrating site.

Portfolio optimization of forest enterprise as a part of multifunctional management

Jan Kaspar¹, Robert Marusak¹, Harald Vacik², Mikko Kurttila³

¹Faculty of Forestry and Wood Sciences CULS Prague, Praha⁶ Suchdol, Czech Republic; ²University of Natural Resources and Life Sciences Vienna, Vienna, Austria; ³Natural Resources Institute Finland (Luke), Joensuu, Finland (kasparj@fld.czu.cz; marusak@fld.czu.cz; harald.vacik@boku.ac.at; mikko.kurttila@luke.fi)

Multifunctional forest management is focused on finding compromise between the using of individual ecosystem services. On the one hand, it requires more input data, which is often almost impossible to obtain, but also more sophisticated decision support tools. On the other hand, integrating the ecosystem services into a business plan expands the portfolio of services and products that a forestry company can offer. Opportunities for new sources of profits, jobs and marketing opens. The basis for success is the right choice and ratio of all services and products in the portfolio. This could be achieved by portfolio optimization. Portfolio optimization is the process of selecting the best portfolio [https://en.wikipedia.org/wiki/Portfolio_(finance)] (asset [https://en.wikipedia.org/wiki/Asset] distribution), out of the set of all portfolios being considered, according to some objective. The objective [https://en.wikipedia.org/wiki/Multi-objective_optimization] typically maximizes factors such as expected return [https://en.wikipedia.org/wiki/Expected_return], and minimizes costs like financial risk [https://en.wikipedia.org/wiki/Financial_risk]. Factors being considered may range from tangible (such as assets [https://en.wikipedia.org/wiki/Asset], liabilities [https://en.wikipedia.org/wiki/Liability_(financial_accounting)], earnings [https://en.wikipedia.org/wiki/Earnings] or other fundamentals [https://

en.wikipedia.org/wiki/Fundamental_analysis]) to intangible (such as selective divestment [https://en.wikipedia.org/wiki/Divestment]). This study presents the portfolio optimization for the university forest enterprise in Czech Republic. Significant steps to achieve increased business profits were set in cooperation with business management as well as indicators of their achievement.

Working across disciplines to incorporate values of the public in an integrated decision support system (DSS)

Rebecca Ford¹, Andrea Rawluk¹, Kathryn Williams¹

¹The University of Melbourne, Parkville, Australia (fordr@unimelb.edu.au; andrea.rawluk@unimelb.edu.au; kjhw@unimelb.edu.au)

Forest managers are challenged with making decisions within complex social-ecological systems. Values (qualities and outcomes that are important to people) are a way of representing social parts of systems in decision-making. However, it is challenging to incorporate such values, with their social and political implications, into decision-making based in biophysical science and quantitative modelling. In this project, we used an action research methodology to contribute to, and observe, the early integration of a social concept of values into a biophysical DSS. Fifteen researchers at the University of Melbourne are developing the DSS to integrate their findings from many years studying biodiversity, carbon, water, fire and social values. As participants in this process, we identified key points where an imperative for integration across disciplines was perceived and then observed what followed. These points included a need to co-develop a definition of the term 'values' to enable decisions about what would be included within the scope of the DSS and a similar need to co-develop a definition of 'scenarios', to enable specification of scenarios for model testing. Development of these definitions began when team members realised they understood terms differently. They then needed to articulate and debate their different understandings, before integrated project definitions could be agreed. Some values of the public (identified through social research), such as experience of nature, were able to be incorporated together with ecosystem services and policy objectives to define an overall structure for the DSS. Other social values were not yet able to be adequately quantified.

C4s: ASSESSING AND MODELLING NON-TIMBER FOREST PRODUCTS

Resin yield from the wound tapping method, prior to timber harvesting in *Pinus pinaster* Ait. stands in Galicia (NW Spain)

Alberto García-Méijome¹, María José Rozados Lorenzo¹, Enrique Martínez Chamorro¹, Edgar Fernández Blanco², Esteban Gómez-García¹ 

¹Centro de Investigación Forestal de Lourizán. Xunta de Galicia, Pontevedra, Spain; ²Resinas Fernández, Vilagarcía, Spain

(alberto.garcia.meijome@xunta.gal; maria.jose.rozados.lorenzo@xunta.gal; enrique.martinez.chamorro@xunta.gal; edgarfdez@hotmail.com; esteban.gomez.garcia@xunta.gal)

Studies of the wound tapping method plus chemical stimulation, carried out in Galicia between 1950 and 1970, reported a mean resin production of 2-3 kg per tree for *Pinus pinaster* Ait. stands. The crisis in the sector and the lack of tradition of resin extraction in the region paralyzed these studies and promotion of the methods. However, interest in resin production has been reactivated in Galicia if production of quality timber can be guaranteed. Since 2015, the Lourizán Forestry Research Centre has investigated resin production in research plots located in pine stands due to be harvested in the near future. The objective is to estimate resin production in relation to the wound size and the wound number per tree, and evaluate the influence caused by resin tapping on timber destined for sawmills. The overall purpose of the research is to develop a method of resin extraction that is compatible with harvesting quality timber.

Oleoresin tapping with the borehole method in *Pinus pinaster* Ait. stands prior to timber extraction in Galicia (NW Spain)

Alberto García-Méijome¹, María José Rozados Lorenzo¹, Enrique Martínez Chamorro¹, Esteban Gómez-García¹ 

¹Centro de Investigación Forestal de Lourizán. Xunta de Galicia, Pontevedra, Spain (alberto.garcia.meijome@xunta.gal;

maria.jose.rozados.lorenzo@xunta.gal; enrique.martinez.chamorro@xunta.gal; esteban.gomez.garcia@xunta.gal)

The borehole method of resin extraction consists of making one or more perforations at the base of trees and collecting the oleoresin in closed containers. This method is compared with the wound tapping method, which is usually used in the Iberian Peninsula. The advantage of the borehole method is that the timber is not affected because the perforations are basal. In addition, the use of closed containers yields higher quality oleoresin and decreases the emission of volatile substances that can attract pests. The main limitation of the method is the rapid crystallization of resin around the perforation, which reduces the amount of oleoresin produced. The proposed improvements involve the application of organic stimulants to inhibit crystallization and thus increase the oleoresin yield, without altering the quality of the product. Early results indicate that this method may be a viable alternative to the wound tapping method, with quality as a goal.

Plant diversity associated with productive Brazil nut trees (*Bertholletia excelsa*) in the major producing regions of Amazonas, Brazil / Diversidade vegetal associada a castanhais produtivos nas principais regiões produtoras do Amazonas

Nadiele Pacheco^{1,2}, Nabor Pio¹, Kátia Emídio²

¹Universidade Federal do Amazonas, Manaus, Brasil; ²Instituto de Desenvolvimento Agropecuário e Florestal Sustentável do Estado do Amazonas, Manaus, Brasil; ²Embrapa Amazônia Ocidental, Manaus, Brasil (nadielep@gmail.com; nspio@ufam.edu.br; katia.emidio@embrapa.br)

Bertholletia excelsa Bonpl., conhecida como castanheira, é uma espécie florestal que produz um fruto chamado ouriço, coletado por populações tradicionais que comercializam suas amêndoas, castanha-do-brasil, como alternativa na composição da renda familiar. Avaliou-se a diversidade vegetal associada a castanheiras no Amazonas, por meio da comparação das diferenças florísticas entre e dentro de seis castanhais naturais. A pesquisa foi conduzida nas principais regiões produtoras do Amazonas: Reserva de Desenvolvimento Sustentável Piagaçu Purus/Anori, Propriedade do Jutica/Tefé, Comunidade Jatuarana/Manicoré, Sítio Gostoso/Amaturá, Comunidade Mufuá/Lábrea e Reserva Extrativista do Rio Unini/Barcelos. As diferenças florísticas foram analisadas por meio da análise Cluster, agrupamento UPGMA (Média não ponderada entre pares de grupos). Todos os indivíduos com DAP \geq 10 cm, vizinhos às castanheiras selecionadas, foram marcados e identificados em 15 parcelas circulares de 15 metros de raio em cada castanhal. As parcelas foram instaladas ao redor de castanheiras selecionadas a partir da classe de produção de frutos (5 de alta, 5 de média e 5 de baixa produtividade). Foram registrados 3039 indivíduos, com Jatuarana tendo o maior número de indivíduos (577). Os ambientes florestais apresentaram grande diversidade florística –diversidade alfa, medida pelo índice de Shannon-Weaver, que varia entre 3,65 a 4,19; porém estes valores não foram estatisticamente significativos (Kruskal Wallis) entre as localidades. No contexto das classes de produção não se observou um padrão de agrupamento das parcelas de mesma classe. Observou-se que os castanhais com maior similaridade florística são Sítio Gostoso e Mufuá; Unini como o mais diferente entre eles.

Use of multispectral images for identifying overwatering in eucalyptus plantation

Anny Mery Marcon Ruiz¹, Edson Luiz Furtado¹, Lisandro de Proença Pieroni¹, Fábio Suzart Albuquerque²

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Universidade de São Paulo, Departamento de Proteção Vegetal, Botucatu, Brasil; ²College of Integrative Science and Arts, Science and Mathematics Faculty, Arizona State University, Phoenix, USA (annymery_ruiz@hotmail.com; edson.furtado@unesp.br; lisandro.pieroni@hotmail.com; fabio.albuquerque@asu.edu)

With 5.63 million of hectares *Eucalyptus* represents the most established forest in Brazil. This corresponds to 91% of all wood produced for industrial purposes, such as paper and pulp production. The productivity of *Eucalyptus* plantations, however, is strongly affected by abiotic and biotic diseases, such as water stress. Waterlogged soil is a key issue for the health of eucalyptus plantations. In this study, we used drones and multispectral sensors to fly over commercial plantations plots, to capture the light they reflect in four separate bands (red, red edge, green and infrared), and to generate custom images and index maps, such as the normalized difference vegetation index (NDVI). We used the NDVI map to visualize and understand the eucalyptus plantation health. Maps and images allowed us to observe abnormalities in only one forest plot. In this area, we observed higher spectral reflectance when compared to the rest of the plantation - NDVI values ranged from -0.02 to 0.96. High NDVI values corresponded to dense vegetation (uniform plantation), while low values represented areas with sparse or no vegetation (planting failures). Field analyses revealed that overwatering as the main cause of the uneven plant development in the affected area. Our results allow us to conclude that multispectral sensors and drones offers a comprehensive, flexible and powerful solution to map damage to eucalyptus plantations. We also conclude that NDVI is an important tool for identifying problems derived from the overwatering on eucalyptus plantations.

Evolution of mechanization index in forest companies

Samara Maschetti¹, Guilherme Oguri², Saulo Guerra¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdades de Ciências Agronômicas, Botucatu, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (maschettis@gmail.com; guilherme@ipef.br; saulo.guerra@unesp.br)

The increased demand for higher yield and quality associate with the cost reduction and labor shortage in some regions of Brazil, push the R&D for mechanization and automation. Brazilian forest chain is world known by its high harvesting and logging technological level, however silvicultural operations have not reached the same level, where agricultural tractors and adapted agricultural implements are presented as the main tools towards mechanization. Based on these assertions, a survey was carried out in three forest-based companies for comparison in the index of mechanization in silvicultural activities in 2015 and 2018. The observed parameters were the tractor index and implement index. Among the determinations highlighting the increase in number of tractors at companies A and C, in 27.77% and 30.13%, respectively, leading to the growth of the tractor index from 2015 to 2018. For the implement index, the observed growth was only 1.11%. Therefore, it was concluded that, in the three evaluated companies, there was an increase in the investments on silviculture processes from 2015 to 2018, with the increase of the tractors fleet and in implements amount by area.

Hyperkeystone palm species demography: modelling and simulation of *Mauritia flexuosa* for sustainable harvest in Tena, Napo

Maria Cristina Peñuela-Mora¹, Mathew Tello¹

¹Universidad Regional Amazonica Ikiam, Tena, Ecuador (crisantema1995@gmail.com; matutello@gmail.com)

Mauritia flexuosa is a versatile multipurpose palm. It is well known for its ability to colonize flooded forests where it creates monospecific dominant patches across the basin. It is of remarkable importance for the ecosystem and it has recently been proposed as a hyperkeystone species. Its consumption by human populations has had a considerable impact in the income of local communities in the Amazon region. Fruit extraction is commonly achieved by chopping down female individuals in the forest causing a huge pressure over natural populations due to its high demand, in spite of there being less harmful alternatives for collecting fruits (climbing). Despite its importance, little is known about its management. In Ecuador the market of *M. flexuosa* is growing, therefore the objective of this study is to propose a sustainable frequency and intensity of harvest and further identification of the age-stage that contributes the most to the population stability for management purposes. For this, a 1-ha plot was established on a flooded forest dominated by *M. flexuosa* in the Napo river basin where 375 individuals were sampled. Population vital rates and growth of every stage (from seedlings to adults) were registered while production and germination rates were also determined. For modelling the population dynamic, integral projection models (IPM) were applied and then harvesting was simulated. The study results show the need of implementing the proposed harvesting in order to prevent local population decline or complete extinction of the palm.

Volumetric yield in lumber for Amazonian species in a sawmill in Rio Branco, Acre, Brazil / Rendimento volumétrico em madeira serrada para espécies Amazônicas em uma serraria de Rio Branco, Acre

José Pedro Melo¹, Marco Amaro¹

¹Universidade Federal do Acre, Rio Branco, Brasil (florestalpedro22@gmail.com; marcoantonioamaro@hotmail.com)

O objetivo do estudo foi determinar o coeficiente de rendimento volumétrico (CRV) em madeira serrada das espécies *Calycophyllum spruceanum*, *Apuleia leiocarpa* e *Manilkara bidentata*, em uma serraria de médio porte no município de Rio Branco, Acre. Desse modo, foram utilizados dados provenientes de toras que tiveram suas dimensões mensuradas previamente ao seu processamento, assim como as dimensões das peças produzidas após o desdobro. As variáveis das toras mensuradas foram: comprimento, em metros; diâmetro 1 e diâmetro 2, medidos em uma das extremidades; e diâmetro 3 e diâmetro 4, obtidos na outra, todos em centímetros. Após o desdobro, foram obtidos: comprimento das peças, em metros; largura e espessura das peças, em centímetros. Para obtenção do volume das toras foi utilizado o método de Smalian, já o volume de madeira serrada foi obtido somando-se os volumes das peças geradas. O CRV foi calculado a partir da razão entre o volume de madeira serrada e o volume da tora, posteriormente, obteve-se o CRV médio por espécie. As estatísticas foram calculadas conforme o estabelecido pela Resolução CONAMA 411/2009. As espécies *C. spruceanum*, *A. leiocarpa* e *M. bidentata* apresentaram CRV médio de 61,06%, 62,30% e 50,10%, respectivamente. As mesmas obtiveram valores superiores ao estabelecido pela Resolução CONAMA 474/2016, expressaram baixa variabilidade, com coeficientes de variação inferior à 10% e um erro amostral relativo abaixo do admissível pelo CONAMA. Desse modo, a serraria em estudo poderá adotar os CRV obtidos para a comercialização da madeira serrada destas espécies, desde que submetido e aprovado pelo órgão competente.

C4t: FOREST INVENTORY AND MODELING: PAST SUCCESSES, CURRENT CHALLENGES AND FUTURE PROSPECTS

Mathematical growth modeling of diameter and height of unthinned stands of *Eucalyptus grandis* in Northeastern Entre Ríos, Argentina / Modelación matemática del crecimiento del diámetro y altura de rodales sin raleo de *Eucalyptus grandis* en el Noreste de Entre Ríos, Argentina

María Fernanda Barrios¹, Mónica Balzarini², María Eugenia Videla³, María de los Ángeles García¹

¹Instituto Nacional de Tecnología Agropecuaria, Concordia, Argentina; ²Universidad Nacional de Córdoba, Córdoba, Argentina; ³Consejo Nacional de Investigaciones Científicas y Técnicas, Córdoba, Argentina (barrios.fernanda@inta.gov.ar; mbalzari@gmail.com; eugenividela@gmail.com; garcia.mariaa@inta.gov.ar)

La modelación matemática del crecimiento es fundamental para la planificación, toma de decisiones en la gestión forestal y la comprensión de la dinámica de los rodales. A ello hay que sumarle la relación existente con la calidad de sitio, que influye sobre la capacidad productiva de las forestaciones de *Eucalyptus grandis*. Existen modelos matemáticos lineales y no lineales que permiten modelar el crecimiento y la calidad de sitio. Con el objetivo de predecir el crecimiento de diámetro normal y altura en rodales sin raleo, se evaluaron 520 parcelas temporales y permanentes de 1 a 20 años de edad, con medidas repetidas en el tiempo, de diferentes sitios y densidades iniciales, se ajustaron los modelos no lineales de Gompertz, Chapman-Richards, Weibull y Schumacher, y un modelo lineal mixto con efecto aleatorio de parcela. El modelo con mejor bondad de ajuste y valores bajos de criterio de Akaike (AIC) y criterio bayesiano de información (BIC) para las variables estudiadas, fue el modelo lineal mixto con efecto aleatorio de parcela, del que se obtuvieron además los BLUP (Best Linear Unbiased Prediction) para rankear las parcelas de acuerdo a los mejores crecimientos en altura y clasificarlos de acuerdo a calidades de sitio de manera sencilla. Además, se realizó el análisis de correlación espacial intraparcela para comprobar si los datos están correlacionados espacialmente. Estos resultados representan los datos base para la comparación de parcelas con raleos.

Estimating diameter distribution in a fragment of Atlantic Forest using artificial neural networks / Estimativa de distribuição diamétrica de um fragmento de Mata Atlântica utilizando redes neurais artificiais

Rodrigo Leite¹, Carlos Torres¹, Samuel Rocha¹, Leonardo Reis², Hélio Leite¹

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Instituto de Desenvolvimento Sustentável Mamirauá, Tefé, Brasil (r.vieiraleite@gmail.com; carlos.eleto@yahoo.com.br; samueljoserocha@gmail.com; leonardopequenoreis@gmail.com; hgleite@gmail.com)

O crescimento e produção em florestas tropicais são objeto de estudo a muito tempo, porém, devido a sua complexidade, estimar sua dinâmica não é tarefa fácil, levando a aplicação de modelos pouco eficientes ou que necessitem de variáveis de difícil obtenção. Uma alternativa seria a utilização algoritmos de inteligência artificial, com destaque no setor florestal para as Redes Neurais Artificiais (RNA). Desta forma, objetivou-se estimar a distribuição diamétrica de um fragmento de Mata Atlântica, em Viçosa/MG, utilizando RNA. Foram utilizados dados de 10 parcelas de inventário medidas em 1994, 1997, 2000, 2004, 2007, 2010, 2013 e 2016. As árvores foram divididas em classes de diâmetro de 5cm, entre 5 e 85cm. As RNA foram treinadas utilizando os dados dos anos 1994 e 1997 e as estimativas foram feitas para os demais anos. As variáveis de entrada foram o número de árvores da classe e das 4 classes mais próximas; classe de diâmetro e período. Para análise dos resultados foi utilizado o teste K-S a 5% de significância, entre a distribuição diamétrica estimada e observada em cada ano. O valor calculado do teste foi 0,003, 0,02, 0,03, 0,02, 0,04, 0,04 e 0,12 para os anos 1997, 2000, 2004, 2007, 2010, 2013 e 2016, respectivamente, sendo não significativo apenas no último ano. O estudo mostra que as RNA podem ser utilizadas para estimar distribuição diamétrica de fragmentos de Mata Atlântica no período de 22 anos, com a vantagem de inclusão de variáveis não paramétricas e variação no período a ser estimado.

Forest litter production in a plant succession gradient in a tropical dry forest in Colombia / Producción de hojarasca en un gradiente de sucesión vegetal de un bosque seco tropical en Colombia

Angie Viviana Montañez Salinas¹, René López Camacho¹, Roy Oswaldo González Martínez²

¹Universidad Distrital Francisco José de Caldas, Bogotá, Colombia; ²Instituto de Investigación de Recursos Biológicos Alexander von Humboldt, Bogotá, Colombia (avmontanez@correo.udistrital.edu.co; rlopezc@udistrital.edu.co; rgonzalez@humboldt.org.co)

La producción de hojarasca es fundamental en el ciclo de nutrientes, el mantenimiento de la fertilidad del suelo y la regulación del carbono en ecosistemas terrestres. Diversos estudios han abordado su variación en diferentes niveles de sucesión vegetal en bosques tropicales, pero aún no es clara su dinámica ecológica en bosques secos tropicales, debido a la compleja interacción de factores bióticos y abióticos allí presentes. Este estudio analiza la variación anual de la caída de hojarasca en un gradiente de sucesión vegetal de bosque seco, localizado al norte del Tolima, Colombia. Siguiendo la metodología Tropi-Dry se establecieron 12 parcelas permanentes de 0.1 ha, las cuales se encuentran distribuidas en 4 estadios sucesionales (bosque maduro, intermedio, joven y rastrojos bajos). En cada parcela se establecieron 8 trampas circulares de hojarasca de 0.5 m², con el fin de coleccionar mensualmente el material vegetal durante 2 años. Los resultados del primer año de muestreo evidencian que la caída de hojarasca es significativamente superior en los bosques maduros e intermedios en comparación con los bosques jóvenes y rastrojos bajos (F₃=14.52, P<0.001). Estos resultados sugieren que la producción de hojarasca aumenta con el grado de sucesión, debido a mayores niveles de biomasa aérea y un dosel más desarrollado. La caída de hojarasca es sensible a la perturbación y puede ser utilizada como indicador de recuperación y restauración de funciones ecosistémicas.

Development of a stand-level growth and yield simulation system for *Eucalyptus tereticornis* plantations growing in Colombia

Alonso Barrios¹, Ana M. López¹, Guillermo Trincado², Victor M. Nieto³

¹Universidad del Tolima, Ibagué, Colombia; ²Universidad Austral de Chile, Valdivia, Chile; ³Corporación Nacional de Investigación y Fomento Forestal, Bogotá, Colombia (abarriost@ut.edu.co; amlopeza@ut.edu.co; gtrincad@uach.cl; victornieto@confif.org.co)

Currently one of the most important tree species for establishing forest plantations in Colombia is *E. tereticornis*. During the last years, about 10.000 ha of this tree species have been planted in the country mainly in the Atlantic Coastal Region. This research represents the first effort to develop and implement a stand-level growth and yield simulation system: SimFOR. Data used in this study came from the measurement of a network of 85 permanent sample plots established on 70 stands from 1 to 12 years-old. In addition, 130 sample trees were selected for destructive sampling to develop taper equations. The simulation system is driven by three main transition functions: dominant height, basal area and mortality. All equations forms were derived applying the algebraic difference

approach. Three types of taper model forms were evaluated: polynomials, segmented and variable-exponent models. The effect of autocorrelation generated by the longitudinal measurements taken along the stem was accounted using a continuous time autoregressive model (CAR) for the error structure. The validation of the stand-level growth and yield simulation system was performed using an independent dataset and measures of bias and error were calculated. Predicted stand volume for *E. tereticornis* under diverse projection scenarios was consistent with observed growth patterns.

Carbon storage in woody vegetation in the Cerradão dry forest in the Vermelho River Basin, Goiás, Brazil / Estoque de carbono na vegetação lenhosa de cerradão na Bacia Hidrográfica do Rio Vermelho, GO

Sabrina Miranda¹, Cássio Cezare², Weuler Vasconcelos³, Laerte Ferreira²

¹Universidade Estadual de Goiás, Palmeiras de Goiás, Brasil; ²Universidade Federal de Goiás, Goiânia, Brasil; ³Universidade Federal do Tocantins, Gurupi, Brasil (sabrinc.miranda@gmail.com; cassio_cezare@hotmail.com; weulervasconcelos@hotmail.com; lapig.ufg@gmail.com)

Este trabalho faz parte do projeto “Estimativa da biomassa aérea lenhosa em formações savânica e florestal do bioma Cerrado através de dados de campo e Lidar aerotransportado”. Nosso objetivo foi estimar o estoque de carbono aéreo na vegetação lenhosa (CAVL) de cerradão a partir de dados de campo. Amostramos dois remanescentes na Bacia Hidrográfica do Rio Vermelho-Goiás localizados nos extremos do transecto (50 km x 200 m) onde foram obtidos dados Lidar aerotransportado: Itapirapuã (cerradão típico/CT) e Goiás (cerradão transição para floresta estacional/CF). Em parcelas de 1.000 m² foram amostrados indivíduos com diâmetro a altura do peito (DAP) ≥ 5cm. Nas estimativas de carbono utilizou-se equação alométrica específica. O CT com densidade de 1.259ind/ha apresentou 73,93 Mg/ha de CAVL. Indivíduos com diâmetro < 15 cm (87,4%) somam 28,3% do CAVL, já aqueles com diâmetro ≥ 30cm (1,5% do total) representam 36,2% do CAVL. Os indivíduos com altura entre 4,0 e 7,9 m (70%) somam 36,3% do CAVL. Por outro lado, aqueles com altura ≥ 10m (5,2%) representam 42,4% do CAVL. No CF a densidade foi de 968ind/ha e o CAVL 154,38Mg/ha. Indivíduos (74,8%) com diâmetro < 15 cm somam 12,6% do CAVL e aqueles com diâmetro ≥ 30 cm (4,5% do total) 48,5% do CAVL. Indivíduos com altura entre 6,0 e 9,9 m (47,3%) somam 10,1% do CAVL, já aqueles com altura ≥ 15 m (13,8%) representam 69% do CAVL. Os remanescentes de cerradão são importantes em termos de armazenamento de carbono e emissões evitadas, com destaque para os indivíduos de maior porte.

Productivity of *Eucalyptus* spp. clones in different spacing arrangements in the semiarid region of Pernambuco, Brazil / Produtividade de clones de *Eucalyptus* spp. em diferentes espaçamentos no semiárido pernambucano

José Antonio Aleixo da Silva¹, Rinaldo Luiz Caraciolo Ferreira¹, José Wesley Lima Silva¹, Marília Regina Costa Castro²

¹Departamento de Ciência Florestal da Universidade Federal Rural de Pernambuco, Recife, Brasil; ²Instituto Federal de Educação, Ciência e Tecnologia, Recife, Brasil (jaaleixo@uol.com.br; rinaldo.ferreira@ufrpe.br; wesleylima_silva@hotmail.com; mariliarcastro@uol.com.br)

O efeito das mudanças climáticas no regime hídrico é evidente no semiárido nordestino, sendo o desmatamento da vegetação nativa um dos principais responsáveis. No Polo Gesseiro do Araripe, produtor de 95% do gesso nacional, a vegetação da Caatinga já perdeu em torno de 70% de sua área em função da alta demanda energética pela indústria do gesso. Uma alternativa para suprir essa demanda é a implantação de florestas energéticas de rápido crescimento. Desta forma, este trabalho teve como objetivo avaliar a produtividade de três clones de *Eucalyptus* spp. (C39, C41, C11) plantados nos espaçamentos 3 m x 3 m, 4 m x 2 m, 3 m x 2 m, 2 m x 2 m e 2 m x 1 m, em um delineamento inteiramente aleatório. O índice histórico de precipitação acumulada por ano da região é 750 mm, durante o período do experimento a média foi 529,4 mm. Na idade de 8 anos foram cubadas rigorosamente pelo método de Smalian, 2896 árvores. O experimento apresentou produtividade média de 76,35 m³ ha⁻¹, e diferenças entre os tratamentos foram encontradas (p<0,05), sendo o clone C39, no espaçamento 2 m x 1 m, o mais produtivo com 136,398 m³ ha⁻¹, segundo o teste de Scott-Knott (p<0,05). O experimento apresentou um incremento médio anual (IMA) de 9,543 m³ ha⁻¹ para os clones. O clone C39, no espaçamento 2 m x 1 m, apresentou o maior IMA, 17,049 m³ ha⁻¹. Comparando com o IMA da Caatinga, 4 m³ ha⁻¹, o uso de clones de *Eucalyptus urophylla* mesmo diante de condições de seca extrema é indicado como uma opção viável para suprir a demanda da indústria do gesso.

Machine learning models to estimate above-ground carbon in seasonal semideciduous forests using LIDAR data / Modelos de machine learning para estimativa de carbono acima do solo de Floresta Estacional Semidecidual com dados Light Detection and Ranging

Renata Paulo Macedo¹, Cibele Hummel do Amaral¹, Carlos Moreira Miquelino Eleta Torres¹, Elpidio Fernandes Filho¹, Walter da Silva Costa², Rodrigo Vieira Leite¹, Pedro Henrique Santos Mota¹, Duberli Geomar Elera Gonzáles³, Lucas Arthur de Almeida Telles¹

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Celulose Nipo-Brasileira S.A, Belo Oriente, Brasil; ³Universidad Científica del Sur, Lima, Peru (renata.macedoufv@gmail.com; chamaraal@ufv.br; carlos.eleta@yahoo.com.br; elpidiofilho@gmail.com; walter.costa@cenibra.com.br; r.vieiraleite@gmail.com; pedromota.enf@gmail.com; duberelera@gmail.com; lucasarthur36@gmail.com)

O uso de novas tecnologias na mensuração de parâmetros biofísicos da floresta tem tornado o inventário florestal mais ágil, obtendo a mesma ou maior precisão das estimativas realizadas no inventário convencional. Dessa forma, esse trabalho tem como objetivo selecionar o melhor modelo de machine learning para estimar o estoque de carbono acima do solo de fragmentos da Floresta Estacional Semidecidual em Minas Gerais. Os dados são provenientes de inventário florestal para cálculo do carbono acima do solo e dados de sobrevoo utilizando a tecnologia laser aerotransportada para o cálculo de métricas LiDAR. A estimativa do carbono foi obtida através da multiplicação de um fator (0,48) pela biomassa acima do solo, calculada utilizando o somatório de DAP, altura total e densidade básica de cada espécie dentro das 29 parcelas selecionadas em campo. Os modelos utilizados no trabalho foram: Random Forest, Support Vector Machine e Cubist; utilizando como variáveis explicativas as cinco métricas LiDAR, extraídas da nuvem de pontos normalizada, com maior valor de importância, de acordo com a ferramenta Recursive Feature Elimination do software R. Os coeficientes de determinação (R²) para as três modelagens foram superiores a 0,91, com Erros Quadráticos Médios (RMSE) inferiores a 19%. Diante dos resultados obtidos nesse estudo, conclui-se que é possível estimar de forma precisa o estoque de carbono acima do solo de Floresta Estacional Semidecidual por meio de dados LiDAR aerotransportado e modelos de machine learning.

C4u: FOREST INVENTORY AND MODELING: PAST SUCCESSES, CURRENT CHALLENGES AND FUTURE PROSPECTS

Modelling forest succession under a harvest regime in mixed stands in Quebec, Canada

Lara Climaco de Melo¹, Robert Schneider¹

¹UQAR, Rimouski, Canada (laraclemo@gmail.com; robert_schneider@uqar.ca)

Understanding forest regeneration over large-scale and under harvesting regime is essential for natural resource management. In this study, we used a dataset from a network of monitoring plots in the regions of Bas-Saint-Laurent and Gaspésie, in Quebec, Canada, as a real-world case study. Based on statistical models, we combined different techniques into an approach that predicts forest succession under harvesting. Firstly, we fitted a binomial model to predict regeneration after harvesting. Once a regeneration was predicted, a gamma model was fitted to estimate the stocking. Forest composition before and after harvest, as well as climatic and topographic variables were used as explanatory variables. The models were evaluated and validated, and the results showed the potential of the approach to provide predictions of forest succession in the area of study. The probability of regeneration was strongly influenced by the topographic variables. The results also revealed the temporal evolution of post-harvest forest composition in terms of stocking. This modelling approach should overcome actual challenges reported by managers in the study regions.

Forest growth and minimal model of forest ecosystem organic matter turnover: implication for sustainable forest management analysis

Alexander Alekseev¹

¹Saint-Petersburg State Forest Technical University, Saint-Petersburg, Russian Federation (a_s_alekseev@mail.ru)

Forest growing stock change in time was derived from minimal model of organic matter turnover in forest ecosystem. Growth curve was calibrated on the base of growth and yield tables data and describe it with high precision as it measured by determination coefficient. Growth and organic matter turnover parameters relationships was established and interpreted. Increment and acceleration curves for growing stock changes were in special manner analyzed and 4 specific tree stands growth stages was formulated as they determined by acceleration curve singular points. Determined growth stages was interpreted and discussed from forest management point of view. Multi-criteria optimization of growing stock use in time was done on the base of special management problem decision and analyzed from point of view of sustainable forest management: carbon cycling, carbon uptake and storage, forest biodiversity conservation, soil and water protection as well as risk of natural and man-made hazards damage. Optimal parameter for continuous cover forestry approach to tree stands use such as proportion between harvested and remaining for further growth growing stock, number of thinning per rotation period and its intensity, time needed for growing stock recovering after harvesting as well as suitability of continuous cover forestry approach for tree stands of different productivity and rate of growth was determined and discussed. Sustainability and resistance of forest growth as well as organic matter turnover in forest ecosystem was examined by catastrophe theory approach and the edge values of external effects were determined in connection with tree stands productivity and growth rate.

Novel TLS device with eccentric automotiv scanner to avoid occlusion in single stand-point LIDAR scanning and obtain block-chain certified snapshots ready for AI-based single tree growth modelling

Guenther Bronner¹, Martin Wieser²

¹Umweltdata GmbH, Wolfsgraben, Austria; ²Technical University of Vienna, Vienna, Austria (g.bronner@umweltdata.at; wieser_martin@gmx.at)

Terrestrial Laserscanning (TLS) in forestry has to deal with occlusion unless scanning from multiple stand-points. A novel patented scanning device can significantly reduce this handicap. A horizontal protruding arm of ~1 meter is mounted on a tripod, rotating at 0.3 rot/min. On the end of this horizontal arm, an (automotive) laser-scanner is rotating vertically at 30 rot/sec. On the opposite end of the arm, CPU and battery help to balance the construction. A prototype will be available at the IUFRO conference. It can carry different sensors like VLP16, Quanergy M8 or the Riegl mini-VUX. Simulation scans with Riegl VZ2000 on multiple circular positions look promising, showing that this geometrical setup can avoid 90-95% occlusion compared to conventional TLS. The resulting point cloud allows accurate reconstruction of DBH, height, taper functions, crown geometry, tree positions and relief properties within 20-50 m radius. This dataset can perfectly serve as input for AI based single tree growth simulation. In combination with digital images, this standardized geo-located snapshot can be certified by blockchain technology. The price of the device will be below 30,000 US\$. This technology has game-changing potential in forest inventory business, especially regarding NFI as well as standardized carbon monitoring. While point cloud interpretation and tree feature extraction will surely be further developed, the geo-located point cloud snapshots can be stored for future monitoring purposes. The device will be ready for testing by March 2019. Until the IUFRO conference we will have plenty of test-data available for presentation and discussion.

Why is the error in top height predictions usually ignored and why is it an error to do so?

Rubén Manso¹, Catia Arcangeli², Paul McLean¹, Robert Matthews²

¹Forest Research, Roslin, United Kingdom; ²Forest Research, Farnham, United Kingdom; (ruben.manso@forestry.gov.uk; catia.arcangeli@forestry.gsi.gov.uk; paul.mclean@forestry.gsi.gov.uk; robert.matthews@forestry.gsi.gov.uk)

Top height has been an essential metric in forest practice and forest science over the last century. Despite the many issues that have been risen in regard to this metric, top height is still popular and useful these days. Crucially, top height is used as the engine of many growth and yield models worldwide, which are the base of national or regional forest planning. Unfortunately, predictions from most of these top height models do not come with an uncertainty assessment, which may have a non-trivial impact on decision making and therefore on forest policy. Our contribution seeks to identify the historical and technical reasons for this systematic omission and to explore the consequences of ignoring uncertainty in this context. To do this, the most popular modelling approaches are described along with the technical issues related to uncertainty. Then an alternative method to easily derive the uncertainty of top height predictions through a modification of the Generalized Algebraic Difference Approach is introduced. Finally, yield predictions are computed with M1, a top height-dependent yield model used to forecast timber production at the national level in Great Britain, both considering uncertainty in top height estimates and ignoring it.

A forest productivity analysis framework to estimate yields, gaps and manage production risks

Arthur Vrechi¹, Eduardo More de Mattos¹, José H. Bazani¹, Gabriela G. Moreira², Luis Fernando Silva²

¹Geplant Forest Technology, Piracicaba, Brasil; ²International Paper do Brasil, Mogi-Guaçu, Brasil, (arthur@geplant.com.br; eduardo@geplant.com.br; bazani@geplant.com.br; gabriela.moreira@ipaper.com; lfernando.silva@ipaper.com)

Comprehending and forecasting planted forests production is actually a challenge for forest managers, mainly due to combined, and generally misunderstood, influences of space-time weather oscillations, pests, abiotic disturbances and lack of management practices. Aiming to provide future stochastic yields estimations for risk assessment and KPI's for current productivity, considering distinctly climate and forest management effects, we developed a framework named GPT (portuguese acronym for total productivity management), that integrates a soil and climate (from 1980 up-to-date) database, a process-based ecophysiological model (an improved version of 3-PG), yield gap concept, Monte Carlo approach, probabilistic analysis, forest inventory and remote sensing. This framework was applied to a group of *Eucalyptus* plantation, ranging from 2 to 4 years old, in northeast Sao Paulo, Brazil, that suffered from defoliation and sporadic mortality due to an intense dry period in 2017. Landsat-8 imagery timeseries were used to estimate different levels of defoliation and eventual mortality. Reference productivity (a timeless reference given by the framework) for this plantation was 270 m³/ha (year 6). Optimist and pessimist scenarios (from probabilistic analysis) ranged from 301 to 223 m³/ha. Actual weather conditions impacted negatively the attainable productivity by 5.4%. Defoliation and mortality impacts over future yield varied from -2% up to -20%, considering optimistic and pessimistic future scenarios, with a most likely estimation of -9.1%. This approach was proven to be helpful for forest managers to predict and prevent yield losses, manage risks and take decisions considering the dynamics of forest growth under changing scenarios.

Variance Estimation in Spatially Balanced National Forest Inventory Sampling

Minna Rätty¹ , Annika Susanna Kangas² , Juha Heikkinen¹ 

¹Natural Resources Institute Finland (Luke), Helsinki, Finland; ²Natural Resources Institute Finland (Luke), Joensuu, Finland (minna.ratty@luke.fi; annika.kangas@luke.fi; juha.heikkinen@luke.fi)

Local pivotal method (LPM) has proven to be an efficient approach to enhance the design phase of National Forest Inventory (NFI). It utilizes auxiliary information, for example remote sensing data, in sample selection aiming at a sample, which is similar to the population in terms of its distribution in the multidimensional auxiliary space i.e. spatially balanced. In Finland, LPM was piloted in the inventory of Åland region in summer 2018. The increased efficiency should be reflected in our estimates of sampling error but for LPM we need a new variance estimator. 'vsb' estimator, which sums squared differences of observations between each pivot and its nearest neighbour in the auxiliary space in similar spirit to the Matérn variance estimator developed for square grid sampling, has been suggested. In a simulation study we assessed the suitability of vsb. We focused on total growing stock volume and compared vsb variance estimates to naive variance estimates associated to simple random sampling (SRS) and Matérn variance estimator. Expectedly, SRS estimates were the most conservative resulting in largest variances. Matérn and vsb variances were smaller than SRS and close to each other. We think that it might be possible to reduce overestimation of variance by alternative Matérn-type approaches.

Climate effect on volume response for mid-rotation fertilization in clonal eucalypt stands

Luciane Schmidt¹, Henrique Scolforo², José Roberto Scolforo¹, Mateus Sanquetta³

¹Universidade Federal de Lavras, Lavras, Brasil; ²Suzano, Limeira, Brasil; ³Universidade Federal do Paraná, Curitiba, Brasil (lunaimekeschmidt@gmail.com; henriquescolforo@hotmail.com; josescolforo@gmail.com; mateus.sanquetta@gmail.com)

It is claimed that climate x mid-rotation fertilization interaction results in different volume gains in forest plantations. There is a dearth of studies, however, evaluating this interaction and its consequently effect on forest production. It is worth mentioning that volume gain is responsiveness to fertilization, although at different rates depending on the climate. To evaluate how volume gain is affected through the mid-rotation fertilization x climate interaction, we offer a modeling approach that relates clonal Eucalypt yields in fertilized vs non-fertilized stands as function of climate variables through the use of a semi-parametric regression. Ridge regression is a technique that enables the evaluation of how the interaction effects volume gain as well as to identify the climate variables that limit the most the fertilization effect on volume gain. The dataset come from inventory of 32 plots at age 14 years distributed in Eastern Brazil. The understanding of the mid-rotation fertilization x climate interaction is a critical step in the decision framework, since it allows better site-specific management, while respecting the budgetary constraints.

Predicting Weibull parameters as a function of stand attributes

Luciane Schmidt¹, Gilson Silva², Clayton Fraga Filho², Mateus Sanquetta³, José Roberto Scolforo¹

¹Universidade Federal de Lavras, Lavras, Brasil; ²Universidade Federal do Espírito Santo, Alegre, Brasil; ³Universidade Federal do Paraná, Curitiba, Brasil (lunaimekeschmidt@gmail.com; fernandes5012@gmail.com; claytonfraga@gmail.com; mateus.sanquetta@gmail.com; josescolforo@gmail.com)

Probability density functions are widely used for forest growth and yield purposes. The diameter distribution is performed by classes, providing detailed yield estimates and making it possible to obtain multiple products. The Weibull function has been used due to its flexibility and good correlation with stands attributes. This study aimed to evaluate the Weibull parameter prediction approach to describe the diameter distribution of clonal eucalypt stands. Data came from 56 permanent plots measured at 36, 60 and 72 months, located in central Minas Gerais. Regression models employing best-correlated stands attributes to Weibull parameters were fitted. The fitted equations presented RRMSE of 9.9% and 2.2% for the shape and scale parameters. The location parameter showed low correlation with stands attributes and its exclusion allowed best estimates. The parameter prediction approach consists in a fast alternative without computational effort demand, which results in accurate estimates that may help in scenarios of industry supply and independent wood producers to predict the amount of available resources at harvesting time.

C4v: REMOTE SENSING AND GEOGRAPHIC INFORMATION SYSTEM FOR FOREST MONITORING AND MANAGEMENT

Derivation of a set of biologically-based LiDAR attributes

Ting-Ru Yang¹, John A. Kershaw¹

¹University of New Brunswick, Fredericton, Canada (tyang1@unb.ca; kershaw@unb.ca)

Canopy surface-based and height distribution-based attributes are primarily used to model area-based forest attributes such as volume or biomass per ha, but those attributes are less effective at estimation of other commonly needed forest attributes, including basal area, density, mean tree size, canopy volume, leaf area, and many others. There is limited generalized theory that has emerged regarding the relationship between LiDAR point clouds and forest structure. To have better predictive capability for stand parameters such as leaf area distribution, structural diversity, and biodiversity, a series of biologically-relevant and generalized LiDAR attributes are required. These attributes should be derived from our biological understanding of forest structure and productivity. The approach we propose builds upon current forest inventory practices, stand development theories, and measures of stand structure and complexity. With these traditional measures, we propose to use them to inform the types of LiDAR attributes which should be extracted or calculated from point clouds. Initially, we perceive four types of LiDAR point cloud attributes: 1) height-based; 2) horizontal density-based; 3) horizontal and vertical variability; and 4) individual tree segmentation. The initial goal is generalizable forest inventory predictions. Implications for sample design, growth and yield modeling, and forest management decision making are explored.

Forest stand 3D segmentation at the tree level from fused airborne LiDAR and Hyperspectral data

Eduardo Tusa-Jumbo^{1,2}, Jean-Baptiste Barré¹, Jean-Mathieu Monnet¹, Mauro Dalla Mura², Raphaël Aussenac¹, Jocelyn Chanussot²

¹Univ. Grenoble Alpes, Irstea, LESSEM, Grenoble, France; ²Univ. Grenoble Alpes, CNRS, Grenoble INP, GIPSA-lab, Grenoble, France (eduardo.tusa-jumbo@irstea.fr; jean-baptiste.barre@irstea.fr; jean-mathieu.monnet@irstea.fr; mauro.dalla-mura@gipsa-lab.grenoble-inp.fr; raphael.aussenac@irstea.fr; jocelyn.chanussot@gipsa-lab.grenoble-inp.fr)

Access to data with high spatial and spectral resolution is becoming more widespread and makes it possible to consider new applications for monitoring forest ecosystems. In particular, it is possible to consider studies of an entire stand but at the tree level. However, this raises questions about the joint use of data from different sensors such as LiDAR and hyperspectral imagers. This study presents a fusion methodology between high-density LiDAR data (45 pts/m² minimum) and VNIR hyperspectral images (HI) - (80 cm spatial resolution) acquired on french Alpine forests along an altitude gradient. The objective is to extract the main architectural characteristics of each individual tree and in particular the dimensions of crowns knowing the species. The methodology is based on the integration of HI and LiDAR data at different levels of fusion. First species are identified using the reflectance attributes contained in HI and the LiDAR canopy model, and then the 3D point cloud is segmented based on the allometric characteristics of the species. The integration of this additional information together with the segmentation algorithm provides an essential association strategy for LiDAR points located in the lower part of the canopy. Finally, the main dimensions of the crowns and associated trees are extracted from the 3D segmentation.

Seasonal change in forest cover in Northwestern Rio Grande do Sul, Brazil, using supervised Landsat image classifiers / Avaliação temporal da cobertura florestal no noroeste do Rio Grande do Sul por meio de classificadores supervisionados de imagens Landsat

Renato Santos¹, Fábio Breunig¹

¹Universidade Federal de Santa Maria, Frederico Westphalen, Rio Grande do Sul, Brasil (renato.souza@ufsm.br; fabio@ufsm.br)

Classificação é o processo de extração de informação, em imagens, para reconhecer padrões e objetos homogêneos. Esse método é amplamente utilizado no sensoriamento remoto. Assim, o objetivo desse estudo foi observar a dinâmica florestal do noroeste do Rio Grande do Sul, utilizando diferentes métodos de classificação supervisionada. O estudo foi realizado em duas microrregiões localizadas no estado do Rio Grande do Sul, situado na região sul do Brasil. Para o estudo foram utilizadas imagens do satélite Landsat 5 e 8, para recobrir os anos 1985, 1995, 2005, 2015 e 2018, sendo utilizadas duas imagens por ano, representando o verão e inverno. Os métodos de classificação de imagens utilizados foram os algoritmos Máxima verossimilhança, Spectral Angle Mapper e Support Vector Machine. Para tal, foram selecionadas diversas classes afim de caracterizar melhor a área. Para a avaliação da qualidade da classificação, foi utilizada a inspeção ponto a ponto de amostras sorteadas aleatoriamente (matriz de confusão). Dentre os classificadores testados, os que apresentaram uma melhor acurácia foram o Spectral Angle Mapper e Support Vector Machine. Verificou-se que houve um aumento na vegetação florestal nos últimos anos dessas áreas estudadas, possivelmente está relacionado à influência de diversos fatores, como por exemplo a reformulação e aplicação efetiva do código florestal, dinâmica populacional e mudanças no padrão de uso do solo eminentemente agrícola para novas abordagens silviculturais.

Improving forest inventory plot registration precision using field and LiDAR data

Demetrios Gatzliolis¹, Przemyslaw Polewski², Adam Erickson³, Nikolay Strigul³

¹USDA Forest Service, PNW Research Station, Portland, Oregon, USA; ²Hong Kong Polytechnic University, Hung Hom, Kowloon, Hong Kong; ³Washington State University, Vancouver, Washington, USA (dgatzliolis@fs.fed.us; przemyslaw.polewski@polyu.edu.hk; adam.erickson@wsu.edu; nick.strigul@wsu.edu)

Precise registration of forest inventory plots is a prerequisite for optimal integration of field measurements with high-resolution remotely sensed data, including ALS and very high resolution (VHR) satellite imagery. Plot positional uncertainty propagates through statistical modeling procedures and, ultimately, reduces the utility of obtained wall-to-wall inventory maps. In most national forest inventory systems, plot registration is obtained using recreational-grade, low-precision GPS devices. However, even industrial-grade devices yield low-precision coordinates in unfavorable conditions for GPS operation, including steep slopes, high canopy cover, and multilayered vegetation. We introduce a fully automated procedure relying on individual-tree height and position relative to the plot center, as recorded in co-located field and LiDAR data, to improve field data registration accuracy and precision. Results are furnished with an estimate of confidence in the optima obtained. Performance is evaluated using a sample of circular inventory plots stratified across classes of canopy cover and tree height in Oregon, USA.

Integrating remote sensing and process-based models to predict wood production of *Eucalyptus* plantations across large space-time gradients

Marcos Augusto A. Dassan¹, Eduardo More de Mattos¹, Arthur Vrechi¹, José Henrique Bazani¹

¹Geplant Forest Technology, Piracicaba, Brasil (marcos@geplant.com.br; eduardo@geplant.com.br; arthur@geplant.com.br; bazani@geplant.com.br)

The extension of Brazilian silviculture brings challenges for monitoring large spatial and temporal gradients across 7.4 M ha of *Eucalyptus* plantations. Field assessment still one of the major tools to monitor forest growth, although the use of satellite imagery is already used in many companies. On the other hand, growth and yield models generally don't explicitly consider the effects of environmental drivers, such as rainfall amount and distribution, solar radiation, soil water holding capacity and so on. Therefore, the integration of remote sensing techniques and process-based models allows the characterization of a closer representation of the actual growth dynamics of trees. This study made the connection between both tools by deriving light interception estimates from vegetation indexes. To test the hypothesis, we applied this method in *Eucalyptus* sp plantations located at the municipality of Agua Clara MS, Brazil. Switching the sub-model that calculate light capture from the canopy in the 3-PG forest growth model we found a relationship between predicted and observed values with high precision ($R^2=0.97$) and accuracy (bias = 3%), with a mean absolute error of 10.14 m³/ha, along 61 observations in stands ranging from 1 to 4 years of age. As a result, this method can be applied to enhance the sensibility of production models over large spatial and time gradients, bringing analytical support and indicators for operational and planning decisions of forest assets.

Mapping forest exploration under forest concession regime using RapidEye images

João Vitor Frigeri¹, Verardo Liesenberg¹, Mariane Moura Andrade¹, Marcos Benedito Schimalski¹

¹Universidade do Estado de Santa Catarina, Lages, Brasil (joaovfrigeri@hotmail.com; veraldo.liesenberg@udesc.br; enairamma@hotmail.com; marcos.schimalski@udesc.br)

The concession of public native forests is an effort of the Brazilian government to avoid predatory exploration of forest resources in the Amazon region. The use of high spatial resolution satellites and different vegetation indices may help in the monitoring of public forest areas under concession regime. In this way, the objective of this chapter is to evaluate the performance of RapidEye images and four vegetation indices to monitor sustainable exploitation within the Jamari National Forest. An image of 2015 was used, the year in which the exploration of native trees in the area was recorded. Three classes of land occupation were determined, being forest infrastructure (FI), unexplored area (UA) and selective cutting (SEC). We collected 100 pixels for each class in which 70 pixels were used as training and 30 pixels as validation. Both Random Forest (RF) and Support Vector Machine (SVM) we used as classifiers. Our results showed that the forest infrastructure class (FI) obtained the highest reflectance values across Rapideye' waveleights and the selective cutting (SEC) and unexplored areas (UA) obtained very close values in the visible region. The Kappa index varied from 0.50 to 0.80. The best result was achieved for the RF classifier using the original RapidEye spectral bands.

The importance of GRSS student grand challenge for promoting UAV applications for both precision forest and farming in Brazil

David Robledo Di Martini¹, Everton Castelhão Tetila², José Marcato Junior¹, Edson Takashi Matsubara¹, Henrique Siqueira¹,

Amaury Antônio Castro Junior¹, Márcio Santos¹, Carlos Henrique Monteiro¹, Hermerson Pistori², Verardo Liesenberg³

The Geoscience and Remote Sensing Society (GRSS) promote on a yearly basis the Student Grand Challenge. It is intended to engage students and young professionals in solving a complex engineering problem within the scope of GRSS and other sister societies (e.g., Aerospace and Electronic Systems, Antennas and Propagation, Ocean Engineering, Computer, Microwave Theory and Techniques). Among five selected projects worldwide, one was selected from Brazil. The Grand Challenge consists on a joint program encompassing several small projects being conducted by students and professionals from UFMS, UCDB and UDESC. All the projects are related with the development of UAVs and innovative machine learning methods applied to both precision forest and farming. The developed UAVs and preliminary results achieved in both precision forest and farming applications will be also presented in this session. Key-words: data contest, student grants, student sponsorships. Sponsored by GRSS, CNPq, and CAPES.

Analyzing forest loss in land categories within Peruvian Amazonia, 2001-2016 / Analisis del comportamiento de pérdida de bosque en categorías territoriales de la amazonia peruana durante el periodo 2001 - 2016

Ethel Rubin-de-Celis Llanos^{1,2}, Zoila Cruz Burga¹, Maria de Los Angeles La Torre Cuadros¹, Nelson Carlos Rosot², Ana Paula Dalla Corte³, Hideo Araki³

¹Universidad Nacional Agraria La Molina, La Molina, Peru; ²Universidade Federal do Paraná. Programa de PósGraduação em Engenharia Florestal Paraná Brasil; ³Universidade Federal do Paraná, Programa de PósGraduação em Engenharia Florestal, Paraná, Brasil; ³Universidade Federal do Paraná, Paraná, Brasil (erubin@lamolina.edu.pe; zcruz@lamolina.edu.pe; mlatorrec@cientifica.edu.pe; nelson.rosot@gmail.com; anapaulacorte@gmail.com; haraki@ufpr.br)

Se analizó el patrón de la pérdida de bosques en 16 categorías territoriales pública y privada, así como de la administración en bosques amazónicos peruanos entre el 2001-2016. El análisis realizado fue descriptivo y multivariado de los datos oficiales de la pérdida de bosques definidos por el Estado peruano. Se revela un incremento gradual de la pérdida de bosque siendo los años 2009, 2014 y 2016 los de mayor incremento. Los departamentos de Martín, Loreto y Ucayali; y las categorías territoriales no categorizadas, comunidades nativas tituladas y predios rurales son los que presentan mayor pérdida de bosques. Se muestra que la categoría territorial no categorizada no afecta la tendencia general de deforestación en la Amazonía peruana siendo la dinámica de pérdida de bosques similar a las otras categorías con derechos asignados.

C4w: REMOTE SENSING AND GEOGRAPHIC INFORMATION SYSTEM FOR FOREST MONITORING AND MANAGEMENT

The use of landscape metrics to evaluate the direct influence zone of the Estação Ecológica de Águas Emendadas – Planaltina, Distrito Federal – Brazil

Ana Paula Camelo¹, Keila Sanches², Eraldo Matricardi¹

¹Universidade de Brasília, Brasília, Brasil; ²Instituto Federal de Brasília, Brasília, Brasil (paulaforestal@gmail.com; keila.sanches@gmail.com; ematricardi@gmail.com)

The Estação Ecológica de Águas Emendadas (ESECAE-DF) located in Planaltina is one of the largest Conservations Units (CU) of the Distrito Federal/Brazil, and it is responsible for the conservation of the water springs of three biggest watersheds. The landscape fragmentation interferes with local socio-environmental quality and shatters the supply and the quality of drinking water. This study analyzes the dynamics of the soil use, the impact of the land use change and the fragmentation in the 3 kilometers buffer zone around the CU. We calculated the transitional matrices and landscape metrics from images of 1986 until 2016. The metrics calculated were: Number of Patches (NP), Total Core Area (TCA), Patches Density (PD), Edge Density (ED), Number of Disjunct Core Areas (NDCA) and Shannon's Diversity Index (SHDI). The biggest land use conversions were from "Savannas Formations" to "Agricultural Use" and from "Forest Formations" to "Savannas Formations". It was observed that 51% of the buffer zone was modified, directly influencing the water cycle. During the studied period, the NP of the Forest Formation and the Savannah Formations increased, and the TCA of those patches decrease, indicating a strong fragmentation. The year 2006 presented the highest fragmentation values and the year 2016 presents a greater uniformity, since, the agricultural use was already more dominant. It was concluded that the analysis of landscape metrics can be useful tools to help public policies to control and manage land use around the unit to prevent internal damage to the forest caused by anthropogenic actions.

Major forest increase on the Loess Plateau, China (2001–2016)

Muyi Kang¹, Yuhang Wang¹, Mingfei Zhao¹

¹Beijing Normal University, Faculty of Geographic Science, School of Natural Resources, Beijing, China (kangmy@bnu.edu.cn; wyhappy1990@163.com; euler_mf@163.com)

The Loess Plateau in China is prone to widespread land degradation (soil erosion, deforestation and water loss) and therefore ecological restoration programmes aiming to re-establish the ecosystem by revegetation have been implemented during recent decades. Consequently, a widespread increase in vegetation cover has been reported, but the state and dynamics of forests remain largely unknown. Here we used field and satellite data to produce annual forest probability scores at 250×250 m between 2001 and 2016. We classified the forest dynamics into three types: net gain, net loss and fluctuation. Assuming that an increasing probability score reflects forest growth, we categorised the annual forest areas into different growing stages indicating the transition between planting and mature forest. In total, the area of forest increase was 48,786 km² and the percentage of forested areas of the region changed from 8.19% to 15.82% within 16 years. In areas of forest net gain, there was a clear transition from low to high probability forest areas, providing evidence that a general forest transition is occurring on the Loess Plateau. The method developed for continuous monitoring of forest probability scores offers a benchmarking for further decision-making on ecological restoration of the region and for mapping of afforestation projects elsewhere. The findings on major forest increases demonstrate that land degradation is in fact reversible, with implications for many ecosystem services (e.g. carbon storage, provisioning of forest products).

Analysis of land use and occupation in the Joana Darc settlement complex and surrounding area in the Brazilian Amazon / Análise do uso e ocupação do solo no complexo de assentamentos Joana Darc e seu entorno, Amazônia Legal, Brasil

Isabela Floreano¹, Luzia Moraes¹

¹Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro, Brasil (isabelafloreano@edu.unirio.br; lmoraes@unirio.br)

Desde a década de 70, a partir da criação do INCRA, assentamentos rurais vêm sendo implantados em diversos Estados do Brasil, com uma rápida expansão na região Norte. De acordo com dados do sistema PRODES- INPE, os focos de desmatamento vem aumentando devido ao corte raso da floresta e atividades agropecuárias. Além disso, a construção de complexos hidrelétricos vem causando impactos ambientais e sociais. A partir do cadastro ambiental rural, é possível realizar o monitoramento do uso e ocupação do solo no interior dos assentamentos, visando à manutenção das reservas legais. O estudo tem como objetivo analisar as mudanças no uso e ocupação do solo no período entre 2008 e 2018 no complexo de assentamentos Joana Darc, Rondônia, e seu entorno, bem como verificar as áreas suscetíveis a inundações. Foram utilizados os programas SPRING-INPE e ArcGIS-ESRI e imagens Landsat, obtidas no site USGS-NASA, para o processamento e classificação de imagens. Posteriormente, foram realizados cruzamentos com dados secundários obtidos em diversas instituições, e primários, obtidos no campo, por meio do projeto RAPATRA. Foi observado que houve um aumento da área ocupada em cerca de 27,3% em 2018, enquanto que a área de mata nativa reduziu em cerca de 11,4% no mesmo período. Observou-se ainda o aumento da massa d' água do Rio Madeira, possivelmente pela implantação de grandes hidrelétricas no local. Assim sendo, torna-se necessário o monitoramento e fiscalização das ocupações dentro e fora do assentamento, incluindo aquelas nas áreas de proteção permanente (APP).

Developing of forest management and wood trading systems by utilizing airborne laser scanning data in Finland

Kalle Karttunen¹, Mika Laihanen¹, Antti Karhunen¹, Tapio Ranta¹

¹LUT University, Mikkeli, Finland (kalle.karttunen@lut.fi; mika.laihanen@lut.fi; antti.karhunen@lut.fi; tapio.ranta@lut.fi)

Forestry digital systems are developing fast. Innovation in forest inventory, data transparency and software management are bringing the opportunity to make a significant decision-making and additional information for the forestry sector. During the last years, airborne laser scanning has been utilized in Finland's forest inventory. The detailed information can be utilized for the Internet based applications, like the forest management and further wood trading services. The aim of the

study was to innovate the open source forest airborne laser scanning data for forest management and wood trading services. The data of forest biomass was based on the latest laser scanning from the final cutting proposals at the regional area of Finland. The laser scanning results indicated the volume of roundwood and the forest energy potentials from stumps and logging residues. However, some restrictions must be done when analysing the regional forest biomass potentials. For example, non-industrial private forest owners' willingness to sell forest biomass for energy purposes has significant role for availability of biomass. The study showed a huge regional potential of forest biomass according to the final cutting proposals. However, realistic and sustainable forest biomass potential must be carefully done by combining several study information. By using airborne laser scanning method, the forest resources can be evaluated more effectively and could be used more sustainably at the regional level. It also enables to develop the new solutions for the digital forest management and wood trading services.

Detection and monitoring of forest cover in Gangwon Province, South and North Korea using Vegetation Index (VI) and time series satellite imagery

Sujong Lee¹, Eunbeen Park¹, Sungeun Cha¹, Hyun-Woo Jo¹, Moonil Kim^{1,2}, Hangnan Yu¹, Woo-Kyun Lee¹

¹Department of Environmental Science and Ecological Engineering, Korea University, Seoul, Republic of Korea; ²International Institute for Applied Systems Analysis, Laxenburg, Austria (leesj3610@gmail.com; heyevvin@gmail.com; tgy2005@korea.ac.kr; endeavor4_a1@naver.com; windy7up@gmail.com; willpower0129@gmail.com; leewk@korea.ac.kr)

Recently, excessive and unreasonable development of forests causes environmental and ecological disturbances, and degradation of forests also impacts on the human ecosystem. For sustainable forest management, it is essential to detect the change of forest cover on time-series. In this study, we used the satellite imageries for time-series (1988, 1999, 2009 and 2018) analysis to focus on the change of forest area in Gangwon Province, which is the most forested area in Korean Peninsula. Reference data is essential for classification, but since North Korea's data are limited, national spatial data of south Korea was used. The classification was conducted using NDVI threshold-based on Gaussian probability density function, which is set for Gangwon province using the national land cover map. Both North and South Korea showed a decreasing trend in forest cover until the 2000s, while increasing trend in the 2010s. In the case of South Korea, the decreasing rate of forest cover from the 1980s to 2010s was -9.34%. However, North Korea showed a significant decline of -26.40%. Error matrix was calculated for validating the detected forest area. The result of the study indicates the lack of awareness of forest protection by North Korean and requires the improvement of policies and infrastructures for forest management. This study is meaningful in that detecting the change of forest areas on the Korean Peninsula by using satellite imagery. Especially, developing base map is an important point for forest management using NDVI threshold on North Korea which is an inaccessible area.

Expanding cultivation of eucalyptus for energy in center-west Brazil: the case of Rio Verde, Goiás / Expansão de cultivo de eucalipto para finalidades energéticas no Centro-Oeste: estudo de caso de Rio Verde, Go

Bruno Moreira Riani Costa¹, Claudio Cesar de Almeida Buschinelli²

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Rio Claro, Brasil; ²Embrapa Meio Ambiente, Jaguariúna, Brasil (bruno.riani@unesp.br; claudio.buschinelli@embrapa.br)

O município de Rio Verde (GO) ocupa hoje uma posição de destaque no cenário agropecuário do Centro-Oeste. O uso da terra em sua extensão territorial passou a sofrer mudanças profundas na segunda metade do século XX, principalmente a partir da década de 1970, na esteira do processo de modernização da agricultura brasileira; sua grande extensão territorial e alta capacidade produtiva agropecuária são alguns dos fatores que motivaram a instalação de grandes empresas e conglomerados do agronegócio em Rio Verde, o que lhe garantiu essa referida posição central no quadro regional. Assim, esse crescimento agroindustrial foi acompanhado de um expressivo aumento no plantio florestal de eucalipto no município de modo a suprir a demanda energética, proveniente principalmente da secagem de grãos e dos frigoríficos. É isso que buscamos demonstrar no presente trabalho; para tanto, foram elaborados mapas de uso e ocupação da terra no município com base em imagens de satélite dos anos de 2006, 2011 e 2017. Através do processamento em SIG foi possível constatar de fato o crescimento do plantio florestal de eucalipto, que de cerca de 6.000 hectares em 2006 passa a ocupar 11.000 hectares no último mapeamento; foi verificado também que a expansão da silvicultura se deu principalmente sobre áreas de pastagem.

Using tablets in field surveys and forest audits: greater productivity and efficiency in protecting natural resources / Uso de tablets em vistorias de campo e fiscalizações florestais - maior produtividade e eficiência na proteção dos recursos naturais

Michel Simon¹, Leonardo Tienne¹, Fabiano Graziotti¹, Rômulo Cuzzuol¹, Thiago Steffen¹

¹Instituto de Defesa Agropecuária e Florestal do Espírito Santo (IDAF), Vitória, Brasil (micheltesch@hotmail.com; ltienne@idaf.es.gov.br; fabiano.graziotti@idaf.es.gov.br; rcuzzuol@idaf.es.gov.br; tsteffen@idaf.es.gov.br)

Em função do desafio que é a proteção dos recursos naturais em um país de grande extensão territorial, como o Brasil, o Instituto de Defesa Agropecuária e Florestal do Estado do Espírito Santo optou por inovar no método de realização de vistorias de campo e fiscalizações florestais. Nesse contexto, desenvolveu-se um novo método com o uso de Sistema de Informação Geográfica livre e de código aberto (Qgis), associado ao emprego de tablets, no campo, para registro de fotos, trilhas e informações geolocalizadas, além de navegação off-line. A metodologia consiste na geração de mapas georreferenciados no Qgis e exportação para um aplicativo no tablet, que utiliza o sistema de GPS para mostrar a localização em tempo real sobre o mapa gerado. Com isso foi possível dispensar o uso de câmeras fotográficas, gps de navegação e mapas impressos nas vistorias e fiscalizações. Empregado há 4 anos no licenciamento ambiental de silvicultura, o método permitiu agilizar procedimentos, saltando de cerca de 600 hectares para 1.944 hectares vistoriados por dia. Na prática representa monitorar três vezes mais área com a mesma equipe. Em paralelo, houve economia de 24% no montante investido para aquisição de equipamentos e o custo médio por hectare vistoriado foi reduzido em 69%. Por fim, considerando o expressivo aumento na demanda de trabalho nas instituições, com a etapa de validação do Cadastro Ambiental Rural, torna-se imprescindível adotar métodos que permitam ganhos de produtividade e maior eficiência no uso dos recursos públicos.

C4x: FOREST ASSESSMENT, MODELLING AND MANAGEMENT

Determining the form factor for the Australian cedar (*Toona ciliata* M. Roem. var. *australis* (F. Muell.) Bahadur) / Determinação do fator de forma do cedro australiano (*Toona ciliata* M. Roem. var. *australis* (F. Muell.) Bahadur)

Antonio Nascim Kalil Filho¹, Ivar Wendling¹, Maria Augusta Doetzer Rosot¹, Marcelo Lazzarotto¹, Juliana dos Santos Guedes²

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (antonio.kalil@embrapa.br; ivar.wendling@embrapa.br; augusta.rosot@embrapa.br; marcelo.lazzarotto@embrapa.br; julisguedes@hotmail.com)

O aumento da população mundial aliado à diversificação nos usos da madeira para a indústria moveleira, madeira tratada, indústria de papel, lenha, carvão e outros explica o aumento da demanda por novas espécies florestais como o cedro australiano (*Toona ciliata* var. *australis*), plantado no Brasil, sendo oriundo da Austrália e parte da Ásia. Sua madeira pode ser utilizada para laminação, indústria moveleira (móveis finos) e acabamentos de construção. Tendo, em vista que equações de volume e estimativas de fator de forma inexistem para o cedro australiano, o objetivo do presente trabalho foi a determinação do fator de forma. O material foi constituído por 117 árvores plantadas em 1999 em espaçamento 3 x 2 m na Fazenda Berneck, Adrianópolis, Paraná, latitude 24° 39' 25" S, longitude 48° 59' 27" W e altitude média de 150 metros. A seleção de árvores para a cubagem deu-se com base em classes de diâmetro. Tendo-se estabelecidos os limites das classes, foram calculadas as frequências (número de árvores) por classe diamétrica, alocando-se cada indivíduo à sua respectiva classe. Uma vez determinadas as sete classes diamétricas, procedeu-se à cubagem empregando-se o método de Smalian. Foram calculados para cada árvore o volume cilíndrico, volume comercial com e sem casca e o fator de forma (volume real / volume cilíndrico). O volume real médio com casca foi de 0,5212058 m³ e sem casca foi de 0,4921751 m³. Os fatores de forma médios calculados para árvores individuais com e sem casca foram de 0,541286 e 0,510058, respectivamente.

Determining the form factor for *Calophyllum brasiliense* Cambess. (guanandi) / Determinação do fator de forma do guanandi (*Calophyllum brasiliense* Cambess.)

Antonio Nascim Kalil Filho¹, Ivar Wendling¹, Maria Augusta Doetzer Rosot¹, Marcelo Lazzarotto¹, Juliana dos Santos Guedes²

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil (antonio.kalil@embrapa.br; ivar.wendling@embrapa.br; augusta.rosot@embrapa.br; marcelo.lazzarotto@embrapa.br; julisguedes@hotmail.com)

O guanandi é uma espécie nativa que ocorre em áreas de várzeas, igapós e banhados desde a América Central (18°N) até o sul da América do Sul (28° 10' S), passando pela Amazônia. Com lento crescimento, a espécie é plantada comercialmente. Sua madeira, cuja cor vermelha assemelha-se ao mogno, possui densidade de 0,45 a 0,65 g/cm³, sendo utilizada para dormentes, batentes de portas, construção civil e móveis. Tendo, em vista que equações de volume e estimativas de fator de forma inexistem para o guanandi, este trabalho objetivou a determinação do fator de forma. O material original foi constituído por 130 árvores plantadas em 1999 em espaçamento 3 x 2 m, na Cia. Berneck, Adrianópolis, Paraná, latitude 24° 39' 25" S, longitude 48° 59' 27" W e altitude média de 150 metros. A seleção de árvores para a cubagem deu-se com base em classes de diâmetro. Tendo-se estabelecidos os limites das classes, foram calculadas as frequências (número de árvores) por classe diamétrica, alocando-se cada indivíduo à sua respectiva classe. Uma vez determinadas as sete classes diamétricas, procedeu-se à cubagem empregando-se o método de Smalian. Foram calculados para cada árvore, o volume cilíndrico, volume comercial com e sem casca e o fator de forma (volume real / volume cilíndrico). O volume comercial médio com casca foi de 0,1213265 m³ e o volume comercial médio sem casca foi igual a 0,1128535 m³. Os fatores de forma médios calculados para árvores individuais com e sem casca foram de 0,649320 e 0,600947, respectivamente.

Teak (*Tectona grandis*) plantation management and financial analysis in Colombia

Fernando VelezEscobar¹

¹Independent professional, Medellin, Colombia (fernando.velez52@gmail.com)

Development of single tree volume and taper equations, yield and growth studies, including potential intermediate thinning and remaining stand density after management, and volume classification, at La Gloria project, Refocosta S.A. company, located at Monterrubio county, Magdalena province, Colombia, 10° 23' N 74° 23' W, 55 m.a.s.l., tropical dry zone (Holdridge's life zones), are the technical bases to calculate productivity under forest management. Productivity and forest management is defined using stand density index concept, with a minimum desirable stand density of 475 stems of 25 cm per hectare, and thinning crops over 25 m³/ha. A simulation model software developed by the author has been used, including all the equations developed on former studies. A financial analysis, based on official plantation costs, local logging costs and Itto's reported international wood prices, shows out and internal rate of return of 4,4%, 5.7% and 6.2% at ages of 20, 25 and 30 years.

***Pinus patula* plantation management under stand density index concept**

Fernando VelezEscobar¹, John Byron UrregoMesa²

¹Independent professional, Medellín, Colombia; ²Smurfit Kappa Cartón de Colombia S.A., Yumbo, Colombia (fernando.velez52@gmail.com; john.urrego@smurfitkappa.com.co)

A *Pinus patula* planted forest stand, located at Cauca province – Colombia, latitude 0° N, longitude 75° W, 2.450 m.a.s.l., 2.250 mm rain-fall, lower montane moist forest Holdridge's life zone, was managed using stand index concept, from age nine until age 25 years. A series of stand density index level, ranging from 200-1.400 stems-25 cm/hectare equivalent, were established every 100 stems-25 cm/hectare. Permanent plots of 2.000 m² were used, yearly measured, calculating yield and current annual increment for all variables, volume classified in five log different sizes, using tree and shape equations developed within the research. Maximum stand density index viable for the species is about 1.300 stems-25 cm/hectare equivalent. Volume growth under bark changed between 19 – 40 m³/hectare/year. An under-stocked stand density level was found for less than 600 stems-25 cm/hectare, with a clear proportional growth increment; a full-stocked stand density was found between 650 - 900 stems-25 cm/hectare, with a closed to constant growth; and over-stocked stand density was found over 950 stems-25 cm/hectare, without a clear growth pattern. Forest management in full-stocked stand level can offer volume growth continuously concentrated in bigger saw-timber size, together with diminishing smaller log sizes.

Effect of forest biomass ash on growth and nutrition of *Pinus taeda* and on the chemical characteristics of the soil / Efeito de cinza de biomassa florestal no crescimento e na nutrição de *Pinus taeda* e em características químicas do solo

Shizuo Maeda¹, Itamar Antonio Bognola¹, João Bosco Vasconcelos Gomes¹

¹Embrapa Florestas, Colombo, Brasil (shizuo.maeda@embrapa.br; itamar.bognola@embrapa.br; joao.bv.gomes@embrapa.br)

As características químicas e físicas dos resíduos gerados nos processos envolvidos na extração de celulose indicam um potencial para aplicação como insumo para a produção florestal, que em sua maior são exploradas em áreas de baixa fertilidade natural. Avaliou-se o efeito da aplicação de cinza de biomassa florestal gerada em caldeira na fertilidade do solo e no desenvolvimento e na nutrição de *Pinus taeda* em um LATOSSOLO BRUNO Distroférico típico, no município de Vargem Bonita, Estado de Santa Catarina. O delineamento experimental utilizado foi o de blocos casualizados com quatro repetições. Os tratamentos foram constituídos pelas doses 0, 10, 20, 40 e 80 Mg ha⁻¹. Os materiais foram aplicados superficialmente em área total, sem incorporação, em plantio de *P. taeda*, com dois anos de idade. Para a avaliação do efeito dos tratamentos foram coletadas amostras de solos na camada 0 a 20 cm, tanto na instalação do ensaio quanto em 2007, 2008, 2011, 2012 e 2013, bem como coletadas amostras de acículas recém-maduras do verticilo inferior do terço superior da copa, em 2008 e 2017. Avaliações biométricas foram realizadas em 2017, com o abate de uma árvore por parcela. A aplicação das doses de cinza promoveu aumentos nos teores de cálcio, magnésio, potássio e fósforo, redução no teor de alumínio e aumentos no pH e na saturação por bases do solo. Observou-se um aumento quadrático no volume sólido de madeira e aumentos nos teores foliares de boro e zinco e redução no teor de enxofre, sem correlação com a biomassa produzida.

Trace elements in the soil after applying wood waste from pulp milling to plantations of *Pinus taeda* / Elementos-traço no solo como resultado da aplicação de resíduos do processamento de madeira para obtenção de celulose em plantio de *Pinus taeda*

Shizuo Maeda¹, João Bosco Vasconcelos Gomes¹, Itamar Antonio Bognola¹

¹Embrapa Florestas, Colombo, Brasil (shizuo.maeda@embrapa.br; joao.bv.gomes@embrapa.br; itamar.bognola@embrapa.br)

Pelas suas características químicas e físicas, os resíduos gerados nos processos envolvidos na extração de celulose apresentam um potencial para aplicação como insumo para o plantio de florestas, normalmente exploradas em áreas de baixa fertilidade natural. Avaliou-se o efeito da aplicação de mistura de lodo celulósico (lo) e cinza de biomassa florestal (ci) em teores de elementos-traço em um neossolo quartzarênico Órtico típico, no município de Pirai do Sul, Paraná. Os tratamentos foram constituídos por cinco doses da mistura de lo e ci na proporção de 7:3, respectivamente. As doses estimadas para manter a condição original do solo e elevar a saturação por bases a 20, 40, 60 e 80% foram 0, 14, 25, 49 e 60 Mg ha⁻¹. Os materiais foram aplicados superficialmente, em área total, sem incorporação, em plantio de *Pinus taeda* que em junho de 2011 estava com seis meses de idade. A avaliação do efeito dos tratamentos foi feita em amostras coletadas na camada 0 a 20 cm, na instalação do ensaio e aos 50 e 60 meses após, sendo determinados os teores de Hg, As, Pb, Cr e Cd, nos tratamentos sem aplicação e na dose máxima da mistura dos resíduos. Os resultados obtidos indicam que, para os teores dos elementos analisados, nos tratamentos sem aplicação dos resíduos e na dose máxima nas três avaliações realizadas, não há indícios de contaminação dos solos pela aplicação da mistura dos resíduos. Os teores encontrados para o elementos analisados são inferiores aos valores de referência estabelecidos pela legislação brasileira.

A hypsometric equation for same-age populations of *Pinus caribaea* var *hondurensis* in the State of Rondônia, Brazil / Equação hipsométrica para um povoamento equiâneo de *Pinus caribaea* var *hondurensis* no estado de Rondônia, Brasil

Karine Silva¹ , Angélica Santos¹, Sabina Ribeiro¹, Lorena Tavares², Janice Nascimento², Paulo Magistrali²

¹Universidade Federal do Acre, Rio Branco, Brasil; ²Instituto Federal de Rondônia, Ji-Paraná, Brasil (karinemilene26@gmail.com; angelicams.ali@gmail.com; sabina.ufac@gmail.com; lorena.tavares@ifro.edu.br; janice.nascimento@ifro.edu.br; magistralipr@gmail.com)

Os plantios de pinus no Brasil estão concentrados nas regiões sul e sudeste, porém nos últimos anos foram difundidos também para a região Norte do país. Esses plantios carecem de equações que possibilitem a estimativa de variáveis-chaves para se obter a produção do povoamento, como a altura. Visto que grande parte das equações hipsométricas disponíveis na literatura foram desenvolvidas para as regiões Sul e Sudeste, este estudo visa contribuir para a geração de equações hipsométricas adequadas para povoamentos na região norte do Brasil. Assim, o objetivo deste estudo foi gerar uma equação hipsométrica para um povoamento equiâneo de *Pinus caribaea* Morrelet var. *hondurensis*, no Município de Vilhena, Rondônia, Brasil. Para isso, foram estabelecidas de forma sistemática 15 parcelas de 20 m x 20 m (0,02 ha), nas quais foi mensurada a circunferência a altura do peito (CAP) de todas as árvores (898 indivíduos) e foi obtida a altura total de 225 árvores com um hipsômetro Haglôf. Cinco modelos hipsométricos foram ajustados aos dados coletados usando-se o programa estatístico RStudio. Os critérios para seleção da melhor equação ajustada foram o maior valor de coeficiente de determinação ajustado (R²aj.), menor Erro médio quadrático (RMSE) e a análise gráfica dos resíduos. A equação de melhor ajuste e com distribuição homogênea dos resíduos foi = 0.6067+0.1760*d+ei (R²aj = 0.9223; RSME=0.2129).

SisPinus software and the management of *Pinus taeda* plantations attacked by Capuchin monkeys (*Sapajus nigritus*)

Edilson Batista de Oliveira¹, Sandra Bos Mikich¹, Dieter Liebsch², José Mauro Magalhães Avila Paz Moreira¹

¹Embrapa Florestas, Colombo, Brasil; ²DL Consultoria Ambiental, Curitiba, Brasil (edilson.oliveira@embrapa.br; sandra.mikich@embrapa.br; dieterliebsch@yahoo.com.br; jose-mauro.moreira@embrapa.br)

The SisPinus software have the objective to inform rural producers about suitable technologies that can be used in the planning and management of forests and provide information that can help optimize production and increase revenue. Through this software, users can consider various climate and soil conditions and test options for forest management, predict current and future production, conduct economic analyses, and finally, implement the best alternative in the field. To adjust the SisPinus software to estimate growth and yield of stands with different levels of damage caused by capuchin monkeys, a computational tool (Macaco-prego_Calc) was developed to be used in association with this software. The procedure allows the SisPinus to quantify timber production, for the years following the attack, both in terms of total volume and volume per industrial use class. This can support forest producers in choosing the best strategy to minimize losses. Both the tool and the software are available for free download at Embrapa Florestas website (www.embrapa.br/florestas [<http://www.embrapa.br/florestas>]).

C4y: FOREST ASSESSMENT, MODELLING AND MANAGEMENT**Evaluation of data continuity in Japanese National Forest Inventory**Fumiaki Kitahara¹¹Forestry and Forest Products Research Institute, Kochi, Japan (bunsho@ffpri.affrc.go.jp)

The National Forest Inventory started in Japan in 1999 with the aim of understanding the state and dynamics of various aspects in forests such as wood production and biodiversity throughout the country. The Japanese NFI has established around 15,000 permanent sample plots in whole forest systematically located in a 4 x 4km grid, and the fourth NFI is completed in 2018. Since 2010, Japanese NFI has implemented a quality assurance program and the Forest Agency reports that the measurement accuracy is improved. Although, field surveyors tended to underestimate tree measurement, after implementation of quality assurance program, measurement accuracy has been corrected in recent years. Therefore, data continuity before and after quality assurance program has become a problem for NFI data analysis. The purpose of this study is to confirm the degree of continuity and evaluate discontinuity quantitatively. To evaluate data continuity, we focused on tree height and compared between time series data of dominant average trees height and reference tree height in the southern part of western Japan. Here, the reference tree height is based on dominant height growth model we developed using long-term forest monitoring data and short-term forest monitoring data.

Research on the integration of multi-source spatial data of forestryRuixia Hou¹¹Research Institute of Forest Resources Information Techniques Chinese Academy of Forestry, Beijing, China (houeix@ifrit.ac.cn)

Spatial data of forest resources is the spatial object of data integration of forest management. The spatial data of various categories can provide a comprehensive picture of the changes in forest resources and the ecological environment. Through the analysis of its internal characteristics and its different manifestations, this paper reveals the relationship and internal change laws among the various factors contained in the forest. And on the other hand, through the analysis of the relevance of spatial data on forest resources, the unified expression of spatial data on multi-source forest resources is realized. So multi-source spatial data provides spatial information support for forest resource information management and shared services.

The visual simulation technology in formatting forest management plan at unit level based on WFTingDong Yang¹, HuaiQing Zhang¹, YongLiang Li¹, XinJian Tan²¹ Research Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing, China; ²Experimental center of subtropical Forestry, Chinese Academy of Forestry, Xinyu, China (yangtd@ifrit.ac.cn; zhang@ifrit.ac.cn; lyl@ifrit.ac.cn; bjtan@caf.ac.cn)

In view of the degree that the forest management plan combined with computer technology is not enough, as well as the solution is not intuitive, this paper used WF workflow technology, combined with the forest management plan of the Hunan Youxian Huangfengqiao state-owned forest farm, Hunan Pingjiang County state-owned Lutou forest farm and Inner Mongolia Chuoyuan forest farm, completed custom workflow modeling process, realized the visual formatting of forest management plan. The results show that the forest level forest management planning process has been displayed, the sub-compartment management measures, cutting volume, ecological benefits in the management period has been shown directly in the three-dimensional scene, this method has strong operability for the operators. In the process of the management plan, the types of forest management, the management measures, the calculation of logging, the effect evaluation and so on are all expressed in the form of flow module. The application of the visual simulation technology in forest management plan can achieve the visual operation of the management plan, realize the effect test of the management process and improve the digitization of forest management.

Construction and application of National Sharing Infrastructure on Forestry Science DataPing Ji¹¹Research Institute of Forest Resources Information Techniques Chinese Academy of Forestry, Beijing, China (jiping@ifrit.ac.cn)

The National Sharing Infrastructure on Science Data of Forestry is one of the 28 National Science and Technology Infrastructure. The Platform collects traceable data on forestry scientific research, develops and implements data integration standards and provides for the sharing of integrated data on the Internet. The platform was construction in 2001 and was completed and put into operation in 2009. At present, the platform has 12 types of data, including: forest resources, grassland resources, wetland resources, desert resources, forest ecosystems, nature reserves, forest protection, forest cultivation, timber science and technology, forestry science and technology literature, forestry science and technology projects, and forestry development. A total of 177 databases were built. The platform also has 10 sub-platforms and more than 30,000 users. This paper describes the structure, content and application of The National Sharing Infrastructure on Science Data of Forestry.

Forest adaptation scenarios using the Korean integrated model considering climate changeMina Hong¹, Moonil Kim², Cholho Song¹, Sea Jin Kim¹, Sungeun Cha¹, Jiwon Kim¹, Woo-Kyun Lee¹¹Korea University, Seoul, Republic of Korea; ²International Institute for Applied Systems Analysis, Wien, Austria (alsdk920902@naver.com; windy7up@gmail.com; cholhosong@gmail.com; bluegulcy@gmail.com; igy2005@korea.ac.kr; keinesorge2@gmail.com; leewk@korea.ac.kr)

Forests contribute to climate change mitigation by absorbing atmospheric carbon dioxide through photosynthesis and storing it in biomass form. Therefore, 'Paris Agreement' encouraged active forest management to reduce greenhouse gas emissions. In this study, an integrated forest model was applied to predict the change in forest growth due to climate change based on RCP scenario. The model also could consider appropriate tree species, impacts of forest disaster (land slides, forest fire, and forest disease), and land cover change. Based on the model, the scenario of forest adaptation management (thinning, tree trimming according to normal cutting age, risk management etc.) was constructed under possible combinations of each options. According to the analysis, when all of the options above are not considered, the current forest growing stock volume is 154.1m³ha⁻¹. The forest accumulation of RCP4.5 and RCP8.5 will be 167.4m³ha⁻¹ and 166.9m³ha⁻¹ respectively in 2030. If the management (tree trimming, thinning) is performed after considering all of the above options, the forest accumulation of RCP 4.5 and RCP 8.5 will be 105.2m³ha⁻¹ and 133.5m³ha⁻¹ respectively in 2030. Therefore, the amount of carbon stored would decrease as the forest becomes older. Thus, though the forest accumulation is reduced. If the reforestation is proceeded, forest growth sector can be managed through tree trimming and thinning to increase carbon absorption and wood production according to climate change. Furthermore, the government needs to develop appropriate policies.

Three-Dimensional Visualization Method of Editing Sub-Compartment Boundary in Forestry

Yongliang Li¹, Huaqing Zhang¹, Tingdong Yang¹, Xinjian Tan²

¹Research Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing, China; ²Experimental center of subtropical Forestry, Chinese Academy of Forestry, Xinyu, China (lyl@ifrit.ac.cn; zhang@ifrit.ac.cn; yangtd@ifrit.ac.cn; bjtan@caf.ac.cn)

Combining 3D virtual scene rendering with forest sub-compartment boundary editing, a forest sub-compartment boundary editing method in the 3D virtual scene is proposed. First of all, the boundary nodes were calculated according to the sub-compartment vector boundary in the 2D, and the boundary nodes were represented by entities in the 3D scene. Secondly, the node entities that need to be edited were picked up by using the mouse, and then interactive editing operations could be done such as moving and building. Lastly, the sub-compartment boundary nodes sorting algorithms for the 3D visual editing such as moving, cutting and merging of the boundary were proposed. The sub-compartment 3D boundary was redrawn according to the order of reordering entities. Taking the 2D vector data and terrain data of the specific sub-compartment as an example, the 3D visualization method of editing the sub-compartment boundary in forestry was verified based on the MORGRE rendering engine. The results show that this method can restore the real 3D existence form of the sub-compartment, reflect its 3D spatial structure characteristics, and directly implement the interactive editing operations and simulation results of 3D visual moving, cutting and merging for any sub-compartment boundary. This method can be directly applied to forest resources investigation, planning to improve the management ability.

Spatio-temporal analysis of anthropogenic activities from ranger-collected data in W National Park of Benin

Tchegoun Blaise Tchétan¹, Akomian Fortuné Azihou², Gerard Nounagnon Gouwakinnou¹

¹Laboratory of Ecology, Botany and plant Biology (LEB), University of Parakou, Parakou, Benin; ²Laboratory of Applied Ecology (LEA), University of Abomey-Calavi, Abomey-Calavi, Benin (tchegounblaise@gmail.com; fazihou@gmail.com; gougerano@gmail.com)

1. Background: Protected areas are currently the cornerstones for biodiversity conservation. However, numerous protected areas are under significant threats from anthropogenic activities which lead deeply to loss of biodiversity; 2. Objective: This study analyzed the spatio-temporal trends of anthropogenic activities in W Biosphere Reserve of Benin in order to provide guidance for planning the patrol system; 3. Methods: We used ranger-collected data on anthropogenic activities in the reserve from 2012 to 2015; 4. Results: Illegal grazing is the most common anthropogenic activity observed in the reserve (1,137 incidents), followed by poaching (469 incidents), agricultural encroachment (285 incidents) and logging (69 incidents). The distribution of these activities in the reserve is highly dependent on zones and also varies between seasons. Generally, incidents of anthropogenic activities were more frequent during the non-hunting season than the hunting season because of flooding, impassability of tracks and closing of plant cover which limit patrol activities during the non-hunting season; 5. Findings and perspective: From these findings, managers of the W National Park can identify high human pressure zones where ranger patrol efforts should be enhanced. However, because spatial and temporal changes in anthropogenic activities occurred, regular patrols throughout the protected area, even in zones of low occurrence, are also required. We propose the use of emerging technologies such as Unmanned Aerial Vehicles to better monitor high pressure zones, especially during the non-hunting season when the reserve is practically inaccessible for rangers.

Standardization of symbols for forest variables used in forest assessment and modelling

Margarida Tomé¹, Paula Soares¹, Susana Barreiro¹, Alberdi Iciar², Ole Martin Bollandsås³, Canellas Isabe², Tron Haakon Eid², Kiviste Andres⁴, Róbert Marušák⁵, Daniel Moreno-Fernandez², Christophe Orazio⁶, Heinrich Spiecker⁷, Jarek Socha⁸, Jens Peter Skovsgaard⁹, Michal Zasada¹⁰; Piernaria Corona¹¹

¹Universidade de Lisboa, Instituto Superior de Agronomia, Centro de Estudos Florestais, Lisboa, Portugal; ²CIFOR-INIA, Madrid, Spain; ³Fakultet for miljøvitenskap og naturforvaltning, Oslo, Norway; ⁴Estonian University of Life Sciences, Tartu, Estonia; ⁵Czech University of Life Sciences Prague, Prague, Czech Republic; ⁶EFI - Planted forests facility, Bordeaux, France; ⁷University of Freiburg, Freiburg, Germany; ⁸University of Agriculture in Krakow, Krakow, Poland; ⁹Swedish University of Agricultural Sciences, Uppsala, Sweden; ¹⁰Warsaw University of Life Sciences, Warsaw, Poland; ¹¹Research Centre for Forestry and Wood, Arezzo, Italy (magatome@isa.ulisboa.pt; paulasoares@isa.ulisboa.pt; smb@isa.ulisboa.pt; alberdi.iciar@inia.es; ole.martin.bollandsas@nmbu.no; canellas@inia.es; tron.eid@nmbu.no; andres.kiviste@emu.ee; marusak@fld.czu.cz; danielmoreno270@hotmail.com; christophe.orazio@efi.int; instww@uni-freiburg.de; jaroslaw.socha@ur.krakow.pl; jps@slu.se; michal.zasada@wl.sggw.pl; piernaria.corona@crea.gov.it)

In 1959, IUFRO adopted and published a standardization of symbols for forest variables used for tree and forest measurements, in forest inventory and, more widely, in forest assessment and modelling. In 1965, these were updated and re-published. This standardization covered a limited set of variables; therefore, a larger set of symbols was proposed and approved at the IUFRO World Congress in 2014. The new set of symbols was based on the similar principles as used in 1959 and 1965. Even if some of the original symbols derive from the German language (e.g., basal area is represented by G, from Grundfläche), and these were retained, the new symbols were based primarily on abbreviations and contractions of the English terms. The symbols were selected in order to be easily recognized, being simple and not conflicting with common mathematical or other symbols commonly found in forest literature. The poster presents the updated list of symbols, organized in three groups: 1. tree variables, represented by lower-case letters; 2. mean tree variables, represented by the symbol for the variable and the letter g (or subscript g), indicating that the variable is for the mean tree (for example dg (or dg) representing the quadratic mean diameter; 3. stand variables, represented by upper-case letters when referring to an area, or lower-case letters when representing a mean value, extreme values or other particular values for a group of trees (for example, V represents total stand volume per hectare; hdom represents dominant height).

C4z: FOREST ASSESSMENT, MODELLING AND MANAGEMENT

Finite element modelling of the wood disintegration using a single-pointed cutting tool

František Šebek¹, Petr Kubík¹, Petr Krejčí¹, Martin Brabec¹, Jan Tippner¹, Stephan Frybort²

¹Mendel University in Brno, Brno, Czech Republic; ²Wood K plus, Tulln, Austria (frantisek.sebek@mendelu.cz; petr.kubik@mendelu.cz; petr.krejci@mendelu.cz; martin.brabec@mendelu.cz; jan.tippner@mendelu.cz; s.frybort@kplus-wood.at)

European wood industry is challenged by the demands on the increasing processing of hardwood due to the changes of species composition of the forests. The theory background of cutting force calculation during the hardwood disintegration is specific. Therefore, an advanced approach should be employed for the phenomena description. The experiments were carried out using a pendulum-based machine to approximately perform a linear cut on a European beech specimens. The cutting process was measured by a 3D force sensor and captured by a stereo vision with high-speed cameras. The numerical simulations were

conducted accordingly using an explicit finite element method via the LS-DYNA software. The anisotropy was considered at every level – within the elasticity, plasticity and failure. Moreover, the non-symmetric fracture behaviour was taken into account distinguishing between the different properties in tension and compression. The chip generation as well as force responses were compared. The fracture formation was reproduced quite accurately, yet the forces were not captured very well due to some oscillations, which are subject to the further studies.

Experimental and numerical investigation of hardwood impact behaviour

Petr Kubik¹, František Šebek¹, Petr Krejčí¹, Martin Brabec¹, Jan Tippner¹, Stephan Frybort²

¹Mendel University in Brno, Brno, Czech Republic; ²Wood K plus, Tulln, Austria (petr.kubik@mendelu.cz; frantisek.sebek@mendelu.cz; petr.krejci@mendelu.cz; martin.brabec@mendelu.cz; jan.tippner@mendelu.cz; s.frybort@kplus-wood.at)

It is important to know and describe the impact behaviour of wood in various industrial applications like the wood machining and disintegration. The impact response description can also be a source of information for mechanical properties under a wide range of strain rates. The impact response of European beech was studied. First, the experiments were carried out to create a reliable background for the comparison with numerical simulations. Secondly, the computations were conducted using an explicit finite element method via the commercial code of LS-DYNA R10.1.0. The wood specimen was modelled as a homogeneous orthotropic elastic-plastic continuum. The yield criterion was covered by Hill's formulation with an associated flow rule and isotropic hardening by *MAT_HILL_3R_3D material model. Then, the failure model was coupled with plasticity using a weakening (softening) function, which decreases the magnitude of the flow stress of matrix. The dependence on the damage parameter was covered by *MAT_ADD_GENERALIZED_DAMAGE material model. Finally, the crack initiation and propagation were performed by the element deletion technique.

Assessing sunlight in different row spacings of African mahogany (*Khaya ivorensis* A. Chev.) / Avaliação da radiação solar em diferentes espaçamentos de Mogno africano (*Khaya ivorensis* A. Chev.)

Matheus Zampetrik Caetano¹, Sybelle Barreira¹

¹Universidade Federal de Goiás, Goiânia, Brasil (matheuszampetrik@gmail.com; sybelle.barreira@gmail.com)

A luz é um recurso muito valioso e importante para o ecossistema florestal, porém, é evidente que em alguns ambientes esse recurso se mostra escasso, devido a densidade do dossel. A radiação solar que entra nesses ambientes decresce significativamente da copa das árvores em direção ao solo devido a absorção dos componentes da floresta determinando "microhabitats" no ecossistema florestal. Essa diferença de micro-clima afeta o crescimento e desenvolvimento de gramíneas, determinando seu desenvolvimento e sua produtividade. O experimento teve como objetivo avaliar o índice relativo de luz para que fosse possível caracterizar a influência do sombreamento na produção das gramíneas. Foi conduzido em um plantio de mogno africano com parcelas de diferentes espaçamentos entre plantas e nas entrelinhas desenvolveu-se a forrageira *Brachiaria brizantha* cv. Marandu. Em cada um dos 5 espaçamentos (3x3, 4x4, 5x5, 6x6 e 6x7) foram alocados 5 pontos de coleta. As coletas foram feitas mensalmente durante os meses de setembro, outubro e novembro de 2018 em 3 horários: 09:00, 12:00 e 15:00 horas. Em cada ponto foi coletada a intensidade de luz, utilizando-se um luxímetro além da coleta de gramínea utilizando um gabarito de 50x50 cm. A partir dos dados foram calculados o índice relativo de luz e a massa seca total das gramíneas. Foram comparados os resultados e foi possível quantificar que enquanto o espaçamento 3x3 apresentou 2.868,0 kg/ha o espaçamento 6x7 obteve 4.604,8 kg/ha de produção da gramínea, mostrando que o espaçamento é um fator que influencia significativamente na produção dessa espécie.

Eucalyptus crown parameters and shading in silvopasture systems / Parâmetros de copa de eucalipto e sombreamento em sistemas silvipastoris

Ana Lúcia Hanisch¹, Gilson José M. Gallotti¹, Adilson Lino de Oliveira²

¹Epagri, Canoinhas, Brazil; ²Universidade do Contestado, Canoinhas, Brazil (analucia@epagri.sc.gov.br; gallotti@epagri.sc.gov.br; adilson.olivers@gmail.com)

Sistemas silvipastoris (SSP) envolvem a produção animal e florestal na mesma área e são excelentes estratégias de manejo sustentável da paisagem no meio rural. Em função de sua complexidade, um dos desafios da pesquisa é a adequação do número de árvores e sua distribuição na área, a fim de que o nível de sombreamento das árvores não prejudique o desenvolvimento das pastagens. O objetivo deste trabalho foi avaliar os parâmetros de copa de árvores de eucalipto em dois espaçamentos em SSP, visando melhor arranjo na projeção da sombra. A área experimental foi formada por oito linhas de 60 m, distanciadas 30 m entre si, onde foram implantadas mudas de eucalipto em dois espaçamentos na linha: 1,5 m e 4,0 m entre árvores. Foi realizada a prática da desrama aos 12 e 36 meses após o plantio, com a retirada de dois terços dos galhos. Cinco anos após a implantação foram amostradas 48 árvores em cada espaçamento. Para cada árvore-amostra, foi calculado o diâmetro da copa, o comprimento da copa, a porcentagem da copa (%) e o índice de abrangência. Não foram observados efeitos dos diferentes espaçamentos de eucalipto nas linhas do SSP sobre nenhum dos parâmetros avaliados. Esses resultados confirmam que o manejo de desrama realizado foi suficiente para homogeneizar a copa das árvores de eucalipto em SSP, independentemente do espaçamento utilizado. Cinco anos pós implantação, a prática da desrama apresenta mais influência nos parâmetros de copa do eucalipto em SSP, que os espaçamentos entre árvores na linha.

Artificial intelligence in estimating the productivity of *Eucalyptus* spp. clones in different spacing arrangements in the semi-arid region of Pernambuco, Brazil / Inteligência artificial para estimativa da produtividade de clones de *Eucalyptus* spp. em diferentes espaçamentos no semiárido pernambucano

Rinaldo Luiz Caraciolo Ferreira¹, José Antônio Aleixo da Silva¹, José Wesley Lima Silva¹, Rute Berger¹

¹Universidade Federal Rural de Pernambuco, Recife, Brasil (rinaldo.ferreira@ufrpe.br; jaaleixo@uol.com.br; wesleylima_16silva@hotmail.com; rute.berger@ufrpe.br)

No Polo Gesseiro do Araripe, semiárido pernambucano, responsável por 95% da produção nacional de gesso do Brasil, a principal fonte energética da indústria gesseira é a lenha proveniente da Caatinga, o que tem aumentado o significativamente o desmatamento, geralmente, ilegal. Visando mitigar esse desmatamento, experimentos com florestas de rápido crescimento do gênero *Eucalyptus* foram implantados na região. Nos últimos anos novas técnicas de inteligência artificial foram desenvolvidas e aplicadas como alternativa nos processos de modelagem clássicos. O objetivo desta pesquisa foi avaliar o uso de técnicas da inteligência artificial na modelagem volumétrica de clones de *Eucalyptus* spp., ferramenta indispensável na condução de planos de manejo florestal sustentáveis. Foram utilizadas as seguintes técnicas: Redes Neurais Artificiais (RNA-MLP), Random Forest, Support Vector Regression (SVR) e como forma de comparação foi ajustado o modelo de Schumacher-Hall. Os dados foram provenientes de 2896 árvores de clones de *Eucalyptus*, em cinco espaçamentos na idade de 8 anos. As

variáveis de entrada foram espaçamentos, clones, DAPs e alturas. Para comparação das técnicas, utilizaram-se: Índice de Ajuste Corrigido de Schläegel (IAc), Erro Padrão da Estimativa (Sxy) e Raiz do Erro Quadrático Médio (REQM). A RNA com configuração 10-12-1 (neurônios por camadas) apresentou IA=0,97, Sxy=14,70% e REQM=0,134 m³ha⁻¹. O Random Forest apresentou IA=0,97, Sxy=14,06% e REQM=0,139 m³ha⁻¹. O SVR apresentou IA=0,98, Sxy=12,98% e REQM=0,129 m³ha⁻¹. O modelo de Schumacher-Hall apresentou IA=0,97, Sxy=12,98% e REQM=0,129 m³ha⁻¹. Para grandes amostras, as técnicas de inteligência artificial apresentam precisão semelhante ao modelo de Schumacher-Hall na prognose de volume.

Analyzing dynamics and changing tendencies in native forest coverage over a 20 year period in Cochabamba, Bolivia / Análisis de la dinámica y tendencia de cambio de la cobertura forestal nativa para 20 años en el municipio de Cochabamba-Bolivia

Alvaro Rico¹, Olivia Oporto¹, Mauricio Ledezma¹, Benjamin Gosweiler¹

¹Universidad Mayor de San Simon, Cochabamba, Plurinational State of Bolivia; ¹Universidad Catolica Boliviana, Cochabamba, Plurinational State of Bolivia (alvarorico.bolivia@gmail.com; olivia-2085@hotmail.com; mledezmap@gmail.com; benjamin.gosweiler@gmail.com)

El presente estudio se lleva a cabo en el municipio de Cochabamba - Bolivia, tiene como objetivo analizar los cambios de la cobertura forestal nativa en el área del municipio en un periodo de 20 años a través de la interpretación de imágenes satelitales y la relación que existe función de los cambios en el tiempo de los factores antrópicos y los físicos-naturales. La metodología incluye enfoques cuantitativos y cualitativos y como resultado se tiene una caracterización y el establecimiento de los factores que han inducido al cambio en la cobertura forestal nativa que determina la dinámica actual y proyección tendencial de estas. El estudio concluye en la importancia de la comprensión de la dinámica de cambio de la cobertura forestal nativa a largo plazo.

Growth rings and their periodicity in mangrove species in the state of Tabasco, Mexico / Anillos de crecimiento y su periodicidad en especie de mangle del estado de Tabasco, México

Juan de La Cruz May¹, Yesica Lopez Falcon¹, Ana Guadalupe Sanchez Luna¹, Guillermina Peña Padilla¹, Miriam Gallegos Gonzalez¹

¹Instituto Tecnológico de La Zona Olmeca, Villahermosa, Tabasco, Mexico (juancmmx@yahoo.com.mx; juancmmx@yahoo.com.mx; juancmmx@yahoo.com.mx; juancmmx@yahoo.com.mx; juancmmx@yahoo.com.mx)

La investigación tuvo como finalidad la evaluación dendrométrica de un rodal de mangle blanco (*Laguncularia racemosa* L.) en el Ejido La Solución Somos Todos, del municipio de Paraiso, Tabasco. Por medio de un estudio destructivo de 8 árboles se recabó información de sus variables dasométricas y posteriormente se realizó un análisis troncal que sirvió además para determinar en la especie en cuestión el crecimiento e incremento en Altura, Diámetro, Área Basal y Volumen (Incremento Corriente Anual (ICA) e Incremento Medio Anual (IMA), así mismo, el número de años que requiere un árbol en pasar de una categoría diamétrica inferior a otra superior (tiempo de paso). Se determinó que el rodal presenta una densidad de población de 2,933 árboles por hectárea, una edad promedio de 13 años, con altura total promedio de 13 m, altura comercial promedio de 11 m y un diámetro normal promedio de 9 cm, el crecimiento e incremento en altura logro su máximo crecimiento instantáneo aproximadamente a los 10 años; el incremento en diámetro esta retardado, debido tal vez a que existen muchos individuos por hectárea o el crecimiento de esta especie para la variable en cuestión inicia cuando culmina su incremento en altura, por su parte, el área basal y la altura presentan similitud con respecto a la variable diámetro. Finalmente, se requiere 4.2 años para pasar de una categoría diamétrica de 5 a una de 10 cm en esta especie de mangle.

C5a: CHARACTERIZING PROPERTIES OF PLANTATION WOOD FOR OPTIMAL VALUE

Study on rapid measurement method for pulpwood characteristics using the near-infrared techniques

Ting Wu¹, Guigan fang¹

¹Institute of Chemical Industry of Forest Products, Chinese Academy of Forestry, Nanjing, China (wuting@icifp.cn; pppfangguigan@163.com)

To meet the demand of rapid analysis of pulpwood, a study was conducted to develop prediction models for the characteristics of pulpwood based on near-infrared spectroscopy and chemometrics. The content of chemical components and basic density of 13 kinds of pulpwood were determined, and the actual moisture content was determined under the condition of artificial control. The NIR spectrum were pretreated by combination pretreatment methods in Matlab 8.0 after collected by a holographic grating spectrometer, and the models were established by loading PLS, LASSO, support vector machine method and artificial neural network algorithms. Then genetic algorithm were used to select the optimal bands. In the analysis of holocellulose content, the pretreatment method of smoothing, vector normalization, first derivative was adopted, 1331.0~2362.1 nm band was selected, and LASSO algorithm was used to establish the calibration model. The RMSEP value is 0.48%, and the model is suitable for quality control. In the moisture content analysis, pretreatment method of smoothing, normalized, first derivative was adopted, the band of 1346.7~1477.4nm and 1790.0~1983.3nm was selected, and the PLS algorithm was used. The RMSEP value of the model is 1.19%. In the basic density analysis, the pretreatment method of smoothing, vector normalization and first derivative was adopted, whole-band was selected and the LASSO algorithm was chosen. The RMSEP value of the model is 6.31 kg·m⁻³. The Klason lignin, pentosan, benzene-alcohol extractives and 1% NaOH extractives models were also developed with good performance. The study provided possibility to realize the rapid analysis of pulpwood.

Use of non-destructive techniques to optimise the production of Structural Products from Eucalyptus Plantations Grown for Fibre

Michelle Balasso¹, Mark Hunt¹, Gregory Nolan^{2,3,4}, Nathan Kotlarewski^{2,3}, Andrew Jacobs⁵, Julianne O'Reilly-Wapstra¹

¹School of Natural Sciences and ARC Training Centre for Forest Value, University of Tasmania, Hobart, Australia; ²School of Technology, Environments & Design, University of Tasmania, Launceston, Australia; ³ARC Training Centre for Forest, Value Hobart, Australia; ⁴Centre for Sustainable Architecture with Wood, Launceston, Australia; ⁵Forico Pty Limited, Launceston, Australia (michelle.balasso@utas.edu.au; m.hunt@utas.edu.au; gregory.nolan@utas.edu.au; nathan.kotlarewski@utas.edu.au; andrew.jacobs@forico.com.au; julianne.oreilly@utas.edu.au)

This study presents an investigation of acoustic testing and additional wood quality characterisation of a plantation *Eucalyptus nitens* resource along the processing chain from standing trees to products in a stand established and managed for fibre production in Tasmania. The role of *Eucalyptus* plantations in meeting market demand for non-fibre wood products is gaining importance as the availability of native forest resources is decreasing internationally. Fibre-managed eucalypt plantations constitute a resource that has potential to meet this increasing demand for structural applications as value-added engineered products. The challenge in meeting these potential markets is to better understand and communicate the wood quality characteristics of standing trees and logs and effectively and reliably relate these to performance attributes in the final products. Non-Destructive Testing (NDT) techniques can be used to characterise

wood quality in standing trees and logs through the estimation of traits related to important structural attributes such as stiffness and density. However, the current ability to relate indirect measures of wood quality to final product performance is hindered by the need for further validation along the production chain (from standing tree to sawn board or engineered product). Trees were followed through the harvesting, segregation and sawing process; wood quality characteristics were tested at different stages to determine the relationships between traits measured with NDT techniques on trees, logs and sawn boards. The results of our study also provide information needed for a possible review of how plantation *Eucalyptus* logs are graded, potentially using a more product performance focussed approach.

Fast basic wood density estimation of standing trees using drill shavings

Fabricao Antônio Biernaski¹, Leticia Miranda¹, Everton Zanlorenzi¹, Marco Aurélio Figura¹, Regiane Abjoud Estopa¹

¹KLABIN S.A., Telêmaco Borba, Brasil (fbiernaski@klabin.com.br; lemiranda@klabin.com.br; ezanlorenzi@klabin.com.br; mafigura@klabin.com.br; restopa@klabin.com.br)

The basic wood density estimation with faster results and non-destructive techniques has been increasing in the forest sector. The traditional methodologies like wood wedges or cores are timing consuming in sampling and laboratory analysis. In the other hand, indirect technologies as near infrared spectroscopy and drilling resistance needs previous calibration for different tree species and environment. A simple and fast way to sampling and estimate basic wood density in standing trees (it can be used in logs too) was tested. Wood cores samples of 100 mm length by 12 mm diameter were collected from pines and eucalyptus trees at breast height (1.30 m) and near the same point wood shavings was collected using a 12 mm diameter cordless drill machine with an adaptation for delimitation of 100 mm depth. The bark was previously removed at the sampling points. All the shavings samples were collected individually from each perforation using a paper bag stapled on the tree. The cores basic wood density was predicted by standard gravimetric method. Each shavings sample was oven dried and weighted. The volume of the drill perforation (100 mm length by 12 mm diameter) was considered as the shavings sample volume, and the basic wood density was calculated dividing shavings dry weight by the perforation volume. The correlation between the two basic wood density methodologies was 0.98. This high correlation allows implementing the use of drill shavings for specific wood density estimation in an easy, cheap and fast way.

Physical, mechanical, and acoustical characterization to *Leucaena leucocephala* wood

Cinthy Bertoldo¹, Ryuji Somo¹, Vinicius Pereira¹, Matheus Garrido¹, Gustavo Garcia¹

¹Universidade Estadual de Campinas, Campinas, Brasil (cinthybertoldo@gmail.com; jujuliosoma@gmail.com; vinicius1236589@gmail.com; matheusbgarrido@hotmail.com; gustavohlgarcia@gmail.com)

Leucaena leucocephala (Lam.) de Wit is an invasive tree that widely occurs in national territory and in different continents. This tree is often observed in abundance on many Brazilian states, occupying agricultural areas and in regeneration state. A strategy adopted in the state of São Paulo to contain its proliferation was establishing a more flexible environmental legislation regarding its suppression. Due to the suppression policy, the leucaena wood becomes abundant and available, however, most of this wood are destined to landfill, since there are few studies and data about the mechanical properties of its wood in scientific literature that justifies a technological application or more noble use. The nondestructive test employing ultrasound are being gradually more adopted to describe mechanicals properties of many materials, due to the methodology, technology and scientific knowledge advances. Therefore, the objective of this work is mechanical characterization, employing destructive and nondestructive tests, and the physically and acoustically characterization leucaena wood. To achieve the research goal were determinate acoustical parameters on trees and on freshly felled logs, the complete elastic characterization of wood was obtained employ the ultrasound tests on polyhedral specimens and mechanical parameters of *Leucaena* wood were determinate by compression and bending tests. With the research results it will be possible a more sustainable use to leucaena wood, due to the possibility of application in more nobles uses, with highest aggregate value.

Structural chemical composition of eucalyptus aboveground and belowground biomass from commercial clones

Elaine Cristina Leonello¹, Fabiana Prieto Castanho¹, Natália Lais Felisardo Veira Arruda¹, Ana Carolina Lopes Amaral Costa¹,

Saulo Philipe Sebastião Guerra¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônômicas, Botucatu, Brasil (leonelloelaine@hotmail.com; fabianacastanho26@gmail.com; nfvarruda@gmail.com; cacostal@hotmail.com; saulo.guerra@unesp.br)

The residual biomass of the *Eucalyptus* stumps and roots is an alternative energy source and its structural chemical properties is important to help identify potential uses and applications for the biomass in question. The objective of this work was to compare the chemical content of hollocelulose, lignina and total extractives contents from crown root, stump and stem wood of four comercial clones of *Eucalyptus* (*Eucalyptus urophylla* – AEC-144, *Eucalyptus urophylla* × *grandis* – AEC-224, *Eucalyptus urophylla* × *camaldulensis* – VM-01 and *Eucalyptus urophylla* × *grandis* – H-77) in a 5.7 up to 7 years old first rotation. Were used ABNT Standards to determine the content of the desired compounds. Samples were collected from DBH from the stem and stump (aboveground biomass of the harvest residual stump-roots system) and crown root (central part and most representative mass of the harvest residual roots). Hollocelulose varies up 58.52 % to 76.86 %. Lignin content varies from 16.51 % to 29.38 %. Total extractives varies between 5.54 % and 17.70 %. Stem and stump shows very similar higher values than crown root for lignin content. Hollocelulose presents higher content in the stem and the lower content in crown root. The total extractives are most present in crown root than stump and stem wood. The values are relevant and innovative for those who have interests on this potencial biomass source of energy

Predicting sawn wood quality of standing *Eucalyptus* trees from non-destructive measurements

Brand Wessels¹, Ashlee Prins¹

¹Stellenbosch University, Stellenbosch Cape Winelands, South Africa (cbw@sun.ac.za; 17150558@sun.ac.za)

The genus *Eucalyptus* is the most widely planted hardwood worldwide due, mainly, to its adaptability and high growth rates. Most *Eucalyptus* species, however, are rarely processed into sawn lumber due to processing problems associated with poor dimensional stability, splitting, brittle heart, cell collapse, and checking after drying. Many of these traits could be improved through genetic tree improvement programs. The objective of this project was to identify and test potential non-destructive prediction tools and methodologies on standing trees of *Eucalyptus grandis* and *Eucalyptus grandis* × *urophylla* that can be used to estimate the splitting, warp, brittle heart, collapse, density and density gradient in sawn boards. The main use of such predictions will be for selecting superior genetic material for tree breeding programs. Several measuring methods including Resistograph, stress wave measurement, and wood density from increment cores were used. A new strain measurement technique was also developed and tested. Models were developed for prediction of sawn board properties in order to quantify and rank trees in terms of their wood quality.

Exploring the possibilities of quantifying Heartwood of *Tectona grandis* Linn. f. using electrical resistivity tomography (ERT) for treeimprovement

Baragur Neelappa Divakara¹, Chitradurga Umesh Nikhitha¹, Anil Kumar Sethy¹

¹Institute of Wood Science and Technology, Indian Council of Forestry Research and Education, Bengaluru, India (bndsira@gmail.com; thoshiitha.cu@gmail.com; sethyanil@gmail.com)

Accurate, cost-effective and non-destructive method of diagnostic technique for quantifying the heartwood content in *Tectona grandis* Linn. f. is indispensable as it helps in selection of trees with more heartwood for further genetic improvement. Tree Tronic tomograms like Electrical Resistivity Tomography (ERT) are one among the advanced non-destructive method aiding for tree inspection. This method gives high resolution with more precision in measuring the sapwood, heartwood, stress and decay in the living trees. In this study, main aim is to explore the possibility of using Electrical Resistivity Tomography (ERT) to determine the sapwood-heartwood (SW-HW) boundary in terms of electrical resistivity. The instrument used to measure electrical conductivity within the *T. grandis* disk was a PiCUS TreeTronic (Argus Electronic GmbH, Rostock, Germany), a multi-channel, multi-electrode resistivity system. ERT study of *T. grandis* disk revealed that, high resistivities occurring in the inner part of the cross-section, with much lower values towards the outside. The demarcation of SW-HW boundary was based on the distinct colour differentiation from blue (low resistance) to red (high resistance). A comparison between ERT and actual SW-HW area measured shows a slope of the linear regression close to unity ($= 0.92$) with a narrow spread of values ($R^2 = 0.90$). The range of resistivities observed among all the *T. grandis* disk were compared. Thus, this study indicates the potential application of ERT for quantifying SW-HW content in *T. grandis*.

Wood properties inference from nursery seedlings

Rafael Gustavo Mansini Lorensani¹, Raquel Gonçalves¹, Mônica Ruy¹, Nádía Schiavon Veiga¹

¹Universidade Estadual de Campinas, Campinas, Brasil (rafaelmansini@hotmail.com; raquelg@g.unicamp.br; monica.ruy@hotmail.com; nadiasveiga@gmail.com)

It is very important the early selection of trees considering its wood properties, allowing the proper targeting of processes (unfolding, drying etc.), avoiding unnecessary expenses. The objective of this research was to evaluate the viability of using parameters measured in nursery seedlings (Velocity of ultrasonic waves (VLs), basic density (BDs), height (Hs), diameter (Ds), strength (fts) and modulus of elasticity (Ets) in tension parallel to the grain), infer properties (basic density (BDt), modulus of elasticity (EMt) and modulus of rupture (fmt)) of the wood from 72-month-old trees (cutting age in Brazilian pulp and paper industry). Preliminary analysis was made to analyze the evolution of the parameters with age, followed by the use of these parameters to propose inference models. All parameters measured in seedlings have potential to be used in predictive model to anticipate selection of clones, but the degree of this anticipation would not be the same. The VLs was the only property that maintained, at the cutting age, the coherence of the differentiation between clones obtained on seedlings. The fts, Ets and Ds maintained coherence from 12-months-old, while the BDs since 24-months-old. The BDt cannot be predicted by any model involving parameters obtained in seedlings. On the other hand, a multiple regression model involving the Hs and VLs was adequate for predicting the EMt of the wood from 72-month-old trees. A simple regression model using the relationship between Ets and fts of the seedling allowed a statistically significant prediction of the fmt of the wood from 72-month-old trees.

Chemical extractives from knots: a comprehensive approach for stand-level forecast

Rubén Manso¹, Paul McLean¹, Philippe Gérardin², Zineb Kebbi-Benkeder², Stéphane Dumarcay², Francis Colin³

¹Forest Research, Roslin, United Kingdom; ²Laboratoire d'Etude et de Recherche sur le Matériau Bois, Université de Lorraine, Vandœuvre les Nancy, France; ³Institut National de la Recherche Agronomique, Champenoux, France (ruben.manso@forestresearch.gov.uk; paul.mclean@forestry.gsi.gov.uk; philippe.gerardin@univ-lorraine.fr; zineb.kebbi_benkeder@yahoo.fr; stephane.dumarcay@univ-lorraine.fr; francis.colin@inra.fr)

One of the main objectives of the biorefinery sector is to find alternative feedstocks for their industrial processes. Among the various raw materials biorefineries seek, chemicals are specifically relevant for the forestry sector because they can be found in different parts of trees such as the knots. Therefore assessing which chemicals can be provided to the industry, in which amount and from which species is a major challenge for forest scientists. For this information to be complete, predictions on chemical extractives need to be included in forest simulators, which are usually only aimed at forecasting timber production. In this contribution we introduce an approach that addresses these needs through case studies. First, models to predict knot volume and the concentration of extractives in knots are presented. This provides the unitary amount of chemicals per knot. Then we discuss a strategy to couple these results with growth models so that predictions on chemicals production from knots can be projected over time. On the practitioners side, the implementation of this approach would allow considering management alternatives to maximize the production of chemicals and to compare the profitability of such alternatives to others aimed at traditional forest products. On the biorefinery end, the approach would serve to inform on the potentiality of forests as feedstocks for the sector.

Constructing models to predict the basic density of *Eucalyptus grandis* W. Hill ex Maiden wood using near infrared spectroscopy (NIRS) / Construção de modelos preditivos da densidade básica da madeira de *Eucalyptus grandis* W. Hill ex Maiden pela espectroscopia no infravermelho próximo (NIRS)

O presente trabalho teve como objetivo obter modelos de predição da densidade básica da madeira de árvores de *Eucalyptus grandis*, plantadas em espaçamento de 3 x 2m, fertilizadas com K e Na, submetidas ao estresse hídrico. Foram selecionadas 54 e 48 árvores, com 5 e 6 anos, respectivamente, cortando seções transversais do lenho na base e DAP do seu tronco. Foram analisadas a seção transversal de 1.222 corpos de prova de madeira, no espectrômetro NIR MPA da Bruker, nos módulos (i) esfera de integração (12800-3600cm⁻¹) e (ii) sonda de fibra óptica (12800-4000cm⁻¹), com resolução espectral 8 cm⁻¹, média de 32 leituras. Posteriormente, foi determinada a densidade básica dos corpos de prova pelo método do máximo teor de umidade. Os dados foram tratados no software The Unscrambler®, sendo simuladas regressões com mínimos quadrados parciais (PLS), baseadas nas informações espectrais e na densidade básica, considerando 6 pré-tratamentos aplicados aos dados espectrais de validação cruzada e independente. Dos 36 modelos, os que apresentam os parâmetros mais adequados segundo a literatura foram (i) esfera de integração: pré-tratamento Derivative 1; R²cv:0,69; RMSECV: 0,021 g.cm-3, LV: 9; R²p: 0,68; RMSEP: 0,022 g.cm-3, RPD: 1,76; (ii) fibra óptica: sem pré-tratamento; R²cv:0,65; RMSECV: 0,022 g.cm-3, LV: 5; R²p: 0,61; RMSEP: 0,024 g.cm-3, RPD: 1,62. Demonstrou-

se, desta forma, que as regressões PLS que correlacionam as informações espectrais e a densidade básica da madeira de *E. grandis*, apresentam estatísticas satisfatórias, com coeficientes de correlação médios, baixos valores de erro padrão da predição, e RPD próximos a 2.

Anatomical and thermochemical investigation on high-speed rotation welding of Australian and tropical hardwood species

Listya Mustika Dewi¹, Benoit Belleville², Ratih Damayanti¹, Gustan Pari¹

¹Forest Products Research and Development Center; Research, Development and Innovation Agency; The Ministry of Environment and Forestry, Bogor, Indonesia; ²School of Ecosystem and Forest Sciences; Faculty of Science; The University of Melbourne, Melbourne (lizthya@gmail.com; benoit.belleville@unimelb.edu.au; ratih_turmuzi@yahoo.com; gustanp@yahoo.com)

Wood welding using high-speed rotation has been successfully applied to join two pieces of wood without using any glues or connectors. The mechanical frictions could generate heat that cause softening of lignin to be natural adhesive. The welded wood products are considered to be eco-friendly wood products as it could minimize the use of non-renewable resources. This research is aimed to investigate the influence of anatomical and chemical properties on wood welding performance and their changes induced by the mechanical friction process of 4 Australian and 1 tropical wood species. Three different parameters i.e. grain orientation, rotational speed, and dowel/hole diameter ratio were treated for *Eucalyptus delegatensis*, *Eucalyptus pilularis*, *Eucalyptus saligna*, *Corymbia maculata*, and *Tectona grandis*. The reference and welded wood samples were investigated for their anatomical and chemical properties. The results show that anatomical characteristics such as cell dimensions (fibre length and fibre wall thickness), fibres proportion, the type of vessels, tyloses, rays, and the presence of mineral inclusions appeared to influence the mechanical performance of welded joints. The deformation of anatomical structure i.e. fibre entanglement has occurred following the welding process. The importance of lignin during wood welding process has proven by the result of pyrolysis GC-MS analysis. Thermal welding has affected the changes of Syringyl, Guaiacyl and other chemical constituents.

Surface knots classification of wood using k-Nearest neighbor and deep learning

Hyunbin Kim¹, Sang-Yun Yang¹, Yonggun Park¹, Hyunwoo Chung¹, Ohkyung Kwon², Hwanmyeong Yeo^{1,3}

¹Seoul National University, Republic of Korea Seoul; ²National Instrumentation Management (NICEM), Seoul National University, Seoul, Republic of Korea; ³Research Institute of Agriculture and Life Sciences, Seoul National University (yoursea@snu.ac.kr; sly1357@snu.ac.kr; gunny007@snu.ac.kr; boltzman1223@gmail.com; zoom@snu.ac.kr; hyeo@snu.ac.kr)

Wood defects occur in various forms during growth and processing. Therefore, it is necessary to objectively assess the quality of the wood for its purpose by correctly classifying its defects. However, because visual classification and species identification by human beings can cause errors based on subjective judgments, automatic video analysis using computer vision is needed to speed up the production of wood. In this study, k-nearest neighbor model with the scale-invariant feature transform (SIFT+k-NN) and the convolutional neural network (CNN) model were used to implement and analyze the accuracy of knot classification models; 1,172 knots were acquired for learning and validation. For the SIFT+k-NN model, characteristics were extracted from the retaining image using SIFT technology, and the classification was carried out using k-NN, with the highest accuracy (approximately 60.53%) when k index was 17. The CNN model consisted of eight convolution layers and a third-story hidden layer and had an accuracy of approximately 88.09% at 1205 epochs, higher than that of SIFT+k-NN model. In addition, the SIFT+k-NN model showed a large variation in the number of images of each type of knots, but the CNN model showed higher classification performance due to its lack of bias in determining the number of knots. The results of this study show that the CNN model is more accurate than the SIFT+k-NN model in classifying wood knots.

C5c: INNOVATIVE UTILIZATION OF BAMBOO AND RATTAN RESOURCES

Visualizing the microfibrils orientation distribution in moso bamboo by polarized laser Raman spectroscopy

Jianfeng Ma¹, XingE Liu¹, Long Feng¹

¹International Center for Bamboo and Rattan, Beijing, China (majf@icbr.ac.cn; liuxinge@icbr.ac.cn; fenglong@icbr.ac.cn)

The variation in the microfibrils orientation of the moso bamboo (*Phyllostachys pubescens*) multilayered fiber and parenchyma was studied by linear polarized laser Raman spectroscopy. Raman imaging revealed that the fiber secondary wall displayed a concentric structure with alternating broad and narrow layers, while parenchyma had no obvious layering structure probably due to the limited spatial resolution. Higher Raman C-O-C band intensity was visualized in the narrow layer of fiber wall, indicating the microfibrils (Mfs) in these regions were more parallel to the incident laser electric vector and more perpendicular to the cell axis. The Mfs orientation in parenchyma wall is uniform. Moreover, Raman band ratio (I1095/I2939) was used to predict microfibrils angle (MFA) in different cell wall types, qualitatively. The results showed that the ratio was highest in parenchyma, followed by narrow layer of fiber wall, and lowest in the broad layer of fiber wall, which indicated the higher MFA in the parenchyma. More importantly, the ratio remains constant in all the successive and alternating broad and narrow lamellae. This study provided a novel method and important theoretical guidance for the investigation on cell wall architecture and micromechanics.

Lignin Topochemistry in Developmental Bamboo Fibre Based on Various Spectroscopic Imaging

Shumin Yang¹, Elin Xiang^{1,2}, Xinge Liu¹, Jianfeng Ma¹, Genlin Tian¹, Lili Shang¹

¹International Centre for Bamboo and Rattan, Beijing, China; ²Research Institute of Wood Industry, Chinese Academy of Forestry, Beijing, China (yangsm@icbr.ac.cn; xiangelin@163.com; liuxinge@icbr.ac.cn; majf@icbr.ac.cn; tiangenlin@icbr.ac.cn; shangll@icbr.ac.cn)

Bamboo has excellent mechanical properties that could offer high strength, toughness and ductility. The characteristic properties are determined to a large extent by the polylamellate structure and chemical composition of fibers. Compared with the structure receiving more care, chemical composition of cell wall is only partially known so far. In this study, The heterogeneity of lignin in fiber cell walls of developing moso bamboo will be revealed through Confocal Raman Microscopy (CRM) combined with other spectroscopic imaging technique, such as UV-microspectrophotometry and confocal scanning laser microscope. The lignification rate is changing in different ages, tissues and anatomical regions. The vessel elements begins to be lignified before fiber and parenchyma. In same fibrous sheath, the fibers near the vessel lignified first, and then toward the periphery of the vascular bundle. Lignin content of secondary wall (SW), cell corner (CC) and compound middle lamellae (CML) of fibre increase gradually within 6 months, and then changed slowly. The average lignin content CC>CML>SW. Guaiacyl, syringyl and p-hydroxyphenyl lignins can be found in cell wall of fibre, and showed obvious heterogeneous microdistribution. These complementary techniques provided accurate information with regard to chemical composition distribution. In situ CRM was an effective method that can be used in studying

the microdistribution of lignin concentration, lignin unit, cellulose and hydroxycinnamic acid. These results will provide important references for further study of the biological formation mechanism, high value-added utilization of bamboo and bionic materials design.

A unique mechanical process for extraction of natural fibre from bamboo derived from a traditional practice in Kerala State, India

Muralidharan E.M.¹ , Thulasidas P K²

¹Forest Genetics and Biotechnology Division, Kerala Forest Research Institute, Peechi, Thrissur, India; ²Wood Science and Technology Division, Kerala Forest Research Institute, Peechi, Thrissur, India (emmurali@kfri.org; thulasidas@kfri.org)

Viscose or rayon produced from bamboo stems (culms) is often confused with or wrongly described as natural fibre yarn. Viscose production involves use of harsh chemicals and regeneration of cellulose fibres which does not retain the absorbent and antimicrobial properties of the natural fibre. Claims of commercial extraction of natural bamboo bast fibre, are relatively ambiguous and mostly use proprietary procedures. The process used in extraction of fibres from reed bamboo (*Ochlandra* species) in the traditional method adopted by artisans of the Kottiyoor area of Kerala State in India, is on the other hand primarily mechanical in nature and also involving retting. The salient features and uniqueness of the procedure, in comparison with similar described processes, is brought out in this paper. Applicability of the procedure to a variety of other bamboo species is demonstrated and prospects for sustainable commercial production and use in bamboo textiles and other products is discussed.

The effect of heat-treatment on fire performance of bamboo scrimber flooring

Hongzhong Xiang¹, Tao Zhang¹, Zehui Jiang¹, Benhua Fei¹, Zhijia Liu¹

¹International Center for Bamboo and Rattan, Beijing, China (532284269@qq.com; 1204624557@qq.com; jiangzehui@icbr.ac.cn; feibenhua@icbr.ac.cn; liuzj@icbr.ac.cn)

Fire characteristics of bamboo scrimber flooring produced from different heat-treated processes were investigated by thermogravimetric analysis (TGA) and cone calorimeter in this research. The results showed that combustion process of samples included moisture removal, oxidative and char combustion. All characteristic temperatures increased with increase in heating rates. Bamboo scrimber flooring treated with low temperature of 140°C for 3 hours (LBSF) had a lower activation energy of 71.82-73.18KJ/mol in the oxidative stage and a higher one of 106.17-110.97 KJ/mol in the char combustion stage than samples treated with high temperature of 190°C for 10 hours (HBSF). HBSF had a lower HRR and a larger TTI. But it had a higher THR, TSP and HHV. The results will be helpful for guiding and promoting the utilization of bamboo scrimber flooring in China.

Development of a “flex” material combining glued laminated bamboo and wood: application in a prototype of a bus stop for public use in Brasilia, Brazil

Divino Eterno Teixeira¹, Jaime Gonçalves de Almeida², Julio Eustáquio de Melo³, Sergio Alberto de Oliveira Almeida¹

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²University of Brasilia (UnB), Brasilia, Brasil (divinot@gmail.com; jagal@unb.br; alej@unb.br; seralm44@hotmail.com)

This article presents the development of a composite material combining bamboo and wood, called “flex material”, in the form of glued laminates, as well as its application as a prototype of a bus directory for public use in the DF-Brazil. The research involved the bibliographical revision on bamboo and wood, a study of the regional socioeconomic context in view of the use of this material; development of industrial processes for laminating bamboo with wood and conducting mechanical tests with samples; exposure to the use of models manufactured to verify their performance against real use; and the formation of a working team involving researchers from several DF institutions. The objective of the research was to promote the use of bamboo with wood and its application experimentally in the combination of bamboo plies, known by the acronym BaLC (glued laminated bamboo), with wood from planted forest. The product was called “flex material” because it is a material resulting from the mixing of two versatile natural raw materials (bamboo and wood). The experimental was worked by the research as demonstration of the possibility of using the proposed flex material as a bus stop for public use in Brasília, DF. All bonding strength studies, production of reduced models, production of mock-ups and physical and mechanical tests, including connections with metallic pins, preceded the production and assembly of the final prototype within a public area of the University of Brasília. The post-construction performance of the structure is now under continuous evaluation.

A contemporary interpretation of the traditional construction material “Bamboo” - INBAR Garden-Pavilion in 2019 Beijing Horticultural Expo

Kewei Liu¹, Mauricio Cardenas Laverde², Changzhuan Shao⁴, Shidong Nie⁵

¹International Bamboo and Rattan Organization, Beijing, China; ²Studio Cardenas Conscious Design, Milan, Italy; ⁴Tsinghua University, Beijing, China;

⁵Chongqing University, Chongqing, China (kwliu@inbar.int; m.cardenas@studiocardenas.it; shaochangzhuan@163.com; nieshidong@cqu.edu.cn)

Bamboo is a gift of nature which has been used for landscape, architecture and interior design for a long time. Since its establishment in 1997, International Bamboo and Rattan Organization (INBAR) has been dedicating to promote sustainable uses of bamboo in many countries. An innovative INBAR Garden-Pavilion with the area of 3600 square meters is under construction for 2019 Beijing Horticultural Expo, which will provide a great opportunity for INBAR to showcase contemporary uses of the traditional material “Bamboo”. Following several highlights of the project: 1) It is a contemporary interpretation of the traditional concept of “a Pavilion in the Garden” by creating one single element Garden-Pavilion, where architecture, landscape and engineering are melted into each other; 2) The Pavilion is mainly a large-span round pole bamboo structure creating an open space beneath the garden. Through calculation and field loading test, it is proved that truss arches with variable cross-section of round pole bamboo structure are feasible as the main bearing members with a span of more than 30 meters; 3) Several innovative measures will be taken to improve its durability in northern China; 4) Engineering Procurement Construction (EPC) was adopted for the project in which an internationally, coordinated and inter-disciplinary way of collaboration was explored. It is expected that INBAR Garden-Pavilion will greatly improve scientific understanding of bamboo as a contemporary construction material for the public as well as other stakeholders like architects, engineers, policy makers, developers and etc.

Policy review: Why China has a successful bamboo industry?

Zhiyong Li¹

¹International Centre for Bamboo and Rattan, Beijing, China (zyl@icbr.ac.cn)

If there is a performance report of the bamboo industry in China, it would read like this: bamboo forest area reaching nearly 7 million hectares including the world's largest area of bamboo plantations, annual production valuing over 30 billion USD, more than 10,000 kinds of bamboo products manufactured, nearly 10 million jobs and livelihoods provided, and the world's largest trade volume of bamboo products scored. Many factors play their distinct part to produce such a remarkable performance, including industry policies whose role is both significant and irreplaceable. The key policies on resources, on businesses, on science and technology, on property rights and on trade have their own background, focus and effects. Particularly, in different development stages of bamboo processing industry, enterprises and bamboo farmers received necessary support, to varying degrees, in finance and tax policies from central and local governments, which show us today's complete industry chain and supply chain, upgraded value chain, and a large variety of products. Three provincial policy cases will be shared in paper.

Quality analysis of charcoal from various species of bamboo converted using improved carbonization technologies in Kenya

Nellie Oduor¹, Emily Kitheka¹, Nathan Nyamai¹, James Kimwemwe¹, Kevin Juma²

¹Kenya Forestry Research Institute, Nairobi, Kenya; ²The Nature Conservancy, Nairobi, Kenya (noduor@kefri.org; emilykitheka@yahoo.com; nmaitha84@yahoo.com; jameskimwemwe@yahoo.com; kevin.juma@tnc.org)

Bamboo is a perennial grass in the family Poacea with over 1,600 species globally. It is one of the strongest and fastest growing plants in the world. Kenya has only one indigenous species *Oldeania alpina* found at altitudes above 2200 asl. Over twenty exotic species were introduced in the country and half of them are growing well in various agro-climatic regions. There are over 10,000 documented uses of bamboo which include fuelwood. Over 70% of Kenya's population is dependent on biomass energy for cooking and heating. Bamboo is a potential source for domestic and industrial energy needs. Since the exotic species were introduced no studies have been carried out to determine their fuel properties as potential feedstock for energy production in Kenya. This study sought to carbonize nine bamboo species - *Oldeania alpina*, *Bambusa vulgaris* var. *Vittata*, *B. vulgaris*, *B. chungii*, *B. tulda*, *Dendrocalamus giganteus*, *D. strictus*, *D. brandisii*, and *D. asper*. *Bambusa tulda* recorded the highest calorific value (8.203 kcal/g) fixed carbon (74.1%), ash content (2.09%) and volatile matter (15.0%). Heat value assessment and burning time using an energy saving stove boiling 5 litres of water was carried out. *Dendrocalamus strictus* attained the highest temperature (662°C) and longest burn time (57 minutes) was observed with *Bambusa tulda*. Generally, the exotic species recorded high calorific values and heat values than the indigenous one, though the burning time was short ranging less than an hour. Bamboo charcoal can be recommended for light cooking, and if briquetted the densification would prolong the burning time.

A simultaneous treatment of bamboo flattening and homogenization

Changhua Fang¹

¹International Centre for Bamboo and Rattan, Beijing, China (cfang@icbr.ac.cn)

Owing to faster growth, shorter rotation and higher mechanical strength compared with other species, bamboo has great potential to supplement timber. However, the non-uniform distribution of vascular bundles embedded in the matrix makes bamboo a heterogeneous material with low density and low mechanical strength towards inner portion of bamboo culm. Furthermore, due to its arc shape, one of the widely used conventional processing of bamboo splits is to plan on the four sides to get uniform and rectangular bamboo strips, which has a very low material use efficiency. In this study, a simultaneous treatment of flattening and homogenization with thermo-hydro-mechanical processing on bamboo splits was performed to obtain flattened and homogeneous material. Green bamboo splits with high moisture content were compressed at 170°C with a special vapor releaser. After treatment, density and mechanical strength increased significantly with much less differences along the radial direction of bamboo culm wall. The hygroscopicity decreased significantly with much lower moisture adsorption rate after treatment.

C5f: QUALITY REQUIREMENTS OF FOREST BIOMASS FOR BIOREFINERY

Forest biomass harvesting and chip quality in mixed hardwood forests for bioenergy production

John Vance¹, Jingxin wang¹, Shawn Grushecky¹, Raffaele Spinelli²

¹West Virginia University, Morgantown, USA; ²CNR IVALSÀ, Florence, Italy (jvance11@mix.wvu.edu; jxwang@wvu.edu; shawn.grushecky@mail.wvu.edu; spinelli@ivalsa.cnr.it)

A mechanized harvesting system combined with whole-tree chipping was investigated on two harvesting sites in central Appalachia, USA. Chips were sampled from the operations to characterize properties and evaluate whole-tree chips as a bioenergy feedstock according to ANSI Standard AD17225-4:2014 Solid Biofuels. Results of properties testing indicated 37.5% green moisture, 0.212 g/cm³ bulk density, 10.5% bark content, 0.49 % ash, and 18.59 MJ/Kg calorific heating value. Size distribution of wood chips were categorized into small (3-16mm), medium (16-45mm), and large (45-63mm). Chip sizes captured 46% small, 45% medium, and 3% large by total mass, respectively. Fines (<2.8mm) composed less than 1% while 4.5% were oversized (>63mm). These whole-tree chips were found to meet the highest grade A1 requirements of the U.S. wood chip fuel quality standard. Production and machine rate data of the operations were collected through time-motion study, with chipping elements defined as feeding, chipping, and loading. Chipping cycles averaged 21.5 minutes to produce 13.35 dry metric tons per truckload, providing hourly rate of 37.32 dry metric tons/PMH. Total cycle time including truck delivery averaged 183 minutes, giving hourly production rate of 4.38 dry metric tons/PMH. The hourly cost of the harvesting system including one feller-buncher, two grapple skidders, and the chipper was \$375.77/PMH or combined per unit cost gives a total cost of \$19.99/dry metric ton to produce in-woods chips at the landing. Total operational costs for felling, skidding, chipping, and truck delivery is estimated at \$23.30 to \$29.91 per dry metric ton.

Identifying key factors of landscape and temporal boundaries to better understand the carbon-based forest bio-fuel economy

Dalia Abbas¹, Lars Högbom²

¹American University, Washington, DC, USA; ²Skogforsk, Uppsala, Sweden (daliaabbas@yahoo.com; lars.hogbom@skogforsk.se)

In a forest-based bio-economy energy supply from renewable biomass sources will have a central role. Bio-energy from forestry is derived from two main categories: i) primary energy sources e.g. logging residues, stumps and non-commercial wood, and ii) secondary sources e.g. bark, re-fuse, lye from pulp mills and chips and sawdust from saw mills. Depending on the fuel source, the carbon footprint is likely to differ significantly. Depending on how spatial and temporal system boundaries are defined the outcomes differ substantially. Temporal factors like length of rotation periods, to what extent regeneration occurs, decomposition or burning, and special factors such as single stand or landscape approaches will all impact the outcome of the estimates carbon emissions. In order to support an increase in the removal of forest material, improved and relevant estimations of greenhouse gas balance is important. For example, inconsistent results of published estimates of carbon balances in forest bio-fuel utilization, range from forest bio-fuels being no better than crude oil - from a carbon balance perspective - to one that is almost carbon neutral. The outcome of these estimates depend to a large extent on how, and why, the system boundaries are defined and other assumptions made by the authors. This discrepancy and inconsistency in the estimates of carbon emissions and boundaries in the forestry sector indicates there is an urgent need to synthesize and critically evaluate published reports to be able to better suggest improvements and more informed understandings of carbon emissions in the forestry sector and its “neutrality”.

The degradation of softwood (*Picea abies* and *Pinus sylvestris*) bark extractives during storage: focus on tannins

Hanna Brännström¹, Jarkko Hellström², Tuula Jyske³, Juha Nurmi¹, Johanna Routa⁴, Eelis Halmemies^{1,5}, Raimo Alén⁵

¹Natural Resources Institute Finland, Kokkola, Finland; ²Natural Resources Institute Finland, Jokioinen, Finland; ³Natural Resources Institute Finland, Espoo, Finland; ⁴Natural Resources Institute Finland, Joensuu, Finland; ⁵University of Jyväskylä, Depa (hanna.brannstrom@luke.fi; jarkko.hellstrom@luke.fi; tuula.jyske@luke.fi; juha.nurmi@luke.fi; johanna.routa@luke.fi; eelis.halmemies@luke.fi; raimo.j.alen@jyu.fi)

Biorefining industries with a focus on new extractives-based products set new kind of demands on raw material supply chain. Many initial extractives suitable for valuable applications are either volatile or chemically unstable. Especially, hydrophilic phenolic compounds which are abundantly present in softwood bark are chemically unstable during the supply chain. Not only storage, but also other phases of the wood handling process affect the extractives content of the biomass material, and the composition of the extractives fraction. In order to provide guidelines on new delivery regimes for biorefining industries storage studies on softwood bark (*Picea abies* and *Pinus sylvestris*) were arranged. The bark of these species is abundantly available from forest industry side-streams in Finland and Sweden. To study the way the different storage conditions affect the preservation of spruce bark extractives, such as tannins, two experimental setups were established: a single stem setup where spruce logs were stored with bark intact, and a bark pile setup of spruce saw mill bark. Also, the effect of the season on the behavior of bark tannins was studied. Storage study was also conducted on pine saw mill bark. It was detected that the content of condensed tannins in bark decreased quickly in piles. However, the rate and magnitude of decrease was different in different areas of the pile. Losses occurred at a slower rate when bark was stored intact on logs. Thus it could be concluded that the utilization of the bark should take place as soon as possible after debarking.

Eucalyptus energy supply chain and the wood moisture content issue on the tropical conditions

Humberto Eufraide-Junior¹, Mauricio Acuna², Mark Brown², Adriano Ballarin¹, Saulo Guerra¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Universidade de São Paulo, Botucatu, Brasil; ²Australian Forest Operations Research Alliance, University of the Sunshine Coast, Sippy Downs, Australia (hdjejunior@gmail.com; macuna@usc.edu.au; mbrown2@usc.edu.au; adriano.ballarin@unesp.br; saulo.guerra@unesp.br)

The energetic and economic conjuncture faced in Brazil in recent years has made forest biomass an energetic source with great potential for expansion. The utilization of the wood in the form of chips for energy generation requires a more efficient production chain in the several steps that compose it: harvesting, forwarding, storage, chipping, transport and conversion systems. The moisture content of the wood is fundamental in the planning of the forestry operations of this chain, because it affects the harvesting season and the volume to be chipped, the number of trucks needed to transport the raw material, the time of storage in the field, among others, which economically affects the chain. The main objective of this work was to evaluate the *Eucalyptus* wood chip production chain for energy generation by assessing wood moisture content and quantifying its effect (in yield and costs) on different chains of forest operations. The results obtained so far make it hard to store the wood in the form of open - air chips piles on tropical conditions. On the other hand, considering the same period, logwood piles reached an average moisture content of 35.5% which is the minimum acceptable value to thermoelectric plant. Considering the scenarios studied, it is recommended to prioritize operations with the storage and transport of the wood in logs, and chipping the wood in the industry for reach a least costly scenario with lower wood moisture content.

Role of wood extractives in emulsion stabilization capacity of hemicelluloses

Petri Kilpeläinen¹, Maarit Lahtinen², Jaana Liimatainen¹, Risto Korpinen¹, Kirsi Mikkonen²

¹Natural Resources Institute Finland, Espoo, Finland; ²University of Helsinki, Helsinki, Finland (petri.kilpelainen@luke.fi; maarit.lahtinen@helsinki.fi; jaana.liimatainen@luke.fi; risto.korpinen@luke.fi; kirsi.s.mikkonen@helsinki.fi)

There is a need for efficient biomass pretreatment methods for biomass utilization. Sawdust and grinding dust are side-streams of the forest industry, which are mostly combusted for energy. To fully utilize these side-streams, more value-added products are needed. Hemicelluloses can be extracted from wood by pressurized hot water flow-through extraction (PHWE). The PHWE extracts can be further utilized as hydrocolloids in the food industry, for example as emulsion stabilizers. Birch and spruce wood sawdust were extracted at 170 °C for 60 minutes and 180 °C for 60 minutes, respectively, using a laboratory scale flow-through reactor. Effects of wood extractives were studied by removing them before PHWE with lipophilic and hydrophilic solvents using accelerated solvent extraction. Extracts were collected and analyzed for hemicellulose and extractives composition. Oil-in-water emulsions were prepared by high-pressure homogenization with 5 wt-% stripped rapeseed oil and 1 wt-% hemicellulose-rich extracts. Physical and oxidative stability of emulsions was monitored by measuring the droplet size distribution and peroxide value during 16 weeks. The emulsions were further evaluated using optical microscopy. We conclude that wood hemicelluloses can be PHWE extracted and used as emulsion stabilizers. Removal of lipophilic and hydrophilic extractives decreased clearly the droplet size of emulsions, indicating that the extractive-free hemicelluloses produced physically more stable emulsions than the crude extracts. The effect of extractives on the oxidative stability of emulsions was different with spruce and birch hemicelluloses. This leads to the conclusion that mechanisms behind antioxidative properties of PHWE extracts may be different between these wood species.

Free formaldehyde phenolic resins for a potential use in adhesives formulation, wood coating and porous materials production

Hamed Issaoui¹, Pedro Luis de Hoyos Martínez^{1,2}, Jalel Labidi², Fatima Charrier - El Bouhtoury¹

¹University of Pau and Pays de l'Adour, IPREM, UMR 5254 CNRS/UPPA, IUT des Pays de l'Adour, Mont de Marsan, France; ²Chemical and Environmental Engineering department, University of the Basque Country, Donostia-San Sebastian, Spain
(hamed.issaoui@univ-pau.fr; pedroluis.dehoyos@ehu.eus; jalel.labidi@ehu.eus; fatima.charrier@univ-pau.fr)

Phenolic resins are materials of significant importance in the industry; they are employed in wide range of applications such as adhesives, composites or coatings. Seen that the component of this resins are derived from petrochemicals, which are non-renewable and therefore ultimately limited in supply, the use of material with a low-carbon footprint is an important issue. In this context, the propose of this work is to fill the need for new commercial products using biobased raw materials and greener technologies to replace materials derived from fossil fuels. Among all the phenolic compounds, lignin and tannins are the most available, they present an environmentally friendly alternative to phenol and formaldehyde and they can be considerate as by-products of wood and paper industries that are interesting to valorize. Thus, different free formaldehyde resins were prepared using tannins and lignin, from pulp industry and organosolv process. The tannin-lignin based resins dedicated to wood-based composites gluing and porous insulating material production were elaborated using lignin previously modified with glyoxal and mixed with a tannin solution and a reticulation agent. In the case of coating for wood and wood derivatives protection, to the previous resin two different inorganic compounds namely organically modified montmorillonite (nanclay) and polyoligomeric silsesquioxanes (nanosilicate) were added. The obtained results are promising and indicate that the combination of tannins and lignin to produce free formaldehyde resins showed to be good candidates for being used in wood composites binding, wood coating as well as for porous insulating materials elaboration.

Mass-flow-analysis of lignocellulosic resources in South Africa and Ethiopia (BioHome)

Emilin Joma da Silva¹, Goran Schmidt², Marco De Angelis¹, Bright Asante¹, Andreas Krause¹, Udo Mantau³

¹University Hamburg, Hamburg, Germany; ²Thünen Institute, Hamburg, Germany; ³Infro-Informationssysteme für Rohstoffe, Hamburg, Germany (emilin.joma.da.silva@uni-hamburg.de; goran.schmidt@thuenen.de; marco.de.angelis@uni-hamburg.de; bright.asante@uni-hamburg.de; andreas.krause@uni-hamburg.de; udo.mantau@infro.eu)

The population growth has consequences on bio-resources consumption and waste production. The urbanization pressure in Sub-Saharan Africa skyrocket the demand for building materials as concrete and wood. The BioHome project investigate the availability, accessibility and competition demand of secondary resources in Ethiopia and South Africa. Resources as wood and non-wood lignocellulosic materials (invasive species, agricultural residues, bamboo, municipal pruning, waste wood), post-consumer thermoplastics (PP, PE, PVC) and ashes (coal, slag, biomass) were surveyed. The Ethiopian building industry is a net importer. In 2017 wood and wood products imports (except pulp and paper) accounted to USD 73 million. Plastic import summed USD 634 million, of which roughly 70% may potentially be recycled. In 2015, the South Africa energy mix contained 77% mineral coal, i.e. 34.4 million tons of ashes. It is generally known that combustion residues are landfilled or utilized in low-value products, e.g. concrete. Latest research showed that those industrial residues can be also utilized in wood-plastic-composites (WPC) and geopolymer-wood-composites (GWC) for instance. This study helps to contextualize the development of such building materials, value addition to secondary resources and cooperate to reduce the trade deficit of building materials.

How attractive is bioenergy production on degraded land? Landowner perceptions in Indonesia

Yustina Artati¹, Wanggi Jaung², Kartika Juniwati¹, Sarah Andini¹, Soo Min Lee³, Hendrik Segah⁴, Himlal Baral¹

¹Center for International Forestry Research, Bogor, Indonesia; ²Department of Biological Sciences, National University of Singapore, Singapore, Singapore; ³National Institute of Forest Science, Seoul, Korea, Democratic People's Republic of; ⁴Global Green (y.artati@cgiar.org; dbsjw@nus.edu.sg; k.juniwati@cgiar.org; sarahandini08@yahoo.com; leesoomin@korea.kr; hendrik.segah@gggi.org; h.baral@cgiar.org)

Bioenergy is promising form of renewable energy which potentially has economic, social and environmental benefits. However, its production erodes its environmental benign due to land use competition. Recently, bioenergy production on degraded lands has gained global interest because of its potential to provide multiple benefits: to meet energy demand, improve degraded environment, and to enhance people's livelihood. These benefits have attracted many countries to promote bioenergy consumption and support technology, knowledge and policies in relate to its production. However, the production would be not feasible without active landowner participation. This paper presents study on investigating factors affecting landowner's preferences for bioenergy production by analyzing 150 landowners with ex-fire experience on their lands in Central Kalimantan Indonesia using Firth's logistic regression model. The results indicate that bioenergy production on degraded land using energy species, nyamplung (*Calophyllum inophyllum*) gains less landowner preference (8%). Majority of them (76%) preferred well-known species such as sengon (*Albizia chinensis*) and rubber (*Hevea brasiliensis*) for the restoration of degraded land and a readily available market. Landowner preferred nyamplung (*Calophyllum inophyllum*) are particular landowners revealed a capacity to handle the uncertainty of the bioenergy market because they had additional jobs and income, had migrated from Java where nyamplung is prevalent, and preferred agricultural extension to improve their technical capacity. These results contribute to identifying key conditions for a bottom-up approach to bioenergy production from degraded land in Indonesia: a stable bioenergy market for landowners, application of familiar bioenergy species, and agricultural extension support for capacity building.

C5g: QUANTIFYING AND FORECASTING MARKET SPECIFIC FOREST PRODUCTS IN THE FORESTRY WOOD CHAIN

Prediction of structural lumber properties of standing *Pinus patula* trees

Brand Wessels¹, Justin Erasmus¹, David Drew¹

¹Stellenbosch University, Stellenbosch Cape Winelands, South Africa (cbw@sun.ac.za; erasj@sun.ac.za; drew@sun.ac.za)

A reduction in harvesting ages over the last three decades, due to accelerated tree growth, has resulted in reduced stiffness of lumber from South African pine saw-log resources. This has critical implications for the sawmill processors, since nearly 70% of all lumber is used in structural applications in South Africa. The objective of this study was to model the final product properties (MOE, MOR, warp) of young *Pinus patula* lumber from standing tree information in order to improve log processing decision-making. Experimental spacing trials were sampled and processed into sawn lumber which were destructively tested in bending. Information from both standing trees as well as data obtainable from increment cores were used including stem diameter, tree height, planting density, branch characteristics, wood density, microfibril angle, and year ring widths. Models were developed to predict individual board MOE and MOR as a function of the measured variables and the board radial position.

An imputation/copula approach to benchmarking stand and individual tree growth and yield models

Yung-Han Hsu¹, Ting-Ru Yang¹, John Kershaw¹, Elizabeth McGarrigle²

¹University of New Brunswick, Fredericton, Canada; ²Nova Scotia Natural Resources, Truro, Canada (yhsu@unb.ca; b00605080@gmail.com; kershaw@unb.ca; emcgarrigle@gmail.com)

When dealing with multiple species across multiple data sources collected over different points in time, traditional statistical methods are pushed to their limit. Linear and nonlinear modeling techniques were once the norm for analyzing and build prediction systems. These have largely been replaced my nonlinear mixed effects and Bayesian approaches. However, even these newer techniques have limitations, and require validation and/or benchmarking. We propose an alternative approach to modeling stand and tree dynamics using an iterative approach of imputation selection and copula sampling. In the first step, multiple imputation is used to identify a set of nearest neighbors based on tree and stand attributes. These data are used to build a copula and the copula is repeatedly sampled to obtain dynamics steps. Because the copula can be repeatedly sampled, uncertainties can be address across time and prediction envelops developed. We propose to use these prediction envelops as a benchmarking tool to assess how well statistical models are capturing forest and tree dynamics. Both short-term and long-term simulations for a variety of stand conditions in northeastern North America are compared with predictions from two statistically driven models of forest dynamics.

CalcMadeira - Validation of sawn timber calculation by the Circumsript square (Block) and Longitudinal Methods

Thomaz Correa e Castro da Costa¹, Mônica Matoso Campanha¹, Walfrido Albernaz², Emanuel Pinto², Renato Castro³, Luiz França⁴

¹Embrapa Milho e Sorgo, Sete Lagoas, Brasil; ²Emater, Sete Lagoas, Brasil; ³Universidade Federal de São João Del Rei, Sete Lagoas, Brasil; ⁴SIG Informatica, Sete Lagoas, Brasil (thomaz.costa@embrapa.br; monica.matoso@embrapa.br; walfrido.albernaz@emater.mg.gov.br; maravilhas@emater.mg.gov.br; renatocastro@ufsj.edu.br; luiz@siginformatica.com.br)

CalcMadeira is a software with eight modules, which estimates sawed lumbers, based diameter and height measured of trees or diameters and length of the log. The logic uses trigonometric rules that differ from optimization techniques, applied in others algorithmics. The goal of this work was to validate Circumsript Square (Block) and Longitudinal Methods. Experiments were performed with *Corymbia citriodora* trees from seeds and Urograndis Clone GG100, which were cubed and sawed. The results were compared to three softwares, CalcMadeira, SawModel/SigmaE and CutLog, which use different logics for the calculation of the sawn wood. In the 1st test, 32 pieces of lumber were sawed by Circumsript Square (Block) method and 33 pieces of lumber were calculated by CalcMadeira. In the 2nd test (operational), the sawed lumber was 136 pieces and 121 pieces were calculated. In the 3rd test (Longitudinal Method), CalcMadeira calculated 91 pieces of lumber and 93 pieces of lumber were sawed.

Could the production of extracts contribute to the resilience of the wood-based industry?

Mariana Hasegawa¹, Nancy Gélinas¹, Daniel Beaudoin¹, Alexis Achim¹

¹Laval University, Quebec, Canada (mariana.hasegawa@sbf.ulaval.ca; nancy.gelinas@sbf.ulaval.ca; daniel.beaudoin@sbf.ulaval.ca; alexis.achim@sbf.ulaval.ca)

Due to the large number of low-quality stems harvested from the hardwood forests of eastern Canada, the forest industry has been facing a decline in profit margins. One solution to this profitability problem would be to add value to the coproducts from sawmills by producing extracts such as betulin. The objective of this work was to estimate to what extent the inclusion of betulin in the traditional wood products portfolio could extend the profitability of the hardwood value chain. The profitability of a selection cut was evaluated from the sawmill perspective, followed by the evaluation of the potential financial gain of producing betulin. Finally, the potential inclusion of betulin in the value chain was assessed. Results showed that the profitability of selection cuts was very low in some forest stands. The sensitivity analysis demonstrated that, among selected costs and revenues, profit was more sensitive to variations in the value of coproducts and residues. If a fraction of coproducts volume was used for betulin extraction, it would generate enough revenue to offset the total costs. However, a major constraint for this integration would be the small size of the current betulin market. Despite that, our results demonstrate the potentially strong contribution of high value-added extracts to the profitability of the wood value chain.

Trade war in the wood pulp global market: winners and losers

Bruno Kaniieski da Silva¹, Luis Henrique Ventrilho França², Luiz Carlos Estraviz Rodriguez²

¹North Carolina State University (NCSU), Raleigh, USA; ²Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil (bkaniies2@ncsu.edu; luis.franca@usp.br; lcer@usp.br)

The global wood pulp market is composed by a complex web of multiple consumers and producers. Driven by economic growth, the demand for wood pulp tends to increase in the upcoming decades. However, the alarming expansion of protectionism through tariffs, quotas and other barriers to trade might change the flux of wood pulp products and impact global welfare in the long run. For instance, during the last months of 2018 the United States and China have bilaterally imposed up to 25% duty on imports of wood pulp products. We use the Global Forest Production Model (GFPM) to simulate the impact of tariffs enforced by the United State and China on international trade of wood pulp products, then we compared to a scenario without tariffs. Our hypothesis is since China and United States are among the largest importers and exporters; the trade war between them will increase global prices of wood pulp products, and therefore create opportunities for other countries to expand their markets. We discuss in detail the effect of this dynamics in key countries like Brazil, Canada, and Germany.

Contribution to modelling the growth of *Pinus radiata* with Yield-SAFE, a parameter sparse process based model

Paulina Fernández¹, João Palma²

¹Department of Ecosystems and Environment, Pontificia Universidad Católica de Chile, Chile, Chile; ²Forest Research Centre, Lisboa, Portugal (pfernan@uc.cl; joaopalma@isa.ulisboa.pt)

Radiata pine (*Pinus radiata* D. Don), is one of the most important commercial conifer species in the world supporting a robust industrial production of pulp and paper, sawnwood, plywood, fiberboards, oriented strand boards, medium density fiberboards, and secondary industry products. Intensive silviculture and the genetic breeding programs of the species have improved considerably the productivity of the species. While deterministic modeling approach has been historically the way to give support to the productive forest system, changes in environmental conditions already experienced in different areas covered with *P. radiata* plantations are determining new site productivities risking scenarios for forest plantations. Modeling strategies need to include the new environmental

scenarios and the use of process-based models seems to be the way forward. Process-based models are based on a theoretical understanding of relevant ecological processes, providing a useful framework to incorporate specific responses to altered environmental conditions. In the current work we contribute for the calibration of the parameter sparse process based model Yield-SAFE to simulate growth of radiata pine. In one hand this model provides the advantage to simulate growth under different environmental conditions and, reserves for future research the assessment of grass competition due to its undestorey competition module. This work provides results of calibration and validation with two independent datasets. During this process, is also shown the effect of a reverse-adjustment of soil depth (while keeping tree parameters fixed) and its impact on model efficiency, bias and precision.

C5h: RESEARCH AND INDUSTRIAL USE OF WOOD BIO-BASED (FORMALDEHYDE FREE) ADHESIVES: RAW MATERIAL AND INTRODUCTION TO THE WOOD-BASED INDUSTRY

Adhesivity of biobased anhydrous citric acid, tannin-citric acid and ricinoleic acid in the manufacture and properties of formaldehyde free particleboard

Divino Eterno Teixeira¹, Danielle do Carmo Pereira², Ana Paula Diniz Nakamura¹, Sarah Silva Brum²

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil (divinot@gmail.com; daniellecarmop@gmail.com; ana.nakamura@florestal.gov.br; sarahsbrum@yahoo.com.br)

Particles of *Eucalyptus grandis* were bonded using three biobased adhesives - anhydrous citric acid (CA), tannin-citric acid (TCA) and ricinoleic acid (RA) - from renewable sources and hot pressed to produce medium density particleboard. The bonding capacity of such adhesives and properties of the particleboards were evaluated and compared to the requirements of seven grades of particleboards according to the EN 312:2010 standard. The RA did not create adhesion reaction with the wood particles. Adhesives formulated with CA and TCA presented capacity to bond eucalyptus particles into particleboard confirmed by esterification reactions of the FTIRS analysis. Particleboard bonded with CA met requirements as high as grade P5 of the EN 312:2010 standard for static modulus of elasticity (MOE) and internal bond (IB) and P2 for modulus of rupture (MOR). Panels bonded with TCA met requirements up to grade P3 for MOE, however did not withstand water intake.

Ricinus oil based adhesive for glued wood products

Caio Cesar Faedo Almeida¹, Aline Maria Faria Cerchiari¹, Diego Lima Aguiar¹, Geraldo Bortoletto Júnior¹, José Nivaldo Garcia¹, Bruno Monteiro Balboni¹, Marina Coelho¹, Vanderlei Benedetti¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo Piracicaba, Brasil (caio.cfalmeida@usp.br; alinemcfaria@gmail.com; diego.aguiar@usp.br; gbjunior@usp.br; jngarcia@usp.br; brunobalboni@gmail.com; marina.ulian@usp.br; vbenedetti@gmail.com)

The seek for natural resources and the reduction of anthropogenic environmental impacts increases the need of adhesives called "bio-polymers" or "green adhesives", in contrast to those usually applied on glued wood products. The objective in this study was to evaluate the performance of Ricinus communis oil based polyurethane (PU) in comparison to the traditional adhesive polyvinyl acetate (PVOH) on engineered wood products for interior use on two species *Tectona grandis* and *Pinus* sp. For that, we have evaluated the shear strength on the glue line for the two species with both adhesives, following the Brazilian Standard NBR7190. The PU was immediately applied to the wood pieces after being synthesized. The grammage of 260 g/m² was used for the specimens with both adhesives, which cured at room temperature under the pressure of 2 MPa. Each treatment was represented by 9 repetitions and their means were compared by an ANOVA followed by a Tukey Test at 5% of probability. Both PU treatments and *Pinus* sp. with PVOH were superior to *T. grandis* with PVOH, the latter with resistance about 50% inferior to the 3 former treatments. The high extractives content on the *T. grandis* wood might have influenced the PVOH adhesion, what was not observed on PU specimens. We advise against the use of PVOH on *T. grandis* wood on products with higher stress demand, on the contrary of the *R. communis* oil based polyurethane, which presented a higher performance additionally to its eco-friendly characteristics.

Nanobioadhesives for use in wood-based composites bonding

Dominika Janiszewska¹, Patrycja Hochmańska¹, Wojciech Bałeczny¹

¹Łukasiewicz Research Network-Wood Technology Institute, Poznan, Poland (d_janisewska@itd.poznan.pl; p_hochmanska@itd.poznan.pl; w_baleczny@itd.poznan.pl)

The aim of the research was to improve the mechanical board properties by reinforcing the industrial resins with silane-modified cellulose nanocrystals. Adhesive compositions with a nanobiopolymer content of 1, 2 and 3 wt% based on solid resin were prepared. Laboratory-scale particleboards were produced and the tensile shear strength of lap joints, mechanical and physical properties as well as formaldehyde content were investigated. The work was improved by describing the viscosity and rheological characteristic related to prepared bio-based adhesives. Furthermore the stability of new nanocellulose-reinforced adhesive compositions, which is of great importance for amino resins producers and customers, was determined. Particleboards prepared with resin containing 1 wt% CNC showed a reduced water absorption and formaldehyde content as well as improved bending and tensile strength in comparison to the boards produced with standard amino resin. The proper viscosity after 4 weeks of storage indicated the possibility to use CNC as a stabilizer extending the pot-life of resin. Concluding the adhesive joints were toughened by the addition of only 1% of modified nanocellulose. Moreover silane-modified nanocrystalline cellulose has proven to be promising material in reinforcement of amino adhesive compositions in terms of the properties of wood-based panels. The research was carried out within the project LIDER/14/0174/L-7/15/NCBR/2016 "New biopolymer adhesives modified with silanes and ionic liquids for application in wood-based materials technology" funded by the National Centre for Research and Development in Poland under the LIDER VII Programme.

C5i: SUSTAINABLE USE OF NON-TIMBER PRODUCTS AND CONSERVATION OF SEMI ARID AND SAVANNA

Technological profiles of babassu palm extractivist cooperatives in Maranhão, Piauí, and Ceará, Brazil / *Análise do perfil tecnológico de cooperativas extrativistas do coco babaçu do Maranhão, Piauí e Ceará*

Ana Paula Diniz Nakamura¹, Thaíse Sarmento¹, Floriano Pastore²

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil (ana.nakamura@florestal.gov.br; taizsarmento@yahoo.com.br; fpastorej@gmail.com)

O babaçu (*Orbignya* sp.) é uma palmeira brasileira, pioneira, com alta capacidade de regeneração e proliferação, apresentando ampla distribuição no Brasil. Seu coco tem potencial para ser aproveitado integralmente e, no passado recente, teve grande importância econômica para comunidades tradicionais do Norte e Nordeste. No entanto, a produção da amêndoa de babaçu no Brasil está em queda, passando de 116.000 toneladas em 2000 para 67.000 toneladas em 2016, sendo baixa mecanização da cadeia produtiva umas das causas disto. Este trabalho discute a inserção de tecnologias nas cooperativas extrativistas de Babaçu. Em 2015 foram realizadas entrevistas com 7 associações e cooperativas, localizadas no Maranhão, Piauí e Ceará, que possuem pelo menos uma máquina para quebra do coco babaçu. Constatou-se que 80% das máquinas não estavam funcionando, e as que estavam em funcionamento apresentavam baixo rendimento. Consequentemente, todos os entrevistados dependiam do uso do machado para a quebra do coco (trabalho considerado penoso e de baixo rendimento). Os principais problemas observados nas máquinas são decorrentes da necessidade de alto impacto para superar a dureza do endocarpo e separar a amêndoa, o que confere baixa eficiência ao processo. Outros equipamentos desintegram excessivamente o coco, danificando a castanha. A inserção de tecnologias na cadeia produtiva de Babaçu é crucial para a produtividade, lucratividade e o aproveitamento integral do fruto. Para reverter esta realidade é essencial maior incentivo e investimento do Estado para o desenvolvimento e disseminação de tecnologias sociais de processamento do coco Babaçu

Characterization of the extraction of Pequi (*Caryocar brasiliense*) pulp oil in the Northern Region of Minas Gerais State, Brazil

Sandra Regina Afonso¹, Luciano Mansor de Mattos², Maria de Fátima Lima¹, Alessandro Moreira¹, João Chiles³, Ronaldo Almeida⁴

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Embrapa Cerrados, Brasília, Brasil; ³Comunidade Pau D'arco, Montezuma, Brasil; ⁴Centro de Agricultura Alternativa do Norte de Minas, Rio Pardo de Minas, Brasil (sandra.afonso@florestal.gov.br; luciano.mattos@embrapa.br; fatima.lima@florestal.gov.br; alessandro.moreira@florestal.gov.br; jmchiles@gmail.com; ronaldo.almeida@caa.org.br)

The pequi tree (*Caryocar brasiliense*) is the symbolic species of the Brazilian savannah and represents great social, environmental, cultural and economic importance for the Northern region of Minas Gerais State, Brazil. The pequi pulp oil utilized in culinary and nutraceutical industry is usually extracted handcrafted in rural properties or by extraction equipment in small industries. The objective of the current study was to analyze aspects related to the extraction characteristics of pequi pulp oil in the same region. All the activities involved in the oil extraction process were identified: harvest and peeling of the fruit; cooking, cooling and maceration of cooked pulp; extraction and washing of the pulp mass extracted; and melting and packaging of pequi pulp oil. It was observed the utilization of different containers in the cooking and varied forms of pulp maceration, then establishing different study scenarios. Questionnaires applied at street markets demonstrated the importance of the oil quality for the consumer, as well as the significant variation of prices practiced in the different municipalities studied. In general, it was observed that, in some cases, the labor value – counted by the time in hours dedicated to the oil extraction multiplied by the local daily value – does not guarantee the due remuneration to the local family farming. Nevertheless, the oil extraction is characterized as an important activity that avoids wasting of fruits with high perishability and values the tradition of the pequi pulp oil extraction by the local peasantry denominated “geraizeiros”.

BIOTEC: biodiversity, economy and technology for the conservation of Brazilian Savanna

Sandra Regina Afonso¹, Janaina Diniz², Maria de Fátima de Brito Lima¹, Carlos Antonio Ferreira Dantas¹, Alessandro Cezar de Oliveira Moreira¹, Ricardo de Oliveira Gaspar²

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil; ³Universidade de Brasília, Brasília, Brasil (sandra.afonso@florestal.gov.br; janadiniz@unb.br; fatima.lima@florestal.gov.br; carlos.dantas@florestal.gov.br; alessandro.moreira@florestal.gov.br; ricogaspar@unb.br)

The Brazilian Forest Service (SFB) and the University of Brasília carry out economic and technological studies and research with a focus on the sustainable use of the various timber and non-timber forest products. Regarding non-timber products, it has been working to promote the valuation and conservation of biodiversity through the qualification of production, income generation and forest recovery, as well as contribute to the strengthening of the productive chains of forest products. For this, it has been developing economic studies on the products of sociobiodiversity, considering all the productive chain (handling, processing, commercialization, forest recovery), in addition to carrying out research activities aimed at improving productive practices, and, thus, adding value and promoting the improvement in the quality of life of those who produce. We highlight the actions of chemical characterization of oils extracted from products from the different Brazilian biomes, indicating the potential of their uses, such as cosmetics, pharmaceuticals, food and fuels. Concomitantly, studies are also carried out to ensure the economic viability of the activity by the producing communities. Research developed in partnership with local communities has contributed to the qualification of production, income generation and forest conservation. In the various study areas, the project has been contributing to the strengthening of productive chains of non-timber forest products in the various biomes, attracting companies interested in the acquisition and development of new products from Brazilian biodiversity. Examples of these products are the pequi (*Caryocar brasiliense*), the baru (*Dyterix alata*) and the curriola (*Pouteria torta*).

NTFP commercialization and the role of actors in Southwest Ethiopia: restoring the forest conservation premise of NTFPs

Tefera Belay Endalamaw¹, Dietrich Darr²

¹Hawassa university, Wondo Genet College of Forestry, Wondo Genet, Ethiopia; ²Rhine-waal university of applied sciences, Kleve, Germany (teferabelay@gmail.com; dietrich.darr@hochschule-rhein-waal.de)

Forests of Southwest Ethiopia are rich in Non-timber forest products (NTFPs), particularly spices, forest honey, wild coffee and bamboo and attracted diverse actors to the forest. The commercial potential of these resources which encourages their overexploitation is leading to the destruction of their very sources. This study, based on empirical data from southwest Ethiopia, explores the role of various actors and how NTFP-based incentives serve or disserve forest conservation ideals. The study showed that the myth of natives as conservationists and settlers as anti-conservation bloc overshadowed the real influence of markets and policy. It is found that forest conversion is determined by accessibility, market and policy conditions; and that all actors (natives, settlers and private agricultural investors) respond to markets and engage in deforestation for expansion of agricultural crops and domestication of NTFPs. Therefore, land-use decisions are mainly dependent on economic incentives rather than settlement history. The study further revealed that NTFPs make a substantial contribution to local livelihood and export income. However, NTFPs are generally undergoing changes from a forest product to an agroforestry product as a result of agricultural expansion and the conversion of the forest to agroforestry systems. This was effectively facilitated by state and market forces. Despite these challenges, NTFPs can still contribute to forest conservation if appropriate institutional reforms are put in place to encourage sustainable NTFP commercialization and halt uncontrolled domestication of the forest landscape.

Eucalyptus oil as a natural pesticide: some insights and prospects for commercialization

Daizy Rani Batish¹

¹Panjab University, Chandigarh, India (daizybatish@yahoo.com)

Forests serve as the major sources of various wood and non-wood products for human society. Among the non-wood products, plant essential oils are important as they possess ecological, biological and commercial significance. *Eucalyptus*, a diverse genus represented by over 700 species, is cultivated throughout the world for its various aesthetic and commercial values. The essential oil of *Eucalyptus* finds extensive use in perfumeries, and food and pharmaceutical industries and has also been investigated for the activity against pests, pathogens and weeds. However, as a commercially viable natural pesticide, it has not received much attention since little has been done to improve its pesticidal value. In view of the greater emphasis on natural pesticides, further efforts are required for the development of eucalypt oil as a commercially viable future pesticide. In this direction, eucalyptus oil-based formulations using adjuvants like thickeners, esterified oils, surfactants, etc., could be developed. Moreover, employing nanotechnology, nano-emulsions or nano-encapsulates of eucalyptus oil can be prepared to enhance its pesticidal efficiency by reducing volatilization and biodegradation and ensuring its controlled release. These techniques will profoundly enhance the commercial value of eucalyptus oil as a natural pesticide. During the deliberations of the conference, all these aspects on the improvement of the commercial value of eucalyptus oil as a natural pesticide would be discussed.

Acacia saligna: food security option for semi-arid áreas / *Acacia saligna*: food security option for semi-arid áreas.

Patricio Rojas¹, Eduardo Caballero², Carmen Soto²

¹INFOR, Santiago, Chile; ²CREAS, Valparaiso, Chile (parojas@infor.cl; ecaballero@creas.cl; carmensoto@creas.cl)

Food security is a strategic issue in coming decades, especially in semiarid areas zones of the planet. *Acacia saligna* occurs as exotic drought tolerant legume in low rainfall region of Chile (Coquimbo, around 100 mm/year) where more than 15.000 hectares were planted for degraded soils, fodder production, charcoal and erosion control since the seventies. *Acacia* seeds are processed in Australia for “bushfood” industry to create high value flavoring agents and functional flours. A project founded by FIA (Ministry of Agriculture of Chile) was developed with the participation of a technological network, agricultural “comuneros” and WorldVision Australia to obtain flours, nutritional and functional foods from *Acacia saligna* seeds. Current resource of *A. saligna* existing area and seeds yield/per tree and per hectare for raw material supply and profitability analysis were evaluated. A 5% contribution of pre-mix flours was as an optimum in food preparation that showed high percentage of acceptability among consumers. Research showed that toasted flours of *Acacia saligna* constitute an excellent raw material for breads and biscuits that have important functional properties as antioxidants (ORAC of 87,327 μMols ET / 100g in dry weight), antihypertensive activity (54%), high protein content (26-28%). The seeds contain also high percentage of djenkolic acid (1.9 gr / 100 grams of seeds) that could control Diabetes Type 2. The innovation project proposes a technological and commercial link with the “comuneros” to supply the niche of functional and healthy foods of high commercial value to combat malnutrition and to improve profitability of plantations.

Strategies for adopting integrated crop-livestock-forest systems favoring livestock sustainability in the dry tropics of Colombia / Estratégias para a adoção de sistemas Agrossilvipastoris que beneficiem a a sustentabilidade pecuária no trópico seco colombiano

Cesar Augusto Forero Camacho¹, Santaigo Andres Roa Ortiz¹, Nelson Perez Almarino²

¹Corporación Colombiana de Investigación Agropecuaria, Bogotá, Colombia; ²Corporación Colombiana de Investigación Agropecuaria, Espinal, Colombia (cforero@agrosavia.co; sroa@agrosavia.co; nperez@agrosavia.co)

A pesquisa tem mostrado que a era do Antropoceno está mais presente hoje e tem sérias implicações sobre os recursos ambientais. O aumento da temperatura, causado principalmente pelo aumento das emissões de gases de efeito estufa (GEE) produzidos pela industrialização para atender a crescente população mundial todos os dias, tem mostrado que a pecuária está sendo considerada um problema global. Estima-se que a fermentação entérica dos ruminantes produz anualmente cerca de 5 giga toneladas de CO₂-eq, principalmente em sistemas pecuários extensivos. A busca por novas áreas para a formação de pastagens tem provocado um desmatamento agressivo, especialmente na América do Sul. Na Colômbia as áreas desmatadas foram duplicadas entre 2016 e 2018 de acordo com dados do governo nacional. Cientes desse problema, pesquisadores da Corporação Colombiana de Pesquisa Agrícola (AGROSAVIA) avaliam a Agrossilvicultura como uma alternativa para mitigar esse problema. Apesar dos bons resultados, a adoção desses sistemas é baixa e, dessa forma, buscam-se alternativas sobre como favorecer a adoção tecnológica por parte dos produtores. Foi utilizada a metodologia proposta por Samoriba (2009) que permite avaliar previamente a adoção das tecnologias propostas e em desenvolvimento. Os resultados indicam percepção de adotabilidade de técnicos e produtores de 72,6% e 65%, respectivamente. Mesmo não apresentando significância estatística, os resultados sugerem uma grande valorização socioeconômica, uma vez que permite observar diferenças significativas de 20% a partir das dimensões de simplicidade, viabilidade, adotabilidade, observabilidade e compatibilidade.

C5j: THE USE OF FOREST AND MILL RESIDUES FOR ADVANCED BIOENERGY/BIOFUELS PRODUCTION

Large-scale feasibility of forest-based biomass-to-bioenergy conversion in Queensland Australia

Sam Van Holsbeeck¹, Mauricio Acuna¹, Sättar Ezzati²

¹University of the Sunshine Coast, Maroochydore, Australia; ²Université Laval, Quebec, Canada (svanhols@usc.edu.au; macuna@usc.edu.au; sattar.ezzati.1@ulaval.ca)

Logging residues are a large potential source of bioenergy to replace fossil fuels, however little is known about sustainable procurement of this resource in Australia. There are large volumes of forest fuel available. However, it is a low-value material and it is very sensitive to procurement cost to make it profitable. This study aimed to estimate forest-based biomass feasibility and provide an optimal logistics network for biomass-to-bioenergy within the state of Queensland. Firstly, a spatial analysis was conducted to pre-analyze the feasibility of the industrial plan such as biomass availability over the landscape and identifying potential bioenergy locations (Strategic plan). Then we developed a location-allocation optimisation model to determine the economic feasibility of the strategic plan (Tactical plan). The preliminary results indicated that globally a total area of 13.5 M ha of forest is available for biomass-to-bioenergy planning, which can provide 1 M od t of biomass recovery on an annual basis. A total number of 847 potential sites were identified as candidate sites for the subsequent installation of bioenergy conversion plan. The number of identified sites was further optimised from the economic points of view.

Production of cellulosic ethanol from steam-exploded *Eucalyptus urograndis* wood chips

Luana Marcele Chiarello¹, Carlos Eduardo Arnt Ramos¹, Sara Zaccaron², Sonja Schiehsler², Antje Potthast², Luiz Pereira Ramos¹

¹Universidade Federal do Paraná, Departamento de Química, Curitiba, Brasil; ²Division of Chemistry of Renewable Resources, Universität für Bodenkultur, Vienna, Austria (luanamarcelechiarello@yahoo.com.br; carlosforestal@itaytyba.com.br; sara.zaccaron@boku.ac.at; sonja.schiehsler@boku.ac.at; antje.pothast@boku.ac.at; luiz.ramos@ufpr.br)

The use of lignocellulosic biomass for fuels and chemicals is increasingly important to mitigate the consumption of fossil fuels and increase the production of renewable energy. In this study, *Eucalyptus urograndis* wood chips were steam-exploded to assess the effect of pretreatment on their chemical composition and enzymatic hydrolysis for the production of cellulosic ethanol. The experiments were organized in a factorial design whose conditions ranged from 174 to 216 °C and from 4 to 11 min with three replicates at the center point (195 °C, 7.5 min). Mass recovery yields, cellulose degree of polymerization and glucose yields after enzymatic hydrolysis using Cellic CTec3 (Novozymes) showed a linear correlation with pretreatment severity. The best condition was set at 210 °C, 5 min due to its higher final yield in glucose after pretreatment and hydrolysis. Pectins were almost completely solubilized after pretreatment while galactoglucomans were more resistant than arabinoglucuronoxylans. Also, alkaline delignification led to 94% lignin removal from the steam-exploded material but its effect on enzymatic hydrolysis was almost negligible. Finally, enzymatic hydrolysis at 20% total solids led to 124 g L⁻¹ glucose in 72 h and the hydrolysates were easily converted to ethanol with 1 g L⁻¹ of the yeast *Thermosacc Dry* (Lallemand), reaching productivities greater than 2.1 g L⁻¹ h⁻¹ in 12 h of fermentation. When a projection of the pretreatment, hydrolysis and C6 fermentation results was carried out, it was concluded that the eucalyptus wood chips had potential higher than sugarcane bagasse for the production of cellulosic ethanol.

Improving enzymatic hydrolysis of *Pinus radiata* biofuel substrate using a novel pretreatment sequence

Tripti Singh¹, Alankar Vaidya¹

¹Scion, Rotorua, New Zealand (tripti.singh@scionresearch.com; alankar.vaidya@scionresearch.com)

Pre-treatment is a critical step in the enzymatic conversion of lignocellulosic substrate to sugars. A unique pre-treatment sequence involving thermo chemical treatment (steam explosion) followed by biological treatment (fungal exposure) was evaluated for *Pinus radiata* as a biofuel substrate. The effect of biological treatment using the white rot *Trametes versicolor* was investigated on control (sapwood blocks) and steam exploded wood (SEW) for changes in the profile of fungal enzyme activity and lignocellulose composition. The results indicated that compared to blocks, *Trametes versicolor* expressed more lignocellulose degrading enzymes when grown on SEW for 6 and 12 weeks. After fungal exposure, the biomass was mixed with a commercial enzyme cocktail for enzymatic hydrolysis. The maximum conversion of biomass to sugars was obtained for *Trametes versicolor* treated SEW, with a yield of 4.80 g of glucose l⁻¹, which is greater compared to that obtained from non-fungal treated SEW (3.80 g of glucose l⁻¹) and *Trametes versicolor* treated sapwood blocks (0.80 g of glucose l⁻¹). Examination by microscopy suggests relative increase in the porosity of SEW after fungal treatment and compositional analysis indicate reduction in lignin content. Both these factors are likely to contribute to the improved hydrolysis of SEW.

Forest biomass as an alternative in energy generation for sustainable development and productive ventures: the results of an ongoing research program in Chile / Biomasa forestal como alternativa de generación de energía para el desarrollo sostenible y emprendimientos productivos, resultados de un programa permanente de investigación en Chile

Juan Carlos Pinilla Suárez¹, Karina Luengo Vergara¹, Mauricio Navarrete Torres¹, Felipe Navarrete Ulloa¹

¹Instituto Forestal de Chile, San Pedro de la Paz, Concepción, Chile (jpinilla@infor.cl; kluengo@infor.cl; mnavarrete@infor.c; fenavarrete@udec.cl)

En Chile la biomasa forestal representa el 24% de la participación en la matriz energética primaria y el 43% del consumo final del sector residencial, donde la Política Energética de los Ministerios de Energía y Agricultura señalan que se debe consolidar la contribución del sector forestal a la seguridad e independencia energética y descarbonización de la matriz de energía, incrementando la producción y utilización de biomasa forestal. El Instituto Forestal de Chile contribuye a ello a través de un programa permanente de investigación en la utilización de la Biomasa Forestal para generación de Energía. Se presentan los principales antecedentes, resultados, estudios empíricos y avances actuales, con la caracterización de la biomasa según especies, sitio y edad, además de nuevos escenarios por el cambio climático y los requerimientos de la comunidad, utilizando bosques de rápido crecimiento, sin descuidar objetivos asociados a una energía accesible, segura y económica. Se entregan antecedentes del caso del Pellet, producto que ha presentado un incremento en su consumo en Chile para calefacción domiciliar o uso industrial, incluyendo la seguridad en el suministro permanente de biomasa, diversificando la oferta de ella (especies y materia prima de plantaciones o residuos) y la difusión de soluciones tecnológicas, fomentando la gestión y manejo forestal, y emprendimientos en beneficio de los propietarios forestales y el sector de la energía, considerando externalidades positivas (descontaminación, protección de suelos, captura de carbono, mitigación de cambio climático, generación de empleos), reconociendo el aporte de la biomasa forestal como energía renovable en el desarrollo sostenible.

Characterization of Eucalypt LignoBoost™ lignin for the production of lignin nanoparticles

Giuliana Pavaneli¹, Maria Juliane Suota¹, Rilton Alves de Freitas¹, Washington Luiz Esteves Magalhães², Luiz Pereira Ramos¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil (pavaneli@ufpr.br; julianesuota@gmail.com; rilton@quimica.ufpr.br; washington.magalhaes@embrapa.br; lramos@quimica.ufpr.br)

Lignin is one of the most abundant renewable resources found on Earth and has the potential of being the source of fuels, chemicals and materials for a wide range of industrial applications. For instance, lignin nanoparticles (LNPs) can be applied as biobased polymers, UV blocking materials, hydrophobic coatings, antimicrobial and antioxidant agents, among others. LNPs can be produced by solvent exchange and their chemical and physical properties may vary considerably, depending on the source, extraction procedure and recovery of the starting materials. For this reason, a detailed lignin characterization must be the first step towards its application in advanced materials or in any other conversion process. In this work, a comprehensive characterization of a technical eucalypt Kraft lignin from the LignoBoost™ process has been carried out with regard to its chemical composition (ash and carbohydrate content, carboxyl and methoxyl groups, aliphatic and phenolic hydroxyl groups and S-G-H ratio) and physical-chemical properties (solubility in various organic solvents, molar mass distribution and thermal properties). Also, batches of LNP were produced by solvent exchange using acetylated and non-acetylated lignin and their properties were tentatively correlated with the composition analysis of the starting material.

Physico-chemical properties of bio-oil produced from *Ficus exasperata* Sawdust using Vacuum Reactor

Gloria Titi Anguruwa^{1,2}, Abiodun Oluwafemi Oluwadare¹, Adejoke Akinyele¹

¹Department of Forest Products Development and Utilization, Forestry Research Institute of Nigeria., Ibadan, Nigeria; ²Department of Forest Production and Products, University of Ibadan Ibadan Nigeria (gloriaanguruwa@yahoo.com; femioluwadare@yahoo.com; akinyelejo@yahoo.co.uk)

This study was conducted to investigate and estimate bio-oil produced from biomass (wood residue) of *Ficus exasperata* through pyrolysis at varied temperature. The energy and chemical potentials of this species in various forms has not been discovered and technical information on the wood for biomaterial and bio-refinery usage is not available. The physico-chemical and compositional analyses of the bio-oil were achieved through carbon-hydrogen-nitrogen-Oxygen (CHNO) studies, calorific value, Fourier Transform-Infra Red (FT-IR) spectroscopy and Gas Chromatography-Mass Spectrometry (GC-MS). The pyrolysis resulted in low bio-oil yield and high amount of bio-char at 600°C, whereas at temperature 500 and 550°C, pyrolysis produced significant amount of bio-oil with less bio-char yield. Temperature difference significantly influenced the CHNO content ($p < 0.05$). Carbon content increased with increase in temperature (76.39, 77.42 and 78.45%) at 500, 550 and 600 °C respectively. While Hydrogen, Nitrogen and Oxygen content decreased with increase temperature. The calorific value of bio-oil gave high heating value of 3.4Mj/Kg. The chemical components identified in bio-oils were classified into five major groups such as Hydrocarbons (Aliphatic and Aromatic), ketones, Amines, Oxygenated phenols and Ethers. The noticeable acid in the oil are the Oxylic, Phtalic and Benzoic acid. The study on bio-oil from *Ficus exasperata* biomass revealed its potentials for fossil fuel substitution and bio-chemical production.

Physical and chemical characteristics of wood from eucalyptus clone GFMO-27 / Propriedades físico-química da madeira do clone de eucalipto GFMO-27

Danieli Cristina Bueno de Oliveira¹, Flávia Alves Pereira¹, Eleandro José Brun¹

¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (danieli_cristina@hotmail.com; flaviapereira@utfpr.edu.br; flaviapereira@utfpr.edu.br)

Considerando a ampla variedade de espécies e clones de *Eucalyptus* cultivados no Brasil, informações sobre as propriedades da madeira tornam-se cada vez mais necessárias. O objetivo deste trabalho foi determinar as propriedades físico-químicas da madeira do clone GFMO-27 nas alturas de 0, 25, 50 e 100% da altura comercial do tronco. A análise química imediata nos discos de eucalipto foi determinada baseando-se na metodologia descrita na norma ABNT/NBR 8112/83, com adaptações, e a massa específica básica a norma ABNT NBR 11941. A quantidade de materiais voláteis, cinzas e carbono fixo nas alturas avaliadas do clone GFMO-27 foram semelhantes, bem como sua massa específica básica. Além disso, não houve correlação significativa entre a massa específica e a análise química imediata. Os teores de materiais voláteis, cinzas e massa específica básica aparente não diferiram nas alturas estudadas. Os teores de carbono fixo diferiram somente a 50% da altura e topo. Com isso, a madeira do clone GFMO-27, aos 5 anos, poderá ter um uso mais amplo, em qualquer posição do fuste por possui características semelhantes.

A pilot scale of torrefied wood pellet production for serving small community enterprise and supply chain of bioenergy production

Pongsak Hengniran¹, Pavina Badan¹, Darika Phewfai¹

¹Kasetsart University, Bangkok, 10900, Thailand (fforpsh@ku.ac.th; pv.badan@gmail.com; dphewfai@gmail.com)

The aim of this research was to find optimal technique for upgrading rubberwood residues to the next generation of bio-solid fuels – black pellets. After air dry condition to reduce their moisture content, abundant wood chips from traditional sawmill were gradually fed into a pilot-scale rotating drum reactor for turning them to black chips under controlled conditions (maximum temperature and tighten oxygen). The influence of feed and rotating speed was studied, therefore chips were fed into the reactor at 25, 50, and 75% by volume and the angular-speed was set at 5, 10 and 20 rpm, respectively. The results showed that the reaction time depended largely on the feed load of wood chip. The more feed load, the longer reaction time needed. However the angular-speed did not related to the residence time directly, it effected on the heating value of black chip products. Their testing properties revealed that when the lower angular-speed applied, the higher heating value and lower yield received. The heating value of torrefied chips increased about 17% compared to that of the original. Next, black chips were ground and mixed with three additives - cassava starch, corn starch, and glycerin - with percentages by weight of 1, 2 and 5, respectively. The properties of black pellets were tested following EN 14961-2 Standard. It was cleared that production yield could reach 56.21%, while almost properties -calorific value, mechanical durability, ash fusion, etc. – passed the standard - only bulk density (max; 381.50 kg/m³) still not met the standard requirement.

C5p: CHARACTERIZING PROPERTIES OF PLANTATION WOOD FOR OPTIMAL VALUE

Use of a non-destructive technique to estimate the wood basic density in standing trees

Nayara Bergamo Casagrande¹, Martha Andreia Brand², Alessandro Bayestorff da Cunha², Marcos Felipe Nicoletti², Maisa Beatriz Koch², Renato Augusto Pereira Damásio¹

¹Klabin S/A, Otacílio Costa, Brasil; ²Universidade do Estado de Santa Catarina, Lages, Brasil

(nayara.casagrande@klabin.com.br; martha.brand@udesc.br; alexsandro.cunha@udesc.br; marcos.nicoletti@udesc.br; maisa_beatriz@yahoo.com.br; rdamasio@klabin.com.br)

Among the wood properties that are affected by innumerable factors, such as growth conditions, environmental and silvicultural practices, the density stands out, which influences all other technological properties. The traditional methods used for density determination use wood samples, consuming time and making the process economically undesirable. Thus, the objective of this study was to establish model equations for the determination of basic density of *Pinus taeda* L., as a function of wave propagation velocity, moisture content of wood, tree diameter and height. Seventy-two trees from commercial plantations at 15 and 16 years of age were evaluated. In each tree, the impulse tomography was applied in the DBH cross-section. The trees were felled and sectioned in short logs at 0%, 33%, 66% of commercial height, in which the tomography was applied, to obtain the stress wave velocity (V), and a disc was removed to determine the basic density (BD) and moisture content (MC), according to ABNT standards NBR 11941 and NBR 14929, respectively. Several statistical models were tested to adjust the basic density of standing trees. As results, it was found for all situations analyzed, except for height at 66%, the best equation was: $\ln BD = \beta_0 + \beta_1 * V^2 + \beta_2 * (V^2 * MC) + \beta_3 * (V * MC^2) + \beta_4 * MC^2$. The best models were those that had the variable wood moisture content present in an isolated way. However, for the conditions of this forest stand, the stress wave velocity could not explain the wood basic density, since the variation of this variable was extremely small.

Colorimetric characterization of eight Amazonian wood species

Maria de Fátima de Brito Lima^{1,2}, Marcella Hermida de Paula², Divino Eterno Teixeira¹, Joaquim Gonçalves², Álvaro Nogueira de Souza²

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil (fatima.lima@florestal.gov.br; marcella.hermida@hotmail.com; divino.teixeira@florestal.gov.br; goncalvez@unb.br; alvarosouza@gmail.com)

Due to the importance of characterization and standardization of wood as raw material for different end uses, this work aimed to demonstrate the color variability of eight Amazonian woods species (Cumarú - *Dipteryx odorata* (Aubl.) Willd., Itaúba - *Mezilaurus lindaviana* Schwacke & Mez., Muirapixuna - *Cassia L.* Maparajuba - *Manilkara amazonica* (Huber) Standl., Sapucaia - *Lecythidaceae* A. Rich A. Rich., Tauari - *Couratari guianensis* Aubl., Tanimbuca - *Buchenavia capitata* (Vahl) Eichler and Timborana - *Piptadenia communis* Benth.) using quantitative colorimetry. The determination of color of these wood species was conducted using the CIE $L^*a^*b^*$ system and the chromatic coordinates L^* , a^* , b^* , C^* and h . The wood species, obtained at the Forest Products Laboratory (LPF) of the Brazilian Forest Service (SFB), were conditioned in a controlled room with temperature and humidity to reach 12% equilibrium moisture content. Ten samples were scanned per species at 10 random colorimetric reading points on the tangential face of each sample. According to results, the wood species were classified as: Cumarú and Sapucaia - brownish yellow, Itaúba - olive brown, Maparajuba - redish brown, Muirapixuna and Tanimbuca - olive, Tauari and Timborana - yellowish olive. Additionally, it was concluded by the clarity (L^*) that species Sapucaia, Tauari and Timborana were considered light-colored and the others dark-colored and the ink angle h , in the CIE $L^*a^*b^*$ system of all colors of wood studied, remained in the first quadrant (between 0° and 90°). These results may assist in the identification of timber species in commercialization or control.

Static and dynamic MOE of spruce and pine wood grown in the plantations of different initial stand density

Benas Silinskas¹, Marius Aleinikovas¹, Mindaugas Skema¹

¹Institute of Forestry, LAMMC, Kaunas, Lithuania (benasil7@gmail.com; marius.aleinikovas@mi.lt; skeminis@yahoo.com)

To determine influence of stand density on wood mechanical and physical properties of Scots pine and Norway spruce, the data were obtained from experimental trials plots, which were established in 1990 by Lithuania Forest Institute. The experimental trial plots divided to 10 smaller plots with different initial stand density: 2 control plots left for natural selection; 2 plots with 4000-5000 trees per hectare, 2 plots with 2000-2400 trees per hectare, 2 plots with 1000-1200 trees per hectare and 2 plots with 500-600 trees per hectare. From each trial plot, except control plot and plots with rarest initial stand density, were chosen 6 model trees; 3 meters long logs were sampled from each tree for determination of MOE. By using nondestructive timber measurement methods, we can obtain information about wood mechanical and physical properties of growing trees and logs. The dynamic modulus of elasticity (MOE_{log}) is obtained by calculating two parameters: sound velocity and wood density. In this study, the acoustic tomography "Arbotom 3D" was used to measure logs. To determine dynamic modulus of elasticity for samples (MOE_{dyn}) Brokheus MTG device was used. By using international standard EN 408:2016, we can obtain information about samples static modulus of elasticity (MOE_{static}) which is cut from logs. Results of this study show that highest values of all types modulus of elasticity have logs from trials plots with initial stand density 4000-5000 trees per hectare.

Characterization of wood from tree roots and branches

Raquel Gonçalves¹, Cinthya Bertoldo¹, Gustavo Garcia¹, Nina Cavalcanti¹

¹Universidade de Campinas, Campinas, Brasil (raquelg@unicamp.br; cinthya.bertoldo@feagri.unicamp.br; gustavohlgarcia@gmail.com; nina.cavalcanti@gmail.com)

The internal structure of roots, branches and trunk differ because of their specific function in tree life and stability. Nevertheless, in general, only the wood from trunk is the frequent focus of studies aiming determining physical and mechanical properties, because of the economic interest in timber and wood composites. So, if properties of wood from root and branches are required, as for example in biomechanics studies aiming tree risk of falling, properties from these parts of the trees are considered like properties from trunk. The objective of this research was to verify the applicability and preliminary results of an ultrasound methodology for the complete characterization of root and branches wood. Complementarily, compression tests were performed to characterize the strength. The tests utilized six species *Swietenia macrophylla*, *Gallesia integrifolia*, *Swietenia* sp., *Schinus molle*, *Handroanthus heptaphyllus* and *Acrocarpus fraxinifolius*. Properties were obtained using ultrasound technology, that allow the determination of the 12 elastic constants of wood (modulus of elasticity in longitudinal (EL), radial (ER) and tangential (ET) directions, shear modulus on the three planes (GLR, GTR and GLT) and six Poisson's ratio (uLR, uLT, uRL, uTL, uRT and uTR). The obtained elastic parameters using ultrasound tests were comparable with the values expected, based on theoretical aspects related to the behavior of the wood. Ultrasound tests was adequate to obtain the 12 elastic constants of roots and branches wood and are feasible for these parts of the tree, because only one specimen is required to obtain these parameters.

Wood density in *Plathymenia reticulata* and *Dalbergia nigra* homogeneous plantations at different ages

David Pessanha Siqueira¹, José Gabriel de Souza Silva¹, Deborah Guerra Barroso¹

¹Universidade Estadual do Norte Fluminense Darcy Ribeiro, Campos dos Goytacazes, Brasil (dps@pq.uenf.br; jgabrielshs@gmail.com; deborah@uenf.br)

The basic wood density is a characteristic directly related to the quality for commercial timber exploitation and with others properties, however, poor informations were found about the de wood density of brazilian forest species in homogeneous plantations at diferente ages. The work aimed to assess the basic density of the wood in homogeneous plantations of *Plathymenia reticulata* and *Dalbergia nigra* at different ages. We selected stands of *P. reticulata* and *D. nigra* with 6 and 27 years old in Linhares city (Espírito Santo state) and Trajano de Moraes city (Rio de Janeiro state), respectively. In *P. reticulata* stands were selected 48 trees and in *D. nigra* stands, 12 trees in each study site. The basic wood density was determined by the water immersion method. In addition, the diameter at 1.30 m (DBH) was measured of all selected trees. The comparison between species and between ages was made by confidence interval ($p < 0.05$). *P. reticulata* showed DBH mean of 13.7 and 26 cm in young and old stands, respectively. The *D. nigra* showed DBH mean of 12.3 and 24.5 cm in young and old stands, respectively. In both species, the wood density was lower in younger stand, with 0.40g.cm⁻³ in young and 0.51g.cm⁻³ in the older stand of *P. reticulata*, and 0.61g.cm⁻³ in the young and 0.71g.cm⁻³ in the older stand of *D. nigra*. In homogeneous plantations, *P. reticulata*, present a softer wood than *D. nigra* independent of the age. There was no correlation between tree diameter and wood density.

Using the Tree and Stand Simulator (TASS) model to predict the effects of stand management on quantity and value of carbon and biomass in British Columbia, Canada

Carlos Mario Di Lucca¹

¹Ministry of Forests, Lands, Natural Resource Operations and Rural Development, Victoria, Canada (mario.dilucca@gov.bc.ca)

The Tree and Stand Simulator (TASS) enables forest managers and timber supply analysts to explore the stand level management impacts on quantity and value of carbon and biomass in British Columbia, Canada. TASS is a spatially explicit individual tree model that provides key growth and yield estimates for the managed forests in British Columbia. It incorporates individual tree biomass equations to predict stand biomass and carbon yields under different management scenarios. The presentation will demonstrate the use and operational applications of TASS with the emphasis on carbon yield and value forecasting.

Interference of intrinsic wood parameters and live trees conditions on velocity of ultrasonic wave propagation

Raquel Gonçalves¹, Stella Palma¹, Mariana Reis¹, Candida Costa¹

¹Universidade Estadual de Campinas, Campinas, Brasil (raquelg@unicamp.br; sspalma@gmail.com; ma.nagle.reis@gmail.com; candidapcosta@gmail.com)

Many technologies related with inspection of wood are based on velocity of wave propagation. The acoustic tomography is based on the variation of the velocity inside the trunk, which is associated to colors using interpolations systems and image software. However, wood is heterogeneous, anisotropic and have natural conditions as knots, reaction wood etc., which causes natural velocity variations and can be mistaken for deterioration. Besides, as the test is made on live trees, there are other parameters that will cause the velocity variation, such as moisture content variations along the different year seasons and flow sap along the day. So, in this research we studied the interference caused by knots, wave propagation direction (radial and tangential), juvenile wood, reaction wood, moisture content and sap flow, on velocities. The objective was to verify if these variations are enough to causes misinterpretation of the ultrasonic tomography. From the results, it was concluded that some of these parameters can affect the interpretation of the tomographic image and so, more attention is necessary to take in account these interference, considering results quantification of those interference as, for example, correction coefficients.

Numerical modeling (FEM) as a tool to evaluate the tree risk of falling

Mônica Ruy¹, Raquel Gonçalves¹, William Vicente¹, Douglas Moraes¹, Celso Milaneto Junior¹

¹Universidade de Campinas, Campinas, Brasil (monkaruy@gmail.com; raquelg@unicamp.br; william.vicente@feagri.unicamp.br; douglaspl1409@gmail.com; juniormilaneto1@gmail.com)

News about trees falls in urban environment is published every year around the world. Therefore, better management of these trees is necessary in order to prevent its failures and to minimize damages caused to the population. The management of tree risk analysis involves multidisciplinary knowledge, including biology and engineering. Through of biomechanics, it is possible to ally biological aspects - growth characteristics, tree anatomy and biodeterioration agents - to the structural behavior of these individuals, that grow searching their structural balance. According to engineering principles, a structural analysis must consider three fundamental aspects: materials properties, structural geometry and loads. Thus, this research aimed to propose a structural model, through a finite element method (FEM) software, that represents the static scheme of a healthy tree. This model will be mixed to biological aspects in a future proposal of trees risk falling classes. We developed models with different levels of complexity through a FEM software. To develop the models, we used architectural and geometrical data of a common specie in urban arborization of the State of São Paulo in Brazil - *Schinus molle*. To insert the properties, the material was adopted as orthotropic and its properties were determined by physical and mechanical characterization of green wood from the same species. By comparing the results, it was possible to conclude about the most appropriate model to be used in futures researches involving tree risk falling assessment.

C5q: CHARACTERIZING PROPERTIES OF PLANTATION WOOD FOR OPTIMAL VALUE

Development of *Aquilaria* plantations and eaglewood production in Southern China

Daping Xu¹, Xiaojin Liu¹, Dongguang Wang¹

¹Research Institute of Tropical Forestry, Chinese Academy of Forestry, Guangzhou, China (gzfrsd@163.com; xjliu@caf.ac.cn; 506566893@qq.com)

There are about 100,000 ha *Aquilaria* plantations in southern China. Tree species used for plantations are *Aquilaria sinensis* (Lour.) Spreng., *A. yunnanensis* S. C. Huang and *A. crassna* Pierre ex Lec. *A. sinensis* is the dominant species. The objective of the plantations is for eaglewood production for medicine, perfume and eaglewood oil. During seedling raising, it is very important to prevent root nematode invading; 2-3 years container-seedlings at the height about 1 m are suitable for plantation establishment. Early fertilizations are very favoured for fast growth of young trees. when average DBH of trees is about 10-15 cm at the age of 5-10 years, it is possible for promoting eaglewood production. There is no eaglewood production without special treatments to the trees until natural injuring happened by insects, diseases or wind damage. Experiments have been conducted to select efficient treatments for promoting eaglewood

production. Inoculation of fungi, dripping of chemicals and plant growth regulators to stem are helpful for eaglewood production. Cutting roots, section cutting bark and drilling holes on stem are useful for eaglewood production too. When trees were hurt or injured, stem-bark respiration was increased, then starch in stem wood was decreased, and finally formed volatile oil accumulated around injured sections. Agarwood formation was an inductive stimulus, resulting in defense response, and produce secondary metabolism during the dynamic process. Artificial wound, use of plant growth regulators and inorganic salt, and fungi inoculation were effective methods for agarwood formation. The stem defense response and respiration had the certain index to predict agarwood formation.

Calorimetric evaluation of wood from four Caatinga species after applying finishing products / Avaliação colorimétrica da madeira de quatro espécies da caatinga após aplicação de produtos de acabamento

Eduardo Reis¹, Peter Wimmer^{1,2}, Luciano Roitman^{1,2}, Marcella De Paula¹, Robert Rossi¹, Joaquim Gonzalez¹

¹Universidade de Brasília, Brasília, Brasil; ²Serviço Florestal Brasileiro, Brasília, Brasil (eduardoreis1995@gmail.com; peter.wimmer@florestal.gov.br; luciano.roitman@florestal.gov.br; marcellahermida@hotmail.com; robertflorestal@gmail.com; goncalz@unb.br)

A cor é um dos atributos mais importantes para a valorização e comercialização da madeira. Esta pode ser influenciada por fatores genéticos inerentes a cada espécie, promovidos pelo ambiente ou pelo beneficiamento da madeira. Este trabalho teve como objetivo avaliar a alteração da cor da madeira de quatro espécies de árvores, típicas da Caatinga do estado do Piauí, com relação a dois produtos de acabamento. A determinação das cores das amostras foi realizada por meio do sistema CIELAB, 1976, pelas coordenadas cromáticas (L*, a*, b*, C e h*). Para isso foi usado um espectrofotômetro ColorEye XTH, fazendo 10 leituras por amostra, sendo cinco amostras por espécie e cinco amostras para cada tratamento. Todas as espécies foram classificadas de acordo com a tabela de cores de madeira, proposta por Camargos e Gonzalez, 2001. Sem tratamento, as espécies *Pterodon abruptus* (Moric.) Benth, *Terminalia fagifolia* Mart., *Diptychandra aurantiaca* Tul. e *Aspidosperma pyrifolium* Mart. foram classificadas como marrom-oliva, marrom-claro, amarelo-amarronzado, e amarelo-claro. Após a aplicação de Cetol a madeira das mesmas espécies foi classificada como amarelo-amarronzado, marrom-escuro, marrom-avermelhado e amarelo-claro, respectivamente. As amostras que receberam o tratamento de seladora foram classificadas como amarelo-amarronzado, marrom-avermelhado, amarelo-amarronzado e amarelo-claro. Sendo assim, ambos os tratamentos alteraram a coloração da madeira de *P. abruptus* sem distinção entre os tratamentos. Cada tratamento aplicado a espécie *T. fagifolia*, gerou uma coloração diferente. Para a espécie *D. aurantiaca*, apenas o Cetol gerou diferença na coloração e nenhum produto aplicado alterou a coloração de *A. pyrifolium*.

Performance of glued laminated beams made of *Couratari oblongifolia* Ducke & R. Knuth using two types of adhesives / Desempenho de vigas laminadas coladas de *Couratari oblongifolia* Ducke & R. Knuth utilizando dois tipos de adesivos

Peter Wimmer^{1,2}, Divino Teixeira¹, Maria Oliveira², Eduardo Reis²

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil (peterwimmer1983@gmail.com; divino.teixeira@florestal.gov.br; meoliveira.florestal@gmail.com; eduardo.reis@florestal.gov.br)

Couratari oblongifolia Ducke & R. Knuth, conhecida popularmente por tauari, é a quarta espécie mais explorada nos planos de manejo florestal das concessões federais em Florestas Nacionais. Apesar do grande volume, a madeira desta espécie é atualmente utilizada para produtos de baixo valor agregado como cabos de vassouras, cabos de ferramentas e caixotaria, possuindo um baixo valor comercial. Por outro lado, a densidade básica média da madeira, sugere que seja possível utilizar esta espécie no desenvolvimento de produtos engenheirados para a construção civil, que envolvem o uso de adesivos. Entre os produtos em destaque atualmente estão as vigas de madeira laminada colada (MLC). Também conhecidas por “glulam”, as vigas são compostas de lâminas (tábuas) de madeiras dispostas paralelamente, unidas entre si pelo uso de adesivos duráveis e resistentes a umidade, sendo um material arquitetônico extremamente versátil, uma vez que permite uma grande variedade de formas. Esse trabalho teve como objetivo avaliar o desempenho de vigas de MLC de *C. oblongifolia*, confeccionadas com dois tipos de adesivos: poliuretano (PUR) e poli(acetato de polivinila) crosslink (PVAc). As vigas compostas de cinco lâminas e dimensões finais de 5 x 10 x 210 cm foram testadas pelo ensaio destrutivo de flexão estática em quatro pontos, de acordo com a norma ASTM D-198/02 (2015). Todos os valores obtidos nos ensaios podem ser considerados altos quando comparados a dados de literatura, indicando o potencial da espécie e dos adesivos. No entanto, o adesivo PVAc gerou vigas mais rígidas e resistentes que o PUR.

Comparing cross-glued laminated wood panels of *Eucalyptus* sp., *Araucaria angustifolia*, *Pinus* sp. with commercial *Pinus taeda* panels / Comparação de painéis de madeira laminada colada cruzada de *Eucalyptus* sp., *Araucaria angustifolia*, *Pinus* sp. com painéis comerciais de *Pinus taeda*

Cecilia Manavella¹, Peter Wimmer¹, Divino Teixeira¹

¹Serviço Florestal Brasileiro, Brasília, Brasil (cecilia.manavella@florestal.gov.br; peter.wimmer@florestal.gov.br; divino.teixeira@florestal.gov.br)

A madeira laminada colada cruzada (MLCC), amplamente utilizada na América do Norte e Europa, apresenta grande potencial para a construção civil no Brasil, incluindo a possibilidade de produção de painéis com diferentes espécies de reflorestamento e de madeiras nativas. O presente estudo comparou as propriedades físico-mecânicas de painéis de *Eucalyptus* sp., de *Araucaria angustifolia* e de *Pinus* sp. confeccionados em laboratório, com painéis comerciais de *Pinus taeda*. Os painéis testados eram compostos de três camadas de madeira, colados com adesivo à base de poliuretano. Os ensaios de flexão, compressão paralela e cisalhamento na linha de cola foram realizados segundo as normas COPANT 555, COPANT 464 e COPANT 463, respectivamente. Os painéis de *Eucalyptus* sp. e *A. angustifolia* apresentaram valores iguais ou superiores ao painel produzido comercialmente, enquanto os painéis de *Pinus* sp. apresentaram valores semelhantes aos do painel comercial de *Pinus taeda*. Nota-se uma tendência de divisão das espécies estudadas em duas classes homogêneas e significativamente distintas entre si. Todos os painéis tiveram bom desempenho nos ensaios de compressão paralela e cisalhamento na linha de cola, quando comparados a resultados obtidos em estudos anteriores. Verificou-se, para todas as espécies testadas, que os painéis apresentam maior resistência quando submetidos a carga com as camadas majoritariamente dispostas na direção longitudinal.

Potential of non-destructive testing of wood and the contribution to climate change mitigation

Haruna Seidu¹, Reginald Tang Guuroh¹, James Govina¹, Emmanuel Appiah-Kubi¹, Charles Essien¹

¹CSIR-Forestry Research Institute of Ghana, Kumasi, Ghana (harryzeib@gmail.com; rguuroh@gmail.com; jgo63@uclive.ac.nz; appiahkemma@gmail.com; amanyessien@gmail.com)

Meeting journal and international best practices in publishing research studies on technological properties of timber, at least 5 trees are required to take care of variability within and between trees. Felling of trees is inarguably a contributing factor to deforestation and to a lesser extent climate change across the globe as

this is a destructive test method. However, presently there are technologies that can determine certain technological properties without necessarily cutting down trees. After executing the various technological tests in the laboratory, the prepared wood samples are mainly used locally as firewood which release CO₂ into the atmosphere. The purpose of this study was to review and quantify the number of trees extracted from different ecological zones in Ghana from the year 1998 – 2018 for technological properties determination. Also, the study estimated the amount of biomass and eventually, carbon that might have been sequestered over the study period. Data on trees and sample sizes based on mechanical, physical and anatomical property test methods were reviewed using Microsoft Excel and allometric equations. The results revealed that a total of 1010 trees were extracted for research only at CSIR-Forestry Research Institute of Ghana, with a total biomass of 920,332.9kg (920.33 tons) over the 20 years period. It can be concluded that these 1010 trees could have continued the sequestration of carbon or at least maintain those sequestered. It is recommended that Non-destructive methods must be encouraged in Ghana to safeguard the dwindling forest cover.

Selected properties of plywood manufactured from alternate layers of densified and non-densified alder veneers

Salca Emilia-Adela¹, Pavlo Bekhta²

¹Transilvania University of Brasov, Brasov, Romania; ²Ukrainian National Forestry University, Lviv, Ukraine (emilia.salca@unitbv.ro; bekhta@ntu.edu.ua)

The aim of this work was to evaluate some selected physical and mechanical properties of plywood samples made of densified and non-densified veneers within the same plywood structure. In this study defect free samples of rotary-cut veneers made of black alder (*Alnus glutinosa* L.) were used. The veneers were densified under a constant hot-pressing schedule in laboratory conditions. To manufacture the 5-layers plywood samples a commercial urea-formaldehyde resin was used and a constant hot-pressing schedule was applied while the glue spread varied as a function of plywood structure type (control non-densified, control densified, and combinations of alternate layers of densified and non-densified veneers). In this study the glue spreading was reduced almost 50% of the recommended value under industrial conditions. Prior to any process step and test, all veneers and plywood samples were kept under constant room conditions for a week. Selected physical and mechanical properties have been determined according to specific standards. The obtained results showed that the selected adhesive ratios provided relevant results for plywood samples in terms of mechanical properties. Similar findings are provided in the specialty literature for plywood made of densified veneers only. Moreover such structural combinations of non-densified and densified veneers used together for plywood production resulted in improved physical and mechanical properties of the final product. It is expected that these plywood combinations would generate value-added wood-based products with low emissions of toxic compounds and low costs, as well, based on their reduced glue consumption.

C5r: INNOVATIVE UTILIZATION OF BAMBOO AND RATTAN RESOURCES

Research on the influencing factors of bamboo certification market in China

Enlong Xia¹

¹International Centre for Bamboo and Rattan, Beijing, China (xiaenlong@icbr.ac.cn)

Bamboo is widely recognized as one of the most important forest resources and emerging as a critical substitute for wood. To develop bamboo resource, the bamboo certification is accepted as an efficient way to repond the environmental issues and global sustainable development. Several certification programs have been identified as the primary mission by some NGOs including the Programme for the Endorsement of Forest Certification (PEFC) and the Forest Stewardship Council (FSC). China is also the first country to successfully create and maintain large FSC management units (FM) and chain of custody (COC), value-chain certificates for bamboo. However, the development of bamboo certification still has long way to go in China. Currently, its bamboo certification market is influenced by many factors, such as the global environmental protection action, the government's green procurement policy, the need for the development of domestic enterprises, and people's consumption concept and habit. Based on a deep analysis the market development of bamboo industry and an updated status of its certification in China, this paper aims to provide some practical suggestions for its future development. The suggestions include: (1) supporting the establishment of bamboo forest certification market; (2) encouraging the public people to green consumption habit of bamboo; (3) improving the supporting guarantee measures of bamboo forest certification; and (4) strengthening supervision of bamboo certification agencies.

Current status and development opportunities of bamboo industry in Ethiopia

Jinhe Fu¹

¹International Bamboo and Rattan Organization, Addis Ababa, Ethiopi (jfu@inbar.int)

Ethiopia has abundant bamboo resources, and owns more than 1.47 million ha of bamboo forest, which take up 5% of the global bamboo forest area and 40% of the African bamboo forest area. Bamboo industry is still in its infancy in Ethiopia, which still adopts the traditional way to process bamboo products, and bamboo industry is encountered with a series of problems, such as lack of bamboo stand management, low level of market development, incomplete bamboo production chain and slow development in science & technology and technical extension. Under the coordination and efforts of International Bamboo and Rattan Organization (INBAR), Chinese president announced to establish "China-African Bamboo Center" in Addis Ababa on the opening speech of China Africa Forum 3 September 2018 in Beijing, INBAR implemented value chain analysis and market assessment of bamboo products and is preparing a national bamboo strategy and action plan together with Ethiopia government, the bamboo industry in Ethiopia is embraced with the unprecedented development opportunity. Its rich bamboo resources and low labor costs create the foundation for the labor-intensive bamboo industry, and its huge market demand for bamboo products and the beneficial investment policies implemented embody the opportunity for investment. Hence, enterprises and investors are suggested to invest in Ethiopia for bamboo industry. Bamboo investors should focus on bamboo industrial products like bamboo pulp and paper, floor, furniture, charcoal and briquette, bamboo shoot etc as well bamboo plantation development.

Analysis on fracture behavior of Moso bamboo (*Phyllostachys pubescens*) in tension and bending using synchrotron radiation micro-computed tomography (SRμCT)

Huanrong Liu¹, Guanyun Peng², Zehui Jiang¹

¹International Center for Bamboo and Rattan, Beijing, China; ²Shanghai Institute of Applied Physics, Chinese Academy of Sciences, Shanghai, China (huanrongliu@126.com; pengguanyun@sinap.ac.cn; jiangzehui@icbr.ac.cn)

Bamboo is a natural bio-composite material that is both tough and possesses excellent mechanical properties. Its delicate structure and fiber arrangements play an important role in the mechanical properties and the fracture performance of bamboo. In this study, the fracture behaviors of bamboo due to tensile strength

and bending were investigated using synchrotron radiation micro-computed tomography and environmental scanning electron microscopy (ESEM). Both tension and bending tests revealed that fibers are the key factors for bearing extra load and impeding crack propagation. Crack paths were found to be different in bamboo strips with different fiber percentages, and the interface between pulled-out fiber bundles and fiber break (in helix breaks and shearing break) was observed to be typical fracture characteristics in tension. Moreover, advanced micro-matrix cracking, interface debonding, fiber bundle bridging and the splitting of cell wall layers were found to be important fracture characteristics in bending. Both in tension and bending, a reasonably weak interface appeared to be beneficial for improving fracture toughness of fiber-reinforced bamboo. Thus, it is clear that “fiber bridging” mechanisms and “shear-lag theory” are well exhibited in bamboo.

Long creep-recovery behavior of bamboo-based products

Xinxin Ma¹

¹International centre for bamboo and rattan, Beijing, China (maxx@icbr.ac.cn)

This paper describes the bending creep behavior of two types of bamboo-based products, bamboo-laminated veneer lumber (BLVL), and glued-laminated bamboo (GLB, also called Bamboo Glulam) at different stress levels for half a year and recovery for the same time. It was found that the stress level of BLVL was more sensitive on creep property than that of GLB; the creep resistance of GLB was worse than that of BLVL in the stress levels of 30–50%; the instantaneous recovery ratio (elastic recovery to elastic creep) decreased with an increase of the stress levels, while the residual ratio (residual deformation corresponded to the total creep deflections) increased with an increase of stress levels for all specimens; Burgers model fit creep data very well for both bamboo-based products, while the recovery Weibull equation does not fit recovery data well for GLB.

Effect of modification with methyl methacrylate on the mechanical properties of *Plectocomia kerrana* Rattan

Lili Shang¹, Zehui Jiang¹, Xing'e Liu¹, Genlin Tian¹, Jianfeng Ma¹, Shuming Yang¹

¹International center for bamboo and rattan, Beijing, China (shangll@icbr.ac.cn; jiangzehui@icbr.ac.cn; liuxinge@icbr.ac.cn; tiangenlin@icbr.ac.cn; majf@icbr.ac.cn; yangsm@icbr.ac.cn)

This study aims to evaluate the mechanical properties of rattan/polymer composites prepared by polymerization with methyl methacrylate (MMA). The *P. kerrana* rattan samples were impregnated in a vacuum system and polymerized in an oven at 60 °C for 8 h, using 0.5 wt.% of azobisisobutyronitrile as a catalyst. The macro-mechanical properties of the treated and untreated samples were analyzed. The bending modulus and strength of the treated rattan increased by 206% and 215%, respectively. Additionally, the compressive modulus and strength increased by 109% and 107%, compared to untreated rattan. Scanning electron microscopy (SEM) images showed that MMA penetrated into the cell lumen. Furthermore, Fourier transform infrared spectroscopy (FTIR) analysis revealed that MMA diffused into the parenchyma and vessels, but it was not found in the fiber wall. Thus, it can be inferred that the improvement in the mechanical properties of treated rattan was mainly caused by the strengthened parenchyma and vessels. Modification with MMA was shown to be an effective way to enhance the macro-mechanical properties of *P. kerrana*.

How HS code's development help promote market development of bamboo and rattan commodities?

Junqi Wu¹, Zhiyong Li², Lucy Binfield¹

¹International Bamboo and Rattan Organisation, Beijing, China; ²International Center for Bamboo and Rattan, Beijing, China (jqwu@inbar.int; icbrlzy@126.com.cn; lbinfield@inbar.int)

As two key Non Timber Forest Products, bamboo and rattan are responsible for a significant global market. The profile of these resources is steadily increasing, especially in the Global South, as is their market, with many new and innovative technologies and designs with good trade prospects. However, those wishing to promote trade in bamboo and rattan still face some challenges: How can the value of bamboo and rattan commodities in the international market be recognized? How can the contribution of bamboo and rattan to economy and trade be reviewed and evaluated? How can an enabling trade policy environment for the trade of these key products be facilitated? Identification and classification of bamboo and rattan as separate from wood and other similar categories in the Harmonizing Coding System (HS) will help to unlock the huge market potential of these two particular resources. HS classification is essential for transparent market monitoring and evaluation and to facilitate trade policies relating to bamboo and rattan. This paper introduces INBAR's work with the World Customs Organization and the Chinese Customs Authority in HS code development, and addresses key issues in this area. Foremost among these is the need for more collaboration among international agencies to push forward HS code improvement for favorable trade. This paper also provides a general picture of trends in bamboo and rattan products in the international market. Finally, recommendations are proposed for further improvements of the HS codes for bamboo and rattan to facilitate international trade and cooperation.

Challenges and opportunities related to bamboo for small rural properties in the state of Paraná, Brazil / Desafios e oportunidades do bambu para pequenas propriedades rurais no Estado do Paraná

Thiago Rodrigues de Paula¹ , Vitor Afonso Hoeflich¹

¹Universidade Federal do Paraná, Curitiba, Brasil (thiago_ufpr@ufpr.br; vitorvitor.ufpr@gmail.com)

O uso do Bambu se estende por uma miríade de produtos e serviços como construção civil, artesanato, móveis, energia, produtos engenheirados como painéis e vigas laminadas. Pode ser utilizado na contenção de encostas, proteção de solos contra erosão e até mesmo para sistemas de irrigação de baixo custo, o que o torna uma cultura multiuso com alto potencial de sucesso, no entanto é pouco explorado no Brasil e no Paraná. No presente trabalho apresenta-se um estudo desenvolvido para avaliar a aplicação de bambu como alternativa que economicamente viável, socialmente justa e ecologicamente correta para que o pequeno agricultor tenha condições de desenvolver sua propriedade. O resultado preliminar indica que, apesar dos avanços recentes no ambiente institucional, como Lei federal que estabelece a Política Nacional de incentivo ao manejo sustentado do bambu e a contemplação da cultura em uma novas legislações, propõe-se a necessidade de um planejamento estratégico para a cultura do bambu no Estado, como mais uma alternativa para o pequeno agricultor, em consórcio com a área florestal, partindo da sistematização da informação e da criação de uma agenda de ações para a criação deste planejamento culminando com a disseminação da informação aos pequenos produtores, via extensão rural.

Physical and chemical characteristics of bamboo (*Dendrocalamus asper*) / Caracterización química y física del bambú (*Dendrocalamus Asper*)

Mary Flor Césare Coral¹, Fatima Hilario Zavalá², Natalie Juana Callupe Vargas², Liz Ania López De La Torre¹, Héctor Enrique Gonzales Mora¹
¹Universidad Nacional Agraria La Molina, Lima, Peru; ²Universidad Nacional Agraria de La Selva, Tingo Maria, Peru (mcesare@lamolina.edu.pe; fatimaamparohz@gmail.com; julia.natalie.03@gmail.com; lldlt@hotmail.com; egonzales@lamolina.edu.pe)

El incremento de la población ha conllevado a presionar los bosques para satisfacer la demanda de materiales estructurales como son los árboles, los cuales requieren gran cantidad de años para su aprovechamiento, lo que no sucede con el bambú, el cual requiere entre 4 a 5 años para su aprovechamiento, esto hace al bambú *Dendrocalamus asper* una buena alternativa, para su aprovechamiento en diferentes usos por la alta resistencia que presenta por su gran contenido lignocelulósico. Por ello el objetivo de este trabajo consiste en realizar la caracterización química, lignocelulósica y física del bambú *Dendrocalamus asper*. El contenido lignocelulósico (celulosa, hemicelulosa, lignina) se basó en los métodos TAPPI, análisis elemental (ASTM D4239), análisis proximal (ASTM D7582) análisis del contenido energético (ASTM D5865-13), contenido de fibras y extractivos, así como sus propiedades físicas (pH, conductividad, densidad aparente, porosidad). Los resultados indican que el bambú presenta altos valores de compuestos lignocelulósicos, siendo la celulosa de mayor contenido seguido de lignina, sus propiedades físicas como la alta porosidad se relaciona con su bajo contenido energético. Concluyéndose que el bambú *Dendrocalamus asper* por su alto contenido de fibras puede ser destinado para la producción de fibras de papel, así como para la producción de biocombustibles de tercera generación por el alto contenido de celulosa.

C5s: FOREST PRODUCTS**Whitebark raspberries (*Rubus* spp.) in the Curitiba metropolitan area: implications for phytotherapy / Amoras-brancas do gênero *Rubus* na Região Metropolitana de Curitiba: implicações para a fitoterapia**

Antonio Aparecido Carpanezi¹
¹Embrapa Florestas, Colombo, Brasil (antonio.carpanezi@embrapa.br)

A denominação popular amora-branca, tradicionalmente, é dada a três espécies nativas do gênero *Rubus* cujos frutos maduros apresentam cor predominante verde-clara: *R. erythroclados* Mart. ex Hook.f. - RE, *R. brasiliensis* Mart. - RB e *R. imperialis* Cham. & Schltdl. - RI. Ao lado delas, na Região Sul do Brasil são encontrados outros táxons de *Rubus* de ocorrência natural ou introduzidos, nestes havendo tanto cultivados como asselvajados. Popularmente, às três amoras-brancas são atribuídas propriedades para a saúde humana, embora os estudos técnicos aprofundados pareçam ater-se a RI. Como é praxe no gênero, a diferenciação botânica baseia-se, grandemente, em caracteres vegetativos. As três amoras-brancas possuem atributos que permitem sua identificação em amostras secas processadas para comercialização, como cor e indumento dos ramos e dos folíolos e presença dos acúleos e sua robustez. Na Floresta Ombrófila Mista da Região Metropolitana de Curitiba - RMC, as espécies RE e RB são razoavelmente comuns em vegetações secundárias, ao passo que RI é rara, não sendo uma fonte plausível para a obtenção do produto comercializado. Amostras obtidas principalmente em lojas da RMC indicam que, comumente, o produto comercializado como amora-branca (a) não se refere a RE, RB ou RI, e (b) frequentemente abriga, em grande parte ou totalmente, matéria de *R. niveus* Thunb., espécie introduzida, invasora, abundante na região em terrenos (sub)urbanos abandonados, com caule e ramos esbranquiçados e frutos maduros escuros. No âmbito acadêmico, a literatura revela incertezas quanto à determinação botânica cotidiana de plantas vivas de RI, indicando ser necessário cuidados para evitar erros.

Evaluation of a thinning under silvopastoral approach in a *Nothofagus antarctica* (ñire) in Chilean Patagonia

Jaime Salinas¹
¹Instituto Forestal, Coyhaique, Chile (jsalinas@infor.cl)

In the Region of Aysen (Chilean Patagonia) there are about 109.000 ha of *Nothofagus antarctica* (ñire) forest (ñirantales), these ecosystems are classified as lenga forest type. This species presents intra-specific polymorphism, which has adapted to the different biotypes, modifying its vegetative body and adopting different forms of life, such as; (i) tree-like, (ii) scrubby bush (iii) chamaephyte. The main use of these forests is the production of firewood and posts. At the same time, the pasture of domestic animals is a common practice in these places, nevertheless, the real potential silvopastoral use that the ñirantales represent is unknown. In addition to this, the current forest legislation does not include plans of usage under a silvopastoral approach to encourage the activity. The present work presents preliminary information of the structure before and after of thinning the lower part in a pure forest of ñire (average domineering height 9,9 m), located in a humid place related to a mallín distant 45 km of the city of Coyhaique, Chile. The dasométric evaluation considered 10 circular plots of 100 m² distributed in random form. The thickness before the intervention was 5.630 trees ha⁻¹, with an average diameter quadratic (DMC) of 10,3 cm. During the year 2014, a thinning was done with an intensity of 34 % of the basal area, up to coming to a residual thickness of 2.270 trees ha⁻¹ that the DMC allowed to increase to 12,9 cm.

Biometric characterization of fruits and seeds from *Dipteryx odorata* (Aubl.) Willd (cumarú-ferro) - Fabaceae / Caracterização biométrica de frutos e sementes de *Dipteryx odorata* (Aubl.) Willd (cumarú-ferro) - Fabaceae

Fiana Natacha Lima de Oliveira¹, Keilyson Naazio Oliveira Moraes¹, Marilene de Campos Bento², Harley Araújo da Silva³, Antônio Gilson Gomes Mesquita⁴

¹Programa de Pós-Graduação em Ciência, Inovação e Tecnologia para a Amazônia, Universidade Federal do Acre, Rio Branco, Brasil; ²Parque Zoobotânico, Laboratório de Análise de Sementes Florestais, Rio Branco, Brasil; ³Universidade Federal do Acre, Parque Zoobotânico, Rio Branco, Brasil; ⁴Universidade Federal do Acre, Laboratório de Genética Molecular e de Microrganismo, Rio Branco, Brasil (fiamanatacha@hotmail.com; keilysonmoraes@hotmail.com; marilenebz@yahoo.com.br; harleyaraujo@ufac.br; mesquitaagg@gmail.com)

Conhecida popularmente no Acre e no Pará como cumarú-ferro, esta espécie é bastante utilizada na construção civil, na indústria de cosméticos e alimentícios. Esse estudo foi conduzido no Laboratório de Análise de Sementes Florestais da Universidade Federal do Acre, com objetivo de caracterizar biometricamente os frutos e sementes de *Dipteryx odorata*. Os frutos foram coletados de matrizes localizadas no Ramal Copaiba, BR 364, estrada de Sena Madureira - Acre, km 64 (68W 15° 50", 9S 43° 51"). Analisaram-se 200 frutos e 200 sementes quanto ao comprimento, largura e espessura, com auxílio de paquímetro digital (0,01 mm); quanto à massa fresca em balança digital de precisão 0,001 g e a massa seca das sementes em estufa elétrica a 105 °C ± 3 °C, por 24 horas. Foram

calculadas as médias, valores mínimos e máximos, desvio padrão, coeficiente de variação e correlação de Pearson (r). A estatística descritiva foi obtida através do programa BioEstat 5.3. Os frutos apresentaram média de massa fresca de $13,06 \pm 1,82$ g, $36,94 \pm 2,02$ mm de comprimento, $15,84 \pm 1,77$ mm de largura e $21,78 \pm 1,50$ mm de espessura. As sementes apresentaram média de massa fresca e seca $1,32 \pm 0,19$ e $0,87 \pm 0,12$ g respectivamente, $26,58 \pm 1,33$ mm de comprimento, $9,0 \pm 0,64$ mm de largura e $8,19 \pm 0,65$ mm de espessura. A correlação (r) foi forte e positiva entre massa fresca e largura dos frutos ($r = 0,6711$) e entre massa fresca e seca das sementes ($r = 0,8676$). Os frutos e sementes de *Dipteryx odorata* apresentam baixa variação nas variáveis analisadas provavelmente devido a homogeneidade da espécie.

“Papa-Papel,” an academic extension project / Projeto de extensão acadêmica “Papa-Papel”

Joyce Fernanda Gondim¹, Sybelle Barreira¹

¹Universidade Federal de Goiás, Goiânia, Brasil (joy_nanda@hotmail.com; sybelle.barreira@gmail.com)

A indústria de papel e celulose causa grandes impactos ao meio ambiente devido a grande demanda e elevado consumo de recursos naturais durante o processo produtivo. Apesar do avanço tecnológico e do uso cada vez mais intenso de computadores, o uso de papel para escrita e impressão continua aumentando, indo na contramão do senso comum. Pensando nisso, em 2015, foi criado o projeto de extensão “Papa-Papel” que tem como objetivo a coleta de papel, parcialmente utilizado, para confecção de blocos de notas, com o intuito de incentivar a reutilização do papel e também minimizar a quantidade consumida nas atividades acadêmicas desenvolvidas na Escola de Agronomia da Universidade Federal de Goiás (UFG). O projeto propôs a redução do consumo e reaproveitamento desse material como forma de educação ambiental, além de incentivar a redução de gastos com papel na unidade e ajudar na conservação dos recursos naturais. Durante os anos de 2016 e 2017 foram coletados 150 quilos de papel sulfite do tamanho A4, o equivalente a 30.000 mil folhas ou 60 resmas, gerando uma economia de aproximadamente R\$ 837,00 e ainda evitando o consumo de 81 mil litros de água, que seriam utilizados para a fabricação dessa mesma quantidade de papel se não houvesse a reutilização. O projeto continua em andamento e visa, cada vez mais, aumentar a quantidade de papel reaproveitado dentro da escola. Além do impacto econômico, o projeto espera servir como exemplo para a sociedade acadêmica, de modo que seu exemplo seja seguido, gerando assim um efeito cascata.

Characteristic features of cellulose nanofibers derived from different tree species with various manufacturing processes

Haruka Suzuki¹, Takeshi Fujiwara¹, Hisashi Abe¹, Youki Suzuki¹, Tsutomu Ikeda¹, Masanobu Nojiri¹, Eiji Togawa¹, Satoshi Kubo¹, Reina Tanaka¹, Noriko Hayashi¹, Kyoko Katsumata², Yuji Matsumoto², Tomoko Kuribayashi², Kouta Ogura³, Yoko Okahisa⁴, Michiko Shimizu⁴, Takashi Endo⁵

Japanese softwood and hardwood were used in this study as raw materials for cellulose nanofibers (CNF). Each trunk of the sample trees was divided into juvenile wood and mature wood. They were chipped, pulped, and then converted into cellulose nanofibers. The Kraft pulping and the soda-AQ pulping were employed for pulp manufacturing. The mechanical fiber fibrillation technology, TEMPO-catalyzed oxidation, and enzyme biotechnology were used to produce various types of CNF. The specific surface area, width, 5% weight loss temperature, and the crystallinity index of the CNFs were determined by the BET (Brunauer-Emmett-Teller) theory, UV-vis-NIR spectrophotometer, TGA (thermogravimetric analysis), and WAXD (wide-angle X-ray diffraction) respectively. The microscopic observations of the CNFs as well as pulps were carried out using both transmission electron microscope (TEM) and scanning electron microscope (SEM). The results of the study revealed that tree species, tree age, pulping method and CNF manufacturing process will all affect the CNF characteristics more or less. CNFs made by different manufacturing methods from different raw materials each have their own unique characteristics. Knowing this fact will help us make the best use of CNFs. This work was supported by a grant from New Energy and Industrial Technology Development Organization (NEDO), Japan. NEDO Project name: Development of Technologies for Manufacturing Processes of Chemicals Derived from Inedible Plants

Potential energy crops from the wild and moist tropical secondary forests

Wan Asma Ibrahim¹, Wan Rasidah Kadir¹, Nor Fadzilah Othman², Puad Elham¹, Wai Mun Ho¹

¹Forest Research Institute Malaysia, Kepong, Selangor, Malaysia; ²TNBR Research Sdn Bhd, Bangi, Selangor, Malaysia (asma@frim.gov.my; rashidah@frim.gov.my; fadzilah.othman@tnb.com.my; puad@frim.gov.my; howaimun@frim.gov.my)

Tropical rainforests store diverse plant species with wide range of uses and of significance to the community and industries. This study was conducted in collaboration with the local Energy Authority Research Institution to evaluate selected plant and tree species growing in the wild and also secondary tropical moist forest. Seven plant species namely *Leucaena leucocephala*, *Shorea roxburghii*, *Pennisetum purpureum*, *Gliricidia sepium*, *Macaranga* spp., *Acacia mangium* and *Melaleuca cajuputi* were screened for their energy properties. Data obtained showed that *Melaleuca cajuputi* was highly potential that produces the best index. However, final selection will also take into consideration species suitability for planting under transmission lines.

Factors influencing consumer tea purchase behavior in China: a study of mianzi, renqing and sustainability awareness

Lingyun Tong^{1,2}, Lei Wang¹, Anne Toppinen²

¹Zhejiang A&F University, Hangzhou, China; ²University Of Helsinki, Helsinki, Finland (2578719866@qq.com; waleland@foxmail.com; anne.toppinen@helsinki.fi)

Previous literature has used the concept of Consumer Style Inventory (CSI) to explore factors driving consumer purchase behavior in China. Yet, the role of underlying norms, in particular Chinese mianzi and renqing, remains unclear. Growing consumer awareness of sustainability is also a potentially influential factor. The aim of our study is to gain a better understanding of tea consumption by examining the impacts of mianzi, renqing and consumer sustainability

awareness on tea purchase decision-making when tea is purchased either as a gift or for household self-use. We use factor analysis to identify five dimensions in Chinese consumers' tea purchase decision-making. Using logistic regression analysis on survey data from Zhejiang province, we examine the relationship between reclassified Chinese consumer decision-making styles and two consumer shopping purposes. The main findings of this study are as follows: Firstly, the likelihood of tea purchases for gift giving is positively influenced by brand and prestige consciousness, while the likelihood of tea purchases for self-consumption is positively influenced by sustainability awareness. The implications are: firstly, consumer segmentation according to purchase purpose is a potentiality for tea suppliers; Secondly, there is also merit in studying the effects of brand and prestige consciousness on other consumer products that are popular in gift-giving traditions in China.

Dermato-cosmetic plants uses in rural communities of the Kara District in Togo

Koudjoukalo Judith Pouwéréou Nabade^{1,2}, Wouyo Atakpama^{1,3}, Hodabalo Pereki¹, Komlan Batawila¹, Koffi Akpagana¹

³Institut National de Formation Agricole de Tové, Kpalimé, Togo (judith.nabede@gmail.com; wouyoatakpama@gmail.com; perekihodabalo@gmail.com; batawilakomlan@gmail.com; koffi2100@gmail.com)

The present study is a contribution to the valorization of plant resources used in traditional cosmetics. More specifically, it aims to: (i) census plant species used in traditional cosmetics; (ii) describe the various forms of use of these resources and (iii) assess indigenous knowledge on cosmetic plant species according to ethnicity, age, sex, and occupation. Information was gathered based on ethnobotanical semi-structured individual and focus groups interviews of 316 informants. Data analyse was based on use indices of plant species and plant parts. One hundred twenty-five (125) plant species belonging to 109 genera and 47 families used in indigenous cosmetic practices were reported. The most represented families were: Poaceae, Papilionaceae, Combretaceae, Caesalpiniaceae, Malvaceae, and Rubiaceae. The listed plants were used for 24 cosmetic effects. The most reported species was *Vitellaria paradoxa* (26.26%). Depending on the specific use, 3 cosmetic groups were discriminated: the classical cosmetics, the clothing cosmetics, and dermatological plants. Leaves were the most used organs (56%). The poultice is the main method of preparation of dermatological plants. Remedies were essentially administered topically. Complementary studies, in particular the evaluation of efficacy and toxicological tests, are necessary for better valorization of plants for cosmetic purposes.

Trade in pangolin parts in Southern Benin, West Africa

Etotépè A. Sogbohossou¹, Chabi Djagoun², Brice Sinsin², Ray Jansen³

¹University of Abomey-Calavi, Cotonou, Benin; ²University of Abomey-Calavi, Abomey-Calavi, Benin; ³Tshwane University of Technology, Pretoria, South Africa (etotepe@gmail.com; dchabi@gmail.com; bsinsin@gmail.com; jansenr@tut.ac.za)

Our world is acknowledging an unprecedented species extinction crisis mainly due to human activities correlates such as habitat degradation and illegal trade. Pangolins are the animal species the most threatened by illegal trade. Despite increasing efforts, people continue to hunt the species in forests and the trade is still important. In Africa, research that should support conservation actions is relatively limited. In order to improve actions to save pangolins in West Africa, we surveyed seven markets in Southern Benin and few stakeholders around Lama Forest, the main protected area in southern Benin. Parts of pangolins were found in all investigated markets; 19.6% of sellers in markets had pangolin products but they have all sold once pangolin products. The most used parts are the head and scales. Pangolin products are bought by a variety of clients, mainly for magical purposes. Despite two pangolin species (*Phataginus tricuspis*, *P. tetradactyla*) are reported to be present in Benin, three species were identified in markets. Nigeria is the first foreign provider of pangolin products in the area. Sellers got pangolins by-products mostly from local and national markets and also from neighbouring countries. Most stakeholders were aware of the threatened status of the species. The pangolin trade is very profitable and products are sought-after. This study that confirms the importance of pangolin trade despite efforts by the government and NGOs and local people awareness. The law should be enforced but the dialogue with the poor local people should be considered.

Analysis of the locational pattern in the market for forest-based products in Paraná, Brazil: 2005-2015 / Uma Análise do padrão locacional para o setor paranaense de produtos de base florestal: 2005-2015

Keila Corrêa Bittencourt¹, Vitor Afonso Hoeflich¹, João Carlos Garzel Leodoro da Silva¹, Junior Ruiz Garcia¹, Romano Timofeiczuk Junior¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ¹Universidade Federal do Paraná, Curitiba, Brasil (keila_cbittencourt@yahoo.com.br; vitor.ufpr@gmail.com; garzelufpr@gmail.com; jrgarcia1989@gmail.com; romano.timo@gmail.com)

A degradação dos recursos florestais nativos colocou em evidência a importância do desenvolvimento das plantações florestais como fontes alternativas de recursos naturais. Assim, o setor florestal tem assumido um importante papel econômico, social e ambiental nas estratégias de desenvolvimento das regiões. Neste contexto, o objetivo deste artigo foi analisar o Quociente Locacional (QL) para os principais produtos de base florestal por mesorregião paranaense entre 2005 e 2015, tais como sementes, mudas, lenha, serraria e laminador, papel e celulose, e outros (nó de pinho, álamo, mourão, lascas e resíduos florestais). O uso do QL se deve ao fato de se observar escassez de trabalhos utilizando tal método na área florestal. Além disso, o período foi selecionado de acordo com a disponibilidade de informações da Secretaria da Agricultura e Abastecimento (SEAB). Os resultados indicaram oscilações tanto positivas quanto negativas no período analisado. Essa dinâmica está relacionada as questões sazonais, burocráticas e de mercado. As conclusões levaram em consideração a cadeia produtiva da madeira para interpretar os resultados e não somente as especificidades de cada produto. Também, constatou-se que é imprescindível a atuação do Estado, por meio de suas instituições para que haja melhor desenvolvimento de cada região, bem como dos produtos comercializados.

Using cover crops for weed control in cultivating mate (*Ilex paraguariensis*) / Uso de coberturas vegetais no controle de plantas daninhas na cultura da erva-mate

Ives Clayton Gomes dos Reis Goulart^{1,2}, Bruno Brasileiro², Delmar Santini³, Ivar Wendling¹, Joel Ferreira Penteadó Júnior¹

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil; ³Cambona, Machadinho, Brasil (ives.goulart@embrapa.br; brasileiro@ufpr.br; desantinflorestal@yahoo.com.br; ivar.wendling@embrapa.br; joel.penteadó@embrapa.br)

A erva-mate é uma espécie nativa do Brasil e seu cultivo é importante na Região Sul. Entretanto, alguns fatores limitam a produtividade, como a competição com plantas daninhas (PD). O objetivo deste trabalho foi avaliar a supressão de PD por coberturas vegetais (CV) em um plantio de erva-mate sombreada. O experimento foi instalado no município da Lapa, Paraná, Brasil, em erva comercial com 2 anos. O delineamento experimental foi blocos casualizados em parcelas subdivididas, sendo alocados nas parcelas o fator CV e na subparcelas o fator adubação da erva-mate em estágio de formação de copa. Foram testadas seis CV: PD, *Arachis pintoi*, *Axonopus compressus*, *Lupinus albus*+*Cajanus cajan*, *Avena strigosa*+*Penisetum glaucum* e *A. strigosa*+*C. cajan*. A adubação teve

dois níveis: sem adubação e com adubação. Foi avaliada a massa seca (MS) das CV e das PD ao final dos ciclos hibernar e estival. Os dados foram submetidos à análise de variância e ao teste SNK. A espécie *A. compressus* reduziu 80% da MS das PD, sendo o maior efeito supressivo observado, enquanto que a combinação *L. albus* + *C. cajan* teve o menor efeito, sem redução de MS de PD. A adubação da erva-mate na fase de maturação de copa não afetou o incremento de MS das PD e das CV. As CV são uma alternativa interessantes para controlar PD em ervais, sem a necessidade de utilizar herbicidas.

Estimated potential yield of mate (*Ilex paraguariensis*) planted in São Mateus do Sul, Paraná, Brazil / Estimativa do rendimento potencial de erva-mate plantada em São Mateus do Sul, Paraná, Brasil

Ives Clayton Gomes dos Reis Goulart^{1,2}, Bruno Brasileiro², Ricardo Oliveira², Delmar Santin³, Joel Ferreira Penteadó Júnior¹
¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal do Paraná, Curitiba, Brasil; ³Cambona, Machadinho, Brasil
 (ives.goulart@embrapa.br; brasileiro@ufpr.br; rico@ufpr.br; desantinflorestal@yahoo.com.br; joel.penteadó@embrapa.br)

A erva-mate é uma espécie nativa do Brasil e seu cultivo é importante na Região Sul. O avanço dos sistemas de produção e do melhoramento genético aumentou a produtividade da erva-mate. Entretanto, não é conhecido o rendimento potencial (RP) da espécie. O objetivo do trabalho foi estimar o RP utilizando modelos clássicos e discutir os principais fatores que afetam o rendimento da erva-mate comercial. O município selecionado foi São Mateus do Sul-PR. Foram obtidos da literatura o Índice de área foliar, a eficiência de uso da radiação e os dados necessários para calcular o índice de colheita da erva-mate (IC). O IC foi calculado dividindo-se a massa seca (MS) da erva-mate comercial pela soma da MS da erva-mate comercial com a MS de galhos grossos. A radiação solar, temperatura e horas de brilho solar foram obtidas da estação meteorológica São-Mateus-do-Sul-A874 (25°83'56"S/ 50°36'89"W) do INMET. Os dados meteorológicos são referentes ao período de 02 de janeiro de 2017 a 02 de junho de 2018, totalizando um ciclo de 546 dias, correspondendo ao ciclo produtivo de um erval comercial. Os métodos utilizados foram propostos por Doorenbos e Kassam (DK), Sinclair (SI) e Loomis e Williams (LW). O RP estimado para São Mateus do Sul-PR foi de 154.039 kg/ha, 64.550 kg/ha e 17.576 kg/ha pelos métodos DK, SI e LW respectivamente. Estudos sobre o RP da erva-mate servem como referência para o manejo de ervais e para pesquisas em melhoramento e sistemas de produção.

User friendly forestry research

Swoyambhu Amatya¹, Shiva Sundar Shrestha²

¹Former Secretary, Ministry of Forests and Soil Conservation, Kathmandu, Nepal; ²Former Director General, Ministry of Agriculture Development, Kathmandu, Nepal (swoyambhu_amatya@yahoo.com; shivastha1951@gmail.com)

Are we conducting forestry research that is conducive to user? Why should we, and for whom forestry research should be carried out? Obviously it is for the overall all development of end users (both large and small scale industries). But in most of the cases, we seldom seek the need of end user, pay attention while selecting research topic and help them out in accelerating their business. A country wide survey carried out in 2017 revealed that Nepalese forest based industries, both timber and non-timber, used to run depending on the raw materials available in natural forests. These industries used to be one of the important revenue sources for the government in the past. Ample and various type of employment were also generated and out migration of Nepalese youths were negligible. In the absence of raw materials available in nature most forest based industries are either not functioning or operating in a lower scale. One of the reasons for this was the unavailability of appropriate forestry research results that users can use and or apply in a simple way followed by complexity of implementing research results and policies related with forestry and industries. This paper examines the factors that hindered operating forestry based industries in Nepal and suggests how forestry research results help in providing industrial raw materials in perpetuity, and provides important features of existing policies that needs to be reviewed.

C5u: FOREST PRODUCTS

Behavior of oriented strand board during natural weathering / Comportamento de painel de partículas orientadas (OSB) frente ao intemperismo natural

Matheus Couto Crisóstomo¹, Marcella Hermida de Paula¹, Joaquim Carlos Gonçalves¹, Cláudio Henrique Soares Del Menezzi¹, Ana Paula Diniz Nakamura²
¹Universidade de Brasília, Brasília, Brasil; ²Serviço Florestal Brasileiro, Brasília, Brasil (matheuscc50@hotmail.com; marcellahermida@hotmail.com; goncalves@unb.br; cmenezzi@unb.br; ana.nakamura@florestal.gov.br)

A qualidade da madeira e seus derivados pode ser alterada por intempéries que podem diminuir sua vida útil, bem como alterar a sua cor, que é um fator preponderante no mercado madeireiro, muitas vezes determinando seu preço final, principalmente quando utilizada em ambientes externos. Nesse contexto, o objetivo deste estudo foi avaliar o processo de degradação de painel OSB (painel de partículas orientadas) submetida a exposição intemperismo natural, durante período de 12 meses. O teste de colorimetria foi realizado utilizando um espectrofotômetro, de acordo com os parâmetros colorimétricos definidos pelo sistema CIELAB proposto por Gonçalves (1993). Os painéis apresentaram alteração de cor muito apreciável ($\Delta E = 23,09$) frente ao intemperismo já nos primeiros três meses, alterando da cor amarelo-claro para oliva. A variação da cor se manifestou, principalmente, pela redução na Luminosidade (L^*), passando de 68,74 para 50,22, e das alterações do componente vermelho-verde (a^*) de 9,38 para 5,48, do componente azul-amarelo (b^*) de 33,16 para 13,39. O percentual de reflectância caiu sensivelmente para os períodos de 3 a 12 meses, comportamento que pode estar associado ao escurecimento apresentado pelo material. As condições climáticas de precipitação, radiação global e temperatura média apresentaram correlação negativa significativa com todos os parâmetros colorimétricos. Já a temperatura média não apresentou correlação definida com os parâmetros. Por tanto, o painel OSB não é recomendado para uso externo sem a aplicação de tratamentos complementares, pois apresentou alto grau de fotodegradação logo aos três meses de exposição ao intemperismo natural.

Performance of acidic lignin-based surface coatings on plywood panels

Rosilani Trianoski¹, Christophe Belloncle², Thiago Souza Rosa¹, Sérgio Saraiva³

¹Universidade Federal do Paraná, Curitiba, Brasil; ²École Supérieure du Bois, Nantes, France; ³Suzano Papel e Celulose SA, São Paulo, Brasil
 (rosilani@ufpr.br; christophe.belloncle@ecoledubois.fr; thiagosouzadarosa@gmail.com; ssaraiva@suzano.com.br)

Plasticized and resin-coated plywood panels have stood out in Brazil in the last years, especially in civil construction, for example in concrete forms, slabs, and scaffolding. This economical growth is mainly due to the characteristics of the coating, which provides greater resistance to humid environments and especially the possibility of reuse, which consequently reduces the costs. One way of adding more value to the plywood panels for this type of application is through the

development of bio-resourced green coatings from lignin, especially acidic lignin, which main properties is their water insolubility. The aim of this study was to evaluate the performance of lignin-based coatings on plywood panels. Commercial *Pinus* Sp. panels were used (15 mm weight; 13 veneers; phenolic resin); two types of coatings were applied to the panels: 1) acidic lignin powder; 2) lignin aqueous solution (32.5%) with addition of non-ionic surfactant. Coatings (180g/m²) were dried at a temperature of 160 °C with a cure time of 5 min. The performance of the coatings was evaluated by surface water absorption and thickness swelling after 2 and 24 hours, steam absorption, and abrasion resistance. Uncoated panels were used as control except for the latter. Coated Panels showed greater dimensional stability than the control. Both coatings absorbed a smaller amount of steam than the control. The wear rate ranged from 27.11 to 57.82 mg/100 cycles and the water-based coating had the best performance. It was concluded that acidic lignin-based coatings provide greater stability to plywood panels, which can increase durability and reusability.

Potential for *Eucalyptus camaldulensis* Dehnh wood in the production of oriented strand board panels / Potencial da madeira de *Eucalyptus camaldulensis* Dehnh para a produção de painéis estruturais OSB

Maximiliano Umlandt¹, Thiago Souza da Rosa², Estela Pan¹, Juan Carlos Medina¹, Vanesa Jiménez¹

¹Universidad Nacional de Santiago del Estero, Santiago del Estero, Argentina; ²Universidade Federal do Paraná, Curitiba, Brasil
(maximiliano.umlandt@gmail.com; thiagosouzadarosa@gmail.com; epan@unse.edu.ar; jcmolina@unse.edu.ar; paulavanesajimenez@gmail.com)

O presente trabalho teve como objetivo investigar o potencial da madeira de *Eucalyptus camaldulensis* Dehnh para a produção de painéis Oriented Strands Board (OSB). Para isso foi realizada uma intensa revisão bibliográfica a qual consistiu na análise de diversos artigos científicos e técnicos, livros, manuais, normas nacionais e estrangeiras, permitindo dessa forma, discutir as variáveis mais importantes no processo produtivo de painéis OSB, como: matéria-prima de utilizada, densidade do painel, geometria das partículas, processo de secagem, adesivos, aditivos, pressão, temperatura e umidade final; em relação às características que a madeira de *Eucalyptus camaldulensis* apresenta: massa específica, acidez, presença de extrativos e inclusão da casca. A partir da revisão pode-se afirmar que a densidade da madeira de *Eucalyptus camaldulensis* (0,89 kg/dm³) é maior do que o recomendado para produção de painéis OSB, no entanto estudos realizados com madeiras cujos valores de densidade são semelhantes aos desta espécie, atenderam os requisitos mínimos exigidos pelas normas, concluindo assim que é viável para realizar testes com a madeira de *Eucalyptus camaldulensis* a fim de obter-se painéis OSB que atendam os valores exigidos pelas normas.

Propagating tension waves in assessing wood quality from two Amazonian tree species / Propagação de ondas de tensão na avaliação da qualidade da madeira de duas espécies arbóreas da amazônia

Claudete Catanhede do Nascimento^{1,2}, Joelma Araujo Costa^{2,3}, Giselle Larissa Rebouças Couto Silva^{2,4}, Cristiano Souza do Nascimento^{5,6}, Roberto Daniel de Araujo^{1,5}

¹Instituto Nacional de Pesquisas da Amazônia, COTEL, LEAM, Manaus, Brasil; ²Univeridade Federal do Amazonas, Programa de Pós-Graduação em Ciências Florestais e Ambientais, Manaus, Brasil; ³Universidade Federal do Acre, Cruzeiro do Sul, Brasil; ⁴Universidade do Estado do Amazonas, Itacoatiara, Brasil; ⁵Instituto Nacional de Pesquisa da Amazônia, Programa de Pós-Graduação em Ciências de Florestas Tropicais, Manaus, Brasil; ⁶Universidade Federal do Amazonas, Manaus, Brasil (catanhed@inpa.gov.br; joelmaalencar3@gmail.com; reboucasgiselle@gmail.com; s-nascimento@hotmail.com; rdanielrda@gmail.com)

A avaliação não destrutiva (AND) é definida como a ciência que identifica as propriedades físicas e mecânicas de determinado material, sem alterar sua capacidade de uso final. Entre as técnicas mais empregadas para avaliação da qualidade da madeira, estão àquelas baseadas nas características acústicas, tais como: Propagação de Ondas de Tensão, Ondas de Ultrassom, Vibração Transversal e Vibração Longitudinal. O objetivo deste estudo foi determinar a qualidade da madeira das espécies nativas da Amazônia *Jacarandá copaia* (Vell). A. DC – Bignoniaceae (Caroba) e *Pithecelobium racemosum* Ducke – Fabaceae (Angelim rajado) por método não destrutivo. As amostras ensaiadas neste trabalho foram obtidas de uma serraria da cidade de Manaus (Amazonas/Brasil); 30 peças de madeiras nas dimensões de 25 mm x 100 mm x 660 foram manufaturadas no LEAM/COTEL/INPA e o Módulo de Elasticidade Dinâmico (MOEd) foi determinado a partir da emissão de ondas de tensão produzidas por Stress Waver Timer, onde o tempo de propagação de onda na peça de madeira foi utilizado nos cálculos. Para a Densidade Aparente considerou-se a umidade a 12%, na determinação do volume por medição com paquímetro digital. As classes de qualidade pela resistência a partir do MOEd variou para Caroba de 103.088,77 - 147.126,09 kgf/cm², e para Angelim rajado de 138.677,93 - 157.713,29 kgf/cm², enquanto a densidade aparente variou de 0,38 - 0,47 e 0,94 - 0,98g/cm³, respectivamente. A técnica utilizada mostrou-se eficiente na avaliação destrutiva das madeiras da região quando comparado com a metodologia tradicional.

Exploring chemical compounds in extracts of *Eschweilera coriacea* (DC.) S. A. Mori. e *Eschweilera truncata* A.C. Sm. (Lecythidaceae) / Prospecção de compostos químicos em extrativos de *Eschweilera coriacea* (dc.) S. A. Mori. *E. Eschweilera truncata* a.c. Sm. (Lecythidaceae)

Cristiano Souza do Nascimento^{1,2}, Claudete Catanhede do Nascimento^{3,4}, Niro Higuchi⁵, Maria da Paz Lima³, Irineide de Almeida Cruz³

¹Programa de Pós-Graduação em Ciências de Florestas Tropicais, Instituto Nacional de Pesquisa da Amazônia, Manaus, Brasil; ²Universidade Federal do Amazonas, Manaus, Brasil; ³Instituto Nacional de Pesquisas da Amazônia, COTEL, Manaus, Brasil; ⁴Programa de Pós-Graduação em Ciências Ambientais e Florestais, Universidade Federal do Amazonas, Manaus, Brasil; ⁵Instituto Nacional de Pesquisas da Amazônia - INPA/CDAM, Manaus, Brazil (s-nascimento@hotmail.com; catanhed@inpa.gov.br; niro@inpa.gov.br; mdapazlima@inpa.gov.br; irineide@inpa.gov.br)

Espécies florestais do gênero *Eschweilera* são conhecidas na Amazônia como matá-matá. Apesar da grande variabilidade de espécies deste gênero, pouco se conhece sobre sua natureza química. Metabolitos secundários presentes na madeira podem auxiliar na identificação botânica atuando como marcadores taxonômicos. Propriedades físicas e biológicas da madeira também podem ser associadas à presença destes compostos, além de revelar características específicas que possam indicar o correto uso na indústria madeireira. Este trabalho teve como objetivo identificar a presença de compostos químicos em extrativos da madeira de *Eschweilera coriacea* e *Eschweilera truncata* (Lecythidaceae). Três indivíduos de cada espécie foram obtidos da Estação Experimental de Silvicultura Tropical/INPA/BRASIL. A serragem a 60 mesh foi utilizada para a obtenção dos extratos hidrofílicos (50 oC), e a triagem fitoquímica foi realizada submetendo-se os extratos a diversos testes qualitativos de precipitação e coloração específicos (18 ensaios), a fim de obter o perfil dos constituintes químicos das espécies. Os resultados da prospecção indicaram a presença de antraquinonas, cumarinas, esteróides, saponinas e taninos condensados/hidrolisáveis nos extrativos das duas espécies. Os extrativos de *E. coriacea* continham ainda alcalóides e catequinas, Substâncias detectadas têm funções de defesa contra patógenos, ação protetora contra temperaturas elevadas, radiação UV, influência no pH, densidade básica entre outros. O extrativo de *E. coriacea* apresentou maior riqueza em classes químicas, sendo que estes resultados demonstram a importância da prospecção química na distinção das espécies, corroborando para a melhor indicação/uso de espécies tropicais de forma sustentável.

Adding value to forest products of secondary atlantic forests in Southern Brazil

Alexander Christian Vibrans¹, Alfredo Celso Fantini², Daniel Augusto da Silva¹, Heitor Felipe Uller¹, Aline Renata Klitzke¹, Geferson Piazza¹, Jackson Roberto Eleotério¹

¹Fundação Universidade Regional de Blumenau, Blumenau, Brasil; ²Universidade Federal de Santa Catarina, Florianópolis, Brasil (acv@furb.br; alfrdeo.fantini@ufsc.br; daneflorestal@gmail.com; heitor.uller.florestal@gmail.com; klitzkealine@gmail.com; gefersonpiazza@gmail.com; eleoterio@furb.br)

Perception of the importance of secondary forests has grown recently. Their role as carbon sink, provider of ecosystem services and multiple forest products both for smallholders and for large scale industrialization has been recognized. However, legal restrictions on sustainable use are still hindering innovative practices within the Atlantic Forest Biome. We report the experience of a pilot management project in a 40 year old restored secondary stand of subtropical evergreen moist forest in Santa Catarina state. Native tree species had been originally planted in the 1970s; nowadays its composition and structure is similar to a natural secondary forest. Different management strategies and harvesting intensities have been tested since 2012. Early secondary species like *Miconia cinnamomifolia* are harvested at their final age and with DBH up to 35 cm; long-lived secondary species like *Hyeronima alchorneoides*, *Cedrela fissilis* and *Nectandra* sp. are submitted to selective logging: poor quality trees are harvested, future crop trees are favoured. Harvesting damages, canopy cover parameters, increment of adults, regeneration and gap colonization are continuously monitored. The harvested timber is processed in the stand owner's sawmill. Boards and other sawnwood products achieve competitive prices, consisting in an important revenue for the landowner. In addition, local craftsmen transform small pieces of hardwood species like *H. alchorneoides*, as leavings from the harvesting process (stumps, branches and damaged trunks) and others from the sawmill processing, into unique and individualized artefacts used in indoor architecture, designed by associated architects and for an increasing local market for innovative and high standard habitations.

Ilex microdonta Reissek (Aquifoliaceae) trees in high summits of Serra do Mar mountain range in Southern Brazil: a first approach for climate reconstructions

Bruno Palka Miranda¹, Carlos Vellozo Roderjan¹, Paulo Cesar Botosso², Tomaz Longhi-Santos¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil; ¹Universidade Federal do Paraná, Curitiba, Brasil (brunopalka@gmail.com; roderjan@ufpr.br; paulo.botosso@embrapa.br; longhi@ufpr.br)

For climate reconstructions we need a network of climate stations with good, long, concise and high-quality data, that is current unavailable in the Serra do Mar mountain range, Paraná, Brazil. As so, tree-ring chronologies can provide important data on climate, that can be reconstructed to understand the temperature variability in these mountains. The most important species of the tropical cloud forests in Paraná State, *Ilex microdonta*, form distinct tree rings and are sensitive to climate change, playing an important role in these communities. The objective of this research is to reconstruct the minimum temperatures in Serra do Mar and indicate the applicability of the technique in this region. The 30 trees for the chronology building (1802-2016) were sampled in Mãe Catira and Sete peaks (1,430 m a.s.l.), and the climate data for reconstruction were obtained by CRU temperature dataset (25,5° S; 49° W). We used PCR methodology with minimum AIC criteria for the best model evaluation. We were able to reconstruct 100 years of late spring and summer minimum temperatures, with RE and CE ≥ 0.498 and $R^2 = 0.32$. Although the results indicate low statistics for climate reconstruction, this was the first approach with tree rings in the Tropical Montane Cloud Forests in Serra do Mar, representing an important contribution for this study field. We also reinforce the need to improve climate research in these areas, in order to better understand the impact of global climate change local and regionally.

C5v: FOREST PRODUCTS

Evaluation of the effect of species and varnish on the quality of surface finish of some amazonian woods

Rosilani Trianoski¹, Christophe Belloncle², Mark Irle², Setsuo Iwakiri¹, Franck Michaud²

¹Universidade Federal do Paraná, Curitiba, Brasil; ²École Supérieure du Bois, Nantes, France (rosilani@ufpr.br; christophe.belloncle@ecoledubois.fr; mark.irle@ecoledubois.fr; setsuo@ufpr.br; franck.michaud@ecoledubois.fr)

The Amazon Rainforest is one of the main producers of tropical timber, covering an area of 550 million hectares. From this amount, 320 million (60%) are within the Brazilian territory. Besides, it houses about 50% of the world's biodiversity and 50% of the world's tropical timber reserve, with variability of up to 300 wood-producing species per hectare. Due to this variability, many species are still technologically unknown and consequently they are not commercially used, especially for high value-added products. Good surface finish will improve the look and durability of these products. Thus, this research evaluated the quality of surface finishes on Amazonian wood species; namely, *Byrsonima crispera*, *Eschweilera odora*, *Eschweilera coriacea*, *Manilkara amazonica* and *Inga alba*, harvested from the Experimental Station of Tropical Silviculture, INPA. Specimens with the dimensions 10x150x650mm were cut and prepared by planing and sanding (60-320). Alkyd, Acrylic Water Based, Nitrocellulose, Polyurethane varnishes were applied with specifications for internal use. Statistical analysis (Anova/Tuckey) was applied to evaluate the effect of species/varnish factors. The properties of the finishes were evaluated via gloss, adhesion and abrasion resistance tests (ABNT 14535:2008). The adhesion was classified as G1, with up to 5% of the detached film area, the polyurethane presented the lowest performance. The abrasion wear rate, adhesion and gloss were affected only by the varnish factor. Regarding the abrasion test, the nitrocellulose and polyurethane presented the lowest and highest performances, respectively. Therefore, it was concluded that the species factor had no effect on the properties of finishes.

Physical, mechanical, and chemical characteristics of piãozinho wood (*Micrandropsis scleroxylon* W. Rod. Euphorbiaceae) / Caracterização física, mecânica e química da madeira piãozinho (*micrandropsis scleroxylon* w. Rod. Euphorbiaceae)

Roberto Daniel de Araujo¹, Cristiano Souza do Nascimento¹, Joaquim dos Santos², Claudete Catanhede do Nascimento³, Estevão Vicente Cavalcanti Monteiro de Paula⁴

¹Programa de Pós-Graduação em Ciências de Florestas Tropicais, Instituto Nacional de Pesquisa da Amazônia, Manaus, Brasil; ²Instituto Nacional de Pesquisas da Amazônia, CDAM, Manaus, Brasil; ³Instituto Nacional de Pesquisas da Amazônia, Cotei, Manaus, Brasil; ⁴Universidade do Estado do Amazonas, Manaus, Brazil (rdanielrda@gmail.com; s-nascimento@hotmail.com; joca@inpa.gov.br; catanhed@inpa.gov.br; estevaompaula@gmail.com)

Na Amazônia, madeiras efetivamente explorada para fins comerciais estão restrita a pouco mais de uma dezena de espécies, entretanto, a floresta produz uma grande variedade, com elevada densidade populacional. A espécie *Micrandropsis scleroxylon* ocorre com grande frequência em florestas de terra firme no Amazonas/Brasil, entretanto, seu baixo diâmetro e a falta de informações técnicas impossibilitam uma aplicação dessa biomassa. O trabalho teve como objetivos

determinar as propriedades físicas, mecânicas e químicas da madeira piãozinho utilizando metodologia tradicional e não destrutiva. Amostras de três árvores foram obtidas da Estação Experimental de Silvicultura Tropical/INPA/BRASIL. Para os ensaios químicos obteve-se a serragem a 60 mesh (ASTM, 2013) e para os testes físico-mecânicos foram confeccionados corpos-de-prova de acordo com as normas técnicas de cada ensaio (NBR 7190, 1997). As concentrações de extrativos totais, polifenóis totais, solubilidade em água quente e NaOH para a madeira de piãozinho foram de 5,17%, 8,91%, 14,69 e 9,00% respectivamente. Nestes materiais encontram-se vários compostos de baixo peso molecular, tais como resinas, gomas, terpenos, alcalóides, flavonóides entre outros. Para os macrocomponentes lignina e celulose os resultados foram 34,30% e 48,18%. Os resultados das propriedades físico-mecânicas estão dentro daqueles obtidos para madeiras amazônicas. O teor de umidade da madeira foi de 14,03%, e sua superfície apresentou grã regular com textura média. A densidade básica foi de 0,645 g/cm³, com MOE de 14,212 MPa. A caracterização tecnológica da madeira de piãozinho é uma etapa primordial para indicação desta espécie no manejo sustentável da Amazônia.

Efficiency of four acetylation methods onto bleached cellulose fibres

Thiago Souza da Rosa¹, Rosilani Trianoski¹, Setsuo Iwakiri¹, Franck Michaud², Christophe Belloncle²

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Ecole Supérieure du Bois, Nantes, France (thiagosouzadarosa@gmail.com; rosilani@gmail.com; setsuo.ufpr@gmail.com; franck.michaud@ecoledubois.fr; christophe.belloncle@ecoledubois.fr)

For the development of natural fibres and thermoplastic polymers composites, chemical modifications are generally required for compatibilization. The esterification reaction promotes fibre surface functionalization from the reaction of the hydroxyl groups which are transformed into hydrophobic ester linkages, which consequently increases the hydrophobicity of the fibres and, therefore, the compatibility between the fibre and polymer. Acetylation is the widely esterification method used and has been used at an industrial scale because it is relatively simple, safe and inexpensive. Numerous acetylation methods can be used by varying the type of solvent, catalyst, time and temperature of reaction. The objective of this work was to evaluate the efficiency of 4 acetylation methods onto bleached *Eucalyptus* cellulose fibres. Bleached cellulose fibres was obtained through paper mill process. The acetylation was conducted using acetic anhydride as an acetylating agent, acetic acid or toluene as the solvent and sulfuric acid as the catalyst. Temperatures of 30 °C, 60 °C and 120 °C were used. The acetylation time was 3 and 24 hours. Acetylated fibres were characterized for physical, chemical, and morphological aspects by acid-base titration, Fourier transform infrared spectroscopy, thermogravimetric analysis, X-Ray diffraction and scanning electron microscopy. All acetylation methods showed partial substitution of the hydroxyl groups for the acetyl groups. The crystallinity of the fibres was reduced according to the efficiency of the method. Changes in fibre morphology were significant mainly in acetylation methods with prolonged reaction time (24h). It was concluded that the acetylation methods conducted with longer reaction times are more efficient.

A preliminary study of a resistive moisture meter in five exotic species planted in Brazil

Joyce de Almeida Pinto¹, José Guilherme dos Santos Moreira¹, Ana Carla Bezerra de Lima¹, Lucas Braga Moulin¹, Djeison Cesar Batista¹

¹Universidade Federal do Espírito Santo, Jerônimo Monteiro, Brasil; ¹Universidade Federal do Espírito Santo, Jerônimo Monteiro, Brasil (joyce.agro@gmail.com; guimoreir@gmail.com; anacarla_blima@hotmail.com; lucasbmoulin@gmail.com; djeison.batista@ufes.br)

Although widely used in the wood industry, moisture measurements made with electric hand-held meters are only estimates. For more accurate measurements it is necessary to perform calibrations and comparisons based on the oven-drying method. This work aimed to carry out a preliminary study to determine the best scale of use of a resistive moisture meter in five exotic timber species planted in Brazil. The resistive-type meter Gann Hydromette HT65 and the species *Eucalyptus grandis* x *E. urophylla*, *Khaya* sp., *K. senegalensis*, *K. ivorensis*, and *Toona ciliata* were used. According to the results of the Student's t-test (paired) performed between measurements of the four scales of the device vs. those of the oven-dried method, it is preliminarily recommended to use the following scales by species: 2 - *E. grandis* x *E. urophylla*, *Khaya* sp. and *K. senegalensis*; 3 - *K. ivorensis*; and 4 - *Toona ciliata*.

Technological properties of murici wood (*Byrsonima crispera* Juss. – Malpighiaceae) / Estudo das propriedades tecnológicas da madeira de Murici (*Byrsonima crispera* Juss. – Malpighiaceae)

Roberto Daniel de Araujo¹, Cristiano Souza do Nascimento², Joaquim dos Santos³, Claudete Catanhede do Nascimento¹, Niro Higuchi³

¹Instituto Nacional de Pesquisas da Amazônia, COTEI/LEAM, Manaus, Brasil; ²Programa de Pós-Graduação em Ciências de Florestas Tropicais - PPGCFT/INPA, Manaus, Brasil; ³Instituto Nacional de Pesquisas da Amazônia, CDAM/LMF, Manaus, Brazil (rdanielrda@gmail.com; cristian@inpa.gov.br; joca@inpa.gov.br; catanhed@inpa.gov.br; niro@inpa.gov.br)

A caracterização tecnológica consiste na avaliação das propriedades químicas, físicas e mecânicas da madeira, com objetivo de indicar o uso racional. Os ensaios das propriedades da madeira são em geral destrutivos que demandam alto custo e tempo. A espectroscopia no infravermelho próximo (NIR) vem sendo utilizada para predição da qualidade da madeira. Esta ferramenta permite estimar várias características sem a necessidade de preparação da amostra, em menor tempo e com a mesma confiabilidade dos resultados dos ensaios tradicionais. O objetivo deste estudo foi caracterizar a madeira de Murici por meio de metodologia não destrutiva (FT-NIR). *Byrsonima crispera* tem grande ocorrência nas parcelas onde são inventariadas em vários sítios do Amazonas/Brasil, e apresenta em geral baixo diâmetro (20-50 cm) em relação a espécies madeireiras. Sua madeira é castanha escura, apresenta grã regular com textura média, a densidade básica foi de 0,49 g/cm³, enquanto o teor de umidade foi de 12,30% e o poder calorífico superior foi de 4.873 kcal/g. O módulo de elasticidade foi de 11.535 MPa. Esses resultados são semelhantes aos descritos para madeiras da Amazônia. Nas estimativas químicas, polifenóis totais e extrativos totais foram de 6,05 e 5,53%, respectivamente, enquanto, para lignina e celulose bruta as concentrações foram de 32,52 e 55,62%, e cinzas 0,61%. Estes resultados foram preditos de modelos FT-NIR com alto coeficiente de correlação (R²<0,90) e baixos erros de calibração e previsão. O resultado desta caracterização indica que a madeira de Murici pode se adequar para uso interior e não estrutural.

Consumption and sale of acai palm fruit by extractivist families in the Amazon River Estuarine region / Consumo e venda de açaí por famílias extrativistas de região Estuarina do Rio Amazonas

Erick Silva dos Santos¹, Claudia Azevedo-Ramos¹, Marcelino Carneiro Guedes²

¹Núcleo de Altos Estudos Amazônicos, Universidade Federal do Pará, Macapá, Brasil; ²Embrapa Amapá, Macapá, Brasil (ericks_santos@hotmail.com; claudia.azevedoramos@gmail.com; marcelino.guedes@embrapa.br)

O fruto açaí é relevante na alimentação e ganhos econômicos de famílias extrativistas da Amazônia. O crescente aumento da demanda nos mercados nacional e internacional pelos seus sub (produtos) amplia a renda e o poder de compra das famílias, gerando o risco de redução da soberania alimentar. Neste estudo

foram quantificados o consumo e a venda de açaí (rasas) por famílias extrativistas da Ilha das Cinzas, Gurupá-Pará. A técnica utilizada foi o monitoramento com “calendário do açaí”, onde 28 famílias preencheram diariamente o consumo, a produção e o valor (US) da rasa de açaí durante os meses de março a junho de 2018. O consumo total familiar de açaí foi 1203 rasas/16240,5 kg, sendo abril e junho os meses de menor e maior consumo, respectivamente, média/família de 43 rasas/580 kg, aproximadamente. A produção total de açaí vendida foi 1731,5 rasas/23375,25 kg, média de 62 rasas/837 kg/família. Em média, o consumo representou 41% da produção, devido ao período de entressafra. Os meses de março e junho foram os de menor e maior volume vendidos, 42 rasas/567 kg e 919 rasas/12406,5 kg, com valor médio da rasa de 21,86 e 6,2, respectivamente. Os valores mínimo e máximo por rasa foram 2,69 e 61,83. O volume de açaí consumido e vendido pelas famílias demonstra a importância do açaí para a soberania alimentar e da atividade econômica para a região estuarina amazônica. Isso corrobora com estudos que indicam sua contribuição elevada na renda de famílias extrativistas ribeirinhas, em torno de 70%.

Effect of chipping edge inclination angle on size distribution of pulp chips produced by a chipper-canter

Victor Grubii¹, Claudia Cáceres¹, Roger Hernández¹, Carl Blais¹

¹Université Laval, Québec, Canada (victor.grubii@gmail.com; claudia.caceres@sbf.ulaval.ca; roger.hernandez@sbf.ulaval.ca; carl.blais@gmn.ulaval.ca)

The effect of oblique cutting on the chipping mechanism of the chipper-canter was studied. A bent knife type was modified in order to obtain an inclination angle (IA) of 30° and 50° between the chipping edge and the log feeding direction. The standard knife had an IA of 40°. These three knives were tested on 15 logs each, under frozen and unfrozen conditions. Logs knot characteristics and physical properties were measured. Experiments revealed that IA had a significant effect on chip formation mechanism. The IA affected how the chipping edge entered the log and the form of the wood slice that was transformed into chips. These changes provoked variations in the chip size. A 30° IA produced wider chips, mostly in the first half of the cut, shaped as an elongated parallelepiped that resulted from a tangential, oblique, and radial splitting in a single chip. Chips obtained with IAs of 40° and 50° resulted in chips shaped more as an upright parallelepiped that were detached mostly by radial and/or oblique splittings. At the beginning and at the end of the cut, chips were produced by tangential splitting. As a result, chip mean thickness increased with the decrease in IA. Knot ratio, basic density, heartwood moisture content, and total knot area were the main covariates affecting chip size distribution. Chipping of frozen wood reduced the chip size. The amount of acceptable chips increased by 6% due to an increase in the IA from 30° to 50° and by 8% when chipping unfrozen wood compared to frozen wood.

Preparation and activity evaluation of tyrosol derivatives from olive fruit residue

Zhihong Wang¹, Chengzhang Wang¹, Hao Zhou¹

¹Institute of Chemical Industry of Forest Products, CAF, Nanjing, China (926289861@qq.com; wangczlzs@sina.com; zhouhaoths@163.com)

Olive fruit residue is rich in hydroxytyrosol and other polyphenols, which have antioxidant, lipid regulation, anti-tumor and other biological activities. The hydroxyl group in the side chain of hydroxytyrosenol can produce new β -ketoester compounds by transesterification. β -keto ester is considered to be an effective intermediate in organic synthesis because of its electrophilic carbonyl group and nucleophilic carbon. In this study, hydroxy tyrosol was used as the substrate to prepare β -ketone ester by transesterification, and then dihydropyrimidinone derivatives were prepared from the intermediate. The inhibitory effects of different target compounds on α -glucosidase and α -amylase activities were also investigated. The results showed that tyrosol β -ketone derivatives prepared by benzyl protected phenolic hydroxyl groups had better inhibitory effects on the two enzymes. At the same time, the inhibitory effect of 3,4-dihydropyrimidinone derivatives prepared by this kind of compounds on enzyme activity was significantly increased, and compared with other substituents, the inhibitory effect of fluorine derivatives on the two enzymes was more obvious. This study provides a new idea for the efficient utilization of olive fruit dregs, and has a certain reference value for the development of new active drug intermediates for the treatment of diabetes.

C5w: FOREST PRODUCTS

Study of laccase-catalysed synthesis of urushiol coumarin derivatives and as hCA inhibitor

Zhiwen Qi¹, Hao Zhou¹, Chengzhang Wang¹

¹Institute of Chemical Industry of Forest Products, CAF, Nanjing, China (angelkissgod@163.com; zhouhaoths@163.com; wangczlzs@sina.com)

Lacquer laccase coexists with lacquer urushiol in *Toxicodendron vernicifluum* (Stokes). And T1 Cu location redox potential of it is lower than that of some laccase from bacterial colony, just reaching 430mV. Laccase catalysis reaction is generally realized by oxidizing to free radicals which are reoxidized to large volume or substrate molecules with high redox potential energy.¹ Acting as novel antitumor ingredients^{2,3}, urushiol easily converts to coumarin derivatives which show human carbonic anhydrase (hCA) inhibitory activity. Since hCA inhibition is one of the underlying mechanisms that account for the activities of some antiepileptic drugs (AEDs), it's expected to have anti-seizure properties.⁴ Herein, we designed as well as synthesized a series of novel C15 triene urushiol derivatives, and the results indicated that they are effective in inhibiting HepG2 proliferation. Moreover, we first analyzed the probable binding-modes of the most active compound by molecular docking algorithms, and calculated their enzymatic bioactivity against hCA. Consequently, some derivatives can excellently reduce the hCA expression.

Assessing the efficacy of natural products and by-products for preserving *Guadua* spp. bamboo collected from different microenvironments within a secondary forest in Rio Branco, Acre, Brazil / Avaliação da eficiência do uso de produtos naturais e residuais para a preservação dos colmos de *Guadua* Spp. Coletados em diferentes microambientes de uma Floresta Secundária- Rio Branco, Acre

Sangela Rodrigues¹, Lucas Romeu¹, Patrícia Amorim¹, Leila Peters¹, Marianne de Sá¹, Michaela Queiroz¹, Janaira Sousa¹, Jessica Silva¹, Moisés Lobão¹

¹Universidade Federal do Acre, Rio Branco, Brasil (sangelalimaa@gmail.com; lucas.romeu14@gmail.com; patriciagomesribeiro@gmail.com; leilappeters@gmail.com; mariane_ps_@hotmail.com; michaelaqueiroz3@outlook.com; janaira.js@hotmail.com; jsnunes239@gmail.com; moiseslobao6@gmail.com)

Há atualmente uma visão integradora que coloca a Terra e a humanidade como unidades de um único sistema, considerando o meio ambiente como fonte de recursos, comum a todos, que deve ser utilizado de forma consciente, dentro dos limites de aceitação da natureza para servir às gerações futuras. Nesse cenário, o bambu é introduzido como fonte alternativa para suprir as demandas sociais, pois é um material renovável e de baixo custo, encontrado em abundância em regiões tropicais e subtropicais. Porém, a maior parte das espécies de bambu são susceptíveis ao ataque de fungos e insetos. Portanto, este trabalho objetivou avaliar a eficiência do uso de produtos naturais (água salinizada) e residuais (óleo de cozinha) para aumentar a resistência do colmo de *Guadua* spp. contra

o ataque de fungos. Foram realizadas as seguintes etapas: i) coleta e identificação de colmos de *Guadua* spp. no interior e na borda da floresta do Parque Zoológico da UFAC; ii) tratamento dos colmos com água salgada e óleo residual de fritura; iii) realização de ensaios de apodrecimento acelerado; e iv) avaliação de perda de massa das taliscas do colmo de bambu. Os resultados estatísticos de perda de massa mostraram que não houve diferença significativa entre os tratamentos utilizados e a testemunha, mas que as amostras tratadas com óleo residual tiveram menor perda de massa, no entanto, recomenda-se que o tempo de ensaio em campo deva ser estendido em estudos futuros, para que se possa ter uma melhor conclusão a respeito desses resultados.

Impact on growth and yield of soybean plants after applying pyroligneous extract / Influência da aplicação de extrato pirolenhoso no crescimento e produtividade de plantas de soja

Darlan Einstein Livramento¹, Adriana de Oliveira Vilela², José Urbano Alves², Núbia Rangel Cândido², Karlane Oliveira Silva², Ronaldo César Rizzo Ciancie²

¹Universidade do Estado de Minas Gerais, Unidade Passos, Passos, Brasil; ²Rima Industrial, Belo Horizonte, Brasil (darlan.livramento@uemg.br; adn@rima.com.br; urb@rima.com.br; nrc@rima.com.br; ksa@rima.com.br; rcc@rima.com.br)

O extrato pirolenhoso é obtido através da pirólise da madeira, sendo sua composição formada por substâncias de diferentes classes de compostos orgânicos. Entre suas funções destaca-se agente esterilizante, redutor de pH, efeito quelante, antioxidante e indutor de resistência. Seu uso na agricultura ocorre a décadas, como melhoria da qualidade do solo, controle de pragas e doenças e como estimulante do crescimento de plantas. Sua combinação com fertilizantes também pode promover incrementos na produção. Dentro desse contexto o objetivo desse trabalho foi avaliar a aplicação de extrato pirolenhoso via foliar em plantas de soja (*Glycine max* (L.) Merr.), no estágio fenológico R1. O experimento de campo foi implantado em um delineamento em blocos casualizados (DBC) disposto em um esquema fatorial: quatro concentrações de pulverização: 0%, 0,5%, 1,0% e 3,0% e três variedades de soja. As avaliações realizadas foram de crescimento vegetativo: comprimento da parte aérea, comprimento de raízes e comprimento total realizado no momento da colheita e de crescimento reprodutivo: produção individual das plantas e produtividade. Os resultados obtidos demonstraram que houve diferença significativa ($p < 0,05$) na interação concentração e variedades. Houve efeito das concentrações de pulverização na variedade BÔNUS 8579 RSF IPRO, onde a aplicação a 1,0% promoveu maior comprimento em todas as características vegetativas avaliadas. Para a produtividade, independente da variedade, a concentração de pulverização a 1,0% apresentou maior efeito nessa característica. Na análise da variedade foi observado que a Desafio RR – 8473RSF, foi mais produtiva em relação as demais também na concentração de pulverização a 1,0%.

Assessing the volume of extraction and technique for harvesting *Lepidocaryum tenue* Mart. (Arecaceae) during the dry and flood periods of the Upper Itaya River Watershed, 2018-2019 / Evaluación del volumen de extracción y técnica de cosecha del irapay *Lepidocaryum tenue* Mart. (Arecaceae) en época de vaciante y creciente en la Cuenca Alta del río Itaya, 2018 - 2019

Adrian Alfredo Correa Huaman¹, Roger Isuiza Naro¹

¹Universidad Científica del Perú, Iquitos, Peru (adrian.ingcorre@gmail.com; profeta.inca2051@gmail.com)

Lepidocaryum tenue Mart. conocida en nuestra región como “irapay”, usado tradicionalmente por el poblador amazónico como material de construcción en los techos de las casas. Esta investigación se realizó para ampliar nuestros conocimientos sobre el rol de este recurso en la vida del poblador de la selva. Se evalúan los volúmenes de extracción y la técnica de cosecha del “irapay” *Lepidocaryum tenue* y se identifican las comunidades productoras del recurso en la cuenca alta del río Itaya; realizado entre los meses de agosto y noviembre del 2018, en época de vaciante. Para la obtención de datos, se realizaron encuestas semiestructuradas, fichas de registro y observación directa en campo. En el puerto Nuevo Cahuide, se ha registrado 850 cargas desembarcadas, equivalente a 283.334 plantas, procedente de la cuenca alta del río Itaya (comunidades categorizadas como productoras de materia prima), generando un ingreso promedio mensual de S/; 2.125.00 nuevos soles. Se ha encontrado, que solo el 60 % aplican técnicas de manejo sostenibles en la cosecha del Irapay, no se destruye la planta, y se cosecha generalmente 3 hojas por individuo. En conclusión la mayor cantidad de cargas de Irapay son extraídas de los manchales de la comunidad Villa Belén debido a que la distancia ha permitido que pocos puedan acceder a este recurso y se encuentren en mejores condiciones en relación a las otras comunidades (Aguas Blancas, Luz del Oriente y 28 de Enero).

Technological innovations for traceability of forest products in Latin America / Innovaciones tecnológicas para la trazabilidad de productos forestales en Latinoamérica

Natalia Ruiz-Guevara¹, Diego Delgado¹, Fernando Carrera¹, Mario Chacon¹, Miguel Cifuentes Jara¹

¹Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba, Costa Rica (natalia.ruiz@catie.ac.cr; ddelgado@catie.ac.cr; fcarrera@catie.ac.cr; mario.chacon@catie.ac.cr; miguel.cifuentes@catie.ac.cr)

La trazabilidad de productos de madera provenientes de bosques naturales, debe ser reforzada para reducir la ilegalidad y degradación de los bosques ligada a emisiones. El uso de tecnologías modernas puede ayudar a estos fines. Para identificar el potencial de innovaciones tecnológicas disponibles, se realizó una sistematización de experiencias de distintos países latinoamericanos. Se ha ensayado el uso de aplicaciones dispositivos móviles, códigos de respuesta rápida (QR), códigos de barras, censos forestales con chip, dispositivos de identificación por radiofrecuencia, polvo “Stardust” y análisis moleculares de ADN. Estas tecnologías, se integran con protocolos de monitoreo y uso de softwares de ordenamiento y procesamiento de datos, algunas veces vinculados a información geográfica y documentaria. Las aplicaciones para teléfonos móviles destacaron por su bajo costo, facilidad de difusión, compatibilidad con diversas funciones y sencillez de uso. Los códigos QR, ya sea impresos en documentos o en chips y etiquetas sobre productos forestales, destacan también por su bajo costo, capacidad para almacenar gran cantidad de información, facilidad de uso y compatibilidad de lectura a través de aplicaciones. Se recomienda la estandarización de los códigos de marcado e indicar información referente al área geográfica, permiso de aprovechamiento, especie forestal, año de cosecha y número de parcela de corta o árbol. Se recomienda el desarrollo de aplicaciones multiuso, para la cubicación de madera, identificación de especies comerciales, registro y control de la extracción y movilización de productos, lectura de dispositivos, entre otros. Se resaltan las experiencias de países como Brasil, Guatemala, Panamá y Surinam.

Assessment of herbicidal potentials of three botanicals leave extract on weed associated with maize field in Oyo State, Nigeria

Nkechinyere Isienyi^{1,2}, Ayodele Ipeaiyeda³, Joy Nwogwugwu¹

¹Forestry Research Institute of Nigeria, Ibadan, Nigeria; ²University of Ibadan, Ibadan, Nigeria; ³University of Ibadan, Ibadan, Nigeria, Ibadan, Nigeria (isiyeni.nc@frin.gov.ng; ayosade2003@yahoo.com; oluprinice120@yahoo.com)

Maize is a major staple food crop widely grown in Nigeria but its production is constrained by weed-interference. Bio-herbicides are effective and eco-friendly in managing-weeds in some crops, its efficacy on maize have not been adequately documented. Therefore, herbicidal potential of Botanicals (*Eucalyptus torrelliana* - Et, *Eucalyptus camaldulensis* - Ec and *Leuceanea leucocephala* - Ll) extract in maize field were investigated. The experiment was laid out in CRD (r=3). Phytochemicals (mg/g) of the botanicals were determined using standard-procedures. Phytotoxicity of Botanicals at 100%, 75%, 50%, 25% were assessed on maize (DTMA-Y-STR) seed-germination using distilled-water as control in the Laboratory. Data on Percentage-Seed-Germination-PSG (%) and Plumule-Length-PL (cm) were assessed. In field, treatments: 100%, 75%, 50%, 25%, 0% of Botanicals and paraquat (5mL/L) were applied before-sowing and five weeks-after-sowing (WAS). Plant-height-PH (cm) and Grain-yield-GY (g/pot) were assessed at intervals of two-weeks starting from 3-WAS. Relative-Important-Values-RIV were determined using standard-procedure. Data were analyzed using descriptive-statistics and ANOVA α 0.05. The Phytochemical contents in Ec were higher in Total-phenols (32.0), tannins (27.4) and saponins (20.2). The PSG of maize in Ll was higher, ranged from 100.0 \pm 0.6 in 25% to 100.0 \pm 1.2 in 75%. The PL was higher in Ll, ranged from 3.4 \pm 0.3 to 11.3 \pm 0.6. At 11-WAS, PH and GY both in Ec was significantly higher, ranged from 126.7 \pm 14.8 to 140.5 \pm 12.3, while GY ranged from 42.0 \pm 5.2 to 68.4 \pm 8.5. *Mariscus-alternifolius* had highest RIV of 48.7 at 3-WAS in Ec-25% and reduced to 18.9 in Ec-25% at 9-WAS. *Eucalyptus camaldulensis* extract reduced weeds in maize-field, and enhanced grain-yield.

Inventory on deciphering interiors of commercially important Indian trees using 3D electrical resistivity tomography (ERT)

Nikhitha Cu¹, Baragur N. Divakara¹, Mohan Karnat¹

¹Institute of Wood Science and Technology, Indian Council of Forestry Research and Education, Bengaluru, India (thoshitha.cu@gmail.com; bndisira@gmail.com; mohankarnat4@gmail.com)

Tree Tronic tomograms are one among the advanced non-destructive method aiding for tree inspection. This method gives high resolution with more precision in measuring the sapwood, heartwood, stress and decay in the living trees. Our study is to focus on the understanding of internal wood structural details using 3D images of Electrical Resistivity Tomography (ERT) of commercially important trees viz. *Dalbergia latifolia* Roxb. (Rosewood), *Santalum album* L. (Sandalwood), *Tectona grandis* L.f. (Teak) and *Pterocarpus santalinus* L.f. (Red sandalwood) of India. Initially, using ERT, the tree resistivity offered across the cross-sections of the stems at different heights from the ground were checked for the individual trees. The combined effect of moisture content in the sapwood and resistivity offered by heartwood gives a non-invasive 2D cross sectional images at each height with colour differentiation from blue (low resistance) to red (high resistance). In the healthy trees the concentric ring structure and the compactness of the wood at the center will offer maximum resistance and gradually decreases towards the bark. However, 2D images failed to give the overall scenario of the structural details at different heights of tree stem. Hence, the combination of 2D images of the individual trees was superimposed in the descending order with respect to the height measurements from the ground to give 3D images. The 3D imagery demonstrated in our study depicts the effective mode of representing the resistivity distributed along the stem to further differentiate the sapwood, heartwood, stress and decay in the standing tree.

Using dendrochronology to assess yearly fruit production of *Theobroma cacao* L. in the Western Brazilian Amazon region / Uso da Dendrocronologia para avaliar a produção anual de frutos da espécie *Theobroma cacao* L. na Amazônia Ocidental brasileira

João Santos¹, Neila Fernandes¹, Michelle Siebra¹, Maria Rosália Da Costa¹, Gleyciane Dos Santos¹, Moisés Lobão¹

¹Universidade Federal do Acre, Rio Branco, Brasil (jo89ro@gmail.com; neila.fernandes@hotmail.com; michelle14florestal@gmail.com; natureza.2@hotmail.com; annel8_5@hotmail.com; moiseslobao6@gmail.com)

A dendrocronologia é uma ciência que permite determinar a idade das árvores, e vários fenômenos naturais ocorridos durante a vida das árvores que ficam marcados em seus anéis de crescimento. Portanto, o objetivo desse trabalho foi analisar se os canais traumáticos existentes nos anéis de crescimento das árvores de *Theobroma cacao* são formados exclusivamente pelo pedúnculo desenvolvido para a nutrição dos seus frutos ou por outros tipos de traumas. Foram selecionadas aleatoriamente seis árvores em Dezembro de 2014, quando realizou-se injúrias na camada cambial do tronco em cada árvore a 1 metro acima do solo. Em Março de 2016 foram retiradas as amostras do lenho de forma não destrutiva em três pontos distintos: a- principal, b- 5 cm acima do principal e c- 5 cm abaixo do principal. Realizou-se o polimento desse material e com auxílio do estereoscópio (aumento 80x) foram obtidas fotos macroscópica na região radial do lenho: 1- próximo a casca, 2- região intermediária, 3- próximo a medula, para verificar os traumas presentes nas amostras. A reação dos tecidos caracterizou-se por camadas de células constituindo uma barreira química no tecido injuriado, diferindo do tecido formado nas regiões dos pedúnculos dos frutos caracterizado pela presença de canais gomíferos traumáticos, demonstrando que estes últimos são formados exclusivamente pelo pedúnculo do fruto. Diante do exposto pode-se inferir que a frequências do conjunto de canais traumáticos no lenho da árvore de *Theobroma cacao* possibilita estimar a produção anual de frutos das árvores através da análise de seus anéis de crescimento anuais.

C6a: THE ROLE OF FORESTS AND TREES IN THE NATURE-BASED SOLUTIONS DISCOURSE

Moving beyond the nature-based solutions discourse: introducing nature-based thinking

Thomas Randrup¹, Cecil Konijnendijk²

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²University of British Columbia, Vancouver, Canada (thomas.randrup@slu.se; cecil.konijnendijk@ubc.ca)

The European Commission (2015) coined a frequently used definition of Nature-based Solutions (NBS); NBS being about “application of knowledge about nature, being inspired and supported by nature, and maintaining and enhancing natural capital”. NBS may be a product of its times. In the 1980s ‘Sustainability’ was conceptualized with equal focus on environmental, economic and social considerations. Where Sustainability was a new paradigm in human relations with nature, NBS has an action focus. To date, NBS have primarily been considered as technical solutions (EEA, 2015). However, when implementing the SDG’s (UN, 2015), actions needs to extend beyond sustainability thinking as well as beyond the current NBS technical approach. The EC (2015) stated that “there is a need to develop a systemic approach that combines technical, business, finance, governance, regulatory and social innovation related to NBS...”. In line with this, we propose that the definition and scope of NBS are widened, to inspire a new Nature-based Thinking (NbT). We see NbT as an integrative way of

acknowledging sustainability thinking, using the categorization of ecosystem services, and adapting these into a framework of knowledge about, inspiration and support from nature in our efforts to maintain and enhance natural capital, e.g. in the shape of forests and trees. NbT applies cross-disciplinary thinking, organizational approaches towards working beyond 'silos', and engaging with others across disciplines and sectors. It systemically involves stakeholders and activates citizens. We believe that NbT is a promising approach to securing long-term solutions to contemporary societal challenges.

Urban Forestry: in the vanguard of delivering nature-based solutions to our increasingly multi-cultural urban futures

Alan Simson¹

¹Leeds Beckett University, Leeds, United Kingdom (a.simson@leedsbeckett.ac.uk)

Cities are the fastest growing habitats on the planet, but research has shown that the degradation of our ecosystems caused by this rapid expansion has not only adversely affected 'nature' but also negatively affected human well-being. The multiple benefits to human well-being provided by urban forestry are increasingly being recognized but, over recent years, a number of related design concepts have been promoted to assist decision-makers in the task of improving the relationship between expanding cities and the natural world. One of the most recent is the concept of Nature-Based Solutions (NBS). Supporters argue that to inform decision-makers, natural assets should be assigned a value - financial or otherwise. Such an approach sees nature as an 'object' or a 'product', to have, to protect or ultimately to lose. Urban Forestry on the other hand, whilst acknowledging that giving nature a value can have some benefits, tends to see nature as a 'process'. Nature and recombinant ecology are activities, and an integral part of the design and life of the city. This presentation will consider whether nature and nature-based solutions should be deemed a 'product' or a 'process'. What cannot be denied is that trees have become a symbol of hope and life in our cities, and this presentation will conclude by suggesting that urban forestry is in the vanguard of delivering NBS and reconciliation ecology, and thus must be incorporated into the design of our increasingly multi-cultural cities as a pre-requisite of their future viability, both for humans and the natural world.

Operationalizing nature based solutions through forests and trees

Vincent Gitz¹, Alexandre Meybeck²

¹CIFOR, Bogor, Indonesia; ²CIFOR, Rome, Italy (v.gitz@cgiar.org; a.meybeck@cgiar.org)

"Nature based solutions" (NBS) are being increasingly promoted to address climate change and other societal challenges. They are defined as actions that use ecosystems to help societies address a variety of environmental, social and economic challenges in sustainable ways. NBS are explicitly considered as alternatives to human made infrastructures and integrate conservation and protection of biodiversity as a basis or a goal. The purpose of this intervention is to examine how the concept applies to forests and trees, how it relates to some other concepts that are already effectively used in forestry and to propose an operational framework to provide NBS through forests and trees. Three main types of NBS have been identified: making better use of existing natural or protected ecosystems, developing sustainable management protocols and procedures for managed or restored ecosystems, and creating new ecosystems. However, most NBS projects relate more to conservation or to the creation of new ecosystems than to improving managed ones. Paradoxically, NBS, to promote the use of nature as solution to human issues, first needs to separate nature and human made. Managed ecosystems are already managed for a purpose, or several, making the integration of a new objective more complex. We propose here to consider NBS as a binding concept between ecosystem managers and other stakeholders, including policy makers: a simple alternative solution to human infrastructures to be implemented by ecosystem managers through options integrated in the broader perspective of sustainable forest management and landscape approaches, thanks to an appropriate enabling environment.

Nature-based solutions for everyone? A distributional and recognitional equity analysis

Lorien Nesbitt¹, Cecil Konijnendijk¹, Michael Meitner¹, Cynthia Girling¹, Stephen Sheppard¹

¹University of British Columbia, Vancouver, Canada (lorien.nesbitt@ubc.ca; cecil.konijnendijk@ubc.ca; mike.meitner@ubc.ca; cgirling@sala.ubc.ca; stephen.sheppard@ubc.ca)

Urban forests increasingly provide nature-based solutions (NBS) to create more liveable cities. Given the importance of NBS to urban residents, it is important to evaluate 1) the distributional equity of urban forests that form part of NBS, and 2) the recognitional equity of processes to define and implement NBS at the local level. This research examined the distributional equity of urban forests in 10 US cities. Urban forests were characterized three ways (mixed vegetation, woody vegetation, and public parks), to reflect the variable NBS associated with different types of urban vegetation. Data were analyzed using Spearman's correlations and spatial autoregressive models. The research also examined the key dimensions of recognitional equity in defining and planning for NBS via an analysis and synthesis of relevant literature. Strong positive associations were observed between urban forests, higher education and income across most cities. Negative correlations between racialized status and urban forests were observed but were weaker and less common. Park area was more equitably distributed than mixed and woody vegetation, although inequities existed across all cities and vegetation types. Four dimensions of recognitional equity emerged from the analysis that can inform how NBS are defined and operationalized at the local level. Cities are spaces in which the world's populations meet and co-create NBS. This reality provides opportunities for mutual learning and improved resilience but can also lead to inequity in our access to and governance of NBS. Our findings can stimulate strategies to foster equitable planning and implementation of NBS.

The fire, the storm, and the broom: nature based solutions to restore degraded ecosystems in Peri-urban protected areas

Fabio Salbitano¹, Cristiano Foderi¹, Carlo Urbinati², Fabrizio Furlani³

¹University of Florence, Firenze, Italy; ²Marche Polytechnic University, Ancona, Italy; ³Regione Marche, Pesaro, Italy (fabio.salbitano@unifi.it; cristiano.foderi@unifi.it; c.urbinati@staff.univpm.it; fabrizio.furlani@regione.marche.it)

On 7 August 2017, a wildfire affected 120 hectares of a cliff on the Adriatic Sea in the Nature Park San Bartolo, a protected area in the periurban fringe of the city of Pesaro (Marche, Italy) belonging to the European Natura 2000 network. The slopes of the cliff, no longer protected by the vegetation, were affected, at the end of March 2018, by dramatic erosion phenomena due to heavy storms causing drastic changes to ecosystems and landscape. The research concerned the process of evaluating the severity of disturbances and determining the best performing NBS to be used in such critical conditions. In parallel, we aimed to identify the perception and preferences of local communities towards the adoption of NBS. According to a discourses analysis and a preferences study, the *Spartium junceum* (weaver's broom) has been identified as a plant deeply felt as iconic for the Park, both by the locals and by the outsiders (e.g. tourists, city dwellers). Remote imageries sequencing was used to define the vulnerability index of the area so to prioritize the need for NBS applications. On the other hand, experimental trials on seeding and planting native species of shrubs (the broom, first of all), grasses, and trees were tested in order to design the best performing NBS solutions associated to soil bioengineering techniques. The results of the test served to implement the design of NBS for the whole area and became a key-communication tool for the community. The brooms bloomed again on the cliff.

C7a: DEVELOPING SUCCESSFUL BIOLOGICAL CONTROL PROGRAMS IN FOREST PLANTATIONS

Is classical biological control viable in large scale forest plantations?

Carlos Wilcken¹, Leonardo Rodrigues Barbosa², Luiz Alexandre Sá³, José Zanuncio⁴

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Embrapa Florestas, Colombo, Brazil; ³Embrapa Meio Ambiente, Jaguariuna, Brazil; ⁴Universidade Federal de Viçosa, Viçosa, Brazil (carlos.wilcken@unesp.br; leonardo.r.barbosa@embrapa.br; luiz.sa@embrapa.br; zanuncio@ufv.br)

The forest plantations (*Eucalyptus*, *Pinus*) have low biodiversity, increasing risks of pest outbreaks and difficulting biological control, mainly in *Eucalyptus* plantations due to short rotation (6-7 years). The last two decades had a substantial increase in the introduction of exotic pests, mainly to *Eucalyptus*. The strategy to manage these pests is only Classical Biological Control (CBC) with the introduction of specific parasitoids from Australia. In Brazil, the use of *Cleruchoidea noackae* x *Thaumastocoris peregrinus* in *Eucalyptus* and *Xenostigmus bifasciatus* x *Cinara atlantica* in *Pinus* had success and that of *Psyllaephagus bluteus* x *Glycaspis brimblecombei* success and *Anaphes nitens* x *Goniopteris platensis* (parasitism decreasing since 2012 in SP and Parana States) partial success. *Seliterichodes neseri* x *Leptocybe invasa* is under evaluation. The forest plantations have the advantages of receiving fewer spraying of chemical insecticides; maintenance of native forest in 25 to 30% of the total area in Brazil and understory, which promoting refuge areas; fast establishment of natural enemies in tropical and subtropical regions; few intense silvicultural procedures and better acceptance to CBC due to forest certifications systems. The main constraints are farmers without full information access on new exotic pests and to CBC programs; regulatory rules increasingly harder; slow parasitoid production in laboratory conditions; difficult field releasing in large areas; complicated logistic to shipping natural enemies in distant areas; lack of governmental programs and funds to implement them.

Biocontrol in practice: managing *Goniopteris platensis* in Portugal

Carlos Valente¹, Catarina Gonçalves¹, Manuel Rainha², Ana Reis³, Manuela Branco⁴

¹Instituto de Investigação da Floresta e Papel, Aveiro, Portugal; ²Navigator Forest Portugal, Valongo, Portugal; ³Altri Florestal, Olho Marinho, Portugal; ⁴Centro de Estudos Florestais, Lisboa, Portugal (carlos.valente@thenavigatorcompany.com; catarina.goncalves@thenavigatorcompany.com; manuel.rainha@gmail.com; ana.reis@altri.pt; mrbranco@isa.ulisboa.pt)

In Europe, Portugal is the country with the largest area planted with *Eucalyptus*. These plantations are the main source of raw material for pulp and paper production, one of the most important industries in the country. The Tasmanian blue gum, *Eucalyptus globulus*, is the forest species most planted in the Country, covering more than 0.8 million ha. This species is particularly susceptible to the attacks of the *Eucalyptus* snout Beetle, *Goniopteris platensis*, an Australian insect present in Portugal since 1995. Even though the populations of the Snout Beetle have been partially controlled by the Australian egg parasitoid *Anaphes nitens*, wood losses have accrued to about 1 million m³ per year. In order to reduce the Snout Beetle's impact, an integrated pest management programme has been implemented. The programme includes the development of classical biological control with Australian egg and larval parasitoids, the replacement of vulnerable eucalypts with more resistant or tolerant ones, and the use of insecticides. In the present work we describe this strategy and discuss its results.

Biocontrol in practice: managing *Sirex noctilio* in South Africa

Brett Hurley¹, Bernard Slippers²

¹Department of Zoology and Entomology, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa; ²Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute, Pretoria, (brett.hurley@fabi.up.ac.za; bernard.slippers@fabi.up.ac.za)

The woodwasp *Sirex noctilio* was first reported in South Africa in 1994. Since then this invasive insect has spread throughout the main pine growing regions of the country. Mortality of pine trees caused by infestations of *S. noctilio* have been severe, especially in the summer rainfall areas of the country. In response to these infestations, a management programme was initiated, with biological control using the parasitic nematode, *Deladenus siricidicola*, as the main control method. Initial low and varying parasitism levels using this nematode led to studies to examine the influence of environment and genetic diversity on the establishment and virulence of *D. siricidicola*. Inoculation trials and laboratory experiments indicate that the tree environment, particularly the moisture content and bluestain fungi present in the wood, indirectly influence parasitism levels by competing for the fungal food source of the nematodes. Development of molecular markers for the nematode has enabled comparison of populations within South Africa and between other countries, revealing a clonal population in South Africa. This has led to the collection and characterisation of *D. siricidicola* populations from around the world, comparing the virulence of these populations and investigating possibilities to increase fitness through hybridisation. Research is ongoing to further our understanding of factors influencing parasitism and use this information to optimize the biological control programme.

Biocontrol in practice: managing *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae) in Brazil

Leonardo Rodrigues Barbosa¹, Luciane Becchi², Luis Renato Junqueira³, José Zanuncio⁴, Carlos Frederico Wilcken²

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Departamento de Proteção Vegetal, Botucatu, Brasil; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ⁴Universidade Federal de Viçosa, Viçosa, Brasil (leonardo.r.barbosa@embrapa.br; luciane.becchi@hotmail.com; renato@ipef.br; zanuncio@ufv.br; cwilcken@fca.unesp.br)

Biological control is the main strategy to manage the bronze bug *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae) in Brazil. This important exotic pest has been introduced in Brazil, severely damaging eucalypt plantations. The bronze bug biological control program has been supported by studies including pest life table analyzes, impact of native natural enemies and using the exotic parasitoid *Cleruchoidea noackae* (Hymenoptera: Mymaridae). Laboratory studies indicated the specificity and efficiency of *C. noackae* to control bronze bug. After its first release in the field in 2012, the establishment of *C. noackae* has been found in several Brazilian states. In 2013, the area infested with *T. peregrinus* decreased compared to 2012, which was attributed to parasitoid efficiency in field. Otherwise, variations in bronze bug infested area from 2013 to 2018 may be related to non-establishment of this parasitoid in some regions and the impact of chemical control. The results obtained with the biological control program of the bronze bug in Brazil show the efficiency of *C. noackae* in adequate conditions. Instead of its results controlling the bronze bug, several issues need to be addressed to increase its efficiency and use. Which include: establishing facilities for mass rearing; periodic releases of this parasitoid in the same site; evaluation of impact by chemical and microbiological insecticides and maintaining of the parasitoid in forestry companies, research institutes and universities. The successive use of *C. noackae* and the answers to questions addressed will increase the beneficial effects of this parasitoid in integrated management of *T. peregrinus*.

Biological control as a key tool for pest management in Uruguayan forestry

Gonzalo Martínez¹ 

¹INIA, Tacuarembó, Uruguay (gmartinez@inia.org.uy)

Commercial tree plantations cover around a million ha in Uruguay, mostly with stands of eucalypt and pine trees. Uruguayan forestry was relatively free of serious health threats until the end of the XX century. Beginning in the 90's, both forestry area and international trade exhibited an exponential growth, soon followed by an increase of invasive insect records. More than half of the pests currently affecting Eucalyptus entered the country after 1995. The high percentage of plantation area currently under FSC and/or PEFC certification schemes (90%) restricted the use of pesticides and pushed the Uruguayan forestry to rely mainly on silvicultural and biological control to suppress insect pest outbreaks. However, there was almost no regulations regarding the use of biological control agents until the last decade, even when biological control for forest pests in the country can be traced back to the 1940s. Here, we present the state-of-the-art of biological control in Uruguayan commercial forestry. Currently, biological control with entomophagous or entomopathogenic organisms has been, or is currently being, implemented for eight insect pests. More than five parasitoid wasps and a nematode have been released and installed in the field. There are also at least two cases of adventive introduction of entomophagous organisms, simultaneously with the pest. Building capacity for biological control and improving the regulatory framework are key issues towards the success of biological control of forestry pests under the current pest scenario.

Ecology and behaviour of *Megarhyssa nortoni*, a parasitoid used as biological control agent against the invasive woodwasp *Sirex noctilio*

Deborah Fischbein¹, Andrés Martínez¹, Victoria Lantschner¹, José Villacide¹, Juan Corley¹

¹Grupo de Ecología de Poblaciones de Insectos, IFAB (CONICET- INTA EEA Bariloche), Bariloche, Argentina (deborah.fischbein@gmail.com; andmarv77@gmail.com; vlantschner@gmail.com; josevillacide@gmail.com; elmallin@gmail.com)

The introduction of parasitoids in classical biological control programs is a key management method deployed against exotic pests in long-lived crops such as plantation forestry. *Sirex noctilio* is a pest of cultivated pines, for which several parasitoids, including the wasp *Megarhyssa nortoni*, have been released in the invaded range. Here, we examine some aspects of *M. nortoni* that can help explain the parasitoid performance as biocontrol agent: (1) climate matching and the climatic factors that best explain current parasitoid distribution in the Southern Hemisphere; (2) interindividual and sex differences in flight performance, in addition to the cost of flight on longevity and; (3) host location ability as mediated by chemical cues while foraging for hosts. *Megarhyssa nortoni* established well in regions with temperate and cold climates as predicted. Particularly, parasitoid distribution constrains to regions with maximum temperature of the warmest month (< 32°C) and minimum temperature of the coldest month (> -21°C). Flight performance was gender-specific: females flew greater distances than males in flight mills and also lived longer. Also, flight did not impact on post-flight longevity for any sex. Females discriminated the odors of infested wood from those of healthy trees and some pine trees over other. In the context of classical biological control studies on established cases allow identifying key attributes. We show that climate matching is necessary to predict establishment success and that knowledge of sex-specific life-history strategies and on the infochemicals use to locate hosts is likely crucial for improving introduction and impact success.

The actual effect from stump treatment in a biological control programme to protect planted Norway spruce from *Heterobasidion* spp. root rot

Jonas Rönnerberg¹, Michelle Cleary¹, Mimmi Blomqvist¹

¹Swedish University of Agricultural Sciences, Alnarp, Sweden (jonas.ronnerberg@slu.se; michelle.cleary@slu.se; mimmi.blomqvist@slu.se)

Heterobasidion root rot causes tremendous economic loss to coniferous forests through reduced growth and quality all over the northern hemisphere. Climate change promotes spread of root rot and adds to the challenge to increase forest productivity. Control programs to reduce the effect from *Heterobasidion* species are needed and include treatment of stumps with various agents to block spore infection on the stumps following harvesting. In Sweden, automatized stump treatment including *Phlebiopsis gigantea* (Rotstop®S) has been practised at mechanized thinnings in a big scale control programme since the mid 1990's but up until now no follow up of the efficacy have been made. In a study in mid- and southern Sweden, stumps from 15 thinnings were sampled for presence of *P. gigantea* added to the stump surface at thinning and the subsequent spore infection levels of *Heterobasidion*. Preliminary results indicate insufficient coverage of stumps and also that some stumps may still become infected after being treated. This might be an effect of imperfect coverage or lack of active *P. gigantea* due to mishandling of the treatment agent. There is an obvious need for education and encouragement of contractors to increase the effect in practice and to show the economic benefits from the stump treatment. There will also be a future pedagogic challenge to explain to landowners why seemingly treated stands may still suffer from development of *Heterobasidion* root rot.

C7b: NEEDLE AND SHOOT DISEASES OF PINE

Population genomics of the forest pathogen *Dothistroma septosporum* reveal adaptations involving the dothistromin virulence factor

Rosie Bradshaw¹ , Andre Sim², Pranav Chettri², Pierre-Yves Dupont³, Yanan Guo³, Lukas Hunziker², Rebecca McDougal⁴, Lindsay Bulman⁵,

Shannon Ormond⁶, I. Kutay Ozturk², Ariska Van der Nest⁶, Arista Fourie⁶, David Wheeler⁷, Murray Cox², Irene Barnes⁶

¹BioProtection Research Centre, Massey University, Palmerston North, New Zealand; ²Massey University, Palmerston North, New Zealand; ³Institute of Environmental Science and Research, Christchurch, New Zealand; ⁴Scion, NZ Forest Research Institute Ltd, Rotorua, New Zealand; ⁵Scion, Rotorua, New Zealand; ⁶Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, South Africa; ⁷NSW Department of Primary Industries, Orange, Australia (r.e.bradshaw@massey.ac.nz; andre.sim@hotmail.com; pranav.chettri@agresearch.co.nz; pierre.dupont@esr.cri.nz; y.guo.1@massey.ac.nz; l.hunziker@massey.ac.nz; rebecca.mcdougal@scionresearch.com; llindsay.bulman@scionresearch.com; s.ormond@massey.ac.nz; kutayozturk@gmail.com; ariska.vandernest@fabi.up.ac.za; arista.fourie@fabi.up.ac.za; office@ngbs.co.nz; m.p.cox@massey.ac.nz; irene.barnes@fabi.up.ac.za)

Dothistroma needle blight is amongst the most serious diseases of pine trees. Epidemics have increased in the last 25 years, especially in the Northern Hemisphere, where associations have been made with changes in climate. The needle blight pathogen *Dothistroma septosporum* occurs world wide but most research into its molecular biology has been with Southern Hemisphere strains from populations with limited genetic diversity. The genome reference strain for the species, for which an in plantatrans criptome is also available, originates from New Zealand where the population of this species is virtually clonal following its introduction in the 1960s. Because of the worldwide significance of *D. septosporum*, we first compared the genome sequence of the New Zealand strain with genomes of 18 isolates from other parts of the world. There was substantial sequence variation within the species and a reciprocal chromosome translocation

found only in New Zealand and Australian isolates. Very high levels of the virulence factor dothistromin produced by the ALP3 isolate from Germany appeared to be associated with chromosome duplications. Secondly, we studied *D. septosporum* isolates collected over a 50 year period in New Zealand forests. Genome analyses revealed insights into the early introduction and diversification of these isolates. Phenotype analyses revealed surprising insights into dothistromin production and virulence that suggest adaptation of this introduced pathogen over 50 years. These studies highlight the importance of population genomics studies for understanding the molecular basis of virulence in forest pathogens, both for populations spread across different regions and those spread across time.

***Dothistroma* needle blight and the risk to jack pine in Alberta, Canada**

Tod Ramsfield¹, Colin Myrholm¹, Bradley Tomm¹

¹Canadian Forest Service, Edmonton, Canada (tod.ramsfield@canada.ca; colin.myrholm@canada.ca; bradley.tomm@canada.ca)

In Canada, *Dothistroma* needle blight is considered to be endemic and the disease has been recorded in the Forest Insect and Disease Survey of the Canadian Forest Service, and the Canadian Plant Disease Survey, since the 1960's. The disease has been recorded as "red skirt", "red band needle blight", "red banded disease" and "needle blight" in seven provinces on 15 different hosts, including jack pine (*Pinus banksiana*). The greatest impact of the disease has occurred in British Columbia on lodgepole pine (*Pinus contorta* var. *latifolia*). Recently, *Dothistroma septosporum* was observed infecting lodgepole pine at various locations in close proximity to jack pine in Alberta. As jack pine is a major plant component of the boreal forest, we are studying the interaction between *D. septosporum* and *P. banksiana* under controlled conditions as well as conducting field surveys. This talk will outline our progress to date in understanding the risk posed by *D. septosporum* to *P. banksiana* in Alberta.

Invasive pine pathogens in Baltics, Northern Europe

Rein Drenkhan¹, Marili Laas¹, Kristina Raitelaitye², Svetlana Markovskaja², Kalev Adamson¹

¹Estonian University of Life Sciences, Tartu, Estonia; ²Nature Research Centre, Vilnius, Lithuania (rein.drenkhan@emu.ee; marili.laas@student.emu.ee; kristina.raitelaityte@gmail.com; svetlana.markovskaja@gamtc.lt; kalev.adamson@emu.ee)

During the last decades, several invasive tree pathogens have arrived in the northern Europe, damaging forest and urban green space trees. Invasive species (e.g. *Lecanosticta acicola*, *Diplodia sapinea*) are considered to cause economic loss and be an important threat to biodiversity. Winter warmings have diminished earlier restrictions for the southern pathogens caused by earlier cold winters. In addition, increasing global trade, when biological material is moved from one geographical location to another, rises the risks involved in the international plant trade and climate change. Pine needle pathogen *L. acicola* has spread by anthropogenic activity into the Baltic countries as a new area for that pathogen, whereby another invasive pine pathogen *D. sapinea* has spread naturally from South to North and possibly on the wave of climate change. In northern Europe ascomycete fungus *L. acicola* was found for the first time in 2008 from Estonia on non-native *Pinus ponderosa* and in 2009 from Lithuania on *Pinus mugo*. Since that time, up to 2016, these pathogens were found only on non-native hosts. *Lecanosticta acicola* was for the first time in northern Europe recorded on native *Pinus sylvestris* in 2016. In total 204 isolations and 11 microsatellite markers were used to analyse the genetic diversity and population structure of *L. acicola* in Baltics. The populations of *L. acicola* in Baltics indicated high number of clones. Both mating types of *L. acicola* were found to be present indicating the growing potential of the pathogen's vitality in northern Europe and increasing risk to native hosts.

***Diplodia sapinea* outbreaks in Sweden. Climatic drivers and genetic diversity**

Jan Stenlid¹, Laura Brodde¹, Jonàs Oliva², Curt Almqvist³

¹Swedish University of Agricultural Sciences, Uppsala, Sweden; ²University of Lleida, Lleida, Spain; ³Forestry Research Institute of Sweden, Uppsala, Sweden (jan.stenlid@slu.se; laura.brodde@slu.se; jonas.oliva@pvcf.udl.cat; curt.almqvist@skogforsk.se)

Diplodia sapinea has recently spread northwards in Europe. In 2016 it caused a severe outbreak in central Sweden and during 2018, massive mortality was associated with *Diplodia* and drought in the island of Gotland. Several lines of investigations are conducted to understand the driving forces behind the epidemics. A) When studying the local weather conditions, outbreaks seem to be particularly associated with early summer droughts. B) We also studied if there are potential new lineages of the fungus. However, microsatellites do not reveal any genetic differentiation between Nordic and southern European populations of *Diplodia*, although there are specific clonal lineages that caused the Swedish outbreaks. C) Community studies using NGS technology have been performed to characterize any difference in the endophytic communities that may explain variation in host susceptibility. D) Investigations are also carried out to track the patterns of susceptibility in the pine host that can be attributed to heritable factors.

Genetic characterization and phylogenetic placement of *Lophodermella montivaga* Petrak and *Lophodermella concolor* (Dearn.) Darker causing needle cast in lodgepole pines in Colorado, USA

Jessa Ata^{1,2}, Kelly Burns³, Suzanne Marchetti⁴, James Worrall⁴, Jane Stewart¹

¹Colorado State University, Fort Collins, USA; ²University of the Philippines Los Baños, Los Baños, Philippines; ³USDA Forest Service, Golden, USA;

⁴USDA Forest Service, Gunnison, USA (jpata@colostate.edu; ksburns@fs.fed.us; sbmarchetti@fs.fed.us; jworrall@forestopathology.org; jane.stewart@colostate.edu)

Lophodermella montivaga and *L. concolor* within Rhytismataceae are common needle cast pathogens in lodgepole pine (*Pinus contorta*) in Colorado, USA. In recent years, severe disease has been observed in Gunnison National Forest (GNF), Colorado and there the disease has spread into new sites. Multiple needle pathogens occur in this region, therefore genetic information is important for efficient control and monitoring of these diseases. This study aims to establish a genetic background and improve understanding of the phylogenetic position of the pathogenic fungi causing *Lophodermella* needle cast. Symptomatic lodgepole pine needles from GNF were collected. Needle cast symptoms of trees infected with *L. montivaga* included brown coalesced longitudinal ridges along the needles, whereas *L. concolor*-infected needles had colorless hysterothecia turning pale pink at maturity. Morphological characteristics of both species matched previously described *L. montivaga* and *L. concolor*, both belonging to *Hypodermella* complex. Three loci were used for genetic characterization: internal transcribed spacer region and 5.8S ribosomal RNA (ITS), large subunit ribosomal nucleic acid (LSU), and translation elongation factor (EF1-a). All isolates of *L. montivaga* and *L. concolor* formed one well-supported clade at the ITS region distinctly delimited from a closely related species, *Lophodermella arcuata*. However, *L. concolor* isolates formed a well-supported sub-cluster separated from the *Lophodermella* group. Similar phylogenetic pattern was also observed at the EF1-a and LSU loci. This warrants further investigation of the taxonomic and phylogenetic relationships of Rhytismataceae species using molecular-based techniques. Results of the study will be useful for conifer needle disease monitoring and assessment, and future molecular studies.

News from *Dothistroma* and *Lecanosticta* needle blights in Switzerland

Ludwig Beenken¹

¹Swiss Federal Institute for Forest, Snow and Landscape WSL, Forest health and biotic interactions, Swiss Forest Protection, Birmensdorf, Switzerland (ludwig.beenken@wsl.ch)

Fungal pine needle blights are dreaded diseases in plantations and natural forests worldwide. *Dothistroma septosporum* and *D. pini*, cause Dothistroma needle blight (DNB) and *Lecanosticta acicola* the brown spot needle blight (BSNB) of pine trees. *Dothistroma septosporum* can infect also other conifers like Norway spruce (*Picea abies*). In Switzerland, first reports of DNB date from 1989 and of BSNB from 1995. The causing pathogens are quarantine pest organisms that are monitored in Switzerland since 2009. Both diseases occurred first in urban habitats. Since 2013, *D. septosporum* was found on several pine species (*P. sylvestris*, *P. mugo* and *P. nigra*) in native and planted forests. Since 2016, *L. acicola* was detected on mountain pines in bogs. We investigate six forest plots in Switzerland in 2018, to estimate the effects of DNB and BSNB on pine and spruce trees. Damages on *P. sylvestris*, respectively, *P. mugo* caused by *D. septosporum* were found in five plots. They were often overshadowed by damages caused by other needle pathogens like *Lophodermella conjuncta*. *Dothistroma septosporum* infected a few needles of five spruce trees in four of these plots. In the remaining plot, DNB was lacking but *L. acicola* caused heavy damages on *P. mugo*. Additionally, we analyzed the mating types of both fungi in order to test whether they reproduce sexually. We found two mating types of *D. septosporum* but only one of *L. acicola*. Consequently, *D. septosporum* can also reproduce sexually and the reproduction of *L. acicola* is solely asexual in Switzerland.

Is the seed trade a significant pathway for the global dissemination of foliar pathogens like *Dothistroma septosporum*, causal agent of dothistroma needle blight?

Katherine Tubby¹, Shelagh McCartan¹, Martin Mullett²

¹Forest Research, Farnham, United Kingdom; ²Department of Forest Protection and Wildlife Management Mendel University, Brno, Czech Republic (kvtubby@gmail.com; shelagh.mccartan@forestry.gsi.gov.uk; martinmullett@hotmail.com)

The international plant trade is a conduit for the accidental movement of many invasive pests and pathogens between and within countries. Such anthropogenic dispersal has contributed significantly to recent range expansion of *Dothistroma septosporum* and *D. pini*, causes of dothistroma needle blight. In contrast seeds are considered to pose a lower biosecurity risk for pathogen spread than live plants. However, importation of *Pinus contorta* var *latifolia* seeds from North America to Britain in the mid-1900s, and similarities found in *D. septosporum* populations in Britain and British Columbia suggest that seed could be a significant pathway. Dothistroma has not been isolated in or on seeds, but poorly cleaned seed lots contain needle fragments potentially infected with the pathogen. Heat treatment routinely applied to open up cones and extract conifer seeds might counter this risk. Our case study investigated whether seed treatments can be manipulated to reduce risks of Dothistroma transmission without affecting seed viability. Dothistroma infected *Pinus* spp. needles were (a) incubated with cones undergoing seed extraction in a commercial facility and (b) exposed to temperatures up to 70 °C in incubators; Dothistroma and seed viability were assessed after 48 hours. The 50 °C maximum temperature reached during commercial processing did not reduce seed or pathogen viability. In laboratory tests, however, *D. septosporum* could not survive ≥ 63.5 °C, whereas seed viability was not impaired. We conclude that commercial seed preparation conditions could allow transmission of pathogens such as Dothistroma, but additional elevated heat seed treatments could reduce this risk without damage to *Pinus* seeds.

Epidemiology and control of red needle cast of pine in New Zealand

Stuart Fraser¹, Carol Rolando¹, Mireia Gomez-Gallego¹, Ralf Gommers¹, Ian Hood¹, Lindsay Bulman¹, Nari Williams¹

¹Scion, Rotorua, New Zealand (stuart.fraser@scionresearch.com; carol.rolando@scionresearch.com; mireia.gomez@scionresearch.com; ralf.gommers@scionresearch.com; ian.hood@scionresearch.com; lindsay.bulman@scionresearch.com; nari.williams@scionresearch.com)

Phytophthora pluvialis the cause of red needle cast (RNC), a disease of *Pinus radiata* in New Zealand. Results from artificial inoculation experiments indicate that copper, applied as cuprous oxide, is effective in reducing disease severity. As well as identifying effective active ingredients, development of a control programme for RNC also requires a fundamental understanding of its epidemiology. This information will assist in the identification of the optimal time of year to spray and also aid disease forecasting to support decisions on whether to spray or not. Research has shown that disease expression, release of inoculum, and infection all peak during winter and spring, between June and November. Observations imply that *P. pluvialis* has a polycyclic life cycle that leads to an epidemic scenario in years when prolonged favourable conditions occur. They thus suggest that to control the disease a fungicide treatment should be applied in autumn to destroy inoculum at the beginning of the infection period, and possibly again several months later to maintain low inoculum build-up. An operational-scale copper spray trial was initiated at two sites in a mature stand of *P. radiata*. At each site, three blocks were treated with 0.84 kg ha⁻¹ cuprous oxide (operational standard rate for control of dothistroma needle blight) in February 2017, while three blocks were left unsprayed. Incidence and severity of RNC at disease peak in September 2017 was significantly lower in the sprayed blocks. An update will also be given on subsequent operational-scale spray trials.

Genomics of adaptation to climate change in the *Pine-Dothistroma* pathosystem

Richard Hamelin^{1,2}, Renate Heinzmann¹, Barbara Wong², Sally Aitken¹, Sam Yeaman³, Kishan Sambaraju⁴, Philippe Tanguay⁴, Mengmeng Lu³, Dragana Vidakovic¹, Nick Ukrainetz⁵

¹The University of British Columbia, Vancouver, Canada; ²Université Laval, Québec, Canada; ³University of Calgary, Calgary, Canada; ⁴Natural Resources Canada, Québec City, Canada; ⁵Ministry of Forests, Lands and Natural Resource Operations, Victoria, Canada (richard.hamelin@ubc.ca; renate.heinzmann@ubc.ca; barb.wong@ubc.ca; sally.aitken@ubc.ca; samuel.yeaman@ucalgary.ca; kishan.sambaraju@canada.ca; philippe.tanguay@canada.ca; mengmeng.lu@ucalgary.ca; dragana@vidakovic.com; nicholas.ukrainetz@gov.bc.ca)

Climate fluctuation can be an important factor in modifying patterns of fungal phenology. For plant pathogens, a layer of complexity is added because climate change will also affect the host and its interaction with biotic stress agents, potentially resulting in changes in disease impact. *Dothistroma septosporum* is a fungal pathogen that causes Dothistroma needle blight (DNB), which results in early defoliation, growth losses, and regeneration failure in pines globally. The incidence of this disease has been increasing in severity on lodgepole pine in western Canada and this has been directly related to climate change. In the CoAdapTree project, we are studying the pine-Dothistroma-climate interactions. In artificial inoculations, RNA-Seq analysis of gene expression showed that resistant pines had DNB strain-specific up-regulation of over 900 genes and stronger gene expression response to DNB than susceptible trees. To conduct a genome-wide association study forty populations from across the range of *P. contorta*, *P. banksiana* and *P. contorta*, *P. banksiana* were inoculated with DNB. There was a clear negative correlation between latitude and susceptibility, suggesting that moving southern genotypes (more susceptible to DNB) north could

have some major phytosanitary implications. The genomes of nearly 300 DNB isolates from North America and Europe have been sequenced to characterize adaptation to climate and hosts in the pathogen. We propose to use this data to develop climate-based seed-transfer policy and provide tree breeding strategies and genomic breeding tools.

C7c: SUSTAINABLE BIOMASS FOR A GREENER FUTURE

Assessing impacts of European Union demand for bioenergy on US forests using national forest inventory data

Houston Sudekum¹ ; Francisco Aguilar², Ashkan Mirzaee¹, Ram Dahal¹, Ronald McGarvey¹, Karen Abt³

¹University of Missouri, Columbia, USA; ²Swedish University of Agricultural Sciences, Umea, Sweden; ³USDA Forest Service, Durham, USA

(hjs5td@mail.missouri.edu; francisco.aguilar@slu.se; amtwc@mail.missouri.edu; dahalr@missouri.edu; mcgarveyr@missouri.edu; kabt@fs.fed.us)

Global wood pellet production grew from 1.7 million tons in the year 2000, to 29.7 million tons in 2015. U.S. mills established over this period account for a large share of new supply triggered by renewable energy targets set by the European Union (EU). There is concern over the potential effects of exponential growth in wood pellet supply on US forests. We offer a systematic quantitative analysis to assess the effects of wood pellet production on forest conditions within wood pellet mill procurement areas. We rely on plot-level information from the US Forest Inventory and Analysis (FIA) database to estimate changes in forest conditions (e.g. trees per hectare, carbon in trees and soil, volume) between inventory years 2000, 2005, 2010, and 2015 across 31 US States. Using spatial analysis and panel-regression for a sample of 7495 plots we discern EU renewable energy policy effects associated with export-oriented pellet mill size and location. Propensity score matching was used as a re-sampling technique to select a subset of FIA plots to control for the non-random process of pellet mill siting. Panel regression models controlled for various anthropogenic and natural factors measure the net impact of wood pellet production on average plot-level forest conditions over time. Preliminary results suggest that forest conditions within wood pellet procurement areas saw decreases in standing dead trees per hectare, and increases in carbon, volume and removal trees per hectare Our findings point to prospects and challenges to sustainable wood pellet production.

Estimating availability of forest biomass resources in the whole of Japan

Kazuhiro Aruga¹ ; Yusuke Matsuoka¹, Takahisa Yamamoto¹, Battuvshin Biligt², Hiroaki Shirasawa³

¹Utsunomiya University, Utsunomiya, Japan; ²Tokyo University of Agriculture and Technology, Tokyo, Japan; ³Forestry and Forest Products Research

Institute, Tsukuba, Japan (aruga@cc.utsunomiya-u.ac.jp; mc196952@cc.utsunomiya-u.ac.jp; ma178506@cc.utsunomiya-u.ac.jp; biligt.blizz@gmail.com;

shirasawa@ffpri.affrc.go.jp)

We developed the model to estimate availability of forest biomass resources from each forestry operation site with appropriate forest operation system according to road networks and geography using GIS data processed by MATLAB in Tochigi prefecture, Japan (Yamamoto et al. online first, IJFE). We are expanding the model to the whole of Japan by obtaining GIS data for private and communal forests from other 46 prefectures and for national forests from the Japan Forestry Agency. The estimated availability will be verified with the statistical data compiled by the Japan Forestry Agency obtained from each prefecture. Then, the model will be used to project future availability of each forestry operation site for sustainable forest management. Forest GIS data were developed separately for national forests by the Forestry Agency, and for private and communal forests by each prefecture. This is the first study of this kind combining private and communal forests with national forests, in the whole of Japan. Furthermore, existing studies developed similar models, but their units of forests were defined using 1 km² mesh or municipality. MATLAB could be used to make estimations for the whole of Japan, within a reasonable timeframe, defining units as forestry operation sites.

Implementation of voluntary sustainability criteria for forest biomass: a case study from Denmark 2016-2018

Søren Larsen^{1,2,3}, Niclas Scott Bentsen³, Inge Stupak³

¹Danish Energy, Copenhagen, Denmark; ²Ørsted A/S Gentofte Denmark; ³University of Copenhagen, Department of Geosciences and Natural Resource Management, Frederiksberg C, Denmark (sla@danskenergi.dk; nb@ign.ku.dk; ism@ign.ku.dk)

During the last few decades there has been a substantial growth in forest biomass consumption for the Danish heat and electricity sector, but questions about its sustainability have been raised. Since 2016 Danish energy companies have addressed sustainability issues through a voluntary industry-initiated agreement. This agreement introduces risk-based sustainability criteria on forest biomass sourcing. We have analysed the Danish energy sector's biomass sourcing, compliance and deployment of sustainability criteria during 2016-2018 based on public sustainability reports. Additionally, we analysed supply chain levels and feedstock use of Danish medium to large energy companies. Results show that 57 % and 70 % of the biomass sourcing was in compliance with the sustainability criteria in 2016 and 2017 respectively with even larger volumes expected for 2018. Most of the volume is sourced by only a few large companies and wood pellets are sourced in much larger volumes than wood chips. Danish energy companies source woody biomass from different supply chain levels: local to global, but especially from the regional supply chain around the Baltic Sea. The Danish voluntary sustainability criteria have been effective in governing biomass sourcing. Overall, the Danish experience shows it is possible within a short time frame to implement sustainability governance with risk-based criteria on multiple energy companies sourcing solid biomass in the megaton scale. A similar approach has been chosen by the EU and will be implemented from 2021.

Allocation and land use in LCA of forestry: case study on beech wood thinning

Lars G. F. Tellnes¹, Ellen Soldal¹, Fredrik Moltu Johnsen¹

¹Ostfold Research, Fredrikstad, Norway (lars@ostfoldforskning.no; ellen@ostfoldforskning.no; fredrik@ostfoldforskning.no)

Beech wood is currently an underutilized resource in Eastern France, and wood thinning in this region is not extensively practiced due to low economic returns. The function of thinning is to clear enough space for some trees to grow large in the early stages of a forest stand. Without thinning, both the yield and quality of beech saw wood will be lower. From a Life cycle assessment (LCA) perspective, allocation between the forest products thinning wood and wood from final harvest is therefore of interest. Valorization of beech wood thinning for feed purpose is under development and it can substitute feed sources with known environmental controversies such as soy protein. In the LCA modelling, the environmental impact category of land use is assumed to be highly relevant for the stakeholders. The objective of this work was to introduce economic allocation and land use characterisation in LCA modelling for the case of beech wood chips from thinning, and to show the importance for the results. The results shows that land use decrease substantially for chips from thinning with economic allocation and specific land occupation data. The results also show that climate change is more important than land use in the previously recommended method

in Europe, but with the new method the opposite is the case. Land use is an LCA impact category which may see increased attention in the near future. Based on the case and the models used, land use appears to be important to include in forestry LCA studies.

Evaluating country-level forest area and biomass estimates using NFI data: a Portuguese application

Susana Barreiro^{1,2}, Margarida Tomé³, João Rua³, Francisco Goes⁴, José Uva⁵, Mart-Jan Schelhaas², Gert-Jan Nabuurs²

¹Universidade de Lisboa, Instituto Superior de Agronomia, Centro de Estudos Florestais, Lisbon, Portugal; ²Forest Ecology and Forest Management Group, Wageningen University and Research, Wageningen, Netherlands; ³Universidade de Lisboa, Instituto Superior de Agronomia, Centro de Estudos Florestais, Lisboa, Portugal; ⁴CELPA – Associação da Indústria Papeleira, Lisboa, Portugal; ⁵ICNF - Instituto da Conservação da Natureza e das Florestas, Lisboa, Portugal (smb@isa.ulisboa.pt; magatome@isa.ulisboa.pt; jcpua@isa.ulisboa.pt; francisco.goes@celpa.pt; jose.uva@icnf.pt; martjan.schelhaas@wur.nl; gert-jan.nabuurs@wur.nl)

The losses caused by severe forest fires in conjunction with the increase of wood demand for the pulp and paper industries led to the development of a scenario driven regional forest simulator (StandsSIM.sd). StandsSIM.sd is NFI-based and was designed to simulate forest condition under different scenarios of demand, fire occurrence, land-use changes and changes in management. The NFI4 (1995-1997) data was used to initialize the simulation and predict the evolution of forest area, standing volume, biomass and carbon stock for a period of 20 years. A business-as-usual scenario based on official statistics reflecting market demands, burnt areas and land-use-changes was prepared for the period of 1997-2015. The scenario was completed with a description of a general forest management approach prepared based on discussions with stakeholders. Simulations were run and the results for forest area, standing volume, biomass and carbon stock by age classes/stand structure estimates were compared with NFI5 and NFI6 published values. Preliminary validation results showed that StandsSIM.sd' predictions were reliable except for forest area. The area of uneven-aged stands was being under-estimated because when even-aged stands were converted after final felling and no approach to generate uneven-aged stands had been integrated in the tool. To tackle this limitation a transition algorithm was developed. This new module is responsible for converting even-aged to uneven-aged stands through the simulation of events such as sanitary thinning or incomplete final harvest.

Restoring land and growing renewable energy: opportunities, challenges and the way forward

Himlal Baral¹, Syed Ajjur Rahman¹, Wanggi Jaung²

¹Center for International Forestry Research, Bogor, Indonesia; ²National University of Singapore, Singapore, Singapore (h.baral@cgiar.org; s.rahman@cgiar.org; w.jaung@cgiar.org)

Primary energy demand in Indonesia has rapidly been increased, i.e. 43% between 2005 and 2016, while domestic energy supply failed to fulfill this needs and leading to the reliance on energy imports. Meanwhile, vast area of degraded lands in Indonesia have also created an opportunity for the biofuel production, fulfilling energy demand, as well as restoring land with environmental and socio-economic benefits. This paper provides an overview of identified potential and challenges associated with biofuel production from degraded land in Indonesia. Our preliminary findings highlighted that some biofuel species in Indonesia is suitable to grow in a degraded land and potentially restore the land that may not be suitable for common agricultural production and/or reforestation. The initial finding also shows that culturally familiar species and stable markets are favorable terms of biofuel species selection for the landowners. Supportive agricultural extension service such as knowledge and technology for honey production can providing an added value in this concept, in addition to social (e.g. strengthening social solidarity, employment opportunities) and environmental (e.g. carbon storage, soil moisture, erosion control, biodiversity) benefits. Meanwhile, to create this overall initiative to be successful, a supportive measure from the policy makers is needed. Further research on capacity of biofuel species to restore degraded lands in different biophysical profiles, analysis on biofuel production feedstocks and potential co-benefits, viable business model, and stable market are necessary to maximize benefit from biofuel production and to restore degraded lands in Indonesia.

Technologies to generate energy from forest biomass / Tecnologias de aproveitamento energético a partir da biomassa florestal

Ana Paula de Souza Silva^{1,2}, Suani Teixeira Coelho¹

¹Grupo de Pesquisa em Bioenergia, Instituto de Energia e Ambiente, Universidade de São Paulo, São Paulo, Brasil; ²Instituto de Pesquisas Tecnológicas do estado de São Paulo, São Paulo, Brasil (aanapaula2010@gmail.com; suani@iee.usp.br)

A biomassa florestal pode ser convertida em combustíveis sólidos, líquidos ou gasosos que poderão ser utilizados para gerar energia em diferentes formas como calor, vapor, eletricidade e biocombustíveis. Essa conversão é feita por meio de processos termoquímicos, bioquímicos e mecânicos. Combustão, gaseificação, pirólise e liquefação são exemplos de processos termoquímicos. Dentre os processos bioquímicos tem a fermentação, para converter açúcar em etanol, e a digestão anaeróbica para produção de biogás. Os processos mecânicos não são exatamente um processo de conversão, uma vez que eles não alteram o estado físico da biomassa. Exemplos de processos mecânicos são a compactação de resíduos na forma de pellets, moagem ou picagem de biomassa e extração mecânica do óleo em filtro prensa (BRIDGWATER, 2006). Esse trabalho teve como objetivo avaliar o estágio de maturidade de algumas tecnologias para aproveitamento energético ou para a produção de biocombustíveis a partir da biomassa florestal. São elas: compactação de biomassa florestal para produção de pellets; pirólise rápida e gaseificação. Para o levantamento do panorama teórico das tecnologias selecionadas nesse estudo foram consideradas bases de dados disponíveis no portal de periódicos da Capes; banco de dados de teses e dissertações de universidades nacionais e internacionais; bancos de dados bibliográficos das principais instituições de pesquisa e ensino superior nacionais e internacionais, entre outros. Resultados preliminares mostram que as tecnologias estudadas possuem potencial para gerar energia e biocombustíveis a partir da biomassa florestal e, também de seus resíduos em diferentes escalas e, as tecnologias se encontram em diferentes estágios de maturidade tecnológica.

Components of assessing the effectiveness of a forest biomass system for generating bioenergy / Componentes de avaliação da eficácia de um sistema de biomassa florestal para geração de Bioenergia

Marcelo Langer¹, Eloise Prates Gorte², Rudson Silva Oliveira¹, Dimas Agostinho da Silva¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Universidade Estadual do Centro-Oeste, Irati, Brasil (marcelolanger@ufpr.br; eloiseprates@yahoo.com.br; rudsonoliveirapbs@gmail.com; dimas.agostinho.silva@gmail.com)

A biomassa é fonte de matéria-prima para geração de biocombustíveis e em 2014, foi responsável por 10% da oferta energética mundial (IEA,2016). O setor de geração de energia primária brasileira é o de menor emissão de carbono no mundo (IEA,2013). No Brasil, em 2017, a biomassa oriunda da lenha e carvão foi responsável por cerca de 8% do total produzido. Na indústria brasileira, o consumo de energia a partir da lenha foi de 8,6% (EPE, 2018). Em uma empresa de

base florestal, a produção de biomassa, utiliza galhos, madeiras diversas, árvores quebradas ou mortas, materiais de limpeza de talhões e servem para a geração de energia térmica e vapor para geração de energia elétrica. Em uma empresa florestal brasileira, apesar de serem necessárias 5 toneladas de biomassa para suprir o potencial energético gerado por 1 tonelada de óleo BPF, o seu custo é 6,2 vezes menor (de R\$386,00 contra R\$2400,00 para a mesma geração de energia). Esta pesquisa analisou a influência da mistura de quatro diferentes fontes de biomassa florestal: biomassa da limpeza de áreas de pinus e eucaliptos; cavacos de madeira do mercado local e cascas oriundas do processo de descascamento de toras para celulose, para geração de bioenergia. Foram testadas diferentes misturas destas quatro fontes de biomassa e realizadas análises química imediata e elementar e o poder calorífico inferior de cada composição. Os resultados estatísticos não apresentaram diferenças significativas para as diferentes composições de produtos, o que demonstra a viabilidade do atual sistema de geração de bioenergia.

C7d: WILL ACTIVE RESTORATION OF SECONDARY AND DEGRADED FORESTS (SDFS) HELP TO ADDRESS SUSTAINABLY THE GAP BETWEEN WOOD DEMAND AND SUPPLY?

Phenomenological modelling scenario of future wood demand by 2050

Jean-Marc Roda^{1,2}, Ainuddin Nuruddin², Chu Lee Ong², Omar Hishamudin², Philippe Guizol³

¹CIRAD, Serdang, Malaysia; ²Universiti Putra Malaysia, Serdang, Malaysia; ³CIRAD, Montpellier, France (roda@cirad.fr; a_ainuddin@yahoo.com; candice.ocl@gmail.com; omarhishamudin@gmail.com; philippe.guizol@cirad.fr)

For the last 5 decades, the main factors of the world timber demand are the construction dynamics, the demographics, the user's income, the price and availability of wood products relatively to alternative materials, and regulations and policies. We measured the long run demand elasticities the major regions of the world, and built phenomenological models which can predict the wood demand up to 2050 with known errors. For the prediction of the wood demand until 2050, factors such as GDP and prices which would only rely on arbitrary scenarios, are discarded, and we measure how much of the variability of the wood demand can be predicted from phenomenological and robust variables such as demographic factors. We find that wood demands of the tropical regions (Latin-America, Sub-saharan Africa, and Tropical Asia) can be reliably modelled with good prediction errors below $\pm 13\%$ to $\pm 24\%$. Conversely, the demand models of the temperate regions where the wood dynamics are more linked with the discarded variables, are less precise and their prediction errors escalate up to $\pm 60\%$. We find that, by 2050, tropical regions will demand between 800 and 1100 million m³ of wood per year, with 95% of confidence. Until now most of the demand by tropical regions was met by a local production, totalling around 500 million m³ per year in 2016. Our findings raises the question of how, by 2050, tropical forests would be able to sustainably produce the double of what they produce today ?

Different contexts, same concerns? Wood gap and forest restoration in Indonesia and Cameroon

Philippe Guizol^{1,2}, Liboum Mbonayem², Abdon Awono², Jean Marc Roda¹, Richard Eba 'a Atyi²

¹CIRAD, Montpellier, France; ²CIFOR, Yaoundé, Cameroon (philippe.guizol@cirad.fr; l.mbonayem@cgiar.org; a.awono@cgiar.org; roda@cirad.fr; r.atyi@cgiar.org)

The gap between demand and supply of sustainable wood, in countries rich forest with a poor governance, is one of the major causes of forest degradation. This phenomenon, which is combining with other major forest degradation causes as agriculture and fires, should not be overlooked as it results in dire deforestation. In Indonesia, uncontrolled development of wood industries, led to a growing wood demand disconnected with sustainable forest management capacity. This started in 70s with log exports development, followed by the plywood industry in the 80s', pulp and paper in the 90s' and the forest conversion to agro-plantations. Tree cover in permanent forest lands dropped from 113.1 million ha to 87.4 million ha, or by 23% in 34 years, from 1982 to 2016. In Cameroon, the growing demand for timber is accelerated by domestic market paired with the population growth above 2.5% per year. Domestic timber and firewood are sourced from poorly managed non-permanent and permanent forest. The rate of deforestation at the national level remains low (0.2 % per year), but deforestation is rapid around cities and along roads. Comparing the two countries, some similarities have been identified, 1) in each case wood gaps are filled by illegal practices, 2) there are miss-perceptions about sustainable wood supplies from forests, 3) governments are now planning forest restoration and 4) low wood prices are discouraging investment into forest plantations, secondary forest silviculture and forest restoration. Finally, we compare how, governments are addressing wood gap and forest restoration.

Can a tropical rainforest destroyed by wildfire and logging recover by rehabilitation with enrichment planting and assisted natural regeneration?

Jan Falck¹, David Alloysius², Yap Sau Wai³, Ulrik Ilstedt¹

¹Swedish University of Agricultural Sciences, Dept. of Forest Ecology and Management, Umea, Sweden; ²Yayasan Sabah, Tawau, Malaysia; ³Yayasan Sabah, Kota Kinabalu, Malaysia (jan.falck@slu.se; dalloysius@gmail.com; yapsauwai@gmail.com; ulrik.ilstedt@slu.se)

In a carbon emission and biodiversity perspective there is a great demand for rehabilitation of extensive parts of the tropical rainforest (TRF), degraded by repeated timber harvesting or wildfire. In such forest in Sabah, in the north of Borneo burned during the El Niño droughts in 1983-84, the Swedish company IKEA and Yayasan Sabah in 1998 started investing in a rehabilitation planting under mostly pioneer canopies, dominated by *Macaranga* species. Twenty years later an area of 10,600 ha has been planted with in total 90 tree species, mainly of the Dipterocarpaceae tree family and some wild fruit species. The more well-stocked land has got the treatment of Assisted Natural Regeneration (locally called "Liberation"). The planted area has been improved by "line planting" or "gap- cluster planting" with a density of between 200 and 400 seedlings per ha depending on land suitability for planting. Maintenance period for the planted seedlings has been up to 10 years. During the last 10 years several experiments and permanent plots has been established. The average survival after 10 years is between 20 and 50%, but remnant seed trees, have added new seedlings to most plots. Several of the planted species have already started producing seeds. The largest tree, a *Shorea leprosula*, planted 1998, had a diameter of 64 cm at age of 20 years. The survival and growth rates vary because of temporal variations, in rainfall and wildlife predation and variations in light at the forest floor, soil conditions and genetics.

Modeling forest restoration potential in Indonesia with G4M

Dmitry Schepaschenko¹, Andrey Krasovskii¹, Stephan A. Pietsch¹, Johannes Pirker^{1,2}, Anton Platov¹, Betha Lusiana³, Subekti Rahayu³, Sidiq Pambudi³, Andree Ekadinata³, Ping Yowargana¹, Esther Boere¹, Florian Kraxner¹

¹International Institute for Applied Systems Analysis, Laxenburg, Austria; ²KU Leuven, Catholic University Leuven, Leuven, Belgium; ³World Agroforestry Center, Bogor, Indonesia (schepd@iiasa.ac.at; krasov@iiasa.ac.at; pietsch@iiasa.ac.at; pirker@iiasa.ac.at; platov@iiasa.ac.at; b.lusiana@cgiar.org; s.rahayu@cgiar.org; s.pambudi@cgiar.org; a.ekadinata@cgiar.org; yowargan@iiasa.ac.at; boere@iiasa.ac.at; kraxner@iiasa.ac.at)

Indonesia experiences significant economic growth based on natural and planted forests. To sustainably meet the growing demand of forest products, an understanding of the economic and environmental contributions of current and future forest cover is pivotal. The Global Forestry Model (G4M, www.iiasa.ac.at/g4m [http://www.iiasa.ac.at/g4m]) is a biophysical model that predicts carbon stock, net primary productivity, increment, potential harvest and optimizes rotation time with a resolution of 1, 10 or 50 km. The model uses monthly weather records or projections and soil information as input and considers various management options. As part of the Restore+ project (http://www.restoreplus.org/ [http://www.restoreplus.org/]), a regionalized version of the G4M was developed for Indonesia in order to simulate forest productivity. The model considered plantations for timber (represented by *Tectona grandis*, *Paraserianthes falcataria* and *Swietenia macrophylla*); plantations for pulp&paper (*Acacia mangium*, *Eucalyptus pellita* and *E. grandis*); non-assisted and assisted restoration on dryland (secondary forest); and assisted restoration on peatland (*Dyera polyphylla*, *Shorea balangeran* and *Coffea liberica*). The model was calibrated based on observations found in the literature and results of a plot-based bio-geochemical model (BGC-MAN, www.iiasa.ac.at/BGC-MAN [http://www.iiasa.ac.at/BGC-MAN]). Using the spatially-explicit economic model GLOBIOM, estimates of G4M on current and potential locations of forest production are evaluated against competing land uses of the AFOLU-sector with the aim to satisfy a growing world demand. G4M estimates on forest carbon stocks are combined with emissions from the AFOLU-sector, enabling GLOBIOM to analyze to what extent and under what forestry-related policies Indonesia is able to meet its environmental targets.

Management potential of secondary tropical cloud forests: implications for Mexico

Tarin Toledo-Aceves¹, Manuel Guariguata², Luciana Porter-Bolland³, Sven Günter⁴

¹Instituto de Ecología A.C., Xalapa, Veracruz, Mexico; ²CIFOR, Lima, Peru; ³Instituto de Ecología A.C., Xalapa, Veracruz, Mexico; ⁴Institute of International Forestry and Forest Economics, Hamburg, Germany (tarin.toledo@inecol.mx; m.guariguata@cgiar.org; luciana.porter@inecol.mx; sven.guenter@thuenen.de)

Tropical Montane Cloud Forests are of high strategic value for sustainable development due to their exceptional diversity and their role in the provision of ecosystem services; however, they are threatened by deforestation, climate change and overharvesting. Secondary cloud forest (SCF), a dominant component in cloud forest landscapes, could contribute to the provision of timber and ecosystem services. However, there is limited information regarding their potential for sustainable management via selective logging by smallholders. We both summarize the research and identify knowledge gaps through an expert review of the structure and dynamics of SCF and the outcomes of silvicultural interventions in the Neotropics, and analyse the main constraints and potential benefits of their management in Mexico. High heterogeneity in structure characterizes SCF and, as succession progresses, total stem density tends to decrease and the forest increases in height, basal area, timber volume and dominance of late successional species. In Mexico, the main benefits of planned selective logging in SCF could include the provision of timber and firewood at a sustainable rate, maintenance of continuous forest cover and management of biodiversity. The main challenges are the small commercial timber volume, the lack of legal definitions for secondary forests and the absence of effective policy instruments and economic incentives for small-scale landowners. Given the high intrinsic heterogeneity of SCF and the important socioeconomic variation that exists among regions in Mexico, the requisites for management should be flexible to allow adjustment to regional variations, thus allowing the inclusion of adaptive management.

Tropical forest restoration and rehabilitation management in Malaysia: opportunities and challenges

Ahmad Nuruddin¹, Musri Ismenyah², Jean-Marc Roda^{1,3}

¹Universiti Putra Malaysia, Serdang, Selangor, Malaysia; ²Universiti Malaysia Sabah, Kota Kinabalu, Malaysia; ³CIRAD, Montpellier, France (ainuddin@upm.edu.my; mrieyza@ums.edu.my; roda.outoffice@gmail.com)

Malaysia has been endowed with a beautiful tropical forest which provides various ecosystem services such as carbon dioxide absorption, water supply and soil stabilization to the community. It is also a timber source for wood-based industries generating RM22 billion in 2016. However, there are illegal encroachment activities in the forests causing the forests to be degraded as well as conversion of land use to agriculture. The enforcement activities carried out by the authorities have resulted in the degraded areas being reclaimed and the forest areas are being restored with planting of local species with commercial value. To date many degraded forest areas have been restored using different approaches. This paper aims at presenting Malaysia's experiences and initiatives in forest restoration and rehabilitation of degraded forests. These activities have created opportunities to improve the forest ecosystem. There are also many challenges need to be addressed in order the forest restoration and rehabilitation to be successful. These challenges will also be discussed.

Active versus passive restoration: recovery of cloud forest structure, diversity and soil condition in abandoned pastures

Alma Lucrecia Trujillo Miranda¹, Tarin Toledo Aceves¹, Fabiola López Barrera¹, Patricia Gerez Fernández²

¹Instituto de Ecología A. C., Xalapa, Mexico; ²Universidad Veracruzana, Xalapa, Mexico (almalucrecia90@gmail.com, tarin.toledo@inecol.mx; fabiola.lopez@inecol.mx; pgerez@uv.mx)

Tropical montane cloud forest is a priority ecosystem for restoration due to its high diversity and the provision of ecosystem services. We assessed the effectiveness of active (mixed plantation with native species) and passive (areas adjacent and non-adjacent to mature cloud forest) restoration strategies implemented in pastures with 21 years of enclosure, and compared these to a mature cloud forest, in Mexico. Active restoration proved more effective than passive restoration at recovering forest structure (higher basal area and tree height). Adult tree diversity was similar across all sites, while composition differed greatly between the mature forest and each of the restoration sites. The restoration sites presented very low tree seedling density (0.39 individuals/m²) relative to the mature forest (1.68 seedlings/m²), probably due to the higher cover of competing vegetation in the restoration sites. In all of the restoration sites, soil pH was higher, and carbon content in the soil and litter was lower, than in the mature forest. In general, the passive restoration site non-adjacent to the forest presented the lowest recovery, indicating the importance of proximity to seed sources. Our results highlight the need, in both actively and passively restored areas, for management practices, in order to assist tree seedling recruitment of key species and recovery of forest attributes. Active and passive restoration strategies could be implemented as complementary strategies for the restoration of cloud forest landscapes.

Site productivity classification for secondary evergreen dipterocarp forests in South-Eastern Vietnam

Thi Thanh Ha Do^{1,2}, John Grant¹, Heidi Zimmer¹, Bon Trinh², Hoang Nguyen², J. Doland Nichols¹, Jerry Vanclay¹ 

¹Southern Cross University, Lismore, Australia; ²Silviculture Research Institute, HaNoi, Vietnam (t.do.16@student.scu.edu.au; john.grant@scu.edu.au; heidi.zimmer@gmail.com; trinhngocbon85@gmail.com; nguyenhuyhoangyfu@gmail.com; doland.nichols@scu.edu.au; jerry.vanclay@scu.edu.au)

Reliable forest site productivity estimation is key to site-specific forest management. Many studies have investigated the estimation of forest site productivity based on species-specific height-age equations for monoculture plantations, and on height-diameter equations for mixed-species forests. However, research into estimation of productivity in secondary forests is scarce. This research classified site productivity, based on a distance-independent individual-tree growth model, to simulate management regimes in native secondary forests in monsoonal Southern Vietnam. The model was based on the spatial variation and vegetation stage at the microsite scale, which was in turn associated with soil and topographic properties, which limit the natural climax vegetation type. Recovery stage of vegetation, after a known logging event, was entered into the model to determine site productivity class. The climax vegetation types (evergreen, deciduous and bamboos), and time to recovery were identified using: the year that the normalized difference vegetation index (NDVI) at the site achieved the asymptote (from 1988 to 2017, 199 sample plots [1000 m²]), and the maximum ratio of evergreen:pioneer basal area (reference from old-growth forest sites). We assumed that climax stage was evergreen mixed dipterocarp forest. Finally, both soil and topographic and stage of recovered vegetation were identified in terms of their capacity for supporting high productivity evergreen dipterocarp forests. We classified the stages of vegetation recovery based on the productivity of dipterocarp trees, and the presence of invasive species (bamboos), and based on this, we describe the recovery potential of each site.

Gaps and challenges for SF owners in Central America to build bankable forest businesses

Jean Pierre M. Aymerich¹

¹CATIE, Turrialba, Costa Rica (jeanmorales.aymerich@gmail.com)

The sustainable development is driven by several national and international agendas such as Sustainable Development Goals, Green Growth, Low-Emission Development Strategies and other. Those initiatives look for public and private commitments to achieve their aims, the public and political sector are engagement, but it is important that the private embrace those initiative. The possibilities of private sector to contribute for reach SDG is huge, because of that it is possible to see initiative such as SDG Business Hub, Business for 2030 and SDG Business Forum. Moreover, it is necessary to move capital for develop small and medium rural business, the international efforts are focus on microfinance (mainly on financial inclusion), impact investment and other. The study focus on analysis of 42 forest business opportunities, the key findings are structuring in business case to show the main gaps and challenges of the forest owner in Central America to build bankable forest businesses cases. The analysis use business case approach as framework to explore viable alternatives, coherence between policies and business strategies, review the stakeholder and risk analysis, to build recommendation for forest owners and practitioners.

C7p: DEVELOPING SUCCESSFUL BIOLOGICAL CONTROL PROGRAMS IN FOREST PLANTATIONS

The parasitoid *Psyllaephagus blastopsyllae* (Hymenoptera: Encyrtidae), as potential control of the eucalypt psyllid *Blastopsylla occidentalis* (Hemiptera: Psylloidea), in Brazil

Dalva Queiroz¹ , Luiz Alexandre de Sá² , Valmir Costa³ , Roosevelt de Paula Almado⁴, José Eduardo Mendes⁵, Daniel Burckhardt⁶ 

¹Embrapa Florestas, Colombo, Brasil; ²Embrapa Meio Ambiente, Jaguariúna, Brasil; ³Instituto Biológico, Campinas, Brasil; ⁴ArcelorMittal BioFlorestas, Vazante, Brasil; ⁵Fibra Celulose S/A, Três Lagoas, Brasil; ⁶Naturhistorisches Museum, Basel, Switzerland (dalva.queiroz@embrapa.br; luiz.sa@embrapa.br; valmircosta@gmail.com; roosevelt.almado@arcelormittal.com.br; jose.mendes@fibria.com.br; daniel.burckhardt@unibas.ch)

In view of future release for the control of the eucalypt pest *Blastopsylla occidentalis*, the parasitoid *Psyllaephagus blastopsyllae* was imported from South Africa into Brazil in 2015, where the specimens were kept in quarantine for preliminary bioecological studies. Within a few months, the specimens died and the establishment of a viable culture failed. While another introduction was planned, the parasitoid was found in eucalyptus plantations in Minas Gerais. This changed the focus of the project to monitor the population in the plantations in Minas Gerais and to search for the parasitoid in other areas in Brazil with eucalypt plantations. The monitoring of the parasitoid showed that the pest is associated with various eucalypt clones, especially those of *Eucalyptus camaldulensis*. The occurrence of the parasitoid was positively correlated (0.82) with the pest population but indifferent to the type of clone. The percentage of parasitism was higher between June and August, the dry season, coinciding with the population peak of the pest. Besides Minas Gerais, the parasitoid was also found in São Paulo and Mato Grosso do Sul. In a survey in SP in October 2018, the observed percentage of parasitism was around 9%. A similar survey in Três Lagoas, MS, in August, yielded a percentage of parasitization of about 11%. Our data represent a small sampling in terms of total eucalypt plantations in Brazil. For promoting biological control, we suggest to increase the number of areas to be surveyed for the occurrence of the parasitoid and to study its control potential.

Selectivity of mycoinsecticides and a pyrethroid to the egg parasitoid *Cleruchoides noackae* (Hymenoptera: Mymaridae)

Maurício Magalhães Domingues¹, Luciane K. Becchi¹, Simone G. M. Velozo¹, Amanda R. Souza², Leonardo R. Barbosa³, José C. Zanuncio⁴, Carlos F. Wilcken¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Gerda Company, Três Marias, Brasil; ³Embrapa Florestas, Colombo, Brasil; ⁴Departamento de Entomologia, BIOAGRO, Universidade Federal de Viçosa, Viçosa, Brasil (mauriciomdomingues@gmail.com; luciane.becchi@hotmail.com; simonemvelozo@gmail.com; agroamandarodrigues@yahoo.com.br; leonardo.r.barbosa@embrapa.br; zanuncio@ufv.br; carlos.wilcken@unesp.br)

Thaumastocoris peregrinus (Hemiptera: Thaumastocoridae), is an exotic pest of great importance for Eucalyptus plantations. The use of the egg parasitoid *Cleruchoides noackae* (Hymenoptera: Mymaridae), is the most used control method. However, other techniques are studied, such as use of entomopathogenic fungi and chemical insecticides. The compatibility of chemical and biological control methods favors integrated pest management. The objective was to evaluate the action of mycoinsecticides and insecticides on the parasitoid *C. noackae* and its parasitism on *T. peregrinus* eggs. Two bioassays were performed: 1) cage surfaces (IOBC standard) were submitted to the application of *Beauveria bassiana* (Boveril) and *Metarhizium anisopliae* (Metarril), both with concentrations of 1 x 10⁸ conidia/g, Bifenthrin (Capture), with a concentration of 400 g/L, and control (water); after drying, 20 adults of the parasitoid were released per replicate (cage); 2) in this bioassay eggs of *T. peregrinus* were submitted to the same treatments; after drying 10 eggs of *T. peregrinus* treated by cage, and released a

couple of *C. noackae* by replicate. Parasitism was allowed for 24 hours ($T=25\pm 2\text{ }^{\circ}\text{C}$; $UR=70\pm 10\%$ and photophase= 12h). The statistical desing was completely randomized with four treatments and five replicates. Mortality, parasitism and viability were evaluated. *B. bassiana* was selective to parasitism and viability, and slightly harmful to adults of *C. noackae*; *M. anisopliae* was innocuous to adults and the viability of offspring, but it reduced parasitism; and bifenthrin was non-selective to *C. noackae* in all bioassays.

Effect of mycoinsecticides and insecticides on emergence of the pupae parasitoid *Tetrastichus howardi* (Hymenoptera: Eulophidae)

Maurício Magalhães Domingues¹, Ana L. Favoreto¹, Diego A. Nascimento¹, Carlos F. Wilcken¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônômicas, Botucatu, Brasil (mauriciomdomingues@gmail.com; analaurafavoreto@gmail.com; diego_acj@hotmail.com; carlos.wilcken@unesp.br)

Tetrastichus howardi (Hymenoptera: Eulophidae) is a gregarious endoparasitoid and a facultative hyperparasitoid. This parasitoid has potential to use to control lepidopterous pests in *Eucalyptus* plantations in Brazil. The use of mycoinsecticides and insecticides in pest management may have deleterious effects on non-target organisms. The recommendation of selective insecticides has great appeal to the conservation of natural enemies and parasitoids. Therefore, the objective of the work was to evaluate the action of mycoinsecticides and insecticides used to *Eucalyptus* pests on the emergence of *T. howardi*. Pupae of *Diatraea saccharalis* were offered to *T. howardi* parasitoids, with parasitism allowed for 48 hours, after which they were individualized in glass tubes and maintained under controlled conditions ($25\pm 2\text{ }^{\circ}\text{C}$; $UR=70\pm 10\%$ and 12 h photophase). The statistical design was completely randomized with seven treatments and 10 replicates. When the pupae were close to emerging the treatments were prepared: *Beauveria bassiana* and *Metarhizium anisopliae* (both with concentrations of 1×10^8 conidia/g), tiamectoxam, bifenthrin, imidacloprid and clorfenapyr (under higher recommended doses) and control (water). The pupae were immersed in the treatments for 10 seconds. After drying, they were transferred to polystyrene tubes until the parasitoids emerged. It was evaluated the number of parasitoids emerged and were retained in pupa. The insecticides were classified according to the International Organization for Biological Control (IOBC). None of the treated pupae affected the emergence of parasitoid adults, therefore, all products classified as innocuous. However, studies to verify the direct effect on the parasitoid still need to be done.

A phylogeographic approach for *Glycaspis brimblecombei* (Hemiptera: Aphalaridae) and its parasitoids in Brazil

Fábio Araújo dos Santos¹, Alberto Corrêa Soares², Sidinei Dallacort¹, Diego Arcanjo do Nascimento¹, Coroline Dias de Souza¹, Luis Renato Junqueira³, Carlos Frederico Wilcken¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Faculdade de Ciências Agrônômicas, Botucatu, Brasil; ²Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Piracicaba, Brasil; ³Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil (fabioaraujofm@outlook.com; ascorrea@usp.br; sidinei.dallacort@gmail.com; diego_acj@hotmail.com; xcarolinedias@gmail.com; renato@ipef.br; carlos.wilcken@unesp.br)

Eucalyptus red gum lerp psyllid, *Glycaspis brimblecombei* (Hemiptera: Aphalaridae) is one of the most important *Eucalyptus* exotic pests. Its first report in Brazil was in 2003, in the state of São Paulo, damaging *Eucalyptus camaldulensis* plantations. The parasitoid, *Psyllaephagus bliteus* (Hymenoptera: Encyrtidae), was reported together with the psyllid and a new introduction of parasitoids from Mexico was performed to improve the efficiency of biological control programs of this pest. Our objectives were to evaluate the genetic diversity of the psyllid and its parasitoid in Brazil using mitochondrial genes sequencing. Insects of both species were collected from different regions in Brazil. Thirty-four individuals of *G. brimblecombei* and twelve samples of *Psyllaephagus* spp were successful sequenced. A single COI gene haplotype was found in *G. brimblecombei* populations from Brazil and this is the same haplotype that occurs in Portugal samples, indicating one (or few) introduction events of *G. brimblecombei* in Brazil is originated from an invasive lineage distributed in other regions from the world. This fact suggests that the invasion routes of *G. brimblecombei* in the world are interconnected, which seems to be a standard for invasive *Eucalyptus* pests. Two distinct haplotypes, with a high genetic distance between them, were identified for the parasitoid. It confirms the presence of two parasitoid species in Brazil, one already identified, *P. bliteus*, and a second species of *Psyllaephagus* not morphologically identified. However, we can confirm that both parasitoid species collected in Brazil are exotic species originated from Australia.

Population dynamics of bronze bug, red gum lerp psyllid and its parasitoid in *Eucalyptus* plantations in three regions of São Paulo, Brazil

Thais Alves da Mota¹, Barbara Oliveira Poretz¹, Luiz Renato Junqueira², José Raimundo Passos³, Renato Meulman Leite da Silva⁴, Paulo Augusto de Souza Zingra Vomero¹, Carlos Frederico Wilcken¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Laboratory of Biological Control of Forest Pests FCA, Botucatu, Brasil; ²Institute for Research and Forest Studies, Piracicaba, Brasil; ³Universidade Estadual Paulista "Júlio de Mesquita Filho", Department of Biostatistics, Institute of Biosciences, Botucatu, Brasil; ⁴International Paper from Brasil, Mogi Guaçu, Brasil (thaisalves_rvs@hotmail.com; bah_poretz@hotmail.com; renato@ipef.br; rexpalf@igmail.com; renato.meulman@ipaper.com; paulovomero@gmail.com; cwilcken@uol.com.br)

The aim of this study was to evaluate the population dynamics of *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae), *Glycaspis brimblecombei* (Hemiptera: Aphalaridae) and its parasitoid *Psyllaephagus bliteus* (Hymenoptera: Encyrtidae) in three distinct regions of São Paulo State (Mogi Guaçu, São Simão, and Altinópolis) during 2014 to 2017. The pests and parasitoid monitoring was correlated with meteorological data: maximum temperature (T_{max}), minimum temperature (T_{min}) and average (T_{med}); rainfall (P); daily solar radiation (R) and vapor pressure deficit (DPV). The insects monitoring was carried out with yellow stick traps (12.5 x 10 cm) monthly during for four years, totaling 275 sample sites. *T. peregrinus* population index declined over the years, differing from *G. brimblecombei* and *P. bliteus*, which ones increased. The correlation between *T. peregrinus* and meteorological data was positive with the considering T_{max} , T_{med} , R and DPV. Rainfall and T_{min} was negative for *G. brimblecombei*, but positively for T_{max} , R and DPV. *P. bliteus* population had positive correlation for the population increasing and T_{max} , R and DPV. These results were similar to field observations, demonstrating monitoring may be essential in decision making for pest control.

Predation of *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae) by *Atopozelus opsimus* (Hemiptera: Reduviidae) under different temperatures

Caroline Dias de Souza¹, Luciane Katarine Becchi¹, Thais Alves Mota¹, Fábio Araújo dos Santos¹, Carlos Frederico Wilcken¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Botucatu, Brasil (xcarolinedias@gmail.com; luciane.becchi@hotmail.com; thaisalves9393@gmail.com; fabioaraujomf@outlook.com; cwilcken@fca.unesp.br)

The bronze bug *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae), native of Australia, is one of the main *Eucalyptus* pest in Brazil. This pest can cause silvering, followed by bronzing and defoliation. The determination of predation rate of *Atopozelus opsimus* (Hemiptera: Reduviidae) on *T. peregrinus* is essential to improve biological control program of this pest. The objective was to evaluate the predation rate of *T. peregrinus* by *A. opsimus*, in different temperatures to promote the most efficient use of this predator. Ten adults of *A. opsimus* with different ages were individualized in Petri dishes containing cotton soaked in deionized distilled water. Ten adults and five *T. peregrinus* nymphs were offered for 24 hours, at 18, 24 and 30 ± 1 °C (RH:60 ± 10%; photophase: 12 h). The number of *T. peregrinus* preyed was recorded. The experiment had ten replications and data analyzed by ANOVA and compared by the Tukey test. The mean predation rate of adults and nymphs of *T. peregrinus* by *A. opsimus* at 18, 24 and 30 °C was 0.7, 2.5, 3.1 and 0.3, 0.7, 0.9, respectively. The number of insect (adults and nymphs) preyed at 24 e 30 °C did not differ significantly. The predator *A. opsimus* is a potential agent to control of *T. peregrinus*, with a tendency to increase predation as the temperature increases.

Bioecology and management of *Leptocybe invasa* in Uruguay

Carolina Jorge^{1,2}, Edson L.L. Baldin³, Gonzalo Martínez⁴, Carlos Frederico Wilcken⁵

¹Instituto Superior de Estudios Forestales. Centro Universitario de Tacuarembó. Udelar, Tacuarembó, Uruguay; ²Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ³Universidade Estadual Paulista "Júlio de Mesquita Filho", Laboratório de Resistência de Plantas a Insetos e Plantas Inseticidas Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ⁴INIA Tacuarembó, Uruguay, Tacuarembó, Uruguay; ⁵Universidade Estadual Paulista "Júlio de Mesquita Filho, Faculdade de Ciências Agrônomicas, Laboratório de Controle Biológico de Pragas Florestais, Botucatu, Brasil (carolina.jorge@cut.edu.uy; edson.baldin@unesp.br; gmartinez@inia.org.uy; cwilcken@fca.unesp.br)

The blue gum chalcid wasp, *Leptocybe invasa* Fisher & La Salle, 2004 (Hymenoptera: Eulophidae) is a pest native from Australia that causes economical losses in *Eucalyptus* plantations. It was first detected in 2011 in Uruguay. Damage resulting from *L. invasa* galls can be particularly severe in *Eucalyptus* nurseries and in young plantations. The use of biological control agents (BCA) and plant resistance have proven valuable tools in keeping *L. invasa* populations under control worldwide. To date, the bioecology and population dynamics of this pest in Uruguay is unknown. The objective of this work was to study the population fluctuation, distribution and management strategies for *L. invasa* in Uruguay. We conduct a survey among foresters. Four yellow sticky traps (YST) were distributed in an area of 0.5 ha of *Eucalyptus* spp. in Tacuarembó and replaced monthly from December 2015 to November 2018. Captures in YST were correlated with temperature and precipitation data. Some genotypes of *Eucalyptus grandis*, *E. benthamii* and *E. grandis* x *E. camaldulensis* hybrids recorded more damage by *L. invasa*. Currently, this species distributed mostly in the North and West parts of the country. Captures in YST peaked on February, May and November and was negatively linked to accumulated precipitation. This study provides key data towards the implementation of biological control of *L. invasa* with *Selitrichodes neseri* (Hymenoptera: Eulophidae) which is currently ongoing in the country.

Effect of trap position to monitoring of *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae) in *Eucalyptus* plantations

Flavia Galvan Tedesco¹, Luciano Ramos², Luciane Becchi¹, Sidinei Dallacort¹, Barbara Puret¹, Claudinéia Paes Fogaça¹, Carlos Frederico Wilcken¹

¹Escola Superior de Agricultura "Luiz de Queiroz", Universidade de São Paulo, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Eldorado Brasil, Três Lagoas, Brasil (flaviagtedesco@gmail.com; luciano.ramos@eldoradobrasil.com.br; luciane.becchi@hotmail.com; sidinei.dallacort@gmail.com; barbarapuret@gmail.com; ferpaes@yahoo.com.br; carlos.wilcken@unesp.br)

The bronze bug is one of the main exotic pests occurs in *Eucalyptus* plantations in Brazil, affecting wood production. Monitoring is one of the most important motions for detection and also for pest control decision making in the field. This experiment had the objective of evaluating the effect of trap position on capture of adults and nymphs of *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae). The study was carried out in October, 2018, in the municipality of Três Lagoas, MS, using yellow adhesive traps in three positions, 1) traps in the trunk, 2) traps between two trees in vertical position and 3) traps between two trees in horizontal position. The traps were installed at 1.60 m, with the aid of strings, having a total of 30 replicates per treatment. After 30 days all traps were collected and sent to laboratory to proceed the insects counting. The average number of adult insects collected was 15 in the trunk, 36 in horizontal and 6 in vertical, and for nymphs this number was seven in the trunk, 39 in horizontal and seven in vertical. There was no significant difference among the traps positions (Scott-Knott test, p 0.05%). More tests will be carried out in different regions of Brazil to confirm the best method of monitoring *T. peregrinus*.

C7q: DEVELOPING SUCCESSFUL BIOLOGICAL CONTROL PROGRAMS IN FOREST PLANTATIONS - 2

Detection and transmission of endosymbionts in populations of *Glycaspis brimblecombei* (Hemiptera: Aphalaridae) and its parasitoid

Ana Favoreto¹, Vanessa Rafaela de Carvalho¹, Murilo Fonseca Ribeiro¹, Maurício Magalhães Domingues¹, Carlos Frederico Wilcken¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Botucatu, Brasil (analaurafavoreto@gmail.com; vanessa.carvalho@unesp.br; murilo.fon.rib@gmail.com; mauriciomdomingues@gmail.com; carlos.wilcken@unesp.br)

The Redgum Lerp Psyllid *Glycaspis brimblecombei* (Hemiptera: Aphalaridae) has defoliated *Eucalyptus* plantations in several regions in Brazil. The main control tactic is biological control with the nymph parasitoid *Psyllaephagus bliteus* (Hymenoptera: Encyrtidae). Associations between insects and endosymbionts are common and these bacteria can aid in food processing, detoxification of plant substances, reproduction and even in the defense of insects against infections. This complex relationship with hosts can influence biology, behavior and interaction with other organisms and the environment. The objective of this work was to identify and to correlate symbiotic bacteria in pest and parasitoid populations. Two populations of *G. brimblecombei* and *P. bliteus* from Botucatu and Mogi-Guaçu (SP, Brazil) were evaluated. Identifications were performed by molecular analysis (PCR) with specific primers for *Arsenophonus*, *Carsonella*, *Hamiltonella*, *Wolbachia* and *Rickettsia*. After the product amplification, Sanger purification and sequencing were performed comparing the results with GenBank. The population of *G. brimblecombei* from Botucatu presented *Carsonella* and *Arsenophonus*, primary and secondary intestinal symbionts, respectively. However, for

P. bliteus from Botucatu no endosymbionts were detected. *G. brimblecombei* population from Mogi-Guaçu presented *Arsenophonus*, *Carsonella* and *Wolbachia*, while the parasitoid *P. bliteus* presented *Wolbachia*. Thus, this infection is characterized as horizontal, by passing from the host to the parasitoid. *Wolbachia* may influence both the feminization of males and / or increase in the reproductive capacity of the pest and parasitoid. These aspects will be studied.

Effect of temperature on flight of *Cleruchoides noackae* (Hymenoptera: Mymaridae), parasitoid of *Eucalyptus* bronze bug

Luciane Katarine Becchi¹, Thamires Lima dos Santos¹, Flávia Galvan Tedesco¹, Carolina Jorge¹, Caroline Dias de Souza¹, Leonardo Rodrigues Barbosa², Carlos Frederico Wilcken¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Campus Botucatu, Botucatu, Brasil; ²Embrapa Florestas, Colombo, Brasil (becchiluciane@gmail.com; tmsantos111@gmail.com; flaviagtedesco@gmail.com; carolina.jorge@cut.edu.uy; xcarolinedias@gmail.com; leonardo.r.barbosa@embrapa.br; cwilcken@fca.unesp.br)

The egg parasitoid *Cleruchoides noackae* (Hymenoptera: Mymaridae) is the main biological control agent of *Thaumastocoris peregrinus* (Hemiptera: Thaumastocoridae), an exotic pest that threatens *Eucalyptus* plantations worldwide. Was evaluate the quality of *C. noackae* in the laboratory by the flight test, at different temperatures. The ESALQ model test unit was used, consisting of a PVC cylinder with the interior covered by black cardboard. On the inner wall an entomological stick ring (0.5 cm wide) was placed to 3.5 cm from the lower to determine parasitoid walkers. To determine flying parasitoids, a Petri dish with stick was embedded in the upper part of the cylinder. A hundred eggs of *T. peregrinus* parasitized by *C. noackae* were individualized in glass tubes, fixed in the center of the test units and placed in climatic chamber at 20, 25 and 30 ± 2 °C, RH: 60 ± 10% and 24:0 photoperiod (L/D). The experimental design was completely randomized with five replicates. Data were analyzed by ANOVA and compared by Tukey test. The increase in the percentage of flying parasitoids was directly proportional to the temperature increase, varying from 29 to 74%, at 20 and 30 °C, respectively. Highest percentage of walking parasitoids (60%) was observed at 20 °C, while at 25 °C there was no difference between flying and walkers. At 30°C, 74% of the parasitoids were classified as flying and 20% as walkers. The temperature affected the *C. noackae* flight in the laboratory. It is suggested to release *C. noackae* in the field at temperatures above 20 °C.

Lignocellulase from Basidiomycota fungi cultivated in woody biomass / Lignocelulases de fungos Basidiomycota cultivados em biomassa lenhosa

Anna Sofya Vanessa Silvério da Silva¹, Fernando Nunes Gouveia¹, Marcelo Fontana da Silveira¹, José Roberto Victor de Oliveira¹, Helson Mario Martins do Vale², Eliane Ferreira Noronha²

¹Serviço Florestal Brasileiro, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil (anna.silva@florestal.gov.br; fernando.gouveia@florestal.gov.br; marcelo.silveira@florestal.gov.br; jose.oliveira@florestal.gov.br; helson@unb.br; elinoronha@gmail.com)

A madeira é uma matéria-prima obtida das árvores, de constituição heterogênea e variável por ser um produto do seu metabolismo. Em virtude da sua composição química básica (celulose, hemicelulose e lignina) pode representar importante substrato para produção de enzimas por organismos xilófagos, especialmente por fungos do Filo Basidiomycota, os quais desenvolveram sistemas bioquímicos complexos capazes de converter e mineralizar a lignocelulose. Esse processo natural pode ser utilizado para fins industriais, como na produção de celulose e na conversão, de alto valor agregado, de resíduos lignocelulósicos em biorrefinarias. Foi realizado screening em meio sólido MYG modificado. Em seguida, foi avaliada a produção de enzimas celulolíticas, hemicelulolíticas e ligninolíticas por fungos de podridão branca e parda cultivados em meio mínimo líquido contendo serragem de *Swartzia psilonema* como única fonte de carbono. Foram determinadas as curvas de crescimento por quantificação da proteína intracelular. Os fungos *Trametes versicolor*/Mad 697, *Bjerkandera fumosa*/L-15918-Sp, *Gloeophyllum trabeum*/Mad 617 e *Meruliporia incrassata*/Piirto-31 apresentaram maior halo de degradação. *Trametes versicolor*/Mad 697 apresentou as maiores atividades específicas de lacases, xilanases e endoglucanases. *Bjerkandera fumosa*/L-15918-Sp apresentou maior taxa de crescimento. A maior atividade de celulases totais foi observada em *Meruliporia incrassata*/Piirto-31. Os extratos brutos fúngicos que apresentaram atividade específica representam fonte potencial de enzimas que podem ser empregadas em coquetéis destinados à despolimerização da biomassa lenhosa.

Effects of parasitism by *Tetrastichus howardi* (Hymenoptera: Eulophidae) on *Oxydia vesulia* caterpillars (Lepidoptera: Geometridae)

Rafaella Freitas Pavan¹, Ana Laura Favoreto¹, Murilo Fonseca Ribeiro¹, Carolina Jordan¹, Carlos Frederico Wilcken¹

¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Botucatu, Brasil (rfpavan@gmail.com; analaurafavoreto@gmail.com; murilo.fon.rib@gmail.com; carolinajordan@gmail.com, carlos.wilcken@unesp.br)

Adaptation of dietary habits of native lepidopteran species to eucalyptus plantations has become a treat to productivity in Brazil. Considered as a secondary pest, *Oxydia vesulia* (Lepidoptera: Geometridae) is frequently reported in *Eucalyptus* plantations and associated with outbreaks and economic damages. New methods have been tested to control several lepidopterous-pests and *Tetrastichus howardi* (Hymenoptera: Eulophidae), a pupae endoparasitoid, that has been reported as efficient for control caterpillars on major crops. Despite being a pupae parasitoid, its parasitism was tested in *O. vesulia* caterpillars. Fourth instar caterpillars were offered to the parasitoids, 10 parasitoids per larvae, with 24 hours old. After exposure larvae were kept in pots with leaves of *Eucalyptus urophylla* changed daily until the pupal stage, kept under laboratory controlled conditions (25 ± 1 °C, RH: 60 ± 10% and photophase: 12 h). *T. howardi* did not emerged from parasitized *O. vesulia* caterpillars, however positive results were found for pest control. A total of 40% of the caterpillars died before reaching the prepupal stage, other 40% reached the pupal stage and died due poor formation or problems at emergence and 20% survived. Although the parasitoid has not been able to complete its cycle in caterpillars, it shows itself as promising in controlling the pest in its most critical stage of occurrence. Studies on the potential parasitism of *T. howardi* on *O. vesulia* in the field must be developed to verify the effectiveness of this parasitoid.

Multiplication and release of the imported natural enemy *Selitrichodes neresi* (Hymenoptera: Eulophidae) for the biological control of the wasp, *Leptocybe invasa* (Hymenoptera: Eulophidae) in *Eucalyptus* plantations in Brazil

Luiz Alexandre Nogueira de Sá¹, Bárbara Oliveira Puzetz², Carlos Frederico Wilcken², Leonardo Rodrigues Barbosa³, Luis Renato Junqueira⁴, José Cola Zanuncio³

¹Embrapa Meio Ambiente, Laboratório de Quarentena "Costa Lima", Jaguariúna, Brasil; ²Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ³Embrapa Florestas, Colombo, Brasil; ⁴Instituto de Pesquisas e Estudos Florestais, Piracaicaba, Brasil (luiz.sa@embrapa.br; barbarapuzetz@gmail.com; carlos.wilcken@unesp.br; leonardo.r.barbosa@embrapa.br; renato@ipef.br; zanuncio@ufv.br)

High productivity and short rotation have made *Eucalyptus* the most cultivated plant in the world for the production of raw material for various industrial sectors. The exotic wasp, *Leptocybe invasa* (Hymenoptera: Eulophidae) from Australia, has spread rapidly in the world. *Leptocybe invasa* was registered in

Brazil in eucalyptus nurseries in the Bahia State in 2007, which made it necessary, in 2015, to import through the Quarantine Laboratory “Costa Lima”, Embrapa Meio Ambiente de Jaguariúna, São Paulo, Brazil, the exotic control bioagent, *Selitrichodes nesi* (Hymenoptera: Eulophidae) from the University of Pretoria in Pretoria, South Africa. This introduction was requested by FCA/UNESP-Botucatu Campus (University of São Paulo State, Faculty of Agrarian Sciences) and by the PROTEF/IPEF (Programa Cooperativo em Proteção Florestal/Instituto de Pesquisas e Estudos Florestais/IPEF). Seedlings of hybrid clones of *Eucalyptus grandis* x *Eucalyptus camaldulensis* were planted in 1.7 L pots with soil sterilized with a mixture of soil-sand-manure (1:1:1) and irrigated daily to obtain the parasitoid galls. These seedlings were kept in an open nursery at FCA/UNESP and infested, naturally, by *L. invasa*. Approximately seventy days after the infestation, the plants with galls were taken to Embrapa and offered to parasitism to multiply *S. nesi* in the laboratory. The production of *S. nesi* adults was 3,020 in 2015, 8,616 in 2016/2017 and 4,700 in 2018; which were sent to UNESP and then to forestry companies associated to PROTEF for releasing in *Eucalyptus* plantations. Acknowledgments: Embrapa, CNPq, FCA/UNESP, IPEF/PROTEF, UFV

First record of microsporidium infection in *Eucalyptus* snout beetle *Gonipterus platensis* (Coleoptera: Curculionidae)

Lorena Estevo Del Compare Hilário¹, Carlos Frederico Wilcken¹

¹Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Faculdade de Medicina, Botucatu, Brasil (carolinarjordan@gmail.com; vanessa.carvalho@unesp.br; murilo.fon.rib@gmail.com; rfpavani@gmail.com; lrs.oliveira@unesp.br; lorenadel2010@hotmail.com; carlos.wilcken@unesp.br)

Gonipterus platensis is the main beetle pest of *Eucalyptus* plantations. This species is from Australia and it has high destructive potential. Several environmental, biological and genetic factors can influence the life cycle of the insect. The presence of intracellular pathogens as microsporidia in insect populations can cause morphological and behavioral changes, such as increase in larval mortality, delay in development, reduction in fecundity and adult longevity, and may also be associated with the failure of parasitism. However there are no records of microsporidia in populations of *G. platensis*. Thus, the objective of this work was to identify possible microsporidia in adults of *G. platensis*. The insects with aspects of microsporidiosis were collected in Botucatu, in June, 2018 in *Eucalyptus* hybrid plantations (“Urograndis”). The insects were evaluated by the molecular PCR technique with the use of specific primers to identify possible microsporidia. The purified PCR products were subjected to Sanger sequencing and the sequences obtained were compared to the GenBank database. The presence of intracellular parasites of the genus *Microsporidia* sp. was confirmed in adults of *G. platensis*. This same genus was also reported in other coleopteran species, causing several deleterious effects. Thus, the first report of the detection of this microsporidium in *G. platensis*. Further studies are needed to identify the species, as well as to know the insect-pathogen interaction, and can also be used as a strategy for biological control of *G. platensis*.

Detection of symbiotic bacteria in *Anaphes nitens* (Hymenoptera: Mymaridae) and *Gonipterus platensis* (Coleoptera: Curculionidae) eggs

Murilo Fonseca Ribeiro¹, Vanessa Rafaella de Carvalho¹, Ana Laura Favoreto¹, Carolina Jordan¹, Rafaella Freitas Pavani¹,
Lorena Estevo Del Compare Hilário¹, Carlos Frederico Wilcken¹

¹Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Faculdade de Ciências Agrônomicas, Botucatu, Brasil (murilo.fon.rib@gmail.com; vanessa.carvalho@unesp.br; analaurafavoreto@gmail.com; carolinarjordan@gmail.com; rfpavani@gmail.com; lorenadel2010@hotmail.com; carlos.wilcken@unesp.br)

Outbreaks of *Gonipterus platensis* (Coleoptera: Curculionidae) in *Eucalyptus* plantations have occurred in the States of São Paulo and Paraná, Brazil, in the last years, due to low parasitism rates of the egg parasitoid *Anaphes nitens* (Hymenoptera: Mymaridae). Symbiotic bacteria can act in different ways on hosts, influencing the parasitism's efficiency. However, there are no records of symbionts in *A. nitens*. This work aims to identify symbiotic bacteria in different parasitoid populations and eggs of their host. Adults of six populations of *A. nitens* (five from São Paulo and one from Espírito Santo state) and eggs from a laboratory population of *G. platensis* were evaluated by PCR using specific primers for identification of nine different genera of cellular endosymbionts. The purified PCR products were sequenced and the sequences obtained were compared to GenBank database. The bacterium *Serratia grimesii* was identified in the eggs of *G. platensis*, it was already reported in midgut of other Coleoptera. All populations of *A. nitens* had presence of cellular endosymbiont *Rickettsia bellii* and bacteria *Erwinia amylovora*, *Yersinia massiliensis* and *S. grimesii*. Bacteria *E. amylovora* and *Y. massiliensis* probably act as intestinal symbionts for the host. *S. grimesii*, found in the parasitoid and host, probably is acquired by horizontal transmission from *G. platensis*. Studies to verify the bacteria quantitative aspects and the effects on *A. nitens* biological parameters are ongoing.

Comparison of antifungal microorganism *Streptomyces blastmyceticus* and the Fungicide Alamo® for the control of oak wilt disease by trunk injection and macro-infusion at root flare

Jin Heung Lee^{1,2}, Soo Wan Park², Joo Hyun Yong², Sang-Tae Seo³, Sun Keun Lee³, Dong-Hyeon Lee³, Jong Kyu Lee¹

¹Gyeonggi-Do Forestry Environment Research Institute, Gyeonggi Province, Republic of Korea; ²Kangwon National University, Chuncheon, Republic of Korea; ³Division of Forest Insect Pests and Diseases, National Institute of Forest Science, Seoul, Republic of Korea (leejinheung@gg.go.kr; swpark@kangwon.ac.kr; joohyuny@kangwon.ac.kr; stseo@korea.kr; lskyou@korea.kr; leedh2009@korea.kr; jongklee@kangwon.ac.kr)

Disease management for oak wilt of *Quercus mongolica* caused by *Raffaelea quercus-mongolica* in Korea have been mainly focused on the control of insect vector (*Platypus koryoensis*) by applications of insecticide, pheromone, sticky roll trap, and fumigation of dead or dying trees and so on. For the control of the pathogen in trees, culture suspension of antifungal *Streptomyces blastmyceticus* was injected into trees by trunk (ChemJet®) or root flare (Macro-infusion) injection before or after artificial inoculation of the pathogen, and then the ratios of non-conductive area, discolored area, and re-isolation of the pathogen from the treated trees were compared for evaluating preventive or curative efficacy. Injection of *S. blastmyceticus* or the fungicide (Alamo®) showed 41.7% and 45.8% in non-conductive area(%), respectively. In addition, *S. blastmyceticus* did not show much differences between injection methods or timings in control effect, but fungicide was better in Macro-infusion at root flare or curative treatments. Re-isolation rates of the pathogen from the treated tree woods in the treatments of pathogen only, preventive and curative were 56.9%, 20.6%, and 36.1%, respectively. These results indicated that *S. blastmyceticus* showed better control efficacy for the control of oak wilt caused by *Raffaelea quercus-mongolica* in Korea than the fungicide Alamo®, which is being widely used for the control of oak wilt caused by *Ceratocystis fagacearum* in the United States.

C7r: DEVELOPING SUCCESSFUL BIOLOGICAL CONTROL PROGRAMS IN FOREST PLANTATIONS - 3

Residual tree species diversity in degraded rainforest ecosystems of Nigeria: potentials for restoration and rehabilitation

Samuel Olajuyigbe¹, Ayodeji Adaja¹

¹University of Ibadan, Ibadan, Nigeria (lekito2001@yahoo.com; dejiadaja@gmail.com)

Nigeria's forest ecosystem is heavily degraded, while secondary succession is impeded by species invasions, agricultural expansion, land encroachment, bush burning, illegal logging and de-reservations. Selective logging and clear felling of economic trees are the predominant methods of timber extraction, with negative impacts on ecological integrity. Tree species composition and diversity, tree canopy structure and regeneration were assessed in some degraded rainforest (Akure-Ofosu and Eda forest reserves), using a systematic line-transect sampling technique. Trees with dbh >10 cm were enumerated for diameter and height. Basal area, volume, density, and community diversity indices were determined. Trees species richness ranged from 38–46 with density ranging 172 – 280 trees ha⁻¹. Plant species from Fabaceae, Sterculiaceae and Moraceae families dominated these forests. The dbh distribution revealed more trees in the lower dbh classes, while there were no trees in the emergent canopy layer (> 40 m). Basal area and total volume were 10.29-13.68 m² ha⁻¹ and 13.20-22.43 ± 1.85 m³ ha⁻¹, respectively. A high level of species diversity was observed with Shannon – Weiner and Species Equitability indices ranging from 3.14-3.65 and 0.93-0.97, respectively. A significant number of species were naturally regenerating (seedlings and saplings). These forests have good regeneration and recruitment potentials, in spite of the continuous pressure from anthropogenic interference which was limiting the ecological recovery process. Nevertheless, there is great potential for restoration through silvicultural interventions such as enrichment planting, seed supplementation and naturally assisted regeneration. Secondary forests require protection from repeated clearing because of limited seed availability and dispersal, as well as competition from pioneer species.

Biochar from sewage sludge: an alternative use for planting *Corymbia citriodora* seedlings / Biocarvão de lodo de esgoto: uso alternativo para o desenvolvimento de mudas de *Corymbia citriodora*

Elton Joneis Souza de Matos¹, Alessandra Maria Ferreira Reis¹, Michelle Conceição Vasconcelos¹

¹Universidade Federal de Sergipe, São Cristóvão, Brasil (jo.neis@hotmail.com; areisgarcia@yahoo.com; michelle_florestal@yahoo.com.br)

O elevado volume de resíduos gerados diariamente de biossólidos ou lodo de esgoto representam um dos principais problemas ambientais do mundo moderno. Uma proposta atual e de grande potencialidade é a utilização como biocarvão de lodo de esgoto para o condicionante físico e químico de solos e substratos. Com o presente trabalho visa-se avaliar o potencial de utilização de diferentes dosagens do biocarvão do lodo de esgoto, em substrato comercial de mudas de *Corymbia citriodora*. Os tratamentos com (0%, 10%, 15%, 20%, 25% e 30% doses do biocarvão) foram dispostos em delineamento inteiramente casualizado, com seis repetições e as avaliações foram realizadas aos 30, 60 e 90 dias após a semeadura, obtendo-se altura da parte aérea, diâmetro do coleto, peso da matéria fresca e seca da parte aérea, o teor de clorofila e o índice da qualidade de Dickson (IQD). Não foi verificada diferença significativa ($p < 0,05$) entre os tratamentos para todos os parâmetros avaliados, porém observou-se que a adição de 15% e 20% proporcionaram um acréscimo nas médias para a altura e diâmetro. O uso de biocarvão do lodo de esgoto para produção de mudas de *Corymbia citriodora* influenciou positivamente no crescimento e nas características morfológicas das mudas, podendo ser então utilizado o máximo da dosagem testada. Sendo assim, uma boa alternativa de uso do biossólido e economicamente viável, pois reduz o custo com substratos comerciais.

Population structure of the brown spot needle blight pathogen *Lecanosticta acicola* in Southeast Europe

Dušan Sadiković^{1,2}, Barbara Piškur¹, Irene Barnes³, Tine Hauptman², Danko Diminić⁴, Michael J. Wingfield⁵, Dušan Jurc^{1,2}

¹Department of Forest Protection, Slovenian Forestry Institute, Ljubljana, Slovenia; ²Department of Forestry and Renewable Forest Resources, Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia; ³Department of Biochemistry, Genetics and Microbiology, Forestry and Agriculture Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ⁴Faculty of Forestry, University of Zagreb, Zagreb, Croatia (dusan.sadikovic@gmail.com; barbara.piskur@gozdis.si; irene.barnes@fabi.up.ac.za; tine.hauptman@bf.uni-lj.si; diminic.sum.fakultet@gmail.com; mike.wingfield@fabi.up.ac.za; dusan.jurc@gozdis.si)

Lecanosticta acicola, the causal agent of brown spot needle blight (BSNB), has been present in Croatia for more than forty years but only in Slovenia since 2008. New discoveries regarding the global distribution of *L. acicola*, and recent outbreaks in Slovenia prompted this study to confirm the identity of the pathogen in these recent outbreaks and to compare populations in these two neighbouring European countries. Sixty-nine isolates obtained from *Pinus mugo*, *P. halepensis* and *P. nigra* were used to verify the species identity as well as to investigate phylogenetic relationships, mode of reproduction and the genetic structure the populations. All isolates were confirmed to represent *L. acicola*. EF1- α region sequencing revealed a novel haplotype and common ancestry of Slovenian and Croatian populations with populations from Central and Northern Europe. Population structure analyses revealed four distinct genetic clusters present in *L. acicola* populations from Slovenia and Croatia, generally corresponding to their respective geographic location. Unequal ratio of mating types, low haplotype count and low genetic diversity suggest asexual proliferation in analysed populations. Although the analysed Croatian population originates from the area where one of the first European occurrences of BSNB were recorded, the results suggest that the outbreaks in Slovenia are the result of unidentified multiple sources.

An assessment of energy forests in Paraguay / Diagnóstico de plantaciones forestales con fines energeticos en el Paraguay

Blas Antonio Otazu Feltes¹, Cesar Ernesto Paredes Bogarin¹, Maria Laura Quevedo Fernandez¹, William Tomaz Folmann²

¹Universidad Nacional de Asuncion, Asuncion, Paraguay; ²Independiente, Asuncion, Paraguay (blasotazu95@gmail.com; cesar.epb@gmail.com; marialauraquevedo@gmail.com; wfolmann@gmail.com)

Para el diagnóstico de plantaciones con fines energéticos fue aplicado un cuestionario en siete empresas y fueron instaladas parcelas permanentes en tres de ellas. Fueron identificados 10 materiales plantados, destacándose el VM01, A08, H13 y I144, generalmente implantados en 1.250 plantas/ha. La limpieza del área 38% de las empresas realiza de forma mecanizada así como la preparación de terreno, que es realizada por lo general entre enero a abril y agosto a noviembre, con rastras pesadas en algunos casos combinadas con rastras liviana y en todos los casos con subsolado, ya sea este con taieado o no; 71% de las empresas no realiza los trabajos de canalización; la plantación en 100% de las empresas es realizada de forma manual por lo general entre los meses de abril a mayo y setiembre a noviembre, para el combate de hormigas, todas las empresas utilizan el fipronil; todas realizan fertilización y 43% de ellas encalado, el control de maleza en línea de plantación es realizada de forma química o química y manual en cuanto que en la entre línea se destaca el método mecánico con químico;

71% de las empresas maneja rebrote y los principales productos leña y chips. El principal factor crítico es el riesgo a incendios. El material VM01 en la empresa 2 se destaca con 36,36m³/ha/año; y la viabilidad económica la empresa 2 resulto con los indicadores mayormente viables con un VPE de 340,76US\$/ha/año. Variación en el precio de venta afecta en mayor medida la viabilidad económica del proyecto.

Diameter growth of *Croton sonderianus* in natural vegetation areas of the Caatinga biome, Brazil

Andreia Taborda dos Santos¹ , Patrícia Póvoa de Mattos² , Evaldo Muñoz Braz² , Sebastião Machado¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil (andreiataborda@yahoo.com.br; patricia.mattos@embrapa.br; evaldo.braz@embrapa.br; samachado@ufpr.br)

The Caatinga is the only Brazilian natural region that is entirely restricted in the national territory. The species richness of this biome contrasts with the lack of information about tree species with economic potential, restricting its use. The aim of this study was to determine the pattern and the growth rate of *Croton sonderianus* in natural vegetation of Caatinga, to be used as basic information for forest plantation and restoration of degraded areas. Discs samples were collected at 1.30 m above ground level (DBH) for dendrochronological analysis and growth modeling. The trees presented DBH (mean) = 4.7 cm, ranging from 4.1 cm to 5.7 cm and mean annual increment of 0.40 cm. The trees had 18 years (mean), with a minimum of 15 and maximum of 23 years. Johnson-Schumacher growth model showed satisfactory statistical parameters ($R^2_{\text{adjust}} = 0.99$; $CV\% = 19$ e $F = 13,773.8$), residue distribution and adherence to real data. The application of this model will allow the prediction of the diameter growth dynamics of *C. sonderianus* in natural conditions in Caatinga biome, Brazil.

Liquefied wood polyols based wood modification for uv resistance and dimensional stability of wood

Anil Kumar¹, Asieleavio John¹, Tara Singh Mehra¹, B. N. Hazarika¹

¹College of Horticulture and Forestry, Central Agricultural University, Pasighat, Arunachal Pradesh, India, Pasighat, India (anil19wst@gmail.com; asieleavio@gmail.com; mehra_chf@hotmail.com; chfdeanpsg@gmail.com)

The major problems encountered in both indoor and outdoor utilization of wood are photo instability and dimensional instability. The modification of *Melia dubia* wood for ultraviolet resistance and dimensional stability with liquefied wood has been carried out through impregnation method under solvent free conditions. The level of impregnation was estimated by determining the weight percent gain and modified wood was characterized by FTIR-ATR and CP/MAS 13C NMR spectroscopy. The effect of liquefied wood polyols on wood percent gain was studied. UV resistance, moisture adsorption and dimensional stability of modified wood were also evaluated. UV resistance of modified wood was evaluated by exposing unmodified and modified wood to UV irradiation in a QUV accelerated weathering tester. Unmodified wood showed rapid colour changes and degradation of lignin upon exposure to UV light. The modification of wood with liquefied wood polyols was effective in reducing light induced colour changes (photo-yellowing) at wood surfaces. In contrast to Unmodified wood, modified wood exhibited bleaching. FTIR analysis of modified wood exposed to UV light indicated stabilization of wood polymers against UV degradation. Modified wood showed good dimensional stability and hydrophobicity. Thermogravimetric analysis showed that modification with liquefied wood polyols improved thermal stability of wood. The results indicates that liquefied wood polyols is a promising reagent for improving dimensional stability and UV resistance of modified wood.

Rehabilitation of burnt coastal forest by three selected indigenous species at Pekan, Pahang

A Ainuddin Nuruddin¹, Nur Farhani Ellias¹

¹Universiti Putra Malaysia, Serdang, Selangor, Malaysia (ainuddin@upm.edu.my; n.farhani9@gmail.com)

Rehabilitation programme that have been conducted to recover the degraded ecosystem can fully achieve its objective if planning is being done properly. A study was conducted at coastal forest of Pantai Nenasi, Pekan, Pahang with the aims to investigate the suitable species combinations for rehabilitation of disturbed coastal forest and the effectiveness of shelter applied. The study consisted of six plots which 3 tree species planted randomly. In three plots, seedlings were sheltered by a shade net of 1 m x 1 m x 1 m. while seedlings for the 3 species for other three plots were not sheltered. Total seedlings planted were 180 but 145 seedlings survived. Diameter and height growth data were recorded for 1-year study period. Based on One-way ANOVA result, there were highly significant difference of tree species on height but diameter increment of tree species were not significant at ($p < 0.05$). Post-hoc tests show only *C. equisetifolia* had highly significant difference on height and diameter ($p < 0.05$) compared to the other two species while there was no significant difference between *C. inophyllum* and *S. grande* on height and diameter ($p > 0.05$). There was highly significant difference between shelter treatment on height ($p < 0.05$) while there was no significant difference between shelter treatment on diameter ($p > 0.05$). This study indicate that this three species suitable to be used in other rehabilitation effort on coastal dune area due to the trees are well-adapted to the environment. The shelter treatment create more desirable condition compared to non-shelter treatment.

First record of *Quadrastichus mendeli* (Hymenoptera: Eulophidae) in Brazil: the Australian parasitoid of Blue Gum Chalcid wasp not recognize geographical barriers

Barbara de Oliveira Puretz¹, Carolina Jorge², Thais Alves da Mota¹, Sidinei Dallacort¹, Vanessa Rafaela de Carvalho¹, Renato Meulman³, Carlos Frederico Wilcken¹

¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²UdelAR, Tacuarembó, Uruguay; ³International Paper, Mogi-Guaçu, Brasil (barbarapuretz@gmail.com; carolina.jorge@cut.edu.uy; thaisalves_rvs@hotmail.com; sidinei.dallacort@gmail.com; vanessa@fca.unesp.br; renato.meulman@ipaper.com; cwilcken@fca.unesp.br)

The Blue Gum Chalcid wasp *Leptocybe invasa* (Hymenoptera: Eulophidae) is considered one of the major exotic pests in *Eucalyptus* plantations worldwide. The biological control with parasitoids and genetic resistance are considered the most adequate methods for management of this pest. More than ten parasitoid species was found associated with *L. invasagalls* in Australia. The most species used in biological control programs of *L. invasa* are *Quadrastichus mendeli* Kim & La Salle and *Selitrichodes neseri* Kelly & La Salle (Hymenoptera: Eulophidae). The latest was imported to Brazil from South Africa in 2015 and are currently released to control this pest. *Q. mendeli* was recently found in unintentional introductions in Italy (2013), South Africa (2016) and Argentina (2016) and in December of 2018 where found in São Paulo state, Brazil. The aims of this work was report for the first time the presence of *Q. mendeli* in Brazil and to evaluate heir impact in the biological control of *L. invasa*. Branches of *Eucalyptus grandis* hybrid with mature *L. invasa* galls were collected in a plantation in the municipality of Luís Antônio in São Paulo State, Brazil on 07/12/2018 and maintained in an acrylic cage. Together with *L. invasa* females emerged 30 females of a one different species from the galls. The specimens were confirmed as a *Q. mendeli* by morphological characteristics and by molecular analysis. Future prospects will be study the bioecology, dispersion and a possible interaction with *S. neseri* of this parasitoid that not recognize geographical barriers.

C7s: WILL ACTIVE RESTORATION OF SECONDARY AND DEGRADED FORESTS (SDFS) HELP TO ADDRESS SUSTAINABLY THE GAP BETWEEN WOOD DEMAND AND SUPPLY?

Active versus passive restoration: recovery of cloud forest structure, diversity and soil condition in abandoned pastures

Alma Lucrecia Trujillo Miranda¹ , Tarin Toledo Aceves¹, Fabiola López Barrera¹, Patricia Gerez Fernández²

¹Instituto de Ecología A. C, Xalapa, Mexico; ²Universidad Veracruzana, Xalapa, Mexico (almalucrecia90@gmail.com, tarin.toledo@inecol.mx; fabiola.lopez@inecol.mx; pgerez@uv.mx)

Tropical montane cloud forest is a priority ecosystem for restoration due to its high diversity and the provision of ecosystem services. We assessed the effectiveness of active (mixed plantation with native species) and passive (areas adjacent and non-adjacent to mature cloud forest) restoration strategies implemented in pastures with 21 years of enclosure, and compared these to a mature cloud forest, in Mexico. Active restoration proved more effective than passive restoration at recovering forest structure (higher basal area and tree height). Adult tree diversity was similar across all sites, while composition differed greatly between the mature forest and each of the restoration sites. The restoration sites presented very low tree seedling density (0.39 individuals/m²) relative to the mature forest (1.68 seedlings/m²), probably due to the higher cover of competing vegetation in the restoration sites. In all of the restoration sites, soil pH was higher, and carbon content in the soil and litter was lower, than in the mature forest. In general, the passive restoration site non-adjacent to the forest presented the lowest recovery, indicating the importance of proximity to seed sources. Our results highlight the need, in both actively and passively restored areas, for management practices, in order to assist tree seedling recruitment of key species and recovery of forest attributes. Active and passive restoration strategies could be implemented as complementary strategies for the restoration of cloud forest landscapes.

Site productivity classification for secondary evergreen dipterocarp forests in South-Eastern Vietnam

Thi Thanh Ha Do^{1,2}, John Grant¹, Heidi Zimmer¹, Bon Trinh², Hoang Nguyen², J. Doland Nichols¹, Jerry Vanclay¹ 

¹Southern Cross University, Lismore, Australia; ²Silviculture Research Institute, HaNoi, Vietnam (t.do.16@student.scu.edu.au; john.grant@scu.edu.au; heidi.zimmer@gmail.com; trinhngocbon85@gmail.com; nguyenhuyhoangvf@gmail.com; doland.nichols@scu.edu.au; jerry.vanclay@scu.edu.au)

Reliable forest site productivity estimation is key to site-specific forest management. Many studies have investigated the estimation of forest site productivity based on species-specific height-age equations for monoculture plantations, and on height-diameter equations for mixed-species forests. However, research into estimation of productivity in secondary forests is scarce. This research classified site productivity, based on a distance-independent individual-tree growth model, to simulate management regimes in native secondary forests in monsoonal Southern Vietnam. The model was based on the spatial variation and vegetation stage at the microsite scale, which was in turn associated with soil and topographic properties, which limit the natural climax vegetation type. Recovery stage of vegetation, after a known logging event, was entered into the model to determine site productivity class. The climax vegetation types (evergreen, deciduous and bamboos), and time to recovery were identified using: the year that the normalized difference vegetation index (NDVI) at the site achieved the asymptote (from 1988 to 2017, 199 sample plots [1000 m²]), and the maximum ratio of evergreen:pioneer basal area (reference from old-growth forest sites). We assumed that climax stage was evergreen mixed dipterocarp forest. Finally, both soil and topographic and stage of recovered vegetation were identified in terms of their capacity for supporting high productivity evergreen dipterocarp forests. We classified the stages of vegetation recovery based on the productivity of dipterocarp trees, and the presence of invasive species (bamboos), and based on this, we describe the recovery potential of each site.

Gaps and challenges for SF owners in Central America to build bankable forest businesses

Jean Pierre M. Aymerich¹

¹CATIE, Turrialba, Costa Rica (jeanmorales.aymerich@gmail.com)

The sustainable development is driven by several national and international agendas such as Sustainable Development Goals, Green Growth, Low-Emission Development Strategies and other. Those initiatives look for public and private commitments to achieve their aims, the public and political sector are engagement, but it is important that the private embrace those initiative. The possibilities of private sector to contribute for reach SDG is huge, because of that it is possible to see initiative such as SDG Business Hub, Business for 2030 and SDG Business Forum. Moreover, it is necessary to move capital for develop small and medium rural business, the international efforts are focus on microfinance (mainly on financial inclusion), impact investment and other. The study focus on analysis of 42 forest business opportunities, the key findings are structuring in business case to show the main gaps and challenges of the forest owner in Central America to build bankable forest businesses cases. The analysis use business case approach as framework to explore viable alternatives, coherence between policies and business strategies, review the stakeholder and risk analysis, to build recommendation for forest owners and practitioners.

C8a: INTENSIFICATION WITHIN LIMITS: INCREASING PRODUCTIVITY WITHOUT COMPROMISING ECOSYSTEM SERVICES

Intensified forest management calls for new protective agents for biocontrol of *Heterobasidion* spp. on Norway spruce

Jonas Rönnerberg¹, Zelma Magazniece²

¹Swedish University of Agricultural Sciences, Alnarp, Sweden; ²Augu Aizsardzības Serviss, Jelgava, Latvia (jonas.ronnerberg@slu.se; zelma.gzibovska@inbox.lv)

Heterobasidion root rot causes tremendous economic loss to coniferous forests through reduced growth and quality in the northern hemisphere. Climate change promote spread of root rot and add to the challenge to increase forest productivity. *Heterobasidion* spores can be prevented by treating stumps with e.g. *Phlebiopsis gigantea*. In Sweden this is the only commercially available alternative with proven effect. Other treatment agents and more effective genotypes of *P. gigantea* benefit the forest sector and reduce ecological risks from using one genotype. The forestry sector is therefore interested in new biological agents. The competitive ability against *Heterobasidion* of ten different isolates of *P. gigantea*, including the commercially available Rotstop®S and a *Pseudomonas* spp. bacteria (Proradix®), were therefore tested in laboratory and in two field studies. Results of the in vitro study indicated that *P. gigantea* (isolate S2384_2_VI) was superior (p<0,05) to the other 9 isolates by means of average growth rate per day on top of wood heavily infected by *Heterobasidion*. Rotstop®S together with one *P. gigantea* isolate (PG342) had the fastest growth in the first two days. Wood colonized by *Pseudomonas* spp. bacteria in vitro was competitive against *Heterobasidion* even after 25 days. In both field studies the regular *P. gigantea* (Rotstop®S) performed the best, even though *Pseudomonas* spp. show some

promising reduction in infection frequency of *Heterobasidion*. Conclusively the use of *P. gigantea* can be further developed and after longer term experiments *Pseudomonas* spp. bacteria may be considered an alternative to *P. gigantea*.

Nitrous oxide (N₂O) and methane (CH₄) efflux: impacts of silviculture and climate variation

Daniel Markewitz¹, Brian Strahm², Jason Vogel³, Kristin McElligott², Raj Shrestha², Carla Gann¹, Lori Sutter¹

¹The University of Georgia, Athens, USA; ²Virginia Tech, Blacksburg, USA; ³University of Florida, Gainesville, USA (dmarke@uga.edu, brian.strahm@uga.edu; jvogel@ufl.edu; kmc2@vt.edu; raj.shrestha@osu.edu; karla14@uga.edu; lsutter@uga.edu)

Nitrous oxide (N₂O) and methane (CH₄) are greenhouse gases that are increasing in the Earth's atmosphere and impact the global energy budget. Globally, forests play a substantial role in GHG budgets and N₂O or CH₄ might be released or consumed in response to forest management or climate variation. In the southeastern USA we investigated the impacts of a throughfall exclusion x fertilization manipulation in loblolly pine, over two years, in three locations. Fertilization increased N₂O efflux but not CH₄ efflux. Efflux of CH₄ significantly responded to throughfall exclusion. A test of N fertilizers (urea, ammonium nitrate, or diammonium phosphate) found significantly increased N₂O efflux from all forms. N₂O and CH₄ efflux were also measured over one year in three sites of a Silviculture x Initial planting density study and three sites of a Mid-Rotation Treatment study. In the silviculture x density study there was no main effect of silviculture or density on N₂O or CH₄ efflux. In the mid-rotation treatment study, where N fertilization had recently occurred, there was an effect of thinning, herbicide, and fertilization treatments on N₂O but not on CH₄. Responses in N₂O and CH₄ efflux to silviculture and climate variation are important considerations in evaluating the ecosystem services of managed forests.

Whole ecosystem NPP and growth efficiency of four coniferous species growing under contrasting vegetation management treatments in the PNW United States

Carlos Gonzalez-Benecke¹, Maxwell Wightman¹, Herman Flamenco¹

¹Oregon State University, Corvallis, USA (carlos.gonzalez@oregonstate.edu; maxwell.wightman@oregonstate.edu; hnoeflamenco@gmail.com)

Silvicultural treatments applied during the early stages of stand development can have long-lasting impacts on forest ecosystems. Forest vegetation management (VM) is an important component of many reforestation programs and although several studies have demonstrated the benefits of VM on planted conifer growth and survival, few reports have been published on the long-term effects of VM treatments on total ecosystem Net Primary Productivity (NPP) and Growth Efficiency (GE). In this study we assessed the effects of two contrasting VM treatments on total tree and ecosystem NPP and GE for Douglas-fir, western hemlock, western redcedar, and grand fir growing in Oregon's central Coast Range and Cascade foothills. The study contained two VM treatments: control and sustained vegetation control using herbicides during the first 5 years after planting. The assessments were made during 3 years, starting at age 16 years, 11 years after treatment application ended. For all species at both sites, VM treatments increased LAI and NPP of crop trees at age 16-19. Sustained VM had no effect on ecosystem NPP. Western red cedar showed lower GE, as allocated proportionally more growth to foliage than other conifers being compared. VM treatments did not affect GE at the Coast Range site, but reduced it for WRC at the Cascade foothills site. The results of this study demonstrate that sustained VM treatments during the first 5 years of stand establishment increases LAI and NPP of crop trees, directing site resources towards planted crop trees.

Pathways to decreased fertilizer use and increased productivity in Southern pine plantations

Jason Vogel¹, Eric Jokela¹, Praveen Subedi¹, Ignacie Tumushime¹, Salvador Gezan¹, Timothy Martin¹, Tania Quesada¹, Gary Peter¹

¹University of Florida, Gainesville, USA (jvogel@ufl.edu; ejokela@ufl.edu; praveensubedi@ufl.edu; tumushime09@tamu.edu; sgezan@ufl.edu; tamartin@ufl.edu; tquesada@ufl.edu; gfpeter@ufl.edu)

Plantation forests grown for maximum productivity are often fertilized, but when excess fertilizer is lost to the atmosphere or water bodies it can compromise ecosystem services. Avoiding this compromise is valuable to society, and the forest landowner, as nutrient loss can represent an economic loss. Here we discuss a series of studies carried out in the Southeastern United States that illustrate ways that forest managers can optimize fertilizer use. One longstanding observation is that sites with inherently high productivity are unlikely to respond to added fertilizer, and that past-fertilized agricultural fields can have background levels of nutrients that support rapid forest growth. New research suggests that fertilization in the previous rotation can contribute to early tree growth and prolong the Assart effect. All indicators of where fertilization can be reduced. Applications of macronutrients other than N and P, or in some soils micronutrient applications, can increase growth and the uptake efficiency for all elements. In addition, recent research suggests that other macronutrients or micronutrients can facilitate the cycling of N and P through altered decomposition rates. Ongoing changes in the effectiveness of competition control, atmospheric N deposition, precipitation amounts, atmospheric CO₂, and tree genetics are also likely affecting the need for fertilizer but significant knowledge gaps exist on how these factors interact with nutrient demands. New experiments and modeling approaches are needed to take into account these changing conditions as they relate to nutrient interactions, uptake, and supply.

Impact of aerial pesticide applications on water quality in New Zealand in an intensifying forest management regime to increase productivity

Brenda Baillie¹, Daniel Neary²

¹Scion, Rotorua, New Zealand; ²USDA Forest Service, Flagstaff, New Zealand (brenda.baillie@scionresearch.com; dan.neary@usda.gov)

The New Zealand forest industry has a long-term vision to sustainably double productivity on a per hectare basis from its forest estate. Implicit in achieving this vision will be the challenge to continue to provide a sustainable source of wood and fibre along with the provision of well-maintained and high quality water resources. Having healthy and productive forests is particularly important in the face of increasing global wood demand trends and forest certification requirements. Forest site establishment and silvicultural activities that enhance site productivity and maintain forest health, such as pesticide use, have the potential to affect water quality. Studies covering a range of New Zealand sites with varying geology, climate and hydrology found that if best management practices are applied during the aerial operations of pesticides, the potential risk to receiving water should be minimised. Highest risks were associated with aerial applications on the day of application or during rainfall events occurring shortly thereafter. It was during these periods that the main pulse of pesticides was detected in stream water and sediments. In general, concentrations returned to baseline levels within hours of application or several weeks after application. Concentrations and exposure times in stream water and sediment indicated a low risk to human health and aquatic environments based on these studies. While planted forests can potentially affect water yield, they produce high water quality for a large portion of the forestry cycle, providing a valuable ecosystem to downstream water users and aquatic biota.

Coverings for clonal nurseries and seasonal weather conditions affect physiological variables of *Eucalyptus urophylla* S. T. Blake and *Corymbia citriodora* F. V. Muell x *Corymbia torelliana* Hook hybrids / Estruturas de cobertura de jardim clonal e estações climatológicas afetam variáveis fisiológicas de cepas de *Eucalyptus urophylla* S. T. Blake e *Corymbia citriodora* F. V. Muell x *Corymbia torelliana* Hook

Rafael Lima dos Santos¹, Gabryella de Farias Duarte², Andrew Kim Lopes Ferraz¹, Fabrício Palla Teixeira¹, Richardson Barbosa Gomes da Silva¹, João Domingos Rodrigues², Magali Ribeiro da Silva¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrômicas, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Instituto de Biologia, Botucatu, Brasil (engftal.rafaelsantos@gmail.com; gabryelladuarte21@gmail.com; fabriciopallas@yahoo.com.br; andrewkim.lf@gmail.com; richardsonunesp@gmail.com; mingo@unesp.br; magali.ribeiro@unesp.br)

A cobertura do jardim clonal com filmes agrícolas pode ocasionar modificações nas condições climáticas do ambiente, e consequentemente, algumas das principais atividades fotossintéticas da planta. O objetivo deste trabalho foi avaliar como as estruturas do jardim clonal e as estações do ano afetam as atividades fisiológicas de cepas de *Eucalyptus urophylla* S. T. Blake e *Corymbia citriodora* F. V. Muell x *Corymbia torelliana* Hook. Foram instalados dois experimentos (dois clones) em esquema fatorial 4 x 2. Os fatores avaliados foram: estruturas de cobertura de jardim clonal (pé direito alto – PDA; minitúnel difusor – MTD; minitúnel azul – MTA e descoberto – DESC) e estações do ano (outono/inverno denominada inverno e primavera/verão denominado verão). Foram avaliadas: assimilação de CO₂ (A), radiação fotossinteticamente ativa interceptada (PARI), condutância estomática (gs) e transpiração (E), concentração interna de CO₂ (Ci) e eficiência de carboxilação (A/Ci). Para ambos os experimentos as variáveis E e A foram maiores no inverno e a Ci foi maior no verão, com as maiores concentrações nas estruturas MTA e MTD no experimento com clone de *Corymbia*, acrescentando a estrutura PDA no experimento com o clone de *Eucalyptus*. As maiores gs foram encontradas nas mudas do MTA e MTD em ambos os experimentos. A PARI foi maior no verão em todas estruturas nos dois experimentos e no experimento de verão não houve diferença entre tratamentos, já no inverno o DESC teve valores superiores às demais estruturas. Em ambos os experimentos ocorreu maior A/Ci no inverno e na estrutura DESC.

Productivity gains in *Pinus taeda* using phosphate fertilization in Southern Brazil / Ganhos de produtividade em *Pinus taeda* com uso de adubação fosfatada na região Sul do Brasil

James Stahl¹, Djalma Chaves², Marco Aurélio Figura¹, Fabricio Antonio Biernaski¹

¹Klabin S.A, Telêmaco Borba, Brasil; ²DMC Consultoria, Lages, Brasil (jstahl@klabin.com.br; dm.chaves@terra.com.br; mafigura@klabin.com.br; fbiernaski@klabin.com.br)

As áreas reflorestadas com *Pinus taeda* constituem a mais importante fonte da base florestal para a cadeia produtiva do setor madeireiro do Sul do Brasil. Em função da sua boa adaptação e dos níveis satisfatórios de produtividade o *Pinus taeda* ficou sendo considerado uma espécie rústica e de baixa exigência em manejo silvicultural pela grande maioria de seus produtores. Entretanto, as informações sobre manejo e resposta a adubação para esta espécie ainda são pontuais. Os dados deste trabalho fazem parte de uma rede experimental instalada com o objetivo de avaliar a resposta a adubação fosfatada de plantios no Planalto Sul Catarinense e na região de Telêmaco Borba, PR. Foram aplicadas doses crescentes de fósforo de 0 a 100 kg.ha⁻¹ de P₂O₅ de forma localizada em duas covetas laterais 30 dias após o plantio das mudas, em parcelas de 60 plantas para cada tratamento com quatro repetições em delineamento de blocos casualizados. As medições foram realizadas aos dois e sete anos para o cálculo de volume por área. Os resultados mostraram que o uso de adubação fosfatada promoveu ganhos significativos na produtividade de *Pinus taeda* até sete anos de idade nos solos de textura média, com a máxima produção para a dose de 100 kg.ha⁻¹ de P₂O₅. Para os solos de textura argilosa não houve resposta significativa ao uso de adubação fosfatada, indicando que o manejo nutricional de fósforo em *Pinus taeda* responde de forma sitio-específica.

Long-term effects of vegetation management on whole ecosystem nutrient allocation in four different conifer species in the Pacific Northwest United States

Callan Cannon¹, Carlos Gonzalez-Benecke¹, Maxwell Wightman¹

¹Oregon State University, Corvallis, USA (callan.cannon@oregonstate.edu; carlos.gonzalez@oregonstate.edu; maxwell.wightman@oregonstate.edu)

Silvicultural treatments are used to alter stand growth and development and can have long-term effects on forest ecosystem structure. Vegetation management (VM) is a common silvicultural treatment used for reforestation in the U.S. Pacific Northwest. While it has been shown that VM treatments increase the biomass yield of crop trees, the effects on forest structure and ecosystem nutrient budgets are not well understood. This study will examine the effects of two different vegetation management treatments on the distribution of 6 macronutrients and 10 micronutrients in stands of 4 different conifer species (Douglas-fir, grand fir, western redcedar and western hemlock) growing in the central Oregon Coast Range, as well as 2 conifer species (Douglas-fir and western hemlock) growing in the Cascade foothills in Oregon. The treatments to be compared are control, consisting only of a pre-planting herbicide application, and the vegetation management treatment, consisting of annual herbicide application for 5 years after planting in addition to the pre-planting application. In a previous study, we showed that while there is a difference in the distribution of biomass between treated and untreated plots, there is no effect on total ecosystem productivity. We will dive further into this finding and report the effects of these treatments 16 years after planting on total ecosystem nutrient levels as well as nutrient pools in various parts of the forest ecosystem including crop trees, understory vegetation, forest floor and soil up to 1 meter in depth.

Economic feasibility of applying doses of nitrogen, phosphorus, and potassium to plantations of *Eucalyptus urophylla* S.T. Blake ex *E. grandis* Hill ex Maiden / Viabilidad económica de la aplicación de dosis de nitrógeno, fósforo y potasio en plantaciones de *Eucalyptus urophylla* S.T. Blake x *E. Grandis* Hill ex Maiden

Marco Antonio Martínez Baez¹, Melanie Niederberger Heilbrunn¹, Maria Laura Quevedo Fernandez¹, William Tomaz Folmann², Carlos Andrés Leguizamón Rojas¹

¹Universidad Nacional de Asunción, Asunción, Paraguay; ²Independiente, Asunción, Paraguay (marcmarti1994@gmail.com; melaniederheil@gmail.com; marialauraquevedo@gmail.com; wfolmann@gmail.com; carlos.leguizamon@agr.una.py)

El presente trabajo tuvo como objetivo estimar la viabilidad económica de la aplicación de fertilizantes en plantaciones con fines energéticos de *Eucalyptus urophylla* S.T. Blake x *E. grandis* Hill ex Maiden. La experimentación se llevó a cabo en el departamento de Paraguarí, Paraguay. Se instalaron 15 unidades experimentales por elemento, en 3 bloques completamente al azar que contuvieron 36 plantas cada una; en estas unidades fueron aplicadas 0, 20, 40, 60 y 80 Kg/ha de nitrógeno, para fósforo los tratamientos consistieron en dosis de 0, 25, 50, 75 y 100 Kg/ha; para los tratamientos con potasio los tratamientos fueron de 0, 30, 60, 90 y 120 Kg/ha. Las mediciones correspondientes al DAP y altura se realizaron a los dos años de haber sido instalada la plantación, con las mismas

se pudo hallar el área basal que sirvió como fuente principal de datos para estimar el crecimiento a los 5 años con el programa SISecalipto, los datos brindados por el programa, además de los costos proveídos por la empresa, sirvieron para estimar los indicadores financieros (VAN, TIR, RB/C y VPE) de los ciclos de rotación. Se realizó un análisis de sensibilidad de con una variación de $\pm 15\%$ en el precio y $\pm 15\%$ en la tasa de interés. El elemento que proporcionó un mayor incremento en cuanto a volumen fue el nitrógeno con una dosis de 100Kg/ha con 30,904m³/ha a los 2 años. De todas maneras, se tiene como escenario más viable económicamente al de fosforo con una dosis de 75Kg/ha

Coverings for clonal nurseries and seasonal weather conditions alter the productivity of strains of *Eucalyptus urophylla* S. T. Blake and *Corymbia citriodora* F. V. Muell x *Corymbia torelliana* Hook / Estruturas de cobertura de jardim clonal e estações climatológicas alteram a produtividade de cepas de *Eucalyptus urophylla* S. T. Blake e *Corymbia citriodora* F. V. Muell x *Corymbia torelliana* Hook

Rafael Lima dos Santos¹, Gabryella de Farias Duarte², Fabrício Palla Teixeira¹, Andrew Kim Lopes Ferraz¹, Richardson Barbosa Gomes da Silva¹, João Domingos Rodrigues², Magali Ribeiro da Silva¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Instituto de Biologia, Botucatu, Brasil (engfal.rafaelsantos@gmail.com; gabryelladuarte21@gmail.com; fabriciopallas@yahoo.com.br; andrewkim.lf@gmail.com; richardsonunesp@gmail.com; mingo@unesp.br; magali.ribeiro@unesp.br)

O viveiro florestal é responsável pelo abastecimento de mudas para a implantação de povoamentos florestais. Para atender essa demanda, os viveiros florestais vêm adotando tecnologias com a finalidade de aumentar a produtividade sem aumentar a área do viveiro, entre elas diferentes estruturas de jardim clonal. O objetivo dessa pesquisa foi avaliar o quanto os microclimas das estruturas do jardim clonal e as estações do ano afetam a produtividade das cepas de *Eucalyptus urophylla* S. T. Blake e *Corymbia citriodora* F. V. Muell x *Corymbia torelliana* Hook. O experimento foi instalado no viveiro de produção de mudas da FCA/UNESP, em Botucatu – SP, e foram instalados dois experimentos, o primeiro com um clone de *Eucalyptus* e o outro com o um clone *Corymbia*, em esquema fatorial 4 x 2. Os fatores avaliados foram: estruturas de cobertura de jardim clonal (pé direito alto – PDA; minitúnel difusor – MTD; minitúnel azul – MTA e descoberto – DESC) e estações do ano (outono/inverno, denominada inverno e primavera/verão, denominada verão). Foi avaliado mensalmente o número de brotos/cepa/estrutura, durante o ano de 2018. A estrutura de jardim clonal MTD foi a mais produtiva em todas as estações para ambos os experimentos (*Eucalyptus* 15 e 20 brotos e *Corymbia* 12 e 15 brotos no verão e inverno, respectivamente). Entre as estações, ambos os minitúneis produziram mais brotos no inverno, nos dois experimentos, ao passo que PDA e DESC apresentaram maior produtividade no verão para o experimento com *Corymbia* e não havendo diferença estatística entre as estações para o experimento com *Eucalyptus*.

Using LIDAR (light detection and ranging) to monitor forest succession in areas of native vegetation / Uso da ferramenta LiDAR (Light Detection And Ranging) para monitoramento de sucessão florestal nas áreas de vegetação nativa

Gabriela Sanches Dolenc¹, Cristiano Cardoso Stézt¹, Samantha Nazaré de Paiva¹, Clewerson Frederico Scheraiber¹

¹Klabin, Telêmaco Borba, Brasil (gabrielasdolenc@gmail.com; ccstetz@klabin.com.br; snpaiva@klabin.com.br; cscheraiber@klabin.com.br)

As áreas de vegetação nativa da Klabin no Paraná totalizam 142.094,76 hectares. A preservação dessas áreas aliada com o manejo em mosaico das áreas produtivas proporciona a proteção dos recursos hídricos e possibilita a conectividade entre os fragmentos nativos, o que contribui para um maior fluxo biológico e a conservação de aproximadamente 2 mil espécies de flora e 898 espécies de fauna. No entanto, além da extensão florestal outro critério importante a ser monitorado ao longo do tempo é a sucessão ecológica, que determina o grau de conservação da vegetação nativa. Tais critérios garantem não somente a sustentabilidade dos fragmentos, mas também vem atender aos compromissos da empresa firmados com as certificações. O objetivo deste trabalho foi criar uma metodologia para otimizar a classificação sucessional das áreas de vegetação nativa. Assim, foi utilizado a tecnologia LiDAR (Light Detection and Ranging) para gerar um mapa de altura de uma das Regiões Florestais da Klabin. Depois foram coletados em campo 30 pontos aleatórios na intensidade amostral de 1 ponto a cada 15 hectares, fazendo-se o registro em campo do estágio de sucessão (baseado na normativa do CONAMA nº 2 de 1994). Os pontos amostrais foram correlacionados com mapa de altura e por meio de ferramentas de geoestatística foi realizado uma interpolação para extrapolar a classificação da sucessão florestal das parcelas para as demais áreas de vegetação nativa.

C8b: SUSTAINABLE MANAGEMENT OF FOREST SOILS FOR TIMBER AND BIOENERGY PRODUCTION

Effect of whole-tree-harvesting on soil properties and reuse of wood ash produced from woody biomass power plant for nutrient compensation to the forest in Japan

Keizo Hirai¹, Tsuyoshi Yamada¹, Junko Nagakura¹, Mayumi Y. Ogasawara², Masahiro Inagaki³

¹Forestry and Forest Products Research Institute, Tsukuba, Japan; ²Kansai Research Center, Forestry and Forest Products Research Institute, Kyoto, Japan;

³Kyushu Research Center, Forestry and Forest Products Research Institute, Kumamoto, Japan (hirai@ffpri.affrc.go.jp; yamadan@ffpri.affrc.go.jp; kurya@ffpri.affrc.go.jp; mayumiogasa@ffpri.affrc.go.jp; inagaki@ffpri.affrc.go.jp)

Newly operation of woody biomass power plants increased drastically with a demand of renewable energy after Great East Japan Earthquake in 2011. Whole-tree-harvesting became popular at forest management in Japan. In these background, we studied the effect of whole-tree-harvesting on soil properties and the reuse of wood ash produced from woody biomass power plant for nutrient compensation to the forest. Our field study demonstrates that the amounts of nutrient removal afterwhole-tree-harvesting was two times higher than those afterstem-only-harvesting regardless of thinning or clear-cutting. Nutrient, especially potassium (K) was stored in above ground biomass at similar levels as those in soils of 0-100 cm depth calculated from Japanese national forest inventory data. K was one of the major nutrients with high concentration in wood ash. We applied to the forest soils and growing media of containerized tree seedlings to reuse ash and compensate soil nutrient loss. Ash recycling to the young Japanese cedar (*Cryptomeria japonica*) and cypress (*Chamaecyparis obtusa*) stands increased or maintained surface soil pH and K, calcium and magnesium until the end of second growing season compared with the stands without ash recycling. Seedling growth of these species grown under different mixing ratios of ash did not increase, but was inhibited under 25% and 10% ash mixing to grown media in Japanese cedar and Japanese cypress respectively. These results suggest the need to establish a guidelines for adequate harvest intensity to maintain long-term soil productivity and for wood ash recycling to the forest.

Impact of intensified timber harvesting on heavy metal export from peatland forest

Liisa Ukonmaanaho¹, Mika Nieminen¹, Sakari Sarkkola¹, Ari Laurén², Tiina M. Nieminen¹

¹Natural Resources Institute Finland, Helsinki, Finland; ²University of Eastern Finland, Joensuu, Finland (liisa.ukonmaanaho@luke.fi; mika.nieminen@luke.fi; sakari.sarkkola@luke.fi; ari.lauren@uef.fi; tiina.m.nieminen@luke.fi)

Increasing demand for bioenergy production has led to an interest on the forest harvesting method which removes also logging residues (tree tops, branches, stumps) in addition to stemwood. However, the impacts of whole-tree harvesting on biogeochemical cycles, tree growth and water quality are largely unknown, especially in drained peatlands. In Finland 4.9 million ha of peatlands have been drained for forestry purposes, and much of them will be harvested in coming years. This biomass would provide a major source of bioenergy. However, forest harvestings, especially the intense whole-tree-harvesting with stump lifting (WTHs), may increase the export of nutrients and heavy metals to recipient water courses. This effect can be enhanced if the underlying bedrock and overburden soil contain heavy metals. In addition, anoxic conditions can develop in stagnant water pools formed as a result of harvesting, especially after stump removal. Anoxic conditions may result in mobilization of heavy metals that have accumulated in the soil, and their subsequent transport to surface waters constitutes an ecotoxicological risk. The impact of stem-only harvesting (SOH), whole-tree harvesting (WTH) and WTHs on the concentrations and loads of Cu, Fe, Hg, Mn, Ni, MeHg and DOC in the ditch water was studied using a paired catchment approach in three locations and in total 24 drained peatland dominated catchments in Finland 2007-2015. Results indicate that there are significant differences in drainage water quality and quantity before and after harvesting (SOH, WTH, WTHs). The change was strongest after first two years since harvesting.

Distribution of biomass in first and second rotation *Eucalyptus* trees / Distribuição da biomassa em árvores de eucalipto cultivadas em primeira e segunda rotação

Gileno Brito de Azevedo¹, Glauce Tais de Oliveira Sousa Azevedo¹, Aldair Ricardo Barêa¹, Jean de Jesus da Silva¹, Humberto de Jesus Eufrade-Junior²

¹Universidade Federal de Mato Grosso do Sul, Chapadão do Sul, Brasil; ²Universidade Estadual Paulista, Botucatu, Brasil (gileno.azevedo@ufms.br; glauce.azevedo@ufms.br; aldair.ricardo@hotmail.com; jean_djesus@hotmail.com; hdjejunior@gmail.com)

Conhecer a distribuição da biomassa nos compartimentos das árvores é fundamental na tomada de decisões relacionadas ao uso da madeira e aproveitamento dos resíduos florestais, como cascas, galhos, folhas, tocos e raízes. Essa distribuição pode ser influenciada por diferentes fatores, como o regime de condução do povoamento. Portanto, objetivou-se avaliar a distribuição da biomassa de árvores de *Eucalyptus urophylla* (clone AEC0144) em primeira e segunda rotação. O estudo foi realizado em Ribas do Rio Pardo/MS, em dois talhões plantados no espaçamento de 3 x 3 m, com idade de 7,2 anos na primeira rotação e de 14,0 anos na segunda rotação (6,3 anos pós-corte). Em cada talhão foram abatidas cinco árvores e arrancadas suas raízes com retroescavadeira. De cada árvore foi obtida a biomassa seca dos compartimentos: galhos + folhas (GF), fuste sem casca (F), casca do fuste (CF), toco + raízes sem casca (TR) e casca de toco + raízes (CR), sendo seus valores expressos em porcentagem da biomassa total da árvore (BT). Utilizou-se o teste t para comparar a distribuição das biomassas entre rotações. A média de BT foi de 186,4 kg na primeira e 186,5 kg na segunda rotação. Em ambas as rotações, a distribuição da biomassa nos compartimentos apresentou a seguinte ordem: FTRGFCFCR, com respectivamente, 65,0%, 18,3%, 8,7%, 6,7% e 1,3% na primeira rotação e 62,9%, 17,1%, 9,4%, 9,2% e 1,4% na segunda rotação. Apenas CF apresentou diferença significativas entre as rotações. Portanto, a distribuição da biomassa nos compartimentos foi pouco influenciada pela rotação do povoamento.

Strategic options for poplar based planted forests considering both material and energy options

Joris Van Acker¹

¹Ghent University - Laboratory of Wood Technology, Ghent, Belgium (joris.vanacker@ugent.be)

The potential of woody biomass production in both volume and quality is key for the future of the forest-based sector. Vertical integration alongside a better tree and wood quality concept should lead to a more structured approach dealing with whether some wood products need to be prioritized and how we could deal with substitution of man-made (building) materials that require more energy. Combining the production of low energy wood products with the important option to produce green energy based on woody biomass is a major challenge for the future. Both structural and chemical mapping can contribute to fit-for-purpose usage, as accurate and detailed knowledge of the material enables guided utilization and optimal performance of wood. At Ghent University - Woodlab a platform has been developed using poplar disks for early selection with a focus on collecting data in the NIR, visual and X-ray spectrum in maximum 30 min per wood disk. Amongst the new methods to produce woody biomass, options to produce chips as well as timber are being assessed in a wide range of agricultural systems. Some are indicated as polycyclic plantations, other are classified under short rotation agroforestry systems. These dual-purpose production systems could be an option to provide, in a sustainable way and based on mid-term strategic decision making processes, lignocellulosic raw materials for material and energy use. The use of fast growing poplar for high end-products will also profit from developments in using hardwoods for construction and several wood modification options.

Impact of biochar soil amendment on growth and physiology of urban tree species in Southern United States

Kamran Abdollahi¹, Zhu Hua Ning¹

¹SU Agricultural Research and Extension Center, Baton Rouge, USA (kamran_abdollahi@subr.edu; zhu_ning@subr.edu)

Biochar from pyrolysis of wood waste in Louisiana was applied as soil amendment in a randomized completely block design study to quantify the impact of biochar soil treatment on the growth and physiology of live oak saplings. Height and diameter growth were measured. Net photosynthesis, respiration, and transpiration of live oak saplings were measured using portable photosynthesis system after biochar soil amendment treatment during three growing seasons. In addition, impact of biochar on chemical properties of the soil was quantified. The results indicated statistically significant impacts on growth and physiology of live oak saplings treated by biochar soil amendment. Chemical soil properties were also significantly impacted by the biochar amendment.

Comparative evaluation of subsoilers for deep soil preparation

Rafael Ribeiro Soler¹ , Guilherme Oguri², Anderson Cleiton Pauli Bogo³, Saulo Philipe Sebastião Guerra¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Faculdade de Ciências Agrônomicas, Botucatu, Brasil; ²Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ³Bahia Specialty Cellulose/Copener, Alagoinhas, Brasil (rrsoler22@hotmail.com, guilherme@ipef.br; bogoflorestal@gmail.com; saulo.guerra@unesp.br)

Tabuleiros Costeiros region located at Brazilian northeast has cohesive soils with pedogenic horizons, densified, very hard or extremely hard in dry conditions, hardly to be broken in smaller fragments, known as fragipãs and duripãs (Embrapa, 2015). Under these conditions, afforestation requires a deep soil preparation and capable of breaking up the impeditive layers, aiming a better root development. Therefore, this evaluation compared two trident rods of different dimensions attached in excavators, model Volvo EC210 LC, for the deep soil preparation at the Bahia state. The conventional trident had 1.1 m of length on the central rod and the prototype had 1.4 m. The experiment was located at Araçás/BA, and Esplanada/BA, where the prototype obtained an average performance of 5.0% and prepared soil volume was 76% higher than the conventional trident. Thereat, it was concluded that the prototype trident subsoiler obtained higher performance and quality in operation compared to the current system.

An assessment of the production chain of *Eucalyptus* for energy in Rio Verde, Goiás, Brazil / Diagnóstico da cadeia produtiva de eucalipto para uso energético em Rio Verde, Go

Marcelo Ricardo Formolo Júnior¹, Tamires Nedel¹ , Flávio José Simioni¹, José Mauro Magalhães Ávila Paz Moreira², Cláudio Cesar de Almeida Buschinelli²

¹Universidade do Estado de Santa Catarina, Lages, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Embrapa Meio Ambiente, Jaguariúna, Brasil (marcelorformolojunior@gmail.com; tamiresnedel@hotmail.com; flavio.simioni@udesc.br; jose-mauro.moreira@embrapa.br; claudio.buschinelli@embrapa.br)

A biomassa florestal representa uma importante alternativa de fonte de energia renovável para compor a matriz energética brasileira. Contudo, o avanço dos plantios florestais para regiões denominadas como “novas fronteiras” apresentam desafios a serem enfrentados para a consolidação das cadeias produtivas. Assim, este trabalho objetiva identificar os principais fatores limitantes e propulsores encontrados na cadeia produtiva de eucalipto para geração de energia no município de Rio Verde (GO). Em parceria com o Sebrae-GO, a pesquisa foi realizada em 2018 e contemplou quinze agentes dos diferentes segmentos da cadeia produtiva (fornecedores de insumos, produtores, colheita, transporte e consumidores). Efetuaram-se visitas a campo, realização de painéis e aplicação do roteiro de entrevistas semiestruturado para obtenção de dados e informações. Os resultados indicaram uma cadeia produtiva estruturada para o fornecimento de biomassa florestal, na forma de lenha e cavaco de eucalipto, destinados à secagem e processamento de grãos. A produção local enfrenta uma reestruturação do mercado, em decorrência de excesso de oferta com consequente queda dos preços, com importantes implicações para o cenário futuro. As informações geradas pelo diagnóstico da cadeia produtiva contribuirão para auxiliar investidores e formuladores de políticas públicas para a definição de estratégias de enfrentamento dos fatores que limitam o seu desempenho competitivo.

An assessment of the production chain of *Eucalyptus* for energy in Cristalina, Goiás, Brazil / Diagnóstico da cadeia produtiva de eucalipto para uso energético em Cristalina, Go

Tamires Nedel¹ , Lucas Gerber Soares¹, Marcelo Ricardo Formolo Júnior¹, Flávio José Simioni¹, José Mauro Magalhães Ávila Paz Moreira², Cláudio Cesar de Almeida Buschinelli²

¹Universidade do Estado de Santa Catarina, Lages, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Embrapa Meio Ambiente, Jaguariúna, Brasil (tamiresnedel@hotmail.com; gerbersoares@outlook.com; mformolojr.ambiental@gmail.com; flavio.simioni@udesc.br; jose-mauro.moreira@embrapa.br; claudio.buschinelli@embrapa.br)

O uso da biomassa florestal de eucalipto é uma das principais fontes para geração de energia térmica para as indústrias de processamento de alimentos no Brasil. Contudo, a inserção de florestas plantadas para atender este tipo de demanda em regiões não consolidadas, como por exemplo, a região Centro-Oeste, tem enfrentado desafios para a estruturação e consolidação da cadeia produtiva. Por esta razão, diagnosticar os pontos propulsores e restritivos ao desempenho competitivo da cadeia produtiva de eucalipto em Cristalina (GO), foi o objetivo deste trabalho. Em parceria com o Sebrae-GO, a pesquisa foi realizada em 2018, utilizando-se como instrumentos de coleta de dados as visitas a campo, realização de painéis e aplicação do roteiro de entrevistas semiestruturado. De modo a contemplar os diferentes segmentos da cadeia, foram amostrados dez agentes de oito segmentos do setor florestal, cujos dados foram examinados por meio da análise de conteúdo. Os resultados indicaram uma cadeia estruturada, essencialmente coordenada por uma cooperativa de produtores florestais. Os principais consumidores são indústrias de alimentos, secagem e processamentos de grãos, revelando a tendência de substituição da lenha por cavaco para produção de energia térmica na forma de calor e vapor. Os sistemas de produção florestais caminham para novas oportunidades de mercado, tais como a integração lavoura-pecuária-floresta ou pecuária-floresta e a implantação e manejo da floresta objetivando outros usos da madeira, tais como o desdobro em serrarias. Assim, as informações obtidas no presente trabalho contribuirão para os diferentes agentes da cadeia estabelecer estratégias de ação visando a consolidação da cadeia produtiva.

C8c: THE BIOECONOMY AND NON-WOOD FOREST PRODUCTS

Commercialization of non-wood forest products through small and medium enterprises as a strategy for rural development: a review

Kathrin Meinhold¹, Dietrich Darr¹

¹Rhine-Waal University of Applied Sciences, Kleve, Germany (kathrin.meinhold@hochschule-rhein-waal.de; dietrich.darr@hochschule-rhein-waal.de)

Non-wood forest products (NWFPs) such as wild foods, medicinal plants, or raw materials for handicrafts make significant contributions to rural livelihoods in the developing world. NWFPs can help fulfil households' subsistence and consumption needs, serve as a safety-net in times of crises, and provide cash income. Benefits from commercializing NWFPs are potentially significant in terms of improved livelihoods for local communities. However, despite rising interest and recognition of the potential contribution of such industries as a key source of employment and their strategic role in the overall growth strategies of developing countries, many NWFP enterprises remain in the informal sector and in-depth understanding of underlying factors remains limited. This review synthesizes the current evidence base examining the contribution of commercialised NWFPs to livelihoods and factors positively affecting NWFP commercialisation and SME development in contrast to subsistence use. Using systematic review methodology studies investigating commercialised NWFPs and their economic impacts have been identified. Despite the diverse nature of NWFPs preliminary findings identify a number of constraining as well as enabling factors affecting NWFP

commercialisation. The former include aspects such as lack of resource access (finances, skills, technologies, etc.), market information or basic infrastructure, the latter amongst others the role of key entrepreneurs, transparency across the value chain, partnerships and producer organisations or clear tenure rights. Negative implications of NWFP commercialisation such as overexploitation of the resource as well as their potentially more significant role in preventing a deepening of poverty are discussed.

The national-level economic importance of environmental products in the bioeconomy: medicinal plants in and from Nepal

Carsten Smith-Hall¹ , Mariève Pouliot¹, Thorsten Treue¹

¹University of Copenhagen, Frederiksberg, Denmark (cso@ifro.ku.dk; mapo@ifro.ku.dk; ttr@ifro.ku.dk)

Environmental products, harvested in forests and other natural non-cultivated environments, constitute a significant source of income to harvesters, traders, industries and governments in a large number of countries. In Nepal, the subset of medicinal plants is subject to large-scale national processing and cross-border trade that are poorly understood. The trade appears to involve millions of low-income small-scale harvesters, thousands of traders and hundreds of industries; the trade is made up of more than one hundred plant species; and annual traded volumes are thousands of tonnes worth hundreds of millions USD. Here we present an overview of the functions and structure of the medicinal plant production networks, with particular emphasis on quantitatively estimating the national-level economic importance of the current medicinal plant trade. Data were collected for the fiscal year 2014-15 and included structured quantitative interviews in Nepal with 362 harvesters, 393 traders, 58 central wholesalers, and 108 processors, as well as 89 regional wholesalers (30 in India and 59 in Tibet). We find that the de facto, but largely unrecorded, medicinal plant export constitutes Nepal's most valuable export product group, and we assess the potential as well as possible constraints of these products to support a transition to green growth as part of the country's bioeconomy.

An assessment of non-timber forest products in the United States under changing conditions

Susan Alexander¹, James Chamberlain², Toral Patel-Weynand³, Marla Emery⁴

¹US Forest Service, Pacific Northwest Research Station, Juneau AK, USA; ²US Forest Service Southern Research Station, Blacksburg VA, USA; ³US Forest Service Research and Development, Washington DC, USA; ⁴US Forest Service, Northern Research Station, Burlington (salexander@fs.fed.us; jchamberlain@usda.gov; tpatelweynand@usda.gov; memery@usda.gov)

Non-timber forest products (NTFPs) are fundamental to the functioning of healthy forests and play vital roles in the cultures and economies of the people of the United States. However, these plants and fungi used for food, medicine, and other purposes have not been fully incorporated into management, policy, and resource valuation. This presentation will summarize a forest-sectorwide assessment of the state of knowledge regarding NTFPs science and management information for U.S. forest and rangelands. The assessment serves as a baseline science synthesis and provides information to inform management of NTFPs in the U.S. In addition, the assessment provides information for national-level reporting on natural capital and the ecosystem services NTFP provide. The report includes chapters on products and production; ecological dimensions; cultural dimensions; social dimensions; economics; laws, policies and regulations; and implications in an era of changing climate. Few policies and assessments address the dependence of forest-based communities on NTFPs and the vulnerability of associated social, cultural, and economic systems to climatic variability. This report takes an important first step, by providing a comprehensive assessment of the multiple dimensions of NTFPs, the ecosystem goods and services they provide, and threats that climate variability and change may pose to their long-term availability. This presentation will summarize the U.S. Report, highlighting findings and recommendations for management and data collection.

A case study on how bamboo contributes to a circular economy in Southwestern China

Yanxia Li¹

¹International Bamboo and Rattan Organisation, Beijing, China (yxli@inbar.int)

Commonly referred to as "poor man's gold", bamboo is a multiuse woody resource that is widely used in construction, pulping, plywood, handicrafts, and a diverse range of subsistence applications, generating job opportunities and cash income. Bamboo is an exceptional plant that offers climate smart benefits and is useful for creating a myriad range of products which in turn help in the sustainable development of the economy. Taking a case study from a famous bamboo town, Chishui municipality in Southwestern China, this paper sheds lights on how bamboo has been used to contribute to a green growth in local economy while offering opportunities to enhance the yield in form of a number of other products. It also indicates the results achieved not only the production value of bamboo created, but also how many job opportunities generated (especially for women) and a circular economy shaped.

From bioprospecting to biorefinery and bioeconomy: valorization strategies of native non-wood forest products in Uruguay

Zohra Bennadji¹

¹INIA Uruguay, Tacuarembó, Uruguay (zbennadji@inia.org.uy)

Since the nineties, Uruguayan native forests have been protected by law and their utilization reduced to some scarce traditional uses if not literally left untouched in many cases. However, in the last years, discussions raised around the ecological significance and the socio-economic future of this natural patrimony and a new national strategy was designed with a quite wide stakeholders participation. In parallel, as part of a national prospective study, the government conducted a bioeconomy study, applied to both planted and native forests. Biorefinery, through the extraction of high-value molecules from non-wood products for green chemistry was identified as one of the challenging approaches to fulfill the expectations of the bioeconomy implementation in the country. This work reports the research advances obtained by the Forestry Department of the National Agricultural Research Institute (INIA-Uruguay) in the field of: (i) the identification, extraction and characterization of secondary metabolites of native forest species as a raw material for biomaterials production and (ii) the way to increase its production through high-value tree domestication for ex situ cultivation providing knowledge to improve the reproduction, growth and yield of promising forest species. Two target native forest species (*Quillaja brasiliensis* and *Prosopis affinis*) were systematically studied through an interdisciplinary agenda and with an interdisciplinary team, covering different steps from the field to the laboratory: bioprospecting, cutting and plant production in vitro, seedling propagation in nursery, laboratory extraction and characterization of secondary metabolites, industrial scaling up and diffusion and technology transfer.

Conservation of the Cerrado from the valorization of socio-biodiversity products: the importance of production chains and local marketing channels

Janaina Diniz¹, Stephane Gueneau², Sandra Afonso³

¹Universidade de Brasília, Brasília, Brasil; ²CIRAD, Montpellier, France; ³Universidade Federal do Maranhão São Luís Brasil; ³Serviço Florestal Brasileiro, Brasília, Brasil (janadinizbr@gmail.com; stephane.gueneau@cirad.fr; sandra.afonso@florestal.gov.br)

The Cerrado occupies an area of about 20 million km² (approximately 20% of the Brazilian territory), being the second largest national biome and the richest savanna in biodiversity of the planet. Although it covers three regions of the country (Northeast, Midwest and Southeast) and housing a significant number of traditional communities and family farmers, is the biome with the lowest percentage of protected areas and therefore one of the most threatened. Strategies for the promotion of non-timber forest products (NTFP) for the conservation of the biome and promotion of sustainable development, with job creation and poverty reduction have been implemented. There are several cases in different states, of products with local supply and demand, but, in the meantime, there are fewer cases of large-scale impacts, reaching in more distant markets. Based on field research carried out in the last five years, we present a comparison of cases of promotion of NTFP chains in different regions of the Cerrado, where we highlight experiences and products of greater demand and occurrence, with the cases of Baru (*Dipteryx alata*), pequi (*Caryocar brasiliense*) and babassu (*Attalea speciosa*), which, based on different strategies of market insertion of agro-extractive organizations, promoted important changes in terms of income generation with local communities and conservation of the biome. Other products, such as buriti (*Mauritia flexuosa*), macaúba (*Acrocomia aculeata*) and other species of lesser occurrence, although less demanded, contribute to the maintenance of the diversity of forest species and the generation of complementary income to the communities.

Contribution of non wood forest products to household income and livelihood improvement in Tunisia: the case of Aleppo pine

Ibtissem Taghouti¹, Emna Ouertani², Bouali Guesmi², Marwa Arfaoui²

¹national research institute for rural engineering water and forestry, Ariana, Nigeria; ²University of Carthage, Mograne Agricultural High School, Zaghwan, Tunisia (ibtissem.taghouti@gmail.com; ouertaniemna2015@gmail.com; bouali.guesmi@upc.edu; marwaarfaoui1992@gmail.com)

Recently, there is a growing interest in the contribution of Non-Wood Forest Products (NWFPs) to livelihoods and food security among the local population. This has gained special attention given the relevance of forest heritage to alleviate poverty and improve household economies. This study focuses on determining the contribution of Aleppo pine production in Siliana province to household livelihood and food security. Data were obtained using structured surveys administered to 250 randomly selected rural household heads during the collection season. The relevance of this region as a leading Tunisian Aleppo pine producer makes the analysis especially interesting. A logistic regression, as well as food security indicators, have been performed to evaluate the contribution of NWFPs to improving household living conditions. Results support evidence that there is a significant difference between the alternative sources of revenues. The utilization of Aleppo pine was significantly influenced by age, gender, household size, distance to market, the importance of off-farm revenue. Finally, Aleppo pine plays an important role in supporting livelihoods and provides an important safety net for local population throughout the year.

C8d: INTENSIFICATION WITHIN LIMITS: INCREASING PRODUCTIVITY WITHOUT COMPROMISING ECOSYSTEM SERVICES

Linking soils, physiology and silviculture to optimize productivity and sustainability of planted forests

Thomas Fox¹

¹Rayonier, Inc, Yulee, USA (tom.fox@rayonier.com)

Precision forestry uses detailed knowledge of soils and physiology to prescribe silvicultural treatments that are applied at the right time in the right location to optimize growth, productivity, and sustainability of the forest. This involves matching species and genotype to each site with an integrated silviculture regime with inputs throughout the rotation to produce the desired products and environmental services from the forest. Because of the variation that exists in soils and site quality, growth responses to silvicultural treatments often vary within a stand and across the landscape. Silvicultural treatments must therefore be implemented at these same spatial scales to address the specific limiting factors. Environmental considerations, local, regional and global markets for timber, non-timber products, and environmental services provided by forests interact with soil quality and the response to silvicultural treatments to determine the limits on intensive management. This will create a mosaic of different management regimes across the landscape that range from intensive plantation management to extensively managed natural stands to forests managed for non-timber objectives and environmental considerations. This presentation will describe how Rayonier, a timber REIT that owns 2.6 million acres, has developed Market Driven Precision Forestry to optimize the productivity, profitability and sustainability of its forest estate in the United States and New Zealand.

Site and stand productivity impacts of slash harvest for energy: experiences from the Nordic countries

Gustaf Egnell¹, Ulrik Ilstedt¹

¹Swedish University of Agricultural Sciences, Department of Forest Ecology and Management, Umeå, Sweden (gustaf.egnell@slu.se; ulrik.ilstedt@slu.se)

After the oil crises in the 1970s forest biomass was considered a potential energy source and a way to decrease the oil dependence in the Nordic countries. Apart from residues from the forest industry this also included primary residues such as branches and tops available following harvest of round wood. One concern was that the moderate increase in biomass harvest, when also branches and tops were harvested, was gained at the expense of a significant increase in the nutrient export from the site. Knowing that growth in the Nordic forests primarily is limited by nutrient availability a negative impact of this additional nutrient export on site productivity and hence the production of the subsequent stand was anticipated. Therefore, a number of field experiments were established from the late 1970s and onwards with the aim to study long-term effects of whole-tree harvest on future site and stand productivity. Here we use a meta-analysis approach on published and unpublished data retrieved from 17 experimental sites planted with Norway spruce and 14 planted with Scots pine, distributed over a wide range of site types in Finland and Sweden. Results include effects on seedling survival, site productivity and stand productivity. Based on the experimental design and silvicultural measures applied over time in these long-term experiments the relevance and the practical implications of the results for whole-tree harvest operations are discussed.

Comparing indicators of site suitability to biomass extraction at the national scale

David Paré¹, Julie Barrette², Brian Titus¹, Francis Manka¹, Fougère Augustin¹, Julien Béguin¹

¹Canadian Forest Service, Quebec, Canada; ²MFFP, Quebec, Canada (david.pare@canada.ca; julie.barrette@mffp.gouv.qc.ca; brian.titus@canada.ca; francis.manka@canada.ca; fougere.augustin@canada.ca; julien.beguin@canada.ca)

There is a growing interest in using logging residues as feedstock in the bioeconomy. There are different approaches, using different rationales, to evaluate sites that are suitable to the extraction of logging residues. However, there are no consensus regarding the best approach to use. This project aims to compare and contrast the results obtained by the use of several types of indicators in a map format, in order to get an understanding of the concordance or discrepancy between indicators and to better evaluate the implications of choosing an indicator. Three types of approach are used: (1) site properties thresholds: thresholds for site properties such as soil pH, % sand or slope are commonly used to define site suitability to intensive biomass extractions; (2) nutrient budget approaches: including the geochemical balance of nitrogen as well as that of base cations and phosphorus and (3) nutrient ratio: this approach evaluates the ratios of harvested nutrient stocks to the status of nutrient reserves in the soil and defines a critical threshold. The nutrient budget approach showed more contrast with the two others. This observation calls for a better scrutiny of the meaning of indicators and a better evaluation of the properties that make a site sensitive to biomass extraction. These results also indicate that there remains much unknown in forest nutrient cycling and that a coordinated research agenda is needed to deal with the greater pressure that is put on forest ecosystem nutrient cycling.

Environment-induced growth changes in the Finnish forests during 1971 – 2010: an analysis based on National Forest Inventory

Helena M. Henttonen¹, Pekka Nöjd², Harri Mäkinen²

¹Natural Resources Institute Finland, Helsinki, Finland; ²Natural Resources Institute Finland, Espoo, Finland (halena.henttonen@luke.fi; pekka.nojd@luke.fi; harri.makinen@luke.fi)

The annual growth of the Finnish forests has more than doubled in less than a century. We quantified the magnitude of increment changes not attributable to changes in growing stock, forest structure and silvicultural practices. The data from National Forest Inventories during 1971 – 2010 were used to develop models for volume, basal area and height increment of individual trees on mineral soils with tree and stand characteristics as predictor variables. Differences between the measured and predicted increment were used to quantify environment-induced increment changes. Then, we estimated the average changes of volume increment per hectare and totals in millions of m³. From 1971 – 1975 to 2006 – 2010, the environment-induced volume increment increase was 8.98 million m³ a⁻¹ (0.69 m³ ha⁻¹ a⁻¹), which equals to 37% of the total observed volume increment increase. During 1971 – 1990, the difference between the observed and predicted change was small. A large shift was observed after the mid-1990s. While the environment-induced increment change was substantial, a considerably larger increase 63 % of the change was attributed to growing stock volume and forest structure, which both changed due to differences in forest management. A comparison between the environment-induced increment changes and growing season temperature sums revealed similarities. In the southern Finland, April-May seemed to be influential, while in the north the temperature sum of May-September showed similar variation. As climate change is predicted to increase growing season temperatures, the trend can be expected to continue in the boreal conditions of Finland.

Stream runoff and nitrate recovery times: evaluating ecosystem response to forest disturbance in the USA and Japan

Mary Beth Adams¹, Tomoki Oda², Mark Green³, Rieko Urakawa⁴, Todd M. Scanlon⁵, Stephen D. Sebestyen⁶, Kevin J. McGuire⁷, Masanori Katsuyama⁸, Karibu Fukuzawa⁹, Nobuhito Ohte⁸

¹USDA Forest Service, Morgantown, WV, USA; ²University of Tokyo, Tokyo, Japan; ³Plymouth State University, Plymouth, NH, USA; ⁴Asia Center for Air Pollution Research, Niigata, Japan; ⁵University of Virginia, Charlottesville, VA, USA; ⁶USDA Forest Service, Grand Rapids, MN, USA; ⁷Virginia Water Resources Center, Blacksburg, VA, USA; ⁸Kyoto University, Kyoto, Japan; ⁹Hokkaido University, Sapporo, Japan (mbadams@fs.fed.us; oh-dah@fr.a.u-tokyo.ac.jp; mbgreen@plymouth.edu; urakawa@acap.asia; tms2v@eservices.virginia.edu; ssebestyen@fs.fed.us; kevin.mcguire@vt.edu; katsuyama.masanori.5m@kyoto-u.ac.jp; caribu@fsc.hokudai.ac.jp; nobu@bre.soc.i.kyoto-u.ac.jp)

Provision of clean water and regulation of nutrients are important ecosystem services provided by forests, and it is important that we can predict how those services will be affected by intensive forest management. One way to evaluate the mechanisms of long-term hydrological and biogeochemical recovery after forest disturbance is to compare recovery times of stream runoff and nitrate concentration. Previous studies have focused on either the response of runoff or stream nitrate concentrations, and some have specifically addressed recovery times following disturbance. However, seldom have these been analyzed together. We explored the relationship between runoff and nitrate recovery times to identify potential factors controlling each, using long-term runoff and stream nitrate concentration data from 20 sites in the USA and Japan. Forest disturbance included clearcutting, partial cutting, tree mortality/defoliation from insects and disease, understory vegetation removal and herbicide application. We examined the relationship between runoff and nitrate recovery times at these sites. Nitrate response was detected at all study sites, while runoff responses were detected at all sites with disturbance intensities greater than 75% of the catchment area. Runoff recovery time was significantly correlated with nitrate recovery time for catchments that had a runoff response. For these catchments, hydrological recovery times were slower than nitrate recovery times. The relationship between these two recovery times suggests that forest regeneration was a common control on both recovery times. However, the faster recovery time for nitrate suggests that nitrogen was less available or less mobile in these catchments than water.

Using herbicides and insecticides to increase site productivity without degrading ecosystem quality and services

Daniel Neary¹

¹USDA Forest Service, Flagstaff, USA (dan.neary@usda.gov)

Forests throughout the world are being evaluated and managed to produce greater outputs of wood fiber and other environmental goods and services for expanding human populations. Any program designed to increase the productivity of production forests must deal with weed and insect infestations that reduce growth rates and tree survival. Cumulative impacts of chemical usage is a topic of concern with many people, agencies, and governments. Modern herbicides and insecticides have been developed to economically control pest species without degrading environmental quality, adversely affecting non-target biota, or impacting human health. Chief concerns are for water quality, aquatic biota, terrestrial non-target plants and animals, recreational uses of forests and their streams and lakes, and human health and safety. Impacts of forest chemical use are a function of toxicity, mode of action, timing of use, loading, and application system. This paper and panel discussion subtopic address the topic of using chemicals to control forest pests in an environmentally sustainable manner and increase forest productivity.

C8e: THE BIOECONOMY AND NON-WOOD FOREST PRODUCTS - 2

Sustainability of resin production systems in Europe according to harvesting methods and contexts based on the evolution of the international pine resin market

Armand Clopeau¹, Christophe Orazio¹

¹European Forest Institute, Cestas, France (armand.clopeau@efi.int; christophe.orazio@efi.int)

The European natural resin extraction industry went through a period of deep crisis during the end of the last century. Public and Private initiatives have been taken in Spain, France and Portugal. The main initiatives implemented are presented in this study which was carried out as part of SustForest+ Project, funded by Interreg Sudoe and the European Regional Development Found (ERDF). First, the study consists in a description of the different production contexts in the world and the associated harvesting methods. This technical information is supplemented by economic data on the past and current resin market. This state of play makes it possible to formulate proposals concerning the evolution of the international resin market. Two scenarios are proposed, favorable or unfavorable to the development of resin production in Europe. The European potentialities of production are then estimated by cost-benefit analysis for each method in each European country, in order to know the profitability thresholds in different production contexts and thus to estimate the viability and sustainability of the various forest management systems designed to harvest resin in south west Europe.

How municipalities can increase their revenue by managing non-timber forest products

Sarah Melo¹, Sarah Linhales¹, Lorena Pinto², Sandra Regina Afonso³, Edson Logato⁴, Maria Auxiliadora Drumond¹

¹Universidade Federal de Minas Gerais, Belo Horizonte, Brasil; ²Instituto Interdisciplinar de Estudos e Pesquisas em Sustentabilidade, Brumadinho, Brasil; ³Serviço Florestal Brasileiro, Brasília, Brasil; ⁴Empresa de Assistência Técnica e Extensão Rural do Estado de Minas Gerais, Belo Horizonte, Brasil (sarahmelo.pequi@gmail.com; sarah.linhales@gmail.com; lorenalana.bio@gmail.com; sandra.afonso@florestal.gov.br; edson.logato@emater.mg.gov.br; alatus@ufmg.br)

Non-timber forest product (NTFP) extractivism's value is invisible to governments and society, and is low priority in the formulation and implementation of Public Policies (PP). Looking to propose PP adaptations for the valuation and valorization of NTFPs, we analyze Brazil's Agricultural ICMS - goods and services tax - which is one of the Robin Hood Law's 17 criteria regarding the distribution of ICMS within the state of Minas Gerais (MG), Brazil. It is calculated based on food production and family farmer data from MG municipalities. Although the LRH also considers extractivists who promote the sustainable management of native forests as family farmers, calculation for distribution of this incentive is based on the area cultivated for food production only, added to pasture areas, and does not take extractive production into account. This calculation excludes all the production of food extracted from municipalities' native vegetation, and devalues the work of extractivists, who are often traditional populations and small farmers who are recognized guardians of biodiversity. Thus, we propose that this calculation be based on the agricultural production of the municipality, including the production of food derived from extractivism, thus contributing to the conservation of NTFPs and generating even more income for the municipalities involved. In the analyzed case of the municipality of São João da Lagoa, this change would provide an increase of approximately 7% in the transfer of resources considering only the harvest of the pequi fruit in 2016. This percentage would be even greater if the production of other extracted NTFPs were considered too.

Development of undergrowth-based economy benefits farmers and rural economic development

Yiqian Zhu¹, Yanru Zeng¹

¹The State Key Laboratory of Subtropical Silviculture, Zhejiang A&F University, Hangzhou, China (631160118@qq.com; yrzeng@zafu.edu.cn)

Decreased tree felling for purposes of ecosystem conservation and improvement has led to fast development of undergrowth-based economy in Zhejiang Province of China. An investigation of 16 undergrowth species produced by 30 organizations in Hangzhou, Lishui, Jinhua, Ningbo and Quzhou of the province has found that Zhejiang is rich in various NTFPs (Non-timber forest products) including both traditional Chinese medicine and edible fungi produced in such forest types as pure plantations and secondary natural forest. There are various undergrowth planting modes with no chemical fertilizer and pesticide applied, which are close-to-organic cultivation with no damage to the original forest ecological environment and have improved forest production through management of planted undergrowth species. In addition, there exist diverse organizational forms such as state-owned enterprises, household-based farms and cooperatives for production and management. The government supports undergrowth economic development by issuing red-headed documents in terms of policy. Researchers from higher learning institutions and local forestry bureaus also actively participate in and technically support the production of undergrowth NTFPs. Moreover, undergrowth planting has not only produced economically profitable NTFPs but also promoted the development of forest tourism, forest-based health industry and tourist products. Some undergrowth NTFP producers are economically strong and play a leading role, which has led to a large radiation area and quickened the transformation of business modes in forestry to increase farmers' income. And finally farmers are happily involved in this form of production. Therefore, Zhejiang Province has a broad prospect for the production of undergrowth NTFPs.

Ecosystem services provided by mammal species in traditional medicine: a biological prospection and conservation implication in Benin

Chabi Djagoun¹, Hugues Akpona^{1,2}, Brice Sinsin¹

¹Laboratory of Applied Ecology, University of Abomey Calavi, Abomey Calavi, Benin; ²Direction Générale des Forêts et des Ressources Naturelles, Cotonou, Benin (dchabi@gmail.com; hakpona@gmail.com; bsinsin@gmail.com)

Mammals is considered as a high proportion of global species diversity among vertebrate and include species that are widely distributed worldwide and play a variety of roles that benefit humans. There are commonly used in traditional medicine, both for the treatment of ailments and for symbolic purposes, such as improving relationships and attaining good fortune. The aim of this study was to identify the mammal species used in traditional medicine and evaluate the contribution of these highly diverse groups to human welfare. We conducted the semi-structured interviews in 22 animal-based medicine markets throughout the country with a total of 110 sellers. Among the 87 mammal species traded on the traditional medicine market in Benin, 46 species were sold by at least half of those traders surveyed; the conservation status of these animals included near threatened, vulnerable and endangered species. This study also found that rarer species were more costly and this constitutes an economic motivation for sellers to develop strategies for the availability of threatened species on their displays. All species are said to have both medicinal and magical values; however their use for magical purposes predominated. This study is a preliminary assessment of mammal used for animal-based medicine purposes in Benin; further investigation is required to increase our understanding of the harvesting and trade of those species, and to assess the impacts caused by the commercial exploitation.

Açaí (*Euterpe oleracea*) in the Amazon: until when a non-timber forest product?Janaina Diniz¹, Nathalie Cialdella²¹Universidade de Brasília, Brasília, Brasil; ²CIRAD, Montpellier, France (janadinizbr@gmail.com; nathalie.cialdella@cirad.fr)

Until the 1990s the açaí was a product basically of local consumption in the states of the Brazilian Amazon, being even known as “food of the poor”. Since then, following the expansion of its market, the exploitation of this fruit has undergone numerous transformations. Nowadays, besides being nationally known, it also has its demand expanded in the international markets, being considered now as a superfood. Such increase in demand has consequently influenced an increase in consumer prices and, in most cases, in the remuneration of extractivists, originally the exclusive suppliers of the fruit. The increase in supply has been due to the multiplication and diversification of actors in the chain, as well as the diversification of management and production practices (native açaí trees densification, increase of monoculture or consortium plantations), depending on the economic context of the producing region, proximity to the industry and time in the activity of the primary suppliers. These changes can also bring vulnerability to more traditional forms and with smaller scale of production. Considering the trajectory of other extractive products that had their demands increased and, in order to meet them, had to identify substitutes, or to change the type of production system, this paper discusses, from recent data, if the main form of açaí offer in the future will still remain through extraction or through cultivation systems. The paper also discusses what forms of market regulation and maintenance of traditional practices could guarantee the permanence of diversified and more sustainable systems.

Traditional knowledge of ecology and *Carapa guianensis* (andiroba) oil extraction from the Mamirauá and Amanã Sustainable Development Reserves in Amazonas, Brazil / O conhecimento tradicional sobre ecologia e extração do óleo de andiroba nas reservas de desenvolvimento sustentável Mamirauá e Amanã, AM, Amazônia BrasileiraEmanuelle Raiol Pinto¹, Ana Cláudia Lira-Guedes², Auristela Santos Conserva³¹Instituto de Desenvolvimento Sustentável Mamirauá, Tefé, Brasil; ²Embrapa amapá, Macapá, Brasil; ³Autonoma, Manaus, Brasil (emanuelle@mamiraua.org.br; ana-lira.guedes@embrapa.br; asconserva@gmail.com)

Por trás do aparato comercial das indústrias de produtos naturais, existe o conhecimento das populações que, tradicionalmente, extraem o óleo de andiroba e encontram dificuldades de acesso ao mercado. O objetivo deste foi identificar o conhecimento tradicional sobre a andiroba e caracterizar o modo de extração dos ribeirinhos das Reservas Mamirauá e Amanã, Amazonas, Brasil. Foram realizadas 30 entrevistas, em 18 comunidades. A maioria dos entrevistados possui ensino fundamental incompleto, a renda familiar é composta pelo extrativismo e bolsas sociais. A extração do óleo de andiroba é realizada prioritariamente para o consumo, embora haja potencial para a comercialização. Os extratores visitam o andirobal uma única vez no ano para coletar as sementes. Não identificam claramente as fases fenológicas, mas, sabem quando é o “tempo de coletar”, por exemplo. A maioria dos informantes afirma que as andirobeiras frutificam entre novembro e junho e a dispersão acontece entre dezembro e julho, sendo melhor para coletar em maio. Declaram que as sementes são todas iguais, porém dizem ter diferença na madeira: branca ou vermelha. Todos os entrevistados relataram saber extrair o óleo e que esta é uma atividade realizada principalmente pelas mulheres. As etapas são: coleta das sementes, cozimento, secagem, descascamento, preparo da massa e escorrimento do óleo. Estas informações facilitam o manejo da atividade nessas áreas, valorizam o conhecimento tradicional associado e o empoderamento feminino na exploração de óleos de sementes florestais. Podendo alavancar a organização social para a comercialização de um produto amazônico de forma sustentável, mantendo a floresta em pé.

C9a: DISCOVERY, CURATION, AND USES OF LEGACY TROPICAL FOREST DATA SETS**The search for legacy tropical forest datasets**Sheila Ward¹, Gillian Petrokovsky²¹Mahogany for the Future, Inc., San Juan, Puerto Rico; ²University of Oxford, Oxford, United Kingdom (mahoganyforthefuture@gmail.com; gillian.petrokovsky@zoo.ox.ac.uk)

Tropical forest tree inventories and plot projects have generated large amounts of data over many decades, but much of this data is in paper or older digitized formats, or still undiscovered. These data sets are in danger of being lost and with them our ability to assess historical changes that can inform research and policy development for land use change and landscape resilience. These legacy datasets are invaluable for understanding how tropical forests, biodiversity, and carbon storage change through time, including the cumulative impacts of changes in land use and climate. Historical data can also help instruct current and future forest management. To locate these data sets, we are reaching out via various electronic media and contacting academics and practitioners. We are also searching older compilations of these data sets such as ATROFI-UK which has metadata on c; 30 studies in need of curation and TROPIS which refers to 6000 plots with uncertain status. The inventories and plots located will be cross referenced against lists of curated datasets such as Forestplots.net and others under the Global Index of Vegetation-Plot Databases (GIVD), to determine which datasets are not already in a long-term data repository. Currently the project has identified some 20 inventory and plot-based studies in need of curation, in countries ranging from Vanuatu to Ghana to Belize. We invite wide participation in the quest for unsecured historical data sets. The guiding principle of the project is that the past can help enlighten the future.

Database of arboreal flora in Northwestern São Paulo, Brazil: importance for conservation, management, and restoration of natural forests in ecotone areas / Base de dados da flora arbórea do Noroeste do Estado de São Paulo, Brasil: importância para a conservação, manejo e restauração de florestas naturais em áreas de ecótonoNatalia Ivanauskas¹, Maria Teresa Toniato¹, Pablo Figueiredo², Alessandra Penha³, Ricardo Rodrigues², Neusa Ranga⁴, Andréia Rezende⁵¹Instituto Florestal, São Paulo, Brasil; ²Universidade de São Paulo, Piracicaba, Brasil; ³Universidade Federal de São Carlos, Araras, Brasil; ⁴Universidade Estadual Paulista, São José do Rio Preto, Brasil; ⁵Universidade Estadual Paulista, Ilha Solteira, Brasil (nivanauskas@yahoo.com.br; mate_zt@yahoo.com.br; pablo_figueiredo@yahoo.com.br; penha.alessandra@gmail.com; rresalq@usp.br; neusatr@ibilce.unesp.br; andreia.rezende@unesp.br)

O conhecimento sobre a vegetação natural remanescente na região Noroeste do Estado de São Paulo, Brasil, foi significativamente ampliado na última década por meio de estudos científicos que se dedicaram a caracterizar a flora e a vegetação de 18 fragmentos naturais, a partir de inventários quantitativos realizados em unidades amostrais permanentes (1 ha em cada fragmento), onde a comunidade arbórea (DAS \geq 5,0 cm) foi registrada em parcelas de 10 m x 10 m e o componente regenerante (altura > 1 m e DAS < 5,0 cm) em sub-parcelas de 2,5 x 2,5 m. Levantamentos qualitativos (coletas de material botânico fértil em caminhamentos) nas mesmas áreas complementaram as informações sobre a flora regional. O banco de dados conta com o registro de 20.853 indivíduos

arbóreos marcados, pertencentes a 292 espécies e 59 famílias. Acrescidos os dados qualitativos, resultam em 347 espécies e 60 famílias. No componente regenerante foram registrados 5.989 indivíduos de 207 espécies. Foram reconhecidas as seguintes formações florestais presentes na região: Savana Florestada (sete fragmentos), Floresta Estacional Semidecidual (seis) e ecótono Floresta Estacional Semidecidual - Savana (cinco). A caracterização dos remanescentes naturais, as unidades amostrais permanentes e o patrimônio constituído pelo conjunto de dados são valiosos e fundamentais para fomentar estudos subsequentes, em especial os relacionados à dinâmica da comunidade e à manutenção de populações ameaçadas de extinção, na busca de indicadores para monitoramento e subsídios para ações de manejo adaptativo, de modo a potencializar o papel desses remanescentes na conservação e restauração da biodiversidade paulista e de seus serviços ecossistêmicos.

Scale and context dependency of deforestation drivers: insights from spatial econometrics in the tropics (Zambia, Ecuador and Philippines)

Rubén Ferrer Velasco^{1,2}, Margret Köthke¹, Melvin Lippe¹, Sven Günter^{1,2}

¹Thünen Institute of International Forestry and Forest Economics, Hamburg, Germany; ²Technical University of Munich, School of Life Sciences Weihenstephan, Department of Ecology and Ecosystem Sciences, Chair of Silviculture, Munich, Germany (ruben.ferrer@thuenen.de; margret.koethke@thuenen.de; melvin.lippe@thuenen.de; sven.guenter@thuenen.de)

It is so far unclear if the well-studied drivers of tropical deforestation behave similarly across nested subnational jurisdictions. A better understanding is a precondition for designing efficient policies and coherent land use planning strategies. We focused on three countries in Africa, America and Asia, which present very different pantropical contexts. Making use of spatial econometrics and a multi-level approach, we conducted a set of spatial regressions. Overall, the final sample comprised 3,035 administrative units from the three countries at micro-level, plus 361 and 49 at meso- and macro-level, respectively. We included forest cover as dependent variable and seven physio-geographic and socioeconomic indicators for well-known drivers of deforestation as explanatory variables. Uniform tropical determinants of forest cover change were detected with highly significant models. As expected, these recurrent drivers are related to population pressure and the natural condition of land suitability for crop production. However, clear differentiations across countries and spatial levels were visible. We also observed more and stronger spatial dependencies at smaller spatial scopes of higher heterogeneity, including spatial errors and interactions between neighboring units. The results provide arguments for both sides of the land sharing vs. land sparing debate. We therefore advocate, that the design and enforcement of policy instruments - such as REDD+ - should start from common international entry points. At the same time, these strategies have to be modified and adapted to particular national, regional or local conditions, avoiding a one size fits all solution.

Resurrecting the dead: re-establishing the rainforest permanent network of the Queensland Forestry Department

John Herbohn¹, Jerry Vanclay², David Lamb^{1,3}, Robin Chazdon^{1,4}, Grahame Applegate¹, Liz Ota¹, Andrew Marshall^{1,5}, Jing Hu^{1,3}, Jack Baynes¹, Phan Quang¹, Shariff Mukul¹, Robert Colwell^{1,4}

¹The University of the Sunshine Coast, Sippy Downs, Australia; ²Southern Cross University, Lismore, Australia; ³The University of Queensland, Brisbane, Australia; ⁴University of Connecticut, Storrs, USA; ⁵University of York, York, United Kingdom (jherbohn@usc.edu.au; jvanclay@scu.edu.au; d.lamb@uq.edu.au; rchazdon@usc.edu.au; gapples@usc.edu.au; lota@usc.edu.au; amarshal@usc.edu.au; jing.hu1@uq.net.au; jbaynes@usc.edu.au; m_p107@student.usc.edu.au; smukul@usc.edu.au; robertkcolwell@gmail.com)

Over a period of over 100 years, scientists from the Queensland Department of Forestry (QDF) and Commonwealth Scientific Industrial Research Organisation (CSIRO) undertook research into the management of tropical rain forests in north Queensland, Australia as part of their commitment to sustainable utilisation of these forests for timber production. Much of this experimental research and growth and yield monitoring was unique and scientifically significant and has been recognised as such by the international forestry community. As part of that research, over 800 'plots' were established, including to monitor growth (28), effects of enrichment planting (585), logging damage (32), regeneration (39) and various forest treatments to improve productivity (91). Many of these plots were established during the 1940's and 1950's, covering a range of rainforest types, altitudes, parent material, and rainfall; and including undisturbed, logged and experimentally-treated forests. The QDF plots were abandoned in 1987 when NQ rainforests were World Heritage Listed. This paper describes the substantial legacy dataset associated with the NQ rainforest plot network and the recent efforts by researchers from the Tropical Forests and People Research Centre. The initial recovery process has focussed on 60 priority plots which were last remeasured in 1997 and a database of over 200,000 records associated with these 60 plots has been created. We outline the challenges faced and the lessons learnt. We also present some contemporary research questions that can be addressed using the legacy datasets that were not envisaged at the time the experiments and associated plots were established.

Biodiversity monitoring and carbon assessment: vital in sustaining ecosystem and governance of rehabilitated mangroves and uplands for resilient communities in Quezon Province, Philippines

Nelson M. Pampolina¹, Dixon T. Gevana², Mutya Maria Q. Manalo¹, Keshia N. Tingson³, Juancho B. Balatibat¹, Jesa P. Ata¹, Lorena A. Sabino², Raffy D. Gordula¹, Erwin L. Tabaco¹, James G. Petonio¹, Ronaldo A. Altamirano⁴

¹Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines Los Banos, Laguna, Philippines; ²Department of Social Forestry and Forest Governance, College of Forestry and Natural Resources University of the Philippines Los Banos, Laguna, Philippines; ³Institute of Renewable Natural Resources, College of Forestry and Natural Resources, University of the Philippines Los Banos, Laguna, Philippines; ⁴TeaM Energy Foundation, Inc., Taguig City, Philippines (nmpampolina@up.edu.ph; dtgevana@up.edu.ph; mqmanalo1@up.edu.ph; kntingson1@up.edu.ph; jbbalatibat@up.edu.ph; jpata@up.edu.ph; lsabino@up.edu.ph; raffygordula_17@yahoo.com; eltabaco@up.edu.ph; jpetonio@up.edu.ph; altamirano@teamenergy.ph)

Permanent Biodiversity and Carbon Monitoring Areas (PBCMA) were established in 2015 across 10yo rehabilitated mangroves in five villages of Padre Burgos and three ameliorated mountainous Protected Areas in Pagbilao-Atimonan Quezon, Philippines. The objective was to generate long-term biodiversity data and carbon estimates that govern regional sustainability and climate resiliency. Twenty six PBCMAs totaling 8,000-80,000 m² were randomly demarcated (5x40 and 20x100 m² plot⁻¹) to baseline biodiversity and monitor biometrics, carbon, plant growth, and succession. Communities and stakeholders were profiled to capacitate through focus group discussion and trainings for participatory monitoring, assessment, and presentation. Ecosystem sustainability and resiliency were evaluated to prepare local policy. Six mangroves and 73 upland species were identified and monitored at PBCMAs, totaling 2,513 individuals over three years. Most indigenous species were dipterocarps and mangroves considered threatened where DBH and height ranges were 0.5-65cm and 0.5-37m, respectively. Importance value was high in mangrove (50.3%) though low diversity (H'¹=0.4965) unlike upland. Ecologically, rehabilitated ecosystems were habitats to 33 vertebrates, 37 fungi, 29 macrobenthos, and enumerable bacteria. Mangrove soil was basic with higher organic carbon than upland. Mangrove aboveground

biomass (15.4-93.3 tons ha⁻¹) was lower than upland (39.4-174.8 tons ha⁻¹) with total carbon (909.83 tons ha⁻¹) sequestration potential to offset local CO₂ emission. Communities and stakeholders expressed interest to discover biodiversity and support carbon management through peoples organization but suggest livelihood incentives and local legislation. Overall, biodiversity and carbon values are realized landscape-wise locally but necessitate regular monitoring and networking across country to sustain ecological functions and strengthen resiliency against climate change.

Uses of legacy data sets for long-term monitoring of tropical Pacific island rainforests

Hans Juergen Boehmer¹

¹University of the South Pacific, Suva, Fiji (neobiota@web.de)

Long-term vegetation records are of crucial importance for investigating plant species' responses to global change, in particular to climate change and biological invasions. Some of the strongest evidence for the impacts on forest ecosystems comes from long-term studies through comparisons of current with previous data, based on methodological consistency and spatially explicit datasets. In the tropical Pacific islands, however, long-term ecological studies in rainforests are limited and often hampered by geographical isolation and the lack of funding and specialized experts, thus not allowing for the necessary institutional persistence. While long-term monitoring of forest plots has been integrated into ecological studies in Hawaii (U.S.A.) and New Caledonia (France), published studies based on permanently marked plots and locations are almost entirely lacking in the other tropical Pacific islands, predominantly belonging to the territories of small island developing states (SIDS). We use legacy data sets for long-term monitoring of tropical island rainforests in Hawaii and Fiji to better understand long-term rainforest dynamics, and to demonstrate challenges, possibilities and limitations in the use of such data sets. This will be discussed in the light of relevant institutional differences between a developed island state, and a small island developing state.

Embracing old, imperfect, long-term, field Data

Andrew Marshall¹, Robin Chazdon¹, Liz Ota¹, Jerry Vanclay³, David Lamb⁴, Grahame Applegate¹, Rob Colwell⁵, Jing HU⁴, Jack Baynes¹, John Herbohn¹

¹University of the Sunshine Coast, Sippy Downs, Australia; ²University of York, York, United Kingdom; ³Southern Cross University, Lismore, Australia;

⁴University of Queensland, Brisbane, Australia; ⁵University of Connecticut, Connecticut, USA (amarshal@usc.edu.au; rchazdon@gmail.com;

lota@usc.edu.au; jerry.vanclay@scu.edu.au; david.lamb@uq.edu.au; gapples@usc.edu.au; robertcolwell@gmail.com; jing.hu1@uq.net.au;

jbaynes@usc.edu.au; jherbohn@usc.edu.au)

Permanently marked ecological experiments have been in existence for decades, particularly in the field of forest ecology and management. However, many of these were designed and implemented according to outdated scientific procedures, or with limited resources. These data therefore require careful consideration for statistical analysis and subsequent interpretation, to address limited replication, spatial and temporal data gaps, and other imperfections. These data are however irreplaceable, often meticulous, and essential to global change science. Our aim is to highlight the utility of old, imperfect, long-term datasets, for the field of applied ecology, with a primary focus on forests. We identify essential contributions that these datasets can make, based on their previous contributions to the advancement of fundamental ecology, and on unanswered ecological questions for which they will be essential. We then identify how imperfections in these data can be overcome by the application of realistic research questions, analyses, and/or written justification for their urgent consideration, despite lacking contemporary aspects of study design.

C9b: PLANTED FORESTS FOR A GREENER FUTURE AND ACHIEVING SUSTAINABLE DEVELOPMENT GOALS (SDGS)

Market driven precision silviculture: linking silviculture with financial analysis and environmental considerations to optimize productivity and sustainability of planted forests

Thomas Fox¹

¹Rayonier, Inc., Yulee, USA (tom.fox@rayonier.com)

Precision plantation forestry uses detailed knowledge of soils and physiology to prescribe silvicultural treatments that are applied at the right time in the right location to optimize growth, productivity, and sustainability. This involves matching species and genotype to each site with an integrated silviculture regime with inputs throughout the rotation to produce the desired products and environmental services from the forest. Modern technology such as field computers, GIS, satellite navigation, drones, and remote sensing tools such as LiDAR are needed to provide foresters the tools needed to efficiently implement precision silviculture. Precision requires a comprehensive understanding of markets and the short term and longer value of timber needed to justify the expenditures that are being made. In order to ensure that precision forestry is sustainable, environmental, social, and governance issues (ESG) must be incorporated into the decision process. Because of the variation that exists in soils and site quality, growth responses to silvicultural treatments, environmental issues, and the local, regional and global markets for timber, non-timber products, and environmental services provided by forests, market driven precision silviculture will create a mosaic of different management regimes across the landscape that range from intensive plantation management to extensively managed natural stands to forests managed for non-timber objectives and environmental considerations. This presentation will describe how Rayonier, a timber REIT that owns 2.6 million acres, has developed Market Driven Precision Forestry to optimize the productivity, profitability and sustainability of its forest estate in the United States and New Zealand.

Forest plantations investments in Southwestern Europe: a comparative trend analysis on returns, markets and policies

Alex Pra^{1,2}, Mauro Masiero², Susana Barreiro³, Lucio Brotto¹, Gabriel Orrandre⁵, Aitor Onaindia⁶, Margarida Tomé³, Davide Pettenella²

¹ETIFOR, Padova, Italy; ²University of Padova, Padova, Italy; ³University of Lisbon, Lisbon, Portugal; ⁴Wageningen University and Research, Wageningen,

Netherlands; ⁵Bosqalia, Pamplona, Spain; ⁶BASOA Foundation, Bilbao, Spain (alex.pra@etifor.com; mauro.masiero@unipd.it; smb@isa.ulisboa.pt;

lucio.brotto@etifor.com; gorradre@bosqalia.es; basoekin.a@basoa.org; magatome@isa.ulisboa.pt; davide.pettenella@unipd.it)

At global level there is a growing interest towards forest plantations as investment opportunities for profit generation, for building strategic assets, but also to address sustainable development challenges with the production of provisioning, regulating and cultural services. In southwestern Europe, forest plantations represent a consolidated segment of investment for landowners. In future years, the increasing demand for timber and fibers driven by bioeconomy and bioenergy policies, might boost the interest towards forest plantations investments, with an increasingly important role played by financial investors as well as

by strategic partnerships. In this study we analyzed and compared potential investment returns at aggregate level for some of the most important forest plantation species in Southwestern Europe, focusing on some regions of Italy, Spain and Portugal. In addition, we carried out a trend analysis, estimating how returns have changed in recent years as a result of the evolution of the key economic and policy drivers. Overall, our results indicate that in southwestern Europe there are some opportunities for reasonably interesting returns for sectorial investors, i.e. landowners and forest-based industry, and in some cases also for financial investors. Nevertheless, it emerges that the regional context is characterized by structural factors - i.e. the dynamicity of the regional timber market structure, the increasing role of forest damage risk, the social demand biodiversity and landscape conservation and the small-scale fragmented forest holdings - that new investors would have to take into consideration, and which could limit the attractiveness of plantations in this region.

Forest plantations and local economic development: evidence from the municipalities of the State of Minas Gerais, Brazil

Roberta Afonso^{1,2}, Daniel Miller¹

¹Department of Natural Resources and Environmental Sciences - NRES - University of Illinois at Urbana-Champaign, Urbana - IL, USA; ²Central Bank of Brazil, Brasilia, DF, Brasil (rafonso@illinois.edu; dcmliller@illinois.edu)

Brazil is one of the most important producers of wood products from forest plantations. Forest plantations are of increasing economic importance for the national economy; however, little is known about its economic impacts at regional and local levels. This study begins to fill an existing gap in the literature regarding empirical research on plantations at local level over a relatively long period of time. The research focuses on the socioeconomic effects of forest plantations in municipalities of the State of Minas Gerais, Brazil, over a twenty-year time period. Minas Gerais, with the largest plantation area since 1970, is the third richest state, but encompasses very unequally developed areas. We employed panel data methods with data from the National Censuses – 1991, 2000, and 2010 –, and Global Forest Watch/TW. Our primary dependent variables were the level of poverty, extreme poverty, migration, and per capita income. Results show that plantation areas are associated with less poverty over time, a positive migration rate, and higher per capita income for the third and fourth poorest quintiles. Plantations did not show direct effects on extreme poverty. Previous studies have found that plantations are associated with more poverty because their expansion occurs in poor areas. In our case, we found this association changed over time, suggesting they bring overall economic improvement. Additionally, migration was found positive over the years, contradicting other qualitative studies. These findings are important, as they provide insights on how plantations are shaping local development and who is benefiting from it.

The potential of investing in breeding forest material for a sustainable intensification of planted forests: management and micro-economic effects in 3 European study cases

Hernán Serrano-León¹, Anssi Ahtikoski², Christophe Orazio¹

¹European Forest Institute, Cestas, France; ²Natural Resources Institute Finland (Luke), Oulu, Finland; ¹European Forest Institute, Cestas, France (hernan.serrano@efi.int; anssi.ahhtikoski@luke.fi; christophe.orazio@efi.int)

Given the limited land resources, increasing the productivity of planted forests and strengthening their management is essential to support a bioeconomy transition that can achieve the Sustainable Development Goals. One way to address the growing global demands for wood and fiber resources and enhance climate change mitigation is by investing in improved forest reproductive material. In addition to improving tree survival to adverse conditions, tree breeding enhances forest growth and resources quality, while reducing the required area for productive land. We analyze the effects of using genetically improved material in terms of silvicultural management, wood production and economic impact in three study cases in Europe with developed breeding programmes (maritime pine in French Landes, Scots pine in Central France, Scots pine in Finland). The growth development of improved stands was simulated assuming standard forest management guidelines and different genetic gain scenarios estimated for the available breeding material; while the financial performance was assessed considering the effect of different wood prices. The improved performance of breeding material resulted in substantially higher production and profitability in all cases, what can encourage forest owners to invest in forest management even in less productive sites. A higher financial stability against the price fluctuations in comparison with using unimproved material can be especially important to reduce the economic impact of unexpected changes in global wood markets. These potential gains from breeding material investment can play an important role on sustainable intensification of forest management under a context of global change.

The importance of non-native tree species for European forest: history, current state and outlook

Elisabeth Pötzelberger¹, Hubert Hasenauer¹, Monika Konnerth², Frits Mohren³, Anna Gazda⁴, Martin M. Gossner⁵, Thomas Wohlgemuth⁵, Pilar Castro-Díez⁶, Joana Vicente⁷, Heinrich Spiecker⁸

¹University of Natural Resources and Life Sciences, Vienna, Vienna, Austria; ²Bavarian Office for Forest Seeding and Planting, Teisendorf, Germany; ³Wageningen University, Wageningen, Netherlands; ⁴University of Agriculture, Krakow, Poland; ⁵Swiss Federal Research Institute WSL, Birmensdorf, Switzerland; ⁶Universidad de Alcalá, Alcalá de Henares, Spain; ⁷CIBIO, Universidade do Porto, Vairão, Portugal; ⁸Albert Ludwig University of Freiburg, Freiburg, Germany (elisabeth.potzelberger@boku.ac.at; hubert.hasenauer@boku.ac.at; monika.konnerth@gmx.de; rlgazda@cyf-kr.edu.pl; martin.gossner@wsl.ch; thomas.wohlgemuth@wsl.ch; mpilar.castro@uah.es; jsvicente@fc.up.pt; instww@uni-freiburg.de) martin.gossner@wsl.ch; thomas.wohlgemuth@wsl.ch; mpilar.castro@uah.es; jsvicente@fc.up.pt; instww@uni-freiburg.de)

The management of non-native tree species has a long tradition in European forestry. Over centuries, new species have been introduced to Europe for various purposes. Besides planting fast growing trees to meet the resource demand from industrialisation, e.g. finding suitable species for afforestation of degraded areas was a strong motivation for introduction. Today, the number of non-native tree species planted in forestry exceeds two hundred, and strong regional differences in the species choice, management goals and regulation of non-natives are apparent. Nevertheless, only seven species or hybrid groups make up for 90% of the growing stock of non-natives - five from North-America (*Robinia pseudoacacia*, *Picea sitchensis*, *Pseudotsuga menziesii*, *Pinus contorta*, *Populus* hybrids), one from Australia (*Eucalyptus globulus*) and one from Asia (*Larix kaempferi* and hybrids thereof). The demands and expectations to non-native forest tree species are increasing and include the provision of ecosystem services and climate change adaptation. But also the ecological risks have come into focus, since the current distribution of non-native trees is artificial and does not reflect a long-term evolution. On the other hand, additional species options may be important for diversification and risk reduction in the forests, as the number of native tree species in central and northern Europe is rather low. To address all these challenges and opportunities, we established a large network of on non-native tree species experts in the form of the COST Action FP1403 NNEXT. Results from NNEXT will be presented.

Silviculture and management of non-native tree species in Europe

Frits Mohren¹, Valeriu0-Norocel Nicolescu², Bill Mason³, Heinrich Spiecker⁴, Jean-Marc Henin⁵, Hubert Hasenauer⁶, Elisabeth Pötzelsberger⁶
¹Forest Ecology and Forest Management Group, Wageningen University and Research, Wageningen, Netherlands; ²Faculty of Silviculture and Forest Engineering, Transylvania University, Brasov, Romania; ³Forest Research, Northern Research Station, Roslin, Midl (frits.mohren@wur.nl; nvnicolescu@unitbv.ro; bill.mason@forestry.gsi.gov.uk; instww@uni-freiburg.de; jeanmarc.henin@spw.wallonie.be; hubert.hasenauer@boku.ac.at; elisabeth.pötzelsberger@boku.ac.at)

As part of the COST Action FP1403 'Non-native Tree Species for European Forests: Experiences, Risks and Opportunities' (NNEXT) general and national-level information and experiences on forest management systems and silvicultural models for the main non-native tree species in Europe (*Abies grandis*, *Eucalyptus* sp., *Picea sitchensis*, *Pinus contorta*, *Pseudotsuga menziesii*, *Quercus rubra*, *Robinia pseudoacacia*) have been compiled. We have compared these data with the standard silviculture and productivity of appropriate native tree species. Non-native tree species have been introduced into the landscape either to increase stand productivity, or to improve soil conditions for tree growth. Selection for increased productivity may come at greater risk of disturbance. An overall comparison of productivity in non-native tree species compared with native species, based variously on reported national performance, yield tables, or national forest inventories, point to an increase that is 20-30% above productivity of native tree species on comparable sites. Throughout Europe, silviculture of non-native tree species mostly focusses on timber production, as the main forest function, using an even-aged system with rotation age defined by growth rate and wood quality. As stands of introduced species age, and management objectives extends beyond productivity, the use of spontaneous regeneration and the development of mixtures of native and non-native tree species is becoming increasingly important, and silviculture increasingly includes management of interspecific competition to maintain mixed stands. In addition, adapting forest management to increase stand resilience to the impacts of climate change, while controlling invasiveness of some species, is of increasing importance

Tree plantations that utilize a landscape approach will help support the Sustainable Development Goals

Gary Dunning^{1,2}, Peter Kanowski³
¹Yale University, New Haven, USA; ²The Forests Dialogue, New Haven, USA; ³Australian National University, Canberra, Australia (gary.dunning@yale.edu; peter.kanowski@anu.edu.au)

The increasing global demand for wood products, and the importance of trees for delivering ecosystem services, suggest a key role tree plantations in realizing the sustainable development goals. However, conflicts over land use and stakeholder involvement persist for tree plantations, as do concerns about their negative impacts on the environment and on local communities. The Forests Dialogue (TFD), a multi-stakeholder dialogue platform, co-convened a series of Tree Plantations in the Landscape (TPL) dialogues in Chile (June 2016), Brazil (March 2018), and New Zealand (November 2018). Key stakeholders focused on 5 priority areas: tree plantations in the context of the global development agenda; tree plantations in the context of the landscape approach; enabling good governance and inclusive development; key externalities associated with tree plantations; and diversification of species composition and the sustainability of plantation forestry systems. All TPL dialogues highlighted opportunities to improve governance, allow for more diverse participation in forestry, support community rights and autonomy, and promote cooperation across sectors. Conversations pointed to the importance of knowledge exchange, the need for truly inclusive dialogue, and the importance of monitoring, reporting and transparency. Most recently, discussions in New Zealand focused on sustainability in intensive production systems, indigenous forestry models, and the role of plantation forests in meeting Paris Agreement commitments. Continued dialogue provides a clearer picture of the current state of tree plantations in landscapes, refines key considerations for future development, and identifies specific policy implications for tree plantations to deliver against the sustainable development goals.

Planted forests and their role in conserving biodiversity in Brazil / Florestas plantadas e seu papel para a conservação da biodiversidade no Brasil

Laura Antoniazzi¹
¹Agroicone, São Paulo, Brasil (laura@agroicone.com.br)

De acordo a FAO, existem 278 milhões de hectares de florestas plantadas no mundo, o que representa 7% do total da área de florestas do globo. Diante do crescimento populacional, que deve alcançar 9,1 bilhões de pessoas até 2050, a área de florestas plantadas deverá aumentar em mais 250 milhões de hectares. No Brasil, a área ocupada com florestas plantadas é de 7,8 milhões de hectares, divididos em 5,6 milhões de plantios de eucalipto e 1,6 milhões de plantios de pinus. As florestas plantadas estão em diferentes biomas, especialmente Mata Atlântica e estima-se crescimento de até 2 milhões de hectares até 2030. Para cada hectare plantado, há 0,7 hectares de florestas nativas conservadas, com a criação de corredores ecológicos que favorecem conectividade e redução do efeito de borda. Somadas às boas práticas de manejo e colheita florestal, grande número de espécies registradas no Brasil foram encontradas áreas conservadas pelas empresas florestais, compreendendo: 161 espécies de anfíbios, 174 répteis, 985 aves, 241 mamíferos e mais de 1.570 espécies da flora. Considerando que até 2020 novas metas de biodiversidade serão acordadas no âmbito da Convenção sobre Diversidade Biológica, alinhadas aos Objetivos de Desenvolvimento Sustentável, exploraremos de que formas o setor pode contribuir, cada vez mais, com a conservação da biodiversidade. Dentre as opções destacam-se o fomento a intensificação sustentável sobre áreas antropizadas, manejo, bom relacionamento com as comunidades, dentre outras. Ademais, incentivar a pesquisa e inovação no setor, fomentar certificação e benefícios sociais dos produtos das florestas plantadas é essencial.

Creating shared value between academia, the forest sector & civil society: the New Generation Plantations - IUFRO Planted Forest Task Force collaborative research program

Luis Neves^{1,4}, Peter Freer-Smith^{2,5}, Miguel Bugalho³
¹WWF, São Paulo, Brasil; ⁴IUFRO Task Force Sustainable Planted Forests for a Greener Future, Vienna, Austria; ²University of California at Davis, Davis, USA; ⁵Forestry Commission Edinburgh, United Kingdom; ³IUFRO Task Force Sustainable Planted Forests for (Insilva@wwfint.org; pfreersmith@ucdavis.edu; migbugalho@isa.ulisboa.pt)

The 2018 New Generation Plantations (NGP) Encounter was held alongside the 4th International Congress on Planted Forests, in Beijing. The joint event was a landmark in the NGP ongoing collaboration with the IUFRO Task Force on Planted Forests for a Greener Future. Scientific knowledge is essential for informing good policies and management practices and addressing major emerging issues. All NGP Participants work with researchers, so by working together with IUFRO, NGP can help to both set the research agenda, and provide focus on key topics of concern to the forestry sector. The partnership aims to aggregate and analyse research findings. Since the objectives of NGP participants and IUFRO Task Force members often overlap there is scope for co – design

of research work. The objectives are to provide data supporting the NGP Principles and to mine data from “hidden research”. The collaboration will move forward through the development of a joint research program, involving the NGP Participants and IUFRO Universities and Research Centers. The program will set common Research questions, mostly of multidisciplinary nature, including questions addressing social, environmental and business-oriented issues. Data already collected by the NGP Participants during their daily basis activities, as well as new data collected by the research partners within the research program, will be used to reply to those questions. Ultimately, the NGP/IUFRO research program will show how best practices in plantations may contribute to the sustainable use of the land and to tackle several of the global environmental challenges humankind is currently facing.

International Commission on Poplars and Other Fast-Growing Trees Sustaining People and the Environment (IPC) – a model for international technical cooperation in forestry

Jim Carle¹, Teresa Cerrillo², Sharon Doty³, Emile Gardiner⁴, Julia Kuzovkina⁵, Mirko Liesebach⁶, Ian McIvor⁷, Giuseppe Nervo⁸, Joris Van Acker⁹, Martin Weih¹⁰, Benjamin Caldwell¹¹

¹Jim Carle and Associates, Mount Maunganui Bay of Plenty, New Zealand; ²Instituto Nacional de Tecnología Agropecuaria, Campana, Argentina; ³University of Washington, Seattle, USA; ⁴US Forest Service, Stoneville, USA; ⁵University of Connecticut, Hartford, USA; ⁶Thünen Institute of Forest Genetics, Grosshansdorf, Germany; ⁷New Zealand Poplar and Willow Research Trust, Palmerston North, New Zealand; ⁸Ministry of Agricultural, Food, Forestry and Tourism Policies, Casale Monferrato, Italy; ⁹Ghent University, Gent, Belgium; ¹⁰Swedish University of Agricultural Sciences, Uppsala, Sweden; ¹¹FAO, Rome, Italy (carle.jim@gmail.com; tcerrillo@gmail.com; sldoty@uw.edu; egardiner@fs.fed.us; jkuzovkina@uconn.edu; mirko.liesebach@thuenen.de; ian.mcivor@plantandfood.co.nz; giuseppe.nervo@crea.gov.it; joris.vanacker@ugent.be; joris.vanacker@ugent.be; martin.weih@slu.se; benjamin.caldwell@fao.org)

Sustainable forest management is necessary to achieve Sustainable Development Goal fifteen; as well, forests are an acknowledged pathway to achieving the other Sustainable Development Goals (SDGs). The IPC is a statutory body within the framework of the FAO that focuses on improvement of rural livelihoods through ecosystem goods and services from fast-growing tree species. These fast-growing trees are part of planted forests established in thirty-eight IPC Member Nations in five continents. Among other work, the IPC helps Member Nations obtain and use improved cultivars and preserve species, with emphasis on an environmentally sustainable systems and on improving people’s livelihoods. Breeding programs have contributed significantly to the main quantitative and qualitative advances achieved by the cultivation of fast growing trees, with important benefits throughout the world. There has been significant expansion in recent years in terms of methodologies, the use of genomic tools, of early selection techniques (especially for adaptation and technology), and of lines of research that provide specific genotypes. The IPC makes this information available to the international community and particularly to Member Nations of the IPC. A case study of the IPC’s global work on cottonwood (*Populus deltoides*) is presented. This case illustrates how forests can help achieve the sustainable development goals. Through the IPC, it also demonstrates a practical institutional model for international technical exchange, facilitating implementation of improvements in forest science in order to achieve the SDGs.

Planted forests vs. natural forests: an inverse environmental kuznets curve?

Daowei Zhang¹

¹FAO, Rome, Italy (daowei.zhang@fao.org)

This study investigates on the relationship between planted forest development and natural forest conservation at country and sub-national levels. Using country level data from 60 countries that have most planted forests and sub-national data from China and United States, we found that planted forests and natural forests are either unrelated or weakly correlated as in an inverse Environmental Kuznets Curve. This finding fits in the division of land theory and the forest transition model. Further studies need to be carried out in other countries.

C9c: RESOURCE EFFICIENCY OF WOOD-BASED PRODUCTS AND MANUFACTURING

Dust emission during helical planing sucupira wood

Bruna Ugulino¹, Roger Hernández¹, José Tarcísio Lima²

¹Université Laval, Quebec, Canada; ²Universidade Federal de Lavras, Lavras, Brasil (braugulino@msn.com; roger.hernandez@sbflaval.ca; jtilima@def.ufla.br)

Concerns have been raised by the repeated exposure to wood dust. Dust produced during the usual operations of wood machining may not be totally captured by the devices integrated to machinery, and be dispersed in the workshops. Thus, the decrease of dust emissions during wood machining is of great interest. The dustiness of the working environment depends, among other things, on the cutting parameters. These parameters act directly in the formation of wood chips and fine particles. On the other hand, helical planing has been proposed as an alternative method to reduce the need for sanding during wood finishing. This process is less noisy than conventional planing and improves the surface quality. The aim of this study was to determine the effects of moisture content (8 and 12%) and feed speed (from 8.5 to 20 m.min⁻¹) on dust emission (0.1 to 15 µm) and surface roughness during helical planing sucupira (*Diptropis* sp.) wood. The results showed that dust emission decreased as feed speed increased with the increase of average chip thickness. Moisture content also affected the amount of dust. Dust emission increased for the higher moisture content but for thicker chips (0.10 mm). For thinner chips, dust emitted was similar for the two studied moisture contents. Furthermore, higher values of feed speed produced higher surface roughness. The best planing condition was obtained when using 8% moisture content and 16 m.min⁻¹ feed speed. This condition was the fastest feed speed allowable to obtain the best surface quality while minimizing dust production.

Experimental methodology to monitor the development of wood drying cracks in real-time

Hanna Botter-Kuisch^{1,2} , Jan Van den Bulcke² , Jan Baetens² , Joris Van Acker² 

¹Anton de Kom University of Suriname, Paramaribo, Suriname; ²Ghent University, Gent, Belgium (hanna.kuisch@ugent.be; jan.vandenbulcke@ugent.be; jan.baetens@ugent.be; joris.vanacker@ugent.be)

Drying is a fundamental step in solid wood processing, yet it is very challenging because of potential drying defects negatively affecting the final product quality. Successful kiln drying depends largely on the diffusivity and permeability of the wood species. Despite many research efforts, predicting kiln-drying schedules for a given wood species is not yet possible. The main reason is that important spatio-temporal variables such as moisture and temperature gradients, and wood anatomical features are considered insufficiently in the predictive modelling framework. We expect that monitoring and controlling drying up to the limit states can be used for any wood species. To understand the influence of parameters determining these limit states we developed an experimental measurement set-up. This set-up allows real-time monitoring of local moisture content gradient inferred from the electrical resistance gradient, wood temperature gradient

and average moisture loss in function of time for any wood species. The obtained data is linked directly to the wood anatomical structure on the end grain, the occurrence of cracks and the transversal shrinkage. This methodology enables to unveil interrelationships between physical parameters and changes of the wood anatomical structure. We present a proof-of-concept with basralocus (*Dicorynia guianensis*).

Comparative assessment of the sustainability performance of glue laminated timber and non-renewable material-based value chains

Marius Aleinikovas¹, Povilas Žemaitis¹, Edgaras Linkevičius²

¹Institute of Forestry, LAMMC, Girionys, Lithuania; ²Vytautas Magnus University Agriculture Academy, Akademija, Lithuania (marius.aleinikovas@mi.lt; povilas.zemaitis@mi.lt; edgaras.linkevicius@asu.lt)

Mitigation of climate change, carbon sequestration and low carbon economy are some of the corner stones of the European bioeconomy strategy. Lithuania has sufficient forest resources and a competitive wood industry, and more than 20% of annual harvest level is exported. Also, Lithuania exports about 80% of glue laminated timber for wooden constructions using only 20% for national house construction. Because of this, Lithuania loses possibility to develop its low carbon economy based on high value added products. The production of glue laminated timber (GLT) is rapidly growing in Lithuania. Timber can be a viable and long-term alternative for storing green Carbon in buildings and substituting GHG emissions from more energy intensive materials. The aim of the study is to quantify and to compare sustainability impacts and climate change mitigation potential of national value chains for non-renewable materials (reinforced concrete (RC)) and renewable materials (GLT) used in construction sector. GLT value chain involve: forest logging–transporting–timber sawing–GLT producing processes; RC value chain involve: raw material extraction for cement and concrete–transporting–cement producing–RC producing. In order to compare sustainability impacts of GLT and RC constructions in practical application, it was designed two floor (765 m²) and five floor (1913 m²) GLT and RC buildings.

Understanding the nature of underutilised timber (UUT) products for the built environment

Harry Mills¹, Joe Gattas¹, Kim Baber¹

¹The University of Queensland, Brisbane, Australia (harry.mills@uqconnect.edu.au; j.gattas@uq.edu.au; k.baber@uq.edu.au)

This project looks at the quantity, quality and values associated with the softwood sawn timber milling and manufacturing industry in Australia. The research highlights the potential quandary facing the timber industry with the rise in Mass Timber Construction (MTC). Undertaking a review of products from local and national merchants in Australia, the research analyses volume and value associated with typical products from softwood milling. With an increasing amount of underutilised timber (UUT) being generated from current milling and manufacturing processes, the ongoing research aims to highlight the potential outcomes as the industry moves into the age of MTC.

Combined FTIR spectroscopy and rheology for measuring adhesive curing as influenced by wood extracts

Merve Özparpucu¹, Elisabeth Windeisen¹, Klaus Richter¹

¹TU Munich, Munich, Germany (oezparpucu@hfm.tum.de; windeisen@hfm.tum.de; richter@hfm.tum.de)

Reliable wood-adhesive bonds are crucial for future wood-biomass utilization. Our ongoing research aims at systematically investigating interactions between structural adhesives and extractable wood constituents. The simultaneous examination of the progress of chemical reactions and changes in viscosity of both pure adhesives and adhesive-extract mixtures using a combination of FTIR spectroscopy and rheology, confirms major influences on the curing process and provides fundamental information for their chemical interpretation. First results based on MUF (in combination with chestnut hardwood) and 1 K-PUR adhesive (in combination with larch hard wood) will be presented and discussed.

Strengthening the Suministro forest supply chain through innovative experiments in sawmilling *Acacia mangium* Willd. in Eastern Colombia / Fortalecimiento de la Cadena Forestal de Suministro a través de Experiencias Novedosas en el Aserrío de *Acacia mangium* Willd. para el Oriente Colombiano

César Polanco Tapia¹, Leidy Natalia Vargas², Jose Nivaldo Garcia³

¹Universidad de Sao Paulo, Bogotá, Colombia; ²Universidad Distrital Francisco Jose de Caldas, Bogotá, Colombia; ³Universidad de Sao Paulo, Sao Paulo, Brasil (cpolanco@udistrital.edu.co; nataliavargasro@gmail.com; jngarcia@usp.br)

Colombia posee 310.138 hectáreas de bosque plantado de las cuales 36.986 hectáreas pertenecen a la especie *Acacia mangium*, esta especie fue introducida en Colombia desde 1990 y es reconocida por su rápido crecimiento y capacidad para desarrollarse satisfactoriamente en suelos degradados y erosionados. Esta especie no cuenta con información disponible respecto a los procesos de aserrío en el país, ignorando la productividad potencial de la madera para el sector de muebles y construcción. Para contrarrestar lo anterior, este estudio evaluó el rendimiento en aserrío de 556 individuos de pequeños diámetros, 278 de clase diamétrica de 10 a 14,99 cm y 278 de 15 a 20 cm, provenientes de plantaciones ubicadas en la Orinoquia Colombiana. Los árboles muestreados presentaron valores medios de altura total de 12,76 m, altura comercial de 7 m, DAP de 0,14 m y factor forma de 0,79. Fabricando dos tipos tradicionales de producto para el mercado, el coeficiente de aprovechamiento llegó al 37%. Adicionando dos espesores de corte no tradicionales, el aprovechamiento llegó hasta el 49%, esto re-aserrando costaneras y utilizando trozas curvas, generando nuevas piezas articuladas a la cadena productiva nacional e involucrando procesos del tipo finger joint. La experiencia demostró que procesos mejor planificados desde la realidad de la silvicultura nacional de la especie, pueden mejorar sosteniblemente los beneficios económicos y por ende sociales de las plantaciones forestales de *A. mangium* en la Orinoquia colombiana.

Life cycle assessment within the context of wood frame construction systems: a bibliographic and bibliometric review / Avaliação do Ciclo de Vida no contexto do sistema construtivo wood frame: uma revisão bibliográfica e bibliométrica

Camila Sanchoatene¹, Anna Claudia Fischer², Marcelo Langer¹, Dimas Agostinho Silva¹, Sérgio Fernando Tavares²

¹Universidade Federal do Paraná, Programa de Pós-Graduação em Engenharia Florestal, Departamento de Ciências Florestais, Curitiba, Brasil;

²Universidade Federal do Paraná, Programa de Pós-Graduação em Engenharia de Construção Civil, Departamento de Const (camilasanchotene@gmail.com; fischerannaclaudia@gmail.com; malanger04@yahoo.es; dimas.agostinho.silva@gmail.com; sergioftavares@gmail.com)

Um importante segmento da produção madeireira de florestas plantadas é o de produtos de madeira destinados à construção civil. O uso da madeira em sistemas construtivos industrializados, como o wood frame (WF), pode contribuir para a redução de resíduos e emissão de Gases do Efeito Estufa oriundos desta

indústria. Contudo, o processo produtivo dos materiais de madeira impacta o meio-ambiente. Neste sentido, a Avaliação do Ciclo de Vida (ACV) possibilita a avaliação de impactos ambientais potenciais associados ao WF, que passou a ter maior aplicação no Brasil a partir de 2011. Por meio de uma análise bibliométrica e bibliográfica, esta pesquisa investigou o progresso dos estudos de ACV relacionados ao WF e produtos de madeira relacionados a sua cadeia. As bases de dados utilizadas foram ProQuest, EBSCO, Scopus, Web of Science e Engineering Village, entre 2002 e 2018. Após o levantamento e seleção dos estudos, foram realizadas análises temporal e espacial e dos tipos de ACV construídas. As análises foram conduzidas em cinco eixos temáticos: Operações Florestais; Materiais de Madeira; Edificações em WF; Comparação de Sistemas Construtivos; e Revisão de Literatura. As publicações concentram-se nos últimos 5 anos, com destaque para 2018. A Europa e a América do Norte lideram as pesquisas no tema, representando 50 e 40% respectivamente. Foi possível estabelecer um framework do tema e sua evolução, com identificação de lacunas científicas para que sirvam como pontos norteadores de estudos do WF na construção civil brasileira.

Inclusión de defectos en la madera estructural como elemento estratégico en la gestión sostenible de los bosques tropicales

Cesar Polanco^{1,2}, Jose Nivaldo Garcia², Juan Francisco Correal Daza³

¹Universidad Distrital Francisco José de Caldas, Bogota, Colombia; ²Universidade de São Paulo, Piracicaba, Brasil (cpolanco@usp.br; jngarcia@usp.br; jcorreal@uniandes.edu.co)

Una premisa de la madera estructural es la eliminación de los defectos naturales de los árboles. Desde nudos hasta pudriciones, han sido considerados como obstáculos en el desempeño estructural, sin ninguna discriminación. Tal situación, trae como consecuencia grandes volúmenes desperdiciados y/o productos de menor valor económico que no alcanzan a cubrir sus costos de producción, incidiendo negativamente en la gestión forestal sostenible (GFS), pues solo el 5 a 20% de los árboles se convierte en producto final. En vista que la madera para construcción civil correctamente especificada y con propiedades mecánicas definidas, se cotiza mejor en los mercados, esta publicación tiene como objetivo presentar los resultados de la inclusión sistemática de defectos en madera laminada encolada (GLULAM) de gran formato con fines estructurales, elaborada con una especie de alta abundancia en el bosque muy húmedo del Litoral Pacífico colombiano, *Campnosperma panamense* Standl. Siete vigas GLULAM de 7500x500x50 mm fueron elaboradas; tres siguiendo estándares tradicionales de fabricación sin defectos y cuatro con defectos no aceptados para estos productos, los defectos fueron predefinidos y localizados estratégicamente. Se registraron todas las variables del proceso productivo. Como resultados se mejoró el aprovechamiento en madera con defectos y no se encontraron diferencias significativas entre los valores de resistencia a flexión para la madera con defectos y sin defectos. Se abre la posibilidad de hacer menos estricta la clasificación para reducir el desperdicio de material, contribuyendo a los objetivos de GFS, al procurar menor cantidad de árboles y el uso integral de los mismos.

C9d: SOCIETAL PERCEPTIONS, NEW PRODUCTS, MARKETS, AND BUSINESS MODELS OF THE CIRCULAR FOREST BIOECONOMY

Perceiving the Forest-based Bioeconomy (PerForm)

Alex Giurca¹

¹Chair of Forest and Environmental Policy, University of Freiburg, Freiburg, Germany (alex.giurca@ifp.uni-freiburg.de)

In this presentation I will talk about the PerFormproject- a European cooperation network of social scientists investigating societal perceptions of the forest-based Bioeconomy. The aim of the project is to better understand regional disparities of national bioeconomy policies and the perceptions of a forest-based bioeconomy. We explore the diversity of perceptions and acceptance of a forest-based bioeconomy in Europe in order to foster participation of different forest stakeholders and the broader public through an informed and open dialogue. We analyze perceptions of various stakeholder groups across Europe (Germany, Austria, Slovakia, France, Italy, Sweden, Finland). Methodologically, we build extensively on qualitative document analysis, stakeholder interviews and innovative communication tools.

Bioeconomy perception by future stakeholders: hearing from European forestry students

Mauro Masiero¹, Hanna Bernö², Ariane Carreira³, Riccardo Da Re⁴, Alexander Dobrovolsky⁴, Blanka Giertliová⁵, Alexander Giurca⁶, Sara Holmgren², Daniela Kleinschmit⁶, Arttu J Malkamäki⁷, Cecilia Mark Herbert², Lenka Navrátilová⁵, Davide Matteo Pettenella¹

¹TESAF Dept. University of Padova, Padova, Italy; ²Swedish University of Agricultural Sciences (SLU), Uppsala, Sweden; ³National Research Institute of Science and Technology for Environment and Agriculture (Irstea), Bordeaux, France; ⁴Saint-Petersburg State Forest Technical University, Saint-Petersburg, Russian Federation; ⁵Department of Economics and Management of Forestry, Faculty of Forestry, Technical University in Zvolen, Zvolen, Slovakia; ⁶Chair of Forest and Environmental Policy, University of Freiburg, Freiburg, Germany; ⁷Department of Forest Sciences, University of Helsinki, Helsinki, Finland; ⁸University of Natural Resources and Life Sciences (BOKU), Vienna, Austria; ⁹Albert Ludwig University, Freiburg, Germany (mauro.masiero@unipd.it; hano0003@stud.slu.se; ariane.carreira@irstea.fr; riccardo.dare@unipd.it; alexander-83@ya.ru; giertliova@tuzvo.sk; alex.giurca@ifp.uni-freiburg.de; sara.holmgren@slu.se; daniela.kleinschmit@ifp.uni-freiburg.de; arttu.malkamaki@helsinki.fi; cecilia.mark-herbert@slu.se; lenka704@gmail.com; davide.pettenella@unipd.it; helga.puelzlf@boku.ac.at; lea.ranacher@boku.ac.at; alessandrasalvalaggio33@gmail.com; laura.secco@unipd.it; arnaud.sergent@irstea.fr; juuso.sopanen@helsinki.fi; christoph.stelzer@students.boku.ac.at; lauri.valsta@helsinki.fi; ida.wallin@ifp.uni-freiburg.de)

The forest sector plays a pivotal role within the European bioeconomy and forestry students should be regarded as key-future stakeholders for the development of a forest-based bioeconomy. Nonetheless, while a number of studies have been conducted on public perception of bioeconomy and bio-based products in Europe, none of them has been specifically focused on forestry students. Researchers of the PerForm European cooperation network developed a quantitative online survey targeted at forestry students, including Bachelor, Master and Doctorate ones. The survey addresses students within eight countries across Europe (Austria, Finland, France, Germany, Italy, Slovakia, Sweden and Russian Federation) and aims to analyse and compare their knowledge and perception of forest-based bioeconomy today and in a future perspective. It consists of a multi-language online questionnaire structured into six sections: from students' knowledge and perception of key-concepts and topics, to concrete application for future job opportunities. A stratified sampling approach is adopted to cover the main forestry courses in selected countries. Data collection and analysis are performed as part of Master theses. Responses are analysed and compared among countries and programmes across Europe, in order to gain an up-to-date and in depth picture of the level of knowledge and perception of forest-based bioeconomy by students, as well as gaps and expectations. Findings from the survey provide useful inputs to develop future action for the promotion of education, training and skills opportunities in forest-based bioeconomy across Europe, thus contributing to key-actions defined by the 2018 European Union (EU) Bioeconomy Strategy Action Plan.

What's all about the fuss? Bioeconomy as perceived by Austrian next generation stakeholders

Helga Püzl¹ , Lea Ranacher²

¹University of Natural Resources and Life Sciences, Vienna (BOKU), Vienna, Austria; ²Wood K plus - Kompetenzzentrum Holz GmbH, Linz, Austria (helga.puezl@boku.ac.at; l.ranacher@wood-kplus.at)

Bioeconomy strategies are devised all over the world, (to some extent) stakeholders are consulted, and researchers have started to show a growing interest into the topic. Forests, their biomass and related products are central to such a new economic format. However to date only initial evidence (see Hodge et al., 2017; Stein, 2017) is provided as to how forest stakeholders perceive this bioeconomy. The present paper will contribute therefore to closing this knowledge gap as it investigates perceptions and expectations of future forest stakeholders in Austria, a highly forested country. We base our research on data collected via an online survey targeted at all forestry students in Austria. We expect the study to provide insights on the future forest stakeholders' perceived problems and chances associated with bioeconomy. From a practical perspective, the results will help to design bioeconomy strategies tailored to stakeholder needs and contribute to its societal acceptance.

How urban people perceive a forest-based bioeconomy in Finland?

Tuuli Suomala¹, Jaana Korhonen^{1,2}, Arttu Malkamäki^{1,2}, Lauri Valsta^{1,2}

¹University of Helsinki, Helsinki, Finland; ²Helsinki Institute of Sustainability Science, Helsinki, Finland (tuuli.suomala@helsinki.fi; jaana.e.korhonen@helsinki.fi; arttu.malkamaki@helsinki.fi; lauri.valsta@helsinki.fi)

Forests have an important role in the Finnish bioeconomy strategy. The forest-based bioeconomy has on a vision that forest industry firms will enter into new sectors and firms from other sectors will enter the forest sector. The sustainability proposition of new forest-based products is based on the substitution of oil with renewables. Nonetheless, the sustainability of the transition toward forest-based bioeconomy raises concerns related to e.g. acceptable level of use of forest resources. In parallel with accelerating urbanization, it is foreseeable that the urban consumers will become increasingly influential actors for legitimizing the bioeconomy policies in the future. Thus, understanding how urban consumers perceive the forest-based bioeconomy becomes increasingly relevant. Relying on the Integrative Worldview Framework (IWF), this study aims to assess the worldviews and how these worldviews are connected with the perception forest-based bioeconomy among urban consumers in Finland. We hypothesize that the worldviews explain the acceptance, understanding and risks of urban consumers associated with the forest-based bioeconomy development. The results will help to coordinate the public discussion and provide information to increase the inclusiveness of forest bioeconomy policies. The analysis is based on a quantitative survey, collected in the center of Helsinki in December 2018. To our knowledge, this is the first study exploring the urban consumers' views on bioeconomy in Finland and conducted as a part of the Perform Bioeconomy project, which is a collaboration of eight European research institutes aiming to understand the regional differences regarding perceptions and acceptance of the forest-based bioeconomy.

Experiencing the implementation of a regional Forest based bioeconomy strategy. The case of SYLVAPOLIS in the New Aquitaine region, France.

Arnaud Sergent¹, Ariane Carreira¹

¹Irstea, Cestas Gazinet, France (arnaud.sergent@irstea.fr; ariane.carreira@irstea.fr)

Since 2017 the regional council of New Aquitaine (France) is leading a project, called SYLVAPOLIS, which aims to implement a regional forest based bioeconomy. Within the framework of a call for tender for "innovative territorial systems" launched by the French state, SYLVAPOLIS seeks to promote sustainable regional growth through the development of forest based bioeconomy and cooperation between rural and urban areas. The strategy consists of increasing investments in the forest based activities related to the construction, the production of consumer goods and ecosystem services. Priority is given to the demand side sectors in order to better articulate innovations (products, process and institutions) with market and people expectations. In a context of emerging bioeconomy concepts, SYLVAPOLIS promotes an eco-economy approach (Marsden T. and Farioli F., 2015) which places an emphasis upon place-based production and consumption chains. This paper aims to provide an empirical experience of the implementation of a regional forest based bioeconomy strategy and to discuss the implications for bioeconomy developments in the forest sector. First it presents the roles attributed to territorial approach and forest sector in the French national bioeconomy strategy. Then it analyzes the implementation process of the SYLVAPOLIS project. Finally it draws on insights from this experience to provide a conceptual basis for forest based eco economy.

Student perceptions on the use of wood in multistory construction in Finland

Jonne Nurminen¹, Eliisa Kylkilahti², Minna Autio³, Sami Berghäll¹, Noora Miilumäki¹, Ritva Toivonen¹, Heini Vihemäki¹, Florencia Franzini¹, Katja Lähtinen³, Anne Toppinen¹

¹University of Helsinki, Department of Forest Sciences, Helsinki, Finland; ²University of Helsinki, Department of Economics and Management, Helsinki, Finland; ³University of Vaasa (jonne.nurminen@helsinki.fi; eliisa.kylkilahti@helsinki.fi; minna.autio@helsinki.fi; sami.berghall@helsinki.fi; noora.miilumaki@helsinki.fi; ritva.toivonen@helsinki.fi; heini.vihemaki@helsinki.fi; florencia.franzini@gmail.com; atja.lahtinen@uwasa.fi; anne

Wooden multistory construction (WMC) has been identified as an important new business opportunity at the cross-section of wood and construction industries and a way to meet demand for sustainable urban living. In several countries, such as Canada, Norway and Finland, WMC has been piloted in the context of student housing. However, there is a very limited evidence base on young consumers' material preferences for wood. Our study investigates which attributes are important for Finnish students' material preferences between brick, concrete, steel and wood, and how these associate with students' environmental attitudes and knowledge and experience about living with wood. Our data was collected using a semi-structured online questionnaire filled by 530 inhabitants of Helsinki metropolitan area student housing company HOAS during the fall 2018. The results indicate that the respondent's living history significantly affects his/her preferences of future housing. The type of family (single, married, with/without kids or pets) also affects their future housing ideal. Those respondents with experience from living in a wooden house were significantly more interested in buying or renting an apartment from a WMC building than the ones with less experience. Willingness to live in a WMC building was predicted by the perceived indoor air quality, sound insulation and structural strength with ecological sustainability also being close to significance. Results can be used to develop higher quality student housing services. Results can be also used in evaluating material competitiveness and acceptability of wood among future homeowners.

To export products or projects? Assessing lucrative export markets for innovative WMC business: cases from Nordic Countries

Anna Lilja¹, Ritva Toivonen¹, Heini Vihemäki¹, Anne Toppinen¹

¹University of Helsinki, Department of Forest Sciences, University of Helsinki, Finland (ritva.toivonen@helsinki.fi; ritva.toivonen@helsinki.fi; heini.vihemaki@helsinki.fi; anne.toppinen@helsinki.fi)

In the era of bioeconomy, wooden multistorey construction (WMC) has rapidly gained interest due to the demonstrated high environmental and technological performance of wood material, and the high carbon-absorption ability of wood material. WMC projects are mainly based on using new wood-based products, such as Cross Laminated Timber (CLT), which allow industrial module-based production, and building higher-rise buildings. This supports global efforts to develop sustainable housing solutions for the growing urban regions. However, in any part of the world, WMC projects are still mainly pilot cases, and manufacturing of CLT remains as domestic business. We hypothesize that rapid market growth would necessitate the markets of wood-based construction materials, and the WMC project business itself to become truly international. However, successful internationalization of new products is amongst the most difficult tasks in marketing. In this paper, we first design a theory-based general framework of critical issues for identification of lucrative export markets in the case of new wood-based construction products/construction project business. Second, qualitative interview data of experts and company specialists from Finland and Sweden is utilized to apply the framework on particularly CLT products and WMC business. Then, a scenario of WMC export markets in 2030 is compiled using back-casting method in the case of Finland, based on qualitative data from futures workshop and group interviews of experts. In conclusion, we discuss the identified differences between the two case countries, the efficient policy measures portfolios enhancing exports, and the applicability of the theory framework.

Comparing millennial and other generations' perceptions of tall wood buildings: Are they really different?

Pipiet Larasatie^{1,2}, Jose Guerrero¹, Eric Hansen¹

¹Oregon State University, Corvallis, USA; ²LPDP, Jakarta, Indonesia (larasatp@oregonstate.edu; jose.guerrero@oregonstate.edu; eric.hansen@oregonstate.edu)

Tall wood buildings (TWBs) constructed from engineered wood products are becoming more popular globally. However, little research has been conducted to assess end user perceptions of these structures, and none have focused on perceptions from various generations. This study compares the perceptions of Millennials and other generations regarding TWBs (structures made primarily from wood that are at least five stories tall). We utilize an online panel of 502 respondents in the Portland, Oregon and Seattle, Washington metropolitan areas in the United States. A majority of respondents believe that layout/floorplan, amount of natural light, and structural materials used are important considerations in the TWB design as a housing option. Regarding to the development of tall wood buildings, respondents only consider the cost of insurance as a barrier and, surprisingly, fewer consider aspects such as flammability, durability, amount of wood required, construction cost, and building code requirements as barriers. To conclude, there are few meaningful differences between respondents described as millennials and other generations, yet those belonging to the other generations assessed TWBs slightly more positively.

Sustainability: a concealed opportunity for global market diffusion for CLT in the urbanizing society – a literature-based meta-analysis

Ritva Toivonen¹, Katja Lähtinen²

¹University of Helsinki, Faculty of Agriculture and Forestry, Department of Forest Sciences, University of Helsinki, Finland; ²University of Vaasa, Department of Marketing and Communication, Vaasa, Finland (ritva.toivonen@helsinki.fi; katja.lahtinen@uwasa.fi)

In the urbanizing society, the energy-intensive construction sector plays major role in enhancing sustainable bio-economy, e.g., through selecting sustainable materials. Cross-laminated timber (CLT) is an engineered wood product enabling, e.g., industrial prefabrication and wooden multistorey construction (WMC). CLT also provides relatively low energy-intensity, and long-term carbon storage. The main markets for the CLT are in Europe, but there is potential for international market diffusion, due to sustainability benefits, and further standardization. However, some experts or consumers are still suspicious about using wood in construction, and knowledge on the issue is limited. For evaluating the existing knowledge on sustainability aspects, the purpose of this paper is to evaluate the sustainability-related strengths and weaknesses of CLT by WMC life-cycle phases. As materials and methods, we first developed a theory-based model of construction material sustainability, which incorporates a building's various life-cycle phases, and the recognized dimensions of sustainability. Then we performed a systematic literature review and a meta-analysis of CLT-based WMC sustainability by utilizing the developed model. The results clearly demonstrate that research on sustainability of CLT is concentrated on technological aspects at the building construction phase, and on environmental issues at the building usage phase. Contrastingly, comprehensive information on social or economic impacts is scarce. The results clearly indicate the need for life-cycle assessment, and consideration of the multiple dimensions of sustainability for well-justified assessments on material sustainability. Thus, to enhance CLT market diffusion, more balanced research on sustainability, and related stakeholder communication is required.

Challenges and opportunities related to wood frame construction systems in Paraná, Brazil: actor perceptions / Desafios e oportunidades do sistema construtivo wood frame no estado do Paraná: a percepção dos atores

Thiago Rodrigues de Paula¹ , Vitor Afonso Hoeflich¹, Jorge L. M. Matos¹

¹Universidade Federal do Paraná, Curitiba, Brasil (thiago_ufpr@ufpr.br; vitor.ufpr@gmail.com; jmatos.ufpr@gmail.com)

Dentre os sistemas construtivos inovadores, baseados em madeira, o wood frame possui o maior potencial de uso em larga escala. A madeira tem função estrutural, podendo o sistema ser industrializado ou construído no local. Apesar das diversas vantagens desta tecnologia, a grande maioria das unidades residenciais no Brasil ainda são construídas com métodos e materiais tradicionais da construção civil e portanto se faz necessário conhecer o grau de percepção da inserção do wood frame por atores da cadeia produtiva. Foi conduzida uma pesquisa qualitativa, para identificar a percepção de diversos atores da cadeia produtiva da tecnologia Wood frame e propor ações para acelerar a sua inserção no Estado do Paraná. Foi utilizado a escala SERVQUAL, cujos resultados foram analisados via estatística descritiva e métodos não-paramétricos. A diferença entre o nível mínimo aceitável e o nível percebido foi de - 53,4%, indicando que a inserção do Wood frame no Estado do Paraná não está satisfatória. Houve disparidade entre as percepções dos diferentes atores, com maior frequência de diferença entre os grupos de atores Construtores e Organizacional. Isto indica que, apesar da relativa proximidade entre estes atores, não há consenso sobre o que deve ser feito, e principalmente sobre quem deverá fazer. Propõe-se a integração dos diversos atores, como a promoção do sistema entre Engenheiros e Arquitetos, lançamento da norma específica, linhas de financiamento adequadas, criação e utilização de infraestrutura de suporte. A partir da experiência acumulada em outros países é possível definir linhas de ação para acelerar a inserção da tecnologia.

Company-level cross-sector collaborations in transition to the bioeconomy: a multi-case study

Jose E. Guerrero^{1,2}, Eric Hansen¹

¹Department of Wood Science and Engineering, College of Forestry, Oregon State University, Corvallis, USA; ²Grupo Argos S.A., Medellin, Colombia (jose.guerrero@oregonstate.edu; eric.hansen@oregonstate.edu)

Existing strategies and policies have emphasized the need for cross-sector collaboration to achieve successful transition a bioeconomy. Cross-sector collaboration initiatives of forest companies with neighboring sectors such as textiles, energy, chemicals, packaging, or plastics are gaining increasing attention as a necessary element for successful a transition. This situation presents a significant opportunity for forest companies to develop new products, explore new markets, improve competitiveness and replace human dependence on fossil-based products with renewable, bio-based materials. Despite this, no research results describe why and how forest companies collaborate with companies from neighboring sectors. This research seeks to document case examples of cross-sector collaboration between forest-based and neighboring sector companies aimed at developing new products. A qualitative, explanatory case study approach is employed to document the case examples. Semi-structured interviews with top executive members (CEOs, VPs, managing directors, etc.), of the companies involved, direct observation of the company operations, and secondary data are used. In total, four cross-sector collaboration cases involving Northern European and North American companies are profiled. Two of the cases are situations where partners expectations were not met and two are ongoing, successful cases. Findings will help to identify best practices, hurdles, and successes, and provide recommendations for successful knowledge-driven, cross-sector collaborations led by forest companies.

Design for recycling in wood construction. Opportunities and barriers in Germany

Helena Braitmayer¹, Michael Risse¹, Klaus Richter¹

¹TU Munich, Munich, Germany (helena.braitmayer@tum.de; risse@hfm.tum.de; richter@hfm.tum.de)

An increased consumption of solid wood products requires a rethinking of the current types of construction to guarantee the continued sustainable use of the resource. The "Design for Recycling" concept aims to establish a resource-efficient handling of wood. Reusing the originally used product with little material loss would allow the reduction of the future resource consumption. Various research results suggest that the cascade use of wood can contribute to a more efficient use of wood and can reduce environmental impacts. However, despite numerous theoretical work, the practical implementation is still in its infancies. By interviewing various stakeholders, the current awareness and dissemination of the topic in practice were recorded. Furthermore the opportunities for an increased implementation of DfR in timber construction and the barriers for the low level of practical execution of DfR in timber construction were determined

C9e: TRADITIONAL, EMERGING AND NEW FOREST PRODUCTS IN A BIOECONOMY: ADVANCES AND APPLICATIONS IN MODELLING THE MARKET POTENTIALS AND SECTORAL IMPACTS

Traditional and upcoming wood-based products in global forest sector scenario analysis

Franziska Schier^{1,2}, Christian Morland¹, Matthias Dieter¹, Holger Weimar¹

¹Thuenen Institute of International Forestry and Forest Economics, Hamburg, Germany; ²University of Göttingen Göttingen Germany (franziska.schier@thuenen.de; christian.morland@thuenen.de; matthias.dietet@thuenen.de; holger.weimar@thuenen.de)

The forest sector takes a major share in the growing bio-based economy. Wood-based industries depend mainly on the use of industrial roundwood from forest or wood processing residues. Long-term resource availability and allocation will be a major challenge for the further development of a bio-based economy. Moreover, wood is a multifunctional raw material, and thus, the forest sector faces various and potentially conflicting interests. Traditional wood processing industries are characterized by a twofold transformation: a technological change and a change in market pattern; new technologies - demanding additional raw materials - are emerging and compete with traditional materials. These changes require a reshaping of wood market analysis in order to reflect new products and demand for wood raw material. In this regard lignocellulose-based products can be seen as most promising. Therefore, this study adds three major lignocellulose-based products (dissolving pulp, cellulose derivatives and cellulose fibres) into partial equilibrium analysis. For this purpose, we use an econometric approach to analyse global data of yet niche but emerging products in order to compute demand and trade elasticities. Second, we apply market elasticities in a modified version of a partial equilibrium model, the GFPM. Thirdly, we implement different bioeconomy scenario pathways on a range from business-as-usual to utopian developments in the modified GFPM. The analysis identifies potential trade-offs, possible shifts in market pattern between sub-sectors and unfeasible pathways due to resource or market constraints.

Impacts of an implementation of biorefineries on the entire wood-based value chain in Austria

Martin Braun¹, Peter Schwarzbauer^{1,2}

¹University of Natural Resources and Life Sciences, Vienna (BOKU); Institute of Marketing & Innovation, Vienna, Austria; ²Team for Market Analysis and Innovation Research, Wood K plus – Kompetenzzentrum Holz, GmbH Linz, Austria (martin.braun@boku.ac.at; peter.schwarzbauer@boku.ac.at)

The European forest-based sector is facing structural changes with increasing pressure on competitiveness and sustainability requirements becoming an important issue for forest product markets. The presented study considers the effect as well as interdependencies of the implementation of biorefineries on the Austrian forest-based sector. Four scenarios were considered including three versions of biorefinery implementation: -Base scenario: without development and implementation of wood-biorefinery technologies by pulp mills. It is used as a reference to comparatively assess the potential impacts of an implementation of biorefineries -Single firm scenario: Simulation of the impacts of biorefineries on the economic situation of a single firm implementing a biorefinery with outputs small enough to focus on high-value added -National biorefinery implementation: Assumption that in one country almost all pulp mills would implement biorefinery technology with an assumed shift to high-volume, low-value commodities -European biorefinery implementation: Assumption that biorefinery technology will become industrial standard. Additional revenues from lignin, hemicelluloses and extractives were defined as revenues relative to weighted average pulp prices (for different pulp grades). The study compared results of previous simulations applied to the partial-equilibrium system dynamics forest-sector model FOHOW with new simulation results from a modelling framework including a climate-sensitive forest growth model (including a basal area increment model, a height increment model, and an ingrowth model) in combination with FOHOW. We analysed socio-economic impacts on the pulp and paper industry as well as on the entire forest-based sector including long-term employment perspectives through biorefinery implementation as well as medium-term employment in construction and engineering

Modelling wood biomass use for salmon feed under different reference scenarios

Alexander Moiseyev¹, Birger Solberg¹

¹Norwegian University of Life Sciences, Ås, Norway (alexander.moiseyev@nmbu.no; birger.solberg@nmbu.no)

Decreasing use of fishmeal derived from wild fish is currently a challenge for the salmon farming sector in Norway. Yeast produced using chips from Norwegian spruce trees can become high quality proteins for farmed fish serving as fishmeal replacement. Adding 20 percent yeast in the feed, prevented the development of intestinal inflammation. However, success of feed from wood biomass will depend on the market prices of the protein ingredients as well as the cost of the tree biomass processing. The objective of the analysis is to examine wood biomass for salmon feed economic availability in terms of supply quantities, prices and sourcing: additional three harvesting, imports and diversion of wood from other uses. Partial equilibrium model EFI-GTM was utilized to analyze the impact of different reference scenarios of the wood use in the EU /EFTA region on the potential supply of wood biomass for salmon feed in Norway. To make the yeast production from wood economically viable, maximum of 65-70 euro/m³ of wood can be paid at a mill gate. With this high maximum price, wood for salmon feed can be supplied up to 10 million m³ under the Base and Maximizing Bioenergy reference scenarios. However, such price would be rather high for pulp & paper and wood panel industry and the major additional supply for wood yeast would be sourced from redirection of wood from material and energy use to wood for feed. Additional harvest is projected to be a minor source of wood for feed.

Modelling prospects for dissolving and other pulps for textile applications and their impacts on global forest sector

A. Maarit I. Kallio¹

¹Norwegian University of Life Sciences, Ås, Norway (maarit.kallio@nmbu.no)

Wood-based cellulose fibres for textiles, hygiene and health products have been in the market for long time, but competition with other natural (cotton, wool, linen) or synthetic materials has kept their market share relatively modest. The shortage of land for the expansion of cotton production, environmental concerns, changes in fashion styles, and new technologies for producing textile fibres from wood are changing the market framework for the favour of cellulosic fibres. Assuming that the demand for the cellulosic man-made fibres will increase in the next coming decades, we model alternative market scenarios with varying degrees of competition with other pulpwood demands and with varying growth assumptions on the wood-based textile fibres. For investments, we allow conversion of the existing chemical pulp mills to dissolving pulp in addition to greenfield mills. We discuss the impacts on these developments into chemical pulp production, wood markets, and the forest sector in more general. We also show market effects of the assumed alternative locations for the textile pulps industries: close to the market vs. close to the raw material. Generally, the results suggest that the negative effects of new pulp production to the other products using pulpwood and chips (papers and boards) and positive effects to industries producing chips as by-products are relatively modest. Due to inelastic demand for the forest products, the production adjustments mainly take place in the roundwood harvests. This may lead to new plantation developments.

Climate change mitigation through product substitution: Participative backcasting study on the uses of wood in Finland

Janni Kunttu^{1,3}, Elias Hurmekoski², Pekka Leskinen¹, Teppo Hujala³, Henrik Heräjärvi⁴, Tanja Myllyviita⁵, Jyri Seppälä⁵

¹European Forest Institute, Joensuu, Finland; ²Ministry of Agriculture and Forestry of Finland, Helsinki, Finland; ³University of Eastern Finland, Joensuu, Finland; ⁴Natural Resources Institute Finland, Joensuu, Finland; ⁵Finnish Environment Institute, Helsinki, Finland (janni.kunttu@efi.int; elias.hurmekoski@gmail.com; pekka.leskinen@efi.int; teppo.hujala@uef.fi; henrik.herajarvi@luke.fi; tanja.myllyviita@ymparisto.fi; jyri.seppala@ymparisto.fi)

Wood utilisation can mitigate climate change, if wood products are used to substitute more emission-intensive materials and fuels. Displacement factor (DF) refers to avoided emissions per unit of wood used when replacing non-wood based products with equal functionality. However, the development of forest carbon sinks should be taken into account too. Recent studies show that the average DF should be at least 2 to compensate the emissions from planned additional harvestings in Finland and result in net avoided emissions in the short-term. The aim of this study is to explore, what structural changes are needed to reach DF=2 level in Finland by 2050. Qualitative descriptions of the future scenarios resulting this do not offer enough information on the magnitude of the changes needed. Furthermore, climate change mitigation scenarios are not necessarily market viable. Thus, a participative backcasting approach combined with explorative scenario development is adopted, and we identify strategic pathways to make different climate change mitigation scenarios market viable. The scenarios assume that average DF must reach the value of 2. To indicate future DFs for different products, a literature review on the future emission reduction potentials is applied to the scenario estimations. In the workshop, the selected stakeholder groups will assess the structural developments for each scenario step by step backwards from the year 2050 to today, by using periodical ten-year milestones. The study shows the extent of transformations needed to strive towards a competitive and climate optimal allocation of wood resources to develop an adaptive strategy.

From early attempts to recent trends: economic simulation as an investigation tool for the forest sector

Sylvain Caurla¹, Miguel Rivière²

¹Institut National de la Recherche Agronomique, Nancy, France; ²AgroParisTech, Nancy, France (sylvain.caurla@inra.fr; miguel.riviere@inra.fr)

Within the field of forest economics, simulation has been used and accepted as a research method since the second half of the 20th century through the use of Forest Sector Simulation Models (FSSM). Our contribution seeks to investigate what FSSM are, how they relate to the concept of simulation and to question the epistemic value of their results. We also aim at exploring the reasons behind the early adoption of simulation as a valid investigation tool in this particular field of economics. First, we discuss the concept of simulation and the extent to which FSSM can be considered simulation tools based on their use by economists. Second, we retrace the early history of FSSM development from the 1950s onwards, and discuss the emergence of several paradigms for modeling the forest sector. Third, we reveal and describe current trends in FSSM development, and reflect on publishing dynamics within the field. Fourth and finally, we question the role of FSSM for policy makers and practitioners. We argue that the strength of a simulation result resides more in its capacity to reveal underlying characteristics of the modeled bioeconomic system's functioning than in its numerical value. We show that because the validation of a simulation is not possible per se, it is only possible to analyze the results of FSSM with regards to the paradigms on which models are built.

C9f: FOREST CERTIFICATION AS A TOOL TO IMPROVE FOREST MANAGEMENT WORLDWIDE

The role of forest certification on the conservation of biodiversity and ecosystem services

Miguel Nuno Bugalho¹, Luís Neves Silva²

¹Centre for Applied Ecology, School of Agriculture, University of Lisbon, Lisbon, Portugal; ²WWF International, Gland, Switzerland (migbugalho@isa.ulisboa.pt; lnsilva@wwfint.org)

Forests harbour half of the world biodiversity, provide raw materials (e.g. timber and fiber) and generate ecosystem services of local, regional and global importance, including carbon sequestration and storage or regulation of the water cycle. For forests to keep generating benefits to the humankind, it is necessary that they are sustainably managed. That is, forest management practices must assure the ecological perpetuity of the forest ecosystem, including promotion of adequate tree regeneration and protection of biodiversity. Forest certification, usually seen as a proxy of sustainable forest management, is a voluntary mechanism under which forest landholders must comply with a third party audited standard of management practices respecting environmental and socio-economic criteria. Although forest certification is expanding globally, there is a dearth of quantitative data informing on how certified forest management practices may be contributing to forest conservation. Establishing certified conservation zones, for example, will influence biodiversity and affect ecosystem services (e.g. carbon storage, risk of wildfire) trade-offs. Complying with forest certification also implies systematic identification, monitoring and appropriate management of conservation values. Inventorying of biodiversity and ecosystem services, together with certified management practices, may be used to develop and implement payment for ecosystem services schemes contributing to forest conservation, which examples will be presented here.

Risk-based approach for forest management certification in Ukraine

Pavlo Kravets¹, Yevhenii Khan¹, Oksana Pavlishchuk², Ivan Lakyda²

¹FSC Ukraine, Kyiv, Ukraine; ²National University of Life and Environmental Sciences of Ukraine, Kyiv, Ukraine (p.kravets@ua.fsc.org; e.khan@ua.fsc.org; pavlishchuk_o@nubip.edu.ua; i.lakyda@nubip.edu.ua)

Unified approaches to forest management in all forests of the world, implemented in the FSC Principles and Criteria and IGIs, are increasingly confronted with risk-accounting requests. Conservative risk factors that are due to natural conditions, historical and cultural peculiarities are reflected at the stage of development of a forest stewardship standard. The SIR conception has enabled the SDG to distinguish a number of indicators, where high risk of adverse effects is due to natural factors such as mountain conditions etc. On the other hand, risk factors that are due to socio-economic conditions of forest management are dynamic and require update more than standard's revision period. Their consideration is relevant for countries with high corruption, low enforcement and unbalanced legislation. In this case, consideration of risk factors is viable at the stage of implementation of the standard. The country's risk profile as a set of information layers on state of forests and forest management on the basis of analysis of non-conformances, official statistics, independent studies and reports of stakeholders should serve as basis for assessing risks of deviation in meeting the standard's requirements mainly due to influence of socio-economic factors. FSC Ukraine, with the assistance of NULES of Ukraine, has begun establishing such system. Incorporating a risk-based approach to certification procedures will enable adequate planning and auditing, focusing on the key parameters of forest management, avoiding unnecessary labor costs, thereby contributing to increased efficiency and confidence in the FSC system in response to global and national challenges.

Forest certification for small producers, an alternative for sustainable practices / *Certificação florestal de pequenos produtores, uma alternativa à prática da sustentabilidade*

Alissa Mayla Pereira¹, Victoria Rizo¹

¹Tree Consultoria e Meio Ambiente, Telêmaco Borba, Brasil (alissamayla@2treeconsultoria.com.br; victoriarizo@2treeconsultoria.com.br)

Obtida no passado pela exploração de fragmentos florestais naturais, sem amparo legal ou consciência ambiental da maioria da população, a madeira, hoje em grande parte proveniente de florestas plantadas, é responsável por compor uma parcela considerável no cenário econômico nacional, através da produção de papel e celulose, madeira serrada, painéis e também, por promover ganhos significativos na esfera ambiental e social. Um caminho para promover a sustentabilidade, é a Certificação Florestal de pequenos produtores. No Paraná e em estados adjacentes, ocorre desde 2014, com a implantação da norma FSC® (padrão SLIMF), na modalidade de grupos. O projeto é custeado por empresa do segmento florestal e aplicado aos silvicultores pela 2Tee Consultoria e Meio Ambiente. Atualmente, são 554 imóveis, manejados por 302 produtores, que ocupam área total de 74.217,16 ha, dos quais 36.410,81 ha referem-se a plantio de *Pinus* e *Eucalipto*. Nos quatro anos do projeto, percebe-se que houve mudanças no dia-a-dia das pessoas que estão relacionadas à atividade, através da melhoria nas condições de saúde e segurança do trabalho, atenção às comunidades e incentivo à educação e saúde. Pensando nos remanescentes naturais, adotou-se medidas de proteção destes recursos, tais como recomposição de áreas de preservação permanente, contenção de processos erosivos e intensificação de monitoramento da fauna e flora. No viés econômico, há ascensão no mercado e valorização do produto, por disporem de um selo internacionalmente conhecido, que traz consigo a certeza da preservação ambiental, do respeito à sociedade e das boas práticas de manejo.

Group certification: a tool for competitiveness among small producers and forest companies, and for sustainability of the sector in Argentina / *Certificación en grupo: una herramienta para la competitividad de los pequeños productores y empresas forestales y la sostenibilidad del sector en Argentina*

Roberta Amaral de Andrade¹, Florencia Chavat²

¹Secretaría de Agroindustria de la Nación Argentina, Buenos Aires, Argentina; ²CERFOAR - PEFC Argentina, Buenos Aires, Argentina (betinha.amaral@gmail.com; fchavat@cerfoar.org.ar)

La certificación forestal es una herramienta para la competitividad y sostenibilidad del sector. Por un lado, trabaja la gestión de los procesos productivos, impulsando la mejora continua y facilitando la inserción en mercados exigentes. Por otro, abarca el cumplimiento legal actuando en temas como la tenencia de la tierra, regulaciones ambientales, normas laborales, impuestos y comercialización. Una empresa certificada cumple con requisitos que pueden contribuir al logro de los Objetivos de Desarrollo Sostenible (ODS) y alcanzar progresos simultáneos, agregando, además, valor al negocio. Argentina cuenta con 143 certificados entre Cadena de Custodia (CdC) y Gestión Forestal Sostenible (GFS) de los principales sistemas (FSC y PEFC), abarcando un área de aproximadamente 500.000 ha. Debido a la falta de recursos económicos y técnicos, los pequeños productores y empresas son los que tienen mayores dificultades para alcanzar los niveles de legalidad y sostenibilidad exigidos en la certificación. Por ello, la certificación en grupo puede ser una alternativa al reducir los costos individuales

del proceso y proporcionar escala a la comercialización. Actualmente se desarrolla en Argentina el “Programa Certificación en Grupo”, liderado por el Sistema Argentino de Certificación Forestal con apoyo del gobierno de la Nación, que invierte en la asistencia técnica para la formación de grupos y en los costos iniciales de la certificación. La actual coyuntura económica del país, favorable a la exportación, sumada a la perspectiva de aumento de la demanda global por madera y a políticas de desarrollo del potencial forestal argentino, apuntan a una gran impulso para la certificación.

Monitoring of non-conformities of FSC forest certification audits in Brazil in 2018

Gabriel Coimbra Rafael¹, Mario Henrique Andrade de Melo²

¹Instituto de Pesquisas e Estudos Florestais, Piracicaba, Brasil; ²Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brasil (gabriel@ipef.br; marioandrademelo@gmail.com)

Forests are an important wealth for human being development providing shelter, food and wood for several uses. Despite its importance, many forests worldwide lack sustainable management practices and, in this sense, forest certification emerges as an important tool to regulate and ensure that wood products are made considering social, environmental and economic aspects of forests. However, forest certification still needs to overcome some challenges to be more implemented. This research aimed to analyse the non-conformities (NCs) of public reports of FSC forest certification audits to identify the difficulties and possible challenges for companies to obtain or maintain the label. In total, 64 public reports from 2018 were systematically analysed and 419 NCs were categorized according to the FSC principles, criteria and themes. The results showed that FSC principles 4 (Community relations and worker's rights) and principle 6 (Environmental Impact) presented the greatest number of NCs, representing 52% of all NCs of forest plantations, 62% for native forests and 44% for small scale (SLIMF). Overall, the topics more recurrent in NCs were labour, employment and gender equity (19%), monitoring the implementation of the management plan and its results (14%), the management plan itself (13%) and engagement and communication processes (12%). These results showed that companies seem to have difficulties to comply with social requirements as well as, developing and implementing the forest management plan. Social programs could be developed by companies and governments to enhance social approach of forest operations and there are opportunities to develop more literature regarding forest management plans.

Non-conformities related to pest management in companies certified by the forest stewardship council (FSC) in Brazil

Pedro Guilherme Lemes¹, Daniela Caroline Silva¹, José Cola Zanuncio²

¹Universidade Federal de Minas Gerais, Montes Claros, Brasil; ²Universidade Federal de Viçosa, Viçosa, Brasil (pedroglemes@ufmg.br; danielacaroline43@yahoo.com.br; zanuncio@ufmg.br)

The Forest Stewardship Council (FSC) Pesticide Policy seeks the identification and prevention on the use of “highly hazardous” pesticides, the reduction and appropriate use of pesticides, and the use of alternative pest control strategies. Certified producers, mainly from tropical countries in the Southern Hemisphere, have experienced negative consequences of this policy on integrated pest management. The objective was to determine the most common nonconformities related to pest management in audits conducted in FSC certified companies in Brazil. All available reports on the FSC platform until March 2017 were downloaded, evaluated and separated by type of certificate (FM, FM/COC, FM/COC/SLIMF or FM/CW). Nonconformities were quantified and grouped into 13 categories and separated as a major or minor corrective action request (CAR). One hundred and eighty-seven reports were evaluated, of which 153 were FM/COC, 24 FM/COC/SLIMF, 7 FM/CW and 3 FM. Problems related to inadequate storage of pesticides, use of prohibited pesticides, absence or inappropriate use of PPE (personal protective equipment), misuse of chemicals, non-guarantee of pest management worker's rights and health, and absence of the environmental impact assessment plan associated with pesticide use, were the most common nonconformities. The certification has improved the integrated management of forest pests in Brazilian companies, specially with better security in the use and storage of pesticides and in the health and safety conditions of the workers.

Shaping the implementation of the FSC standard: the case of auditors in Brazil

Marie-Gabrielle Piketty¹, Isabel Garcia-Drigo²

¹CIRAD, Montpellier, France; ²Nexus Socioambiental, Sao Paulo, Brasil (marie-gabrielle.piketty@cirad.fr; isabel.drigo@gmail.com)

The Forest Stewardship Council (FSC) label is one of the most robust and widely accepted standards aimed at assessing long-term sustainable forest management worldwide. Through audits, accredited certification bodies assess the level of conformity of a company's performance against the standard to grant or not the certificate on behalf of the FSC. In this paper, we assess the scope auditors have to shape the implementation of the FSC standard in Brazil. Our work is based on the analysis of certification bodies' rules and of 250 full assessment and annual audit reports covering the period 2005-2017, including native and plantations reports. All reports were publicly available on FSC database. The analysis was completed with interviews with key informants. We show that most indicators of the Brazilian FSC standard leave no scope for interpretation. However, companies are certified and re-certified with a significant number of minor non-conformance with social, legal and environmental indicators. We conclude that some indicators are too broad and need to be clarified. Also, conformity with some indicators depends on actions from governments. The development of new national standards is an opportunity to limit the risks of interpretation of indicators. The updating of standards is also an opportunity to clarify the role of public policies in respect of specific indicators. States wishing to promote FSC certification could seize this opportunity to identify what improvements are needed in the functioning of their institutions and public policies.

FSC's knowledge management journey

Michael Marus¹, Kim Carstensen¹

¹FSC International, Bonn, Germany (m.marus@fsc.org; director.office@fsc.org)

Initiated in the 1990th, 3rd party, voluntary certification of forest management (FM) evolved over time. The Forest Stewardship Council's (FSC) FM public audit reports yield a rich corpus of economic, social and environmental data (e.g., species, set-aside areas, ecosystem services, health and safety), needed to measure and demonstrate compliance of FM with the certification standard, and the effects of certification. To facilitate access to these data, FSC has set out on a journey to be fully digitally data driven, extracting knowledge and gaining insights from hard data from FM reports and forest products trade. With this journey FSC implements its members' General Assembly Motion to “Harnessing audit data to improve assurance integrity, monitoring and evaluation, and the value proposition for FSC” (Motion 2017/16). The modernized FSC audit capture and data analytics and reporting platform will enable FSC and stakeholders to use comparative analytical capabilities to test and compare reach and effectiveness of a variety of FSC strategic scenarios and improvements. Improved access to data will strengthen robustness of certification decision processes, allow evaluation of impacts of certification interventions. This will result in better demonstration of the value proposition for sustainable FM to inform decision making of forest managers, politicians, product buyers, and other stakeholders. We will present the set of knowledge products as key outcomes of this journey towards outcome-based decision making, such as dashboards, open data, real-time management and stakeholder reporting.

C9g: FOREST CERTIFICATION AS A TOOL TO IMPROVE FOREST MANAGEMENT WORLDWIDE

Price premium of the FSC certified wood products in Japan: a case study on cutting boards made of Hinoki (*Chamaecyparis obtusa*)

Ikuo OTA¹, Masumi Kamakura², Masashi Konoshima¹

¹Faculty of Agriculture, University of the Ryukyus, Okinawa, Japan; ²Shikoku Kako Co. Ltd., Ehime, Japan (ikuota@agr.u-ryukyu.ac.jp; masumi@yoroi-kabuto.com; konoshim@agr.u-ryukyu.ac.jp)

The authors conducted a series of experimental sales of FSC certified wood products. Several types of cutting boards, with different design and size, made of Hinoki were sold on an internet shopping site. We prepared the same type of products from FSC certified wood and non-certified wood, and simultaneously sold them at different prices. Customers who are interested in purchasing cutting board could choose each of them while watching the price of products. We set the price difference of 4 level, between 20% and 50%, by shifting the timing. The most large size of the cutting board was 460mm×240mm×30mm with the basic price about 33 USD, and the smallest one was 200mm×200mm×25mm with the basic price about 26 USD. The result is as follows: Twenty seven percent of customer chose certified product for 20% price premium, 18% of customer chose certified product for 30% price premium, 11% of customer chose certified product for 40% price premium, and 8% of customer chose certified product for 50% price premium. All of these price premium was found to be statistically significant. The authors conclude that the price premium of the FSC certified products can exist up to 50% in the case of small wood products like cutting boards.

Tetra Pak and FSC: responsible sourcing and its impacts on consumer awareness

Luana Pinheiro¹

¹Tetra Pak Ltda, Monte Mor, Brasil (luana.pinheiro@tetrapak.com)

Tetra Pak is the world's leading food processing and packaging solutions company. Together with our customers and suppliers, we provide safe, innovative and environmentally sound products that each day meet the needs of hundreds of millions of people in more than 160 countries. Our motto, "Protects what's good" reflects our vision to make food safe and available, everywhere and in a sustainable way. For us, responsible sourcing consists of looking at what we purchase beyond aspects of cost, quality and delivery time. This is one of the strategic objectives for our supply chain operations, and means we consider ethics, labour rights, social and environmental issues when sourcing products and services. Our goal is to minimise negative impacts and make a positive contribution to the businesses, people and communities. Around 75% of a Tetra Pak carton by weight is paperboard. Although we don't own or manage any forests, we apply our purchasing power to promote sustainable forest management. We see FSC as offering a credible universal standard and we actively encourage our customers to display the logo on their packages. Since the introduction of the FSC label on our first package in 2007, we have produced 350 billion FSC-labelled packs globally. Having achieved full FSC Chain of Custody certification for all our operations, we can now supply FSC-labelled packages from anywhere in the world. By communicating with consumers in this way, we are raising the bar for sustainable sourcing across our industry and beyond.

The importance of local and diverse stakeholder's engagement to improve the certification schemes: the Brazilian plantation sector case

Camilla Marangon¹, Nathalia Granato Loures¹

¹Indústria Brasileira de Árvores, São Paulo, Brasil (camilla.marangon@iba.org; n.granato@iba.org)

The engagement of NGOs, researchers and companies in the forest certification schemes is key for its continuous improvement and growth, especially to make its standards more locally relevant, outcome-orientated, data-driven and recognized by the market. The commitment of this sector with the sustainable forest management goes far beyond the implementation of standards on its 5,8 million hectares and implies in deeply engagement within the certification schemes. This sector has been expressively taking part of FSC and PEFC, joining General Assemblies (GA), proposing motions, attending regional meetings, participating in the revision and development of the standards. In 2016, Ibá (Brazilian Tree Industry) and IPEF (Forestry Science and Research Institute) were informally nominated as secretariat of the FSC Latin America economic chamber and were responsible for preparing the members for the 2017 GA. This leadership has played an important role in South America with positive impacts within FSC system and has been recognized by the FSC and its members worldwide. In the PEFC system, the sector has been closely working with the Cerflor (Brazilian certification scheme endorsed by PEFC) to boost its performance, raise the level of recognition by the market and ensure its financial sustainability. This engagement has been producing gains and helping the sector to positively influence the certification agenda in order to make it more efficient and feasible and thus spreading the sustainable forest management to new areas.

Negotiation process of setting national FSC standards: what matters in different contexts

Marine Elbakidze¹, Constance McDermott², Sara Teitelbaum³, Maria Tysiachniouk⁴

¹Swedish University of Agricultural Sciences, Skinnskatteberg, Sweden; ²Oxford University, Oxford, United Kingdom; ³Montreal University, Montreal, Canada; ⁴Center for Independent Social Research, St Petersburg, Russian Federation (marine.elbakidze@slu.se; constance.mcdermott@ouce.ox.ac.uk; sara.teitelbaum@umontreal.ca; tysiachn@yandex.ru)

Biodiversity conservation and local/indigenous communities' wellbeing are amongst the crucial sustainability targets of global policy, designed to steer global development for the coming decades. The FSC system provides an excellent case study for understanding how certification as a non-state market-driven approach addresses global sustainability goals. In many countries FSC certified forest management has also provoked considerable public debate, reflecting the diversity of interests and perspectives of actors who hold a stake in its outcomes. We provide an overview of findings from an international research project that compares how these differences have shaped FSC's approach to biodiversity conservation and wellbeing of local/indigenous communities across the circumboreal forests in the three countries with the large FSC certified area (Sweden, Canada, and the Russian Federation). Forests as complex social-ecological systems create a greater challenge to the design of sustainable institutions, including the FSC certification system. This study applied Ostrom's Institutional Analysis and Development framework to analyse how institutions affect actions and outcomes of FSC-negotiation processes in different contexts. Key informant interviews were done at the national level in each country with (i) stakeholders directly involved in FSC national initiatives, and (ii) stakeholders from private, public and private sectors that are critical to FSC. We discuss how differences in understanding a resource system and resource units that are governed by diverse organizations with different rules create conflicts and debates in negotiating FSC processes and how these influence outcomes in terms of the content of national FSC standards.

Sustainable intensification: the role of the forest certification in a world that will triple its wood consumption by 2050

Esteveao Braga¹, João Carlos Augusti¹, Michael May¹

¹Suzano S.A., São Paulo, Brasil (esteveab@suzano.com.br; joao.augusti@suzano.com.br; mike@futuragene.com)

The population growth, combined with changes in purchasing power, replacement of fossil-based raw materials by renewable sources, and megatrends such as growth in Asia and packaging for e-commerce will increase the demand for wood and fibers. Wood consumption is predicted to triple to 10 billion m³ per annum, far exceeding the productivity of present-day natural forests and forest plantations combined. The production of adequate wood and forest-based products to meet this demand while avoiding potential social and environmental externalities will be one of the most important issues for the next generation. This means also increased pressure to improve forest management in a sustainable way. The sustainable intensification encompasses several scientific innovations, technologies, and approaches aiming to produce more food and fibers while using less or equal natural resources while conserving or improving environmental values and promoting shared value to society. The forest certification has a great potential in setting policies and standards to ensure a responsible and sustainable origin of the forest-based products while exploring the opportunities of expanding its presence in the global market share. The discussion about the role of the forest certification in driving the intensification of the production to a sustainable path has already started in FSC and PEFC. Both schemes are exploring their roles in leading a dialogue on sustainable intensification, given their governance structure that blends different perspectives, providing a neutral platform suited for managing complex discussions such as sustainable intensification aiming to produce more from less with sound social and environmental footprints.

Future perspectives on the role of forest certification

Kim Carstensen¹, Jeremy Harrison¹, Michael Marus¹

¹FSC International, Bonn, Germany (director.office@fsc.org; j.harrison@fsc.org; m.marus@fsc.org)

The future role of forest certification in the context of the global sustainable development agenda is influenced by a range of powerful forces and is under constant pressure to evolve and adapt. The success of certification as a solution for driving sustainable development in forest value chains will depend on its ability to understand the implications of these forces and respond appropriately in collaboration with value-chain stakeholders. The drivers of future global demand for forest products include industrial consumption patterns, consumer behaviour and the need for climate change mitigation measures. These demand drivers will lead to a corresponding pressure on the supply of forest products and production systems, with profound implications for smallholder producers and plantation production. In addition, these pressures must be viewed within the context of multiple land-use needs (e.g. production of other commodity crops) and the need for broader sustainable landscape management solutions. Other forces at play include consumer attitudes towards sustainable development, government and business interventions and the role of academic institutions and NGOs. Probably more importantly for certification and other sustainable development solutions will be the ways in which these stakeholders interact, and the extent to which effective collaboration can be achieved. This presentation and panel discussion will examine the forces that are shaping future forest value chains and provide perspectives on the future role of forest certification as a solution to ensure forests and wider landscapes are managed sustainably.

Trees outside forests: magnifying the contribution of forests and trees to societal challenges

Ben Gunneberg¹, Thorsten Arndt¹

¹PEFC - Programme for the Endorsement of Forest Certification, Geneva, Switzerland (ben.gunneberg@pefc.org; t.arndt@pefc.org)

Trees grow in forests, but they also grow beyond the forest, throughout landscapes and within cities. These trees outside forests (TOF) provide vital ecosystem services like clean air and water, habitat for animals, and climate regulation. They also provide food, materials and rural livelihoods for millions of people. Until now, it has not been possible for the owners of TOF – often small-scale farmers – to achieve certification of their sustainable management practices. However, with the release of our latest PEFC forest management standard, smallholder farmers can now obtain PEFC certification. TOF certification offers, among others, the following benefits: Extending the impact of certification beyond the forest: Through encouraging the planting of trees and improved management of trees outside forests in ways that optimize their social, environmental and economic contributions, we can promote an additional natural solution to climate mitigation within forest certification. Supporting rural development: TOF certification encourages and recognizes agroforestry practices and support small landowners to access markets that are requiring proof of sustainably management as delivered through PEFC certification. Improving sustainability of urban forests: TOF certification will better support cities and municipalities in improving the sustainable management of their trees and urban forests. Taking the pressure off natural forests: TOF certification also stands to take the pressure off natural forests in countries where the pressure and exploitation of the resource is too great or where there are already logging bans in place.

The Brazilian forest certification program: factors for success and future prospects / Programa Brasileiro de Certificação Florestal: fatores de sucesso e perspectivas futuras

Alessandra Julião Weyandt¹, Cristiane Sampaio¹

¹Inmetro, Rio de Janeiro, Brasil (weyandt.alessandra@gmail.com; cmsampaio@inmetro.gov.br)

A demanda global por madeira pode triplicar até 2050. Essa estatística reflete o crescente consumo de madeira sólida e produtos de papel, em decorrência do crescimento populacional e econômico. No entanto, a cada ano o mundo perde uma parcela considerável de suas florestas naturais, tendo como principais causas a exploração de madeira, a agricultura e as políticas públicas de desenvolvimento. A certificação florestal é um mecanismo para que as florestas sejam gerenciadas para alcançar as metas econômicas, ambientais e sociais que são a base do manejo florestal sustentável e do desenvolvimento sustentável. No Brasil, o Programa Brasileiro de Certificação Florestal (Cerflor) foi concebido na década de 1990, tendo sido lançado oficialmente pelo INMETRO, Instituto Nacional de Metrologia, Qualidade e Tecnologia, em 2002. Neste mesmo ano, foi solicitado o endosso do Cerflor pelo PEFC (Programme for the Endorsement of Forest Certification), que foi obtido em 2005. O Cerflor é um programa voluntário desenvolvido com representantes de partes interessadas em nível nacional, que têm oportunidade de expressão, quanto às questões relacionadas a sua realidade. A estruturação participativa e o endosso pelo PEFC são fatores de sucesso do Cerflor, que é uma importante ferramenta para promover as boas práticas no manejo florestal sustentável e a competitividade dos produtos madeireiros de base florestal brasileiros. Buscando potencializar a excelência do Cerflor, sua gestão está sendo aperfeiçoada e ações estão sendo empreendidas, desde o ano de 2018, com perspectiva para sua total implementação em até dois anos. Dentre estas, destacam-se marketing, pesquisa, capacitação e independência financeira.

C9p: FOREST POLICY AND ECONOMICS - I

Where does your panel fit into society? Production and usage of reconstituted wood panels / “Qual seu painel na sociedade?” Produção e uso de painéis reconstituídos de madeiraFlávia Alves Pereira¹, Eleandro José Brun¹¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (flaviapereira@utfpr.edu.br; flaviapereira@utfpr.edu.br)

A madeira é matéria prima para processos, como celulose e papel, geração de energia e produção de painéis de madeira. Suas dimensões e características, como anisotropia, densidade e seus defeitos naturais podem limitar sua utilização. Os painéis de madeira se destacam como alternativa para aumentar a oferta de produtos gerados, com melhor custo/benefício, e ampliar o uso da madeira. O objetivo deste trabalho foi ensinar alunos do ensino fundamental de escolas públicas e organizações não governamentais do sudoeste do Paraná, sobre painéis reconstituídos de madeira e suas aplicações. Este trabalho vem sendo desenvolvido há três anos por graduandos do curso de Engenharia Florestal. Num primeiro momento, há o contato com professores e diretores das escolas da região para programar as atividades. Uma apresentação sobre painéis é realizada, utilizando-se recursos digitais e/ou figuras, que representem o processo produtivo. Ressalta-se que alunos de diferentes faixas etárias são contemplados. Para fixar o conteúdo e facilitar a compreensão do assunto, atividades lúdicas educativas são elaboradas e aplicadas. É interessante que este tema seja ambientado desde a infância e adolescência, para que haja maior difusão do conhecimento. Através deste trabalho foi possível a interação entre alunos universitários e do fundamental e a experiência didática, com a transformação da linguagem acadêmica em uma linguagem mais simples para a apresentação do conteúdo. Estas atividades reforçam a importância da madeira e seus produtos. O Paraná é um dos maiores produtores de painéis do país e essa atividade tem relevância social e econômica em todo estado.

Demographic changes and their influence on the demand for wooden houses in JapanKoji Matsushita¹, Kozo Yamaguchi¹, Yoshio Yoshida¹, Tetsuji Senda¹¹Kyoto University, Kyoto, Japan (matsu@kais.kyoto-u.ac.jp; yamaguchi.kozo.5e@kyoto-u.ac.jp; yoshidayoshio.2z@kyoto-u.ac.jp; senda@media.kyoto-u.ac.jp)

The total population of Japan has been decreasing since 2010. Such demographic changes influence the demand for wooden housing, which is an important timber consumption sector in Japan. The decrease in total population and increasing tendency for young people to move from rural to metropolitan areas has resulted in a decrease in wooden housing construction in rural areas. As the average number of people per household has decreased (to 2.33 persons, according to the 2015 Population Census of Japan), the total number of wooden houses constructed and their average floor areas have decreased accordingly. The proportion of the population ≥ 65 years of age reached 26.6% in 2015 (Population Census), which was among the highest in national proportions worldwide, and is predicted to further increase with time. As Japanese households continue to decrease in size and their occupants increase in age, the percentage of one- to two-person households is increasing. Some occupants select non-wooden condominiums or other compact dwellings as they increase in age; as a result, decreases are expected in the percentage of homes constructed with wood and in the total floor area of wooden housing for aging people. In summary, the trend in total timber demand for wooden housing will decrease in Japan in the future. Forestry policies relating to domestic timber production in Japan are therefore at a turning point as changes in population demographics affect domestic timber consumption.

Estimating the impact of the national forest conservation program on the timber product industry in Heilongjiang province, China: use of a synthetic control methodHongge Zhu¹, Zhujun Han², Mengshi Feng¹, Yihao Li¹¹Northeast Forestry University, Harbin, China; ²Nanjing University, Nanjing, China (honggebill@163.com; 1203553269@qq.com; 1051856587@qq.com; 592134959@qq.com)

Based on data from the China Forestry Statistical Yearbook between 2001 and 2015, this study analyzed the impact of the second phase of the National Forest Conservation Program on the timber product industry in Heilongjiang province, China. Due to the implementation of the program and logging ban policy, the timber harvest in Heilongjiang was reduced to 1.568 million m³ in 2015 from 7.739 million m³ in 2001, corresponding to a reduction of 79.7%. A descriptive analysis indicated that the output of the timber product industry in Heilongjiang continued to increase during the second phase of the program. An analysis based on the synthetic control method indicated that the timber product industry in Heilongjiang has been significantly affected by the implementation of the second phase of the program. The output of the timber product industry was reduced by 62.79%.

Pages from Forest Technology Transfer (TT Florestal): making information accessible to users / Páginas de Transferência de Tecnologia Florestal (TT Florestal): tornando a informação acessível ao usuárioSimone Santos Soares¹, Luciane Cristine Jaques¹, Katia Regina Pichelli¹¹Embrapa Florestas, Colombo, Brasil (simone.santos@embrapa.br; luciane.jaques@embrapa.br; katia.pichelli@embrapa.br)

Muitos produtores rurais e até mesmo pessoas que estão começando a plantar espécies florestais procuram a Embrapa Florestas para saber informações básicas sobre como cultivar florestas. Isso ficava evidente ao analisar as principais demandas que chegavam ao Serviço de Atendimento ao Cidadão (SAC) da empresa, com a grande maioria das demandas sobre os diferentes itens de um sistema de produção. Estas informações estavam em diferentes locais no site da Embrapa Florestas ou, então, acessíveis somente em publicações com linguagem técnico-científica, dificultando o entendimento por parte do usuário. Para solucionar este problema, os setores de Transferência de Tecnologia e Comunicação da Embrapa Florestas trabalharam na proposição de uma solução, que consiste na publicação das “Páginas de Transferência de Tecnologia”, sendo uma para cada tema definido como prioritário. Temas que já foram publicados: eucalipto, erva-mate, pupunha, pragas florestais, sistemas silvipastoris, softwares florestais. Cada página/tema, hoje, conta com: perguntas e respostas; principais publicações sobre o tema; reportagens; vídeos; programas de rádio; soluções tecnológicas. O fluxo de trabalho contemplou: análise das demandas do SAC; definição de conteúdo; elaboração de perguntas e respostas, com adequação de linguagem; aprovação por parte dos pesquisadores; levantamento de materiais; definição de layout. Um trabalho de divulgação, em especial em mídias sociais, alavancou a audiência das páginas, que hoje são as mais acessadas dentro do Portal da Embrapa Florestas.

Multi-national pulp industries within the global value networks: systemic assessment on the changing operational environment

Veera Tahvanainen¹, Ossi Pesälä¹, Teppo Hujala¹, Lucía Pittaluga², Jouni Pykäläinen¹

¹University of Eastern Finland, Joensuu, Finland; ²Universidad de la República (Uruguay), Montevideo, Uruguay (veera.tahvanainen@uef.fi; ossi.pesala@uef.fi; teppo.hujala@uef.fi; luciapittaluga@gmail.com; jouni.pykalainen@uef.fi)

The operational environment of the Multi-National Pulp Industries is affected by numerous of factors, such as: climate change, changes in economic conditions and society, new technologies and emerging innovations. The changes in operational environment affect both the multi-national organizations and the SMEs in local levels. The recent developments have disrupted the existing market structures, enabled birth for novel value creation mechanisms, and brought up increasing recognition and utilization for the evolving value networks. This calls for systemic assessment of the factors capable of altering the operational environment within the global pulp industries. In this study the present situation and future perspectives of pulp industry of Uruguay and Finland is presented and their relation to each other in a frame work of global challenges and bioeconomy is studied. These challenges are identified and possible future changes and innovations evaluated. The data consists of document analysis and expert interviews collected during fall 2018 and spring 2019 in Uruguay and Finland. The multi-level perspective model is used to analyze the socio-technical regime, landscape level issues and niche innovations in a country level. The pulp industry forms a considerable part of the production matrix of both countries and they share the global challenges facing the multi-national pulp industry, however the socio-technical regimes in these countries are rather different. The objective of the study is to provide multi-level insight on future aspects, opportunities, and threads related to pulp industries from national and international perspectives to support the transition to a more sustainable bioeconomy.

Government metrics for sustainable forest management in Romania

Stefan Neagu¹, Catalin Calota¹, Gheorghe Marin¹, Marius Dumitru¹, Marius Nitu¹, George Florin Garbacea¹

¹National Institute for Research and Development in Forestry "Marin Drăcea", Voluntari, Romania (stefanneagu@yahoo.com; catalin.calota@roifn.ro; ghmarin@roifn.ro; mariusd@roifn.ro; dannitu@roifn.ro; george.garbacea@yahoo.com)

The main purpose of the National Forest Inventory (NFI) is to document the present-day circumstances and latest trend of the Romanian wooded area in a descriptive and verifiable manner, by means of implementing various data sources and methods for a methodically analysis of sustainable forest management (SFM). Relating SFM goals with data needs is a staggering undertaking since data are stockpiled in relational databases by several stakeholders (environment and socio-economic data) and assessed by means of specifically developed methods. Forest policy government metrics represented by SFM indicators are necessary new models and tools based on existing information for analysis and predictions in order to generate an effective and pertinent decision support system (DSS) at national and regional levels. The evaluation of information sources, features, and classification is described in the methodology, which will furthermore explore their integration procedures to generate trustful and reliable SFM metrics matching the European wide requirements (MCPFE, 2011, 2015). The outcomes and conclusions wrap up the available data features and suitability for producing SFM parameters relevant to stakeholders and decision makers. References: MCPFE, 2011, Proceedings of Forest Europe Ministerial Conference, Forest Europe Ministerial Conference on Protection of Forests in Europe, Oslo, p; 216. MCPFE, 2015, Proceedings of Forest Europe Ministerial Conference, 7th FOREST EUROPE Ministerial Conference and FOREST EUROPE Extraordinary Ministerial Conference, Madrid, p; 246

Modelling the effects of regeneration method on growth and economy of Scots Pine stands

Mikolaj Lula¹, Renats Trubins¹, Urban Nilsson¹

¹Swedish University of Agricultural Sciences, Southern Swedish Forest Research Centre, Alnarp, Sweden (mikolaj.lula@slu.se; renats.trubins@slu.se; urban.nilsson@slu.se)

Scots pine (*Pinus sylvestris* L.) is the most widely distributed conifer in the world and, presently, the second most important commercial tree species in Sweden after Norway spruce (*Picea Abies* L.). However, the share of Scots pine in regenerations in southern Sweden has decreased alarmingly during the last twenty years, yielding space to Norway spruce. Recent surveys have shown that Scots pine is rarely the species of future crop trees in young stands. Forest owners' perception of the uncertainty of Scots pine regeneration outcomes has been identified as one of the main factors causing this trend. Conventional regeneration methods for Scot Pine in southern Sweden are planting, direct seeding and natural regeneration with seed trees or under shelterwood. There is still a lack of knowledge about the long term effects of the regeneration method on growth and economy of Scots pine stands in the region. In present study long term development of Scots pine stands is simulated starting from short term regeneration outcomes observed in actual field experiments. Economy of the stand management is analysed in terms of cash-flow and Land Expectation Value (LEV), volume growth in terms of mean annual increment (MAI) for whole rotation. Effects of different discount rates and regeneration costs on the LEV outcomes are tested.

Gains in nature conservation based on compensatory plantations in the Atlantic Forest, Brazil / Ganhos em conservação da natureza com base em plantios compensatórios na Mata Atlântica, Brasil

Natasha Choinski¹, Marcelo Pinto¹, Felipe do Vale¹, Alessandra Xavier de Oliveira¹, Romulo Silva¹, Marlon Prestes¹, Daniela Bussmann²

¹Instituto de Pesquisa em Vida Selvagem e Educação Ambiental, Curitiba, Brasil; ²Arteris, Joinville, Brasil (natasha.choinski@spvs.org.br; marcelob@spvs.org.br; felipe.vale@spvs.org.br; alessandra.xavier@spvs.org.br; romulo.silva@spvs.org.br; sig@spvs.org.br; daniela.bussmann@arteris.com.br)

A Mata Atlântica é considerada um hotspot global que recobria 15% do território brasileiro, o equivalente a 1.306.421 km². Distribuída ao longo da costa brasileira é formada por um conjunto de ecossistemas de grande importância para manutenção de serviços ecossistêmicos. Porém, com o processo de desenvolvimento brasileiro, a área original do bioma foi reduzida para 7,84%, e estudos indicam a continuidade do desmatamento que no período entre 2016/ 2017 foi de 12.562 hectares (125 km²). Por causa da fragmentação florestal, projetos de restauração em parceria com o setor empresarial são importantes e podem integrar ações para a conservação da natureza em um cenário em que medidas compensatórias para obras de infraestrutura que causam impactos negativos a biodiversidade são regra no Brasil. Nesse contexto, uma cooperação técnica inovadora entre uma empresa do setor de infraestrutura e uma instituição que trabalha pela conservação da natureza foi estabelecida. A cooperação objetiva direcionar uma compensação ambiental para a restauração de áreas protegidas da Mata Atlântica, ecossistema de Restinga, ameaçado de extinção, e conta com as seguintes etapas: a) delimitação da área de trabalho para implantação das técnicas de restauração (núcleos de Anderson, galharias e poleiros artificiais); b) corte e controle de espécies exóticas invasoras; c) marcação de matrizes florestais porta sementes; d) coleta de sementes; e) produção de mudas; f) implementação das técnicas de restauração e g) monitoramento. Além dos resultados ambientais, essa iniciativa serve como um modelo para futuras ações de compensação ambiental no Brasil, que envolve um ciclo completo de restauração ecológica.

C9q: FOREST POLICY AND ECONOMICS - II

Forest investment in Toona ciliata: real options approach as a competitive strategyDanilo Simões¹ , Rafael Macedo Prestes² ¹Universidade Estadual Paulista "Júlio de Mesquita Filho", Faculdade de Ciências Agrômicas, Botucatu; ²Centro Universitário Internacional UNINTER, Indaiatuba, Brasil (danilo.simoes@unesp.br; rafaelmprestes@gmail.com)

Investments in forest assets are irreversible and have associated uncertainties. Therefore, the forestry producer must wait for favorable market conditions for decision making, in addition, to consider strategies that allow adding value during the life of the investment project. In this perspective, the objective was to evaluate an investment project in Toona ciliata using the approach of the Real Options Theory with combined options, with the perspective of measuring the economic feasibility and the probabilities of executing these options. The evaluation considered the plantation of one hectare with 816 trees of Toona ciliata located in the State of São Paulo, Brazil. The cash flow was projected considering the clearcutting, that is, for a horizon of 15 years. The discount rate was calculated using the Capital Asset Pricing Model (CAPM). The asset was modeled using the binomial pricing model, where the deferral option was weighted in the second year, in order that the uncertainties are eliminated for project continuity, and the expansion option of 30% of the planted area in the seventh year, in response to possible favorable market conditions. The jointly exercised options indicated 51% possibility of the forest producer to wait for two years to execute the investment project in forest assets and 13% to perform the expansion of the planted area of Toona ciliata. The value of both options was USD 11,256.01, resulting in an expanded net present value of USD 20,379.50, which allowed to add 123% of value to the forest investment project.

Economic viability of cultivating *Schizolobium parahyba* var. *amazonicum* Huber ex (Ducke) Barneby as a function of soil management practices in an agroforestry system / Viabilidade econômica do cultivo de *Schizolobium parahyba* var. *amazonicum* (Huber ex Ducke) Barneby em função de práticas de manejo do solo em sistema agroflorestal

Agust Sales¹, Silvio Nolasco de Oliveira Neto¹, Haroldo Nogueira de Paiva¹, Márcio Lopes da Silva¹, Helio Garcia Leite¹, Marco Antonio Siviero², Sabrina Benmuyal Vieira³¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Grupo Arboris, Dom Eliseu, Brasil; ³Universidade Federal do Pará, Belém, Brasil (agustsales@hotmail.com; snolasco@ufv.br; hnpaiva@ufv.br; mlopes.ufv@gmail.com; hgleite@gmail.com; m.g@masiviero.com.br; sabrina.benmuyal@grupoarboris.com.br)

Análise econômica é fundamental para definição de arranjos estruturais e manejo de sistemas agroflorestais. Analisou-se a rentabilidade e o risco de investimento do cultivo de paricá (*Schizolobium parahyba*) em sistema agroflorestal em função de práticas de manejo solo, em Ulianópolis, Pará, Brasil. Implantou-se o paricá no espaçamento 5 x 2 m, consorciado com soja (*Glycine max*), no primeiro ano, e milho (*Zea mays*) no segundo. Para o cultivo de paricá aplicou-se os tratamentos T1 = subsolagem, adubação de base, adubação de cobertura, inoculação, consórcio com soja/milho; nos T2, T3, T4 e T5 aplicou-se as mesmas práticas do T1, exceto subsolagem (T2), adubação de base (T3), adubação de cobertura (T4) e inoculação (T5); sendo o T6 a testemunha sem práticas de manejo do solo. Considerando horizonte de planejamento de cinco anos e taxa de juros de 6,75% a.a., realizou-se análise econômica através do VPL (Valor Presente Líquido), VAE (Valor Anual Equivalente), CMP (Custo Médio de Produção de madeira), Razão B/C (Benefício/Custo) e VET (Valor Esperado da Terra), incluindo análises de riscos de investimentos. O VPL, VAE, CMP, Razão B/C e VET indicam que os tratamentos tornam o sistema viável economicamente, com risco inexistente de VPL zero ou negativo. Custos, preço e produção de madeira em pé de paricá foram as variáveis que mais influenciaram o VPL. As receitas dos cultivos agrícolas amortizam, em média nos tratamentos, 88% do custo total, indicando viabilidade econômica das práticas de manejo do solo e do cultivo de paricá em sistema agroflorestal.

Monitoring a degraded area undergoing forest restoration as environmental compensation for a paper mill in Pirai, Rio de Janeiro, Brazil / Monitoramento de uma área degradada em processo de restauração florestal como compensação ambiental de uma indústria de fabricação de papel de Pirai, RJ

Barbara Costa^{1,2}¹Escola Nacional de Botânica Tropical, Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brasil; ²Costa Consultoria Ambiental, Rio de Janeiro, Brasil (contato@costaconsultoria.com)

No âmbito do licenciamento ambiental, a restauração florestal vem sendo utilizada como ferramenta para as mais variadas compensações ambientais. Após a implantação de projetos, é estritamente necessário o devido monitoramento para avaliação do desenvolvimento da área a ser restaurada. Este estudo avaliou uma área de aproximadamente 1,5 hectares em processo de restauração há um ano, em Pirai - RJ, baseado nos critérios da Resolução INEA nº 143/2017. Foram analisados todos os parâmetros pertinentes a metodologia do Diagnóstico Ecológico Rápido e catalogados os indivíduos existentes em cinco parcelas de 100 m² cada. Registrou-se 36 espécies, das quais 44% são zoocóricas, distribuídas em 17 famílias botânicas. A densidade encontrada foi de 1.740 ind.ha⁻¹, com percentual de cobertura de gramíneas de 80% e altura média de 2,5 m. Os índices de Diversidade (H') e Equidade (J) foram 3,58 e 0,84, respectivamente. Após análise da pontuação dos parâmetros avaliados a partir dos resultados do levantamento, obteve-se a nota 6,14, considerada compatível com a idade de implantação do projeto. Os parâmetros em que não se atingiu pontuação mínima foram: percentual de indivíduos zoocóricas, cobertura de gramíneas/copa e altura média. É necessário implantar enriquecimento com pelo menos cinco espécies zoocóricas. Além das boas características do solo de várzea, aceiros contínuos para prevenção de possíveis queimadas, manutenção de cercas, assim como controle contínuo de formigas cortadeiras, vem contribuindo para o sucesso do projeto.

Optimizing agricultural and forest production, considering remediation of conservation areas via complete planning and land use capacity / Otimização da produção agrícola-florestal considerando recuperação de áreas destinadas a conservação através de programação inteira e capacidade de uso do solo

Lucas Arthur de Almeida Telles¹, Marcio Lopes da Silva¹, Helio Garcia Leite¹, Daniel Henrique Breda Binotti², Gustavo Eduardo Marcatti³, Pedro Henrique Santos Mota⁴, Nero Lemos Martins Castro¹, Alexandre Simões Lorenzon¹, Brenner de Almeida Oliveira¹

¹Universidade Federal de Viçosa, Viçosa, Brasil; ²Centro Universitário São Camilo, São Paulo, Brasil; ³Universidade Federal de São João Del Rei, Sete Lagoas, Brasil; ⁴Plantar Reflorestamento S/A, Curvelo, Brasil (lucasarthur36@gmail.com; mlopes.ufv@gmail.com; gleite@gmail.com; danielhbbinotti@gmail.com; gustavomarcatti@ufsj.edu.br; pedromotaenf@gmail.com; nerolmcastro@gmail.com; alexandre.lorenzon@ufv.br; b.oliveiraefl@gmail.com)

A produção agrícola e florestal tem demandado a utilização otimizada de recursos aliada a definição precisa de atividades operacionais. Modelos matemáticos podem conciliar capacidade de uso do solo, atividades de ciclo longo e recuperação de áreas destinadas a conservação em um contexto espaço-temporal. Logo, o objetivo deste estudo foi desenvolver um modelo de programação matemática para maximizar o valor presente líquido de atividades florestais e agrícolas, considerando a capacidade de uso do solo da propriedade. O modelo de programação inteira formulado possui restrições de saldo mínimo, duração máxima, singularidade, nulidade, capacidade de uso do solo, produção mínima e máxima, opções de recuperação e reflorestamento. O modelo foi aplicado a uma propriedade simulada de 36 hectares, com atividades produtivas e presença de passivo ambiental, considerando um horizonte de 30 anos. Prescrições envolveram atividades agrícolas, fruticultura, reflorestamento e recuperação em um cenário de restrições de demanda variável segundo culturas e saldos anuais positivos. Através da aplicação do modelo, áreas produtivas foram utilizadas segundo sua capacidade de uso do solo enquanto áreas destinadas a conservação foram recuperadas ao longo do horizonte de planejamento. Quando possível, demandas foram atendidas sem a máxima exploração de unidades produtivas. A recuperação foi financiada pela receita da produção, tornando-a independente de recursos externos. A transição da produção foi eficiente e a propriedade gerenciada por demanda de culturas e saldo. Logo, o modelo proposto constitui uma ferramenta de gestão que viabiliza uma produção menos agressiva ao solo, recupera áreas destinadas a conservação e maximiza o lucro da produção.

Communications to overturn myths and encourage knowledge about the Araucaria / Ações de comunicação para desmistificar conceitos e incentivar o conhecimento sobre a araucária

Katia Regina Pichelli¹, Paula Geron Saiz¹, Luciane Cristine Jaques¹

¹Embrapa Florestas, Colombo, Brasil (katia.pichelli@embrapa.br; paula.saiz@embrapa.br; luciane.jaques@embrapa.br)

A araucária (*Araucaria angustifolia*) faz parte do ecossistema “Floresta com Araucária”, presente nos estados do Paraná, Santa Catarina e Rio Grande do Sul, e de forma esparsa na região Sudeste do Brasil. A exploração intensiva da araucária a levou à lista das espécies brasileiras ameaçadas de extinção. Isso aconteceu pelo avanço da fronteira agrícola, crescimento das cidades, possuir madeira de qualidade para móveis e ser boa matéria-prima para papel e celulose. No entanto, a proteção da lei a está prejudicando: muitos produtores rurais não a plantam mais ou permitem sua regeneração natural, por medo de serem punidos caso precisem mexer nas árvores. Também existem mitos junto ao público urbano, que protege a espécie de forma radical, sem conhecer melhor as possibilidades de uso, manejo e conservação. Em paralelo, a Embrapa Florestas, órgão federal de pesquisa florestal, tem trabalhado com pesquisas e transferência de tecnologia com araucária. Por isso, diversas ações de comunicação acontecem em apoio a estes trabalhos, para desmistificar conceitos e fazer com que os diversos públicos entendam a espécie, sua importância, possibilidades de uso e conservação. Diversas estratégias são utilizadas, como produção de materiais impressos e digitais em linguagens específicas para cada público, inclusive o urbano; participação em eventos (feiras, exposições, aulas de culinária etc, atingindo mais de 5.000 pessoas), com materiais elucidativos; lançamentos de publicações e tecnologias; trabalhos junto à imprensa e mídias sociais. Este conjunto de ações de comunicação tem contribuído para que a sociedade repense a importância da araucária, seus aspectos econômicos, sociais e ambientais.

The science behind food: Embrapa Florestas’ participation in a food week event highlighting the seed of *Araucaria angustifolia* / A ciência por trás dos alimentos: produção de materiais para participação da Embrapa Florestas na Semana Sabores do Pinhão

Paula Geron Saiz¹, Katia Regina Pichelli¹, Luciane Cristine Jaques¹

¹Embrapa Florestas, Colombo, Brasil (paula.saiz@embrapa.br; katia.pichelli@embrapa.br; luciane.jaques@embrapa.br)

Mostrar ao público urbano a ciência por trás da produção de alimentos oriundos da floresta, como o pinhão. Esta foi a proposta da Embrapa Florestas durante a Semana Sabores do Pinhão, promovida pela Secretaria de Abastecimento de Curitiba, em parceria com o Mercado Municipal e a Abrasel, em junho de 2018. Para atingir um público de 3 mil visitantes, a elaboração dos materiais usados no estande da Embrapa Florestas focou na adequação da linguagem, no impacto visual e no baixo custo de produção. Foram produzidos materiais digitais (telas) e impresso (cartão postal). Os digitais, exibidos em TV, traziam de forma objetiva, de fácil entendimento e visualmente atrativa, informações sobre pesquisas e tecnologias com araucária e pinhão, desenvolvidas na Unidade. Abordaram-se os temas: -Conservação da araucária: Destaque para a tecnologia de araucária de pinhão precoce e curiosidades sobre a árvore símbolo do Paraná (formato, reprodução, etc); -Projeto Estradas com Araucárias: Incentivo ao produtor para plantio de araucária nas divisas com rodovias, por meio do pagamento por serviços ambientais; -Pinhão- saudável e rico em possibilidades para culinária: Informações sobre aspectos nutricionais do pinhão e sua versatilidade em receitas doces e salgadas. O postal impresso, distribuído aos visitantes, continha no verso QR Codes remetendo a conteúdos disponíveis no site da Unidade, reunidos em página organizada especialmente para o evento. Os materiais chamaram a atenção dos visitantes, mostrando-se ótimas alternativas para levar informações de pesquisa ao público leigo quando trabalhados em linguagem acessível e com atrativos visuais, em função do baixo custo e praticidade.

Charging for water use in pulp production / Cobrança pelo uso da água na produção de celulose

Gabriel Soares Lopes Gomes¹, Júlia Graziela da Silveira¹, Laércio Antônio Gonçalves Jacovine¹, Amana de Magalhães Matos Obolari¹, Maria Tereza Angeletti Nunes¹

¹Universidade Federal de Viçosa, Viçosa, Brasil (gabriel.flo@hotmail.com; juliagrazielasilveira@gmail.com; jacovine@ufv.br; amanaobolari@gmail.com; mtangeletti@hotmail.com)

Na indústria de papel e celulose há grande preocupação quanto ao consumo de água e tratamento dos efluentes. Uma das alternativas para incentivar a racionalização de uso e gerar recursos financeiros para financiar a recuperação das bacias hidrográficas é a cobrança pelo uso da água. O objetivo do estudo foi comparar os custos de empresas de celulose brasileira quanto ao emprego dos recursos hídricos para produção da celulose e identificar medidas adotadas por estas para minimizar os gastos hídricos durante todo o processo. O estudo foi realizado com referência à quatro fábricas de celulose: “A” (Aracruz- ES),

“B” (Jacareí- SP), “C” (Belo Oriente- MG) e “D” (Limeira- SP). Com base no ano 2017, realizou-se o cálculo do custo d’água (R\$/ton) através da relação entre o valor pago pelo uso d’água e a tonelada de celulose produzida para cada empresa estudada. A empresa “A” apresentou o menor custo, o qual atingiu R\$ 0,55, enquanto a empresa “C” atingiu o maior valor R\$ 1,41, seguido pela empresa “D” com custos de R\$ 1,37. A diferença no valor pode estar associada à eficiência na utilização de água entre as empresas. A empresa “A” investiu na modernização nas etapas de branqueamento, assim como investiu na reutilização de condensados de evaporação, o que proporcionou reduções de 50% e 30%, respectivamente, no consumo de água durante o processo. Assim, empresas que utilizam técnicas que favoreçam a reutilização da água podem diminuir o custo pelo uso desse recurso natural.

Project Terracert: a new paradigm in forest legislation for building efficient landscapes in municipalities within the Amazon / Projeto Terracert: um novo paradigma na legislação florestal para construir paisagens eficientes em municípios da Amazônia

Jaqueline Carvalho¹, Rene Poccard², Marie Gabrielle Piketty³, Isabel Drigo⁴, Mario Oliveira Gomes⁵, Pablo Pacheco⁶

¹*Prefeitura Municipal de Paragominas, Secretaria de Assuntos Jurídicos, Paragominas, Brasil;* ²*CIRAD, Paragominas, Brasil;* ³*CIRAD, Bogota, Colombia;* ⁴*Instituto de Manejo e Certificação Florestal e Agrícola, Piracicaba, Brasil;* ⁵*Embrapa Oriental, Paragominas, Brasil;* ⁶*WWF, Washington, USA(jaquelineadvambiental@gmail.com; renepoccard@gmail.com; piketty@cirad.fr; isabel.drigo@gmail.com; mario.gomes@embrapa.br; pablo.pacheco@wwf.gov)*

A gestão florestal na Amazônia Brasileira alcançou bons resultados nos últimos 15 anos, em termos de combate ao desmatamento. Em Paragominas, o conjunto de ações implementadas pela política de combate ao desmatamento obteve grande sucesso no seu controle, contudo, referida política nunca considerou a eficiência da matriz florestal para produção de serviços ecossistêmicos. Fragmentação florestal, extração madeireira ilegal e incêndios recorrentes causam degradação florestal acelerada, acarretando prejuízos ambientais bem superiores ao desmatamento, necessitando de adaptações na legislação. Atualmente, os produtores agrícolas intensificam os sistemas de produção, selecionando para isso, as áreas de maior aptidão agrônômica e abandonando as outras. A política municipal de paisagem eficiente visa reordenar essas matrizes espaciais de uso agropecuário e de uso florestal. A cartografia das aptidões permite delimitar áreas prioritárias para serviços ecossistêmicos e outras para intensificação agropecuária, sendo a base para uma lei municipal de microzoneamento. Referida lei define protocolos de recomposição eficiente da paisagem para cada propriedade. A adesão a esses protocolos é voluntária, trazendo as seguintes vantagens ao produtor: acesso a crédito para intensificação, contabilização dos ativos ambientais ligados a restauração em áreas prioritárias, autorização de remoção da vegetação nas áreas de aptidão para a produção. A competência do município para a gestão florestal é limitada as florestas secundárias. Para incluir no ordenamento todos os tipos de floresta, e assim, ganhar eficiência, o município vem construindo diálogos nos níveis estaduais e federais. Esse projeto piloto é construído de forma a ser replicado em outras jurisdições da região amazônica.

THEME D: BIODIVERSITY, ECOSYSTEM SERVICES AND BIOLOGICAL INVASIONS

D1c: DISTURBANCE, ECOSYSTEM MEMORY, RISK AND FOREST MANAGEMENT IN A CHANGING SOCIO-ECOLOGICAL ENVIRONMENT¹

Forest owner’s preferences towards risk and uncertainty, and adaptation decisions towards climate change

Marielle Brunette¹, Marc Hanewinkel², Rasoul Yousefpour²

¹*Institut National de la Recherche Agronomique, Nancy, France;* ²*University of Freiburg, Freiburg, Germany (marielle.brunette@inra.fr; marc.hanewinkel@ife.uni-freiburg.de; rasoul.yousefpour@ife.uni-freiburg.de)*

Natural disasters represent the main risk that European forest managers face. In addition, climate change increases the frequency and intensity of these disasters, introducing uncertainty (in addition to risk) in the decision-making process. In this context, we focus on the forest manager’s preferences towards risk and uncertainty, and also on their impact on adaptation decisions. More precisely, we propose to: i) quantify risk aversion and uncertainty aversion coefficients of forest managers; ii) observe the effect of the obtained coefficients on the fact to adapt (or not) and on the type of adaptation strategy; iii) compare forest managers from France and Germany as regard to their preferences towards risk and uncertainty, and also as regard to their adaptation decisions. For that purpose, we realize a computerized survey sent by email in September 2018 to forest managers (private and public) in Grand-Est region in France and Baden-Wurttemberg in Germany. The questionnaire is composed of four parts. The first and second parts are dedicated to the measurement of risk and uncertainty aversion through lottery choices. The third part is about climate change and adaptation. One question is about perception of climate change, and the others are related to the adaptation strategies implemented and those that the managers forecast to implement in a near future. The adaptation strategies considered in the questionnaire are: plant genetically modified species, assist in tree regeneration, species mix, forest fertilization, harvesting age, thinning, forest insurance, and other measures. The last part is dedicated to questions about socio-economics characteristics.

Multiple uncertainties require a change of conservation practices for saproxylic beetles in managed temperate forests

Andrey Lessa Derci Augustynczik¹, Rasoul Yousefpour¹, Marc Hanewinkel¹

¹*University of Freiburg, Freiburg, Germany (andrey.lessa@ife.uni-freiburg.de; rasoul.yousefpour@ife.uni-freiburg.de; marc.hanewinkel@ife.uni-freiburg.de)*

In Europe, intensive forest management has severely compromised the habitat of forest insects, especially saproxylic beetles, due to the removal of deadwood and veteran trees. The loss of insect diversity may disrupt ecosystem functioning and affect the provision of important ecosystem goods and services in the future. Here we propose a novel approach for the implementation of conservation policies, by optimally allocating forest reserves and deadwood islands under multiple sources of uncertainty and minimizing economic risk. We use the saproxylic beetle *Lucanus cervus* as umbrella species, requiring that deadwood islands were spaced within its dispersal capacity. We show that current management and conservation practices are increasingly inefficient under changing environmental conditions and that the consideration of uncertainty requires a major expansion of conservation areas. Moreover, our results indicate that a strong diversification of management regimes, with a focus on selection forest systems, is required to reduce economic risk of forest management. We conclude that the integration of uncertainty into conservation planning may reduce the tradeoff between production and conservation objectives in forest landscapes and is key to increase the efficiency of forest management in the future.

Bark beetle risk management in the framework of strategic planning

Jan Kaspar¹, Robert Marusak¹, Harald Vacik²

¹Faculty of Forestry and Wood Sciences CULS Prague, Prague, Czech Republic; ²University of Natural Resources and Life Sciences Vienna, Vienna, Austria (kasparj@fd.czu.cz; marusak@fd.czu.cz; harald.vacik@boku.ac.at)

The Czech Republic's largely coniferous forests are facing the worst bark beetle infestation in at least 200 years. The amount of spruce wood damaged by bark beetles has risen steadily in the past few years, from 12 % of annual total cut in 2015 to more than 100 % of annual total cut in 2018. Experts are warning that the nation's forests could be wiped out if the current monoculture forestry format is not unchanged. The ongoing bark beetle disturbances and climate change have been forced to find rapidly new approaches of forest management which allow to react to new conditions on the wood market. One of the proposed solutions is to keep the dead trees without cutting and concentrate all human and financial capacities to protect the forest sites where there are still living trees. It will be necessary to create buffer zones in which management will need to be very effective and accurate in order to optimize all available resources and at the same time to prevent further spread of bark beetle. The presented study is aimed at possible way of risk management of forest stands damaged by bark beetle associated with spatial planning of management interventions in buffer zones.

Species mixture vs. age mixture: how to conciliate wood production and carbon sequestration objectives under drought and windstorm risks in forest

Sandrine Brêteau-Amores¹, Rasoul Yousefpour², Marc Hanewinkel², Mathieu Fortin³

¹Institut National de la Recherche Agronomique - BETA, Nancy, France; ²University of Freiburg, Freiburg-in-Breisgau, Germany; ³Canadian Forest Service, Ottawa, Canada (sandrine.breteau-amores@inra.fr; rasoul.yousefpour@ife.uni-freiburg.de; marc.hanewinkel@ife.uni-freiburg.de; mathieu.fortin@agroparistech.fr)

Forests provide ecosystem services such as wood production and carbon sequestration. However, forests are sensitive to climate change, and financial and amenity losses are expected for forest owners and society, respectively. The forests in the Grand-Est region (France) are dominated by beech, which is predicted to decline in the future due to repeated drought events driven by climate change. Forests in this region are also threatened by windstorm event. Beech forests need to adapt and mixture is known to decrease drought and storm risks. In this context, the objective of the paper was to compare, from an economical perspective, different forest adaptation strategies with the objective of reducing drought-induced and storm-induced risks of decline. For this purpose, we studied two types of mixture that we analysed separately and jointly: species mixture with oak and age mixture (i.e. from an even-aged to an uneven-aged forest). We also considered two types of loss (financial, and in terms of carbon sequestration) under different frequencies of drought and storm risks. We combined a forest growth simulator (MATHILDE) with a classical forest economic approach (Hartman's LEV). Maximizing the LEV criterion allowed the identification of the best adaptation strategies in economic terms. An optimisation of forest management was performed according to wood production and carbon sequestration objectives. The results are discussed taking into account the trade-offs between the financial balance and the carbon balance, and the underlying question of the additivity (or not) of the two risks as well as of the two adaptation strategies.

Impact of clear cuttings on biodiversity of boreal forests

Remigijus Daubaras¹, Laima Cesonienė², Vidas Stakenas³, Vytautas Tamutis², Marcin Zych⁴

¹Botanical Garden of Vytautas Magnus University, 46324, Lithuania; ²Botanical Garden of Vytautas Magnus University, 46324, Lithuania; ³Institute of Forestry of Lithuanian Research Centre for Agriculture and Forestry, 53101, Lithuania; ⁴Botanic Garden, Faculty of Biology, University of Warsaw, 00478, Poland (remigijusd@hotmail.com; laima.cesoniene@vdu.lt; vidas.stakenas@mi.lt; dromius@yahoo.lt; mzych@biol.uw.edu.pl)

The dynamic of chemical composition of forest soil, understory plants and variation of insects were investigated in *Pinus sylvestris* dominated forests after clear-cuts. We detected an increase in litter pH, while soil investigations have shown that concentrations of Ca²⁺ and Mg²⁺ also increased in the clear-cut areas. Significantly higher amounts of NO₃-N+NO₂-N mg kg⁻¹ and NH₄-N mg kg⁻¹ were determined after clear-cutting, while the mobile P₂O₅ and K₂O decreased in forest litter and mineral soil (in 0-10 cm depth) in clear-cut plots. We predict that suddenly increased supplies of NO₃-N+NO₂-N and NH₄-N influenced the development of *Ericaceae* species negatively. Logging residues could be extracted in Arenosols in order to avoid enhanced leaching of organic carbon and nutrients, especially mineral nitrogen. Clear-cuttings demonstrated a negative effect on the abundance of forest-related dwelling beetles, both in terms of species number and individuals in litter assemblages. However, clear-cuttings did not significantly reduce the total species richness because the quantity of beetle assemblages was supported by numerous open land or eurytopic species. Increased amount of new flowering plant species in clear cut areas effected mutualistic relationships of pollinators positively. Reaction and possibilities to restore different populations of *Ericaceae* are species-specific. *Vaccinium vitis-idaea* is able to survive after clear-cut damages. The ability of this drought resistant species to spread through underground rhizomes would promote its reproducibility. Nevertheless, the rhizomatous plant *Vaccinium myrtillus* demonstrated significantly stronger negative response in the cutted forests.

Ecosystem memory of boreal slash and burn forests

Pille Tomson¹, Kalev Sepp¹

¹Estonian University of Life Sciences, Tartu, Estonia (pille.tomson@emu.ee; kalev.sepp@emu.ee)

Slash and burn cultivation (SB) lasted up to the beginning of 20th century in Northern Europe. In South-Estonia SB was carried out in special areas named *buschlands* in the 19th century. Some plots were used for SB every year but the rest of the *buschlands* were a mosaic landscape with recovering forests. The aim of current study is to analyse the legacies of historical slash and burn cultivation in boreal forests. The study based on fieldworks in 80 grown-up forests stands in Southern Estonia, where 45 stands were chosen on former SB land (SBL) and 35 in forest land (FL) identified using the 19th century maps. Light differences were found between SBL and FL in ground vegetation. Samplings of deciduous trees and large relict trees were more present in SBL. Also abiotic legacies like field banks, gullies, clearance cairns were found in SBL. Analyses did not reveal any differences in soil chemical characteristics. Despite the evident legacies, the SBL are well-restored forest habitats. SB was stand-replacing disturbance but at the landscape level it was likely less disturbing than deforestation for permanent fields because of its mosaic landscape and short cultivation period. The bigger number of deciduous tree samplings in these forests allow to predict the faster changes in tree layer composition than in FL under the pressure of climate changes. Therefore, in the management practises of these forests for producing ecologically stable ecosystems today the legacies of the SB should be considered.

After the catastrophe. Turning off or speeding up? How French forest owners cope with climatic extreme events

Philippe Deuffic¹, Vincent Banos¹

¹IRSTEA, Cestas, France (philippe.deuffic@irstea.fr; vincent.banos@irstea.fr)

Although climatic catastrophes are scrutinized for a long time, their impacts on change of practices by forest owners remain ambiguous. For some researchers, extreme events act as a window of opportunity which induces major changes. On the opposite others observe, after the initial trauma, a return to routines. Our contribution aims to question if socio-ecological memory of past extreme weather events guides future conducts and induce changes in forest management. Based on two catastrophes (a severe drought in 2003 and a windstorm in 2009 in France), we assume extreme events do not entail disruption, nor status quo but a so-called 'assisted deviation'. Our analysis shows that strategies range from a return to routine to an acceleration of changes in forest practices. On one hand the lack of social memory affects the capacity to learn from experience and contributes to modest changes of practices also induced by a loss of economic flexibility. On the other hand, major changes of practices are often encouraged by economic and cognitive capability to implement new forest practices but also by a vivid memory of past catastrophes and lessons learnt from their recurrence. However, the ecosystem memory and the forest sector economic legacy and structure may lead to two very different adaptive strategies: the intensification of past practices based on resistance of ecosystem or the introduction of innovative practices based on resilience. Finally, we suggest catastrophes should be not only risks for the future but also experience which test the relevance and efficiency of adaptive strategies

Dealing with risk and uncertainty in forestry with multi-criteria decision analytic approaches

Donald Hodges¹, Lidija Zadnik Stirn², Donald Grebner³

¹University of Tennessee, Knoxville, TN, USA; ²University of Ljubljana, Ljubljana, Slovenia; ³Mississippi State University, Mississippi State, MS, USA (dhodges2@utk.edu; lidija.zadnik@bf.uni-lj.si; don.grebner@msstate.edu)

Forest management always has required planners to make decisions in an environment that included physical and financial risk factors, the probability of disturbance, and a wide range of uncertainty. The level of risk and uncertainty is projected to increase substantially in the future, due to changes in climate, threats from native and invasive pests, and increasing interest in a range of ecosystem services that goes beyond the commodities from past forest management planning. While traditional economics-based forest management approaches, such as Faustmann, offers a means by which risk and uncertainty can be incorporated into decision making, today's management planning requires approaches that maximize forest functions and values that frequently are in the form of multi-criteria and indicators. Multi-criteria decision analysis (MCDA) techniques such as Analytic hierarchy process (AHP) have been introduced to incorporate social values into the decision-making process, and offer a more robust approach to risk factors and uncertainty. The presentation will explore the current and probable future environment in which management decisions must be made, review traditional approaches to decision making with risk and uncertainty, present MCDA approaches, and evaluate the ability of these techniques to address risk and uncertainty in forest management decisions.

Catastrophic fire and ecological memory drive the habitat trajectories of a critically endangered arboreal marsupial in the mountain ash forests of Victoria, Australia

Patrick Baker¹, Raphael Trouve¹, Craig Nitschke

¹University of Melbourne, Richmond, Australia (patrick.baker@unimelb.edu.au; raphael.trouve@unimelb.edu.au; craign@unimelb.edu.au)

The Eucalyptus *regnans* (mountain ash) forests of Victoria's Central Highlands are amongst the most productive forests in the world and support a range of threatened species. The management of these forests has become highly contentious in recent decades due to competing demands for habitat conservation and forest products. Catastrophic bushfires are the driving disturbance within these landscapes. Soil seed banks and the density of standing trees (both alive and dead) are critical components of the ecosystem's memory, shaping post-fire stand development and landscape-scale heterogeneity. Leadbeater's Possum, a critically endangered arboreal marsupial that is heavily dependent on the mountain ash forests, requires large hollow-bearing trees for nesting and dense *Acacia* for foraging and movement within the forest. However, these two features of the forest develop at very different rates after fire and persist for different lengths of time. Hollow-bearing trees may take a century or more to form and can persist for several centuries, whereas the *Acacia* component establishes rapidly after the fire, but senesces and returns to the soil seed bank in less than 100 years. Forest management strategies that aim to conserve Leadbeater's Possum must accommodate both the fast cycling of the ephemeral *Acacia* component and the slow cycling of hollow-bearing trees within the broader landscape.

After removing the Chusquea understory, is it necessary to underplant to restore degraded evergreen North-Patagonian forests?

Jan R Bannister¹, German Travieso¹, Manuel Acevedo², Eduardo Cartes², Marta González², Nicole Galindo¹

¹Instituto Forestal, Castro, Chile; ²Instituto Forestal, Concepción, Chile (jbannister@infor.cl; gtravieso@infor.cl; macevedo@infor.cl; ecartes@infor.cl; mgonzalez@infor.cl; ngalindo@infor.cl)

In order to facilitate the restoration of the structure and tree species composition in North-Patagonian forests that were opened by illegal logging, a common discussion between managers has been the advantage of removing the dense *Chusquea quila* understory that grows after selective cutting in these forests. In this study, using a restoration experiment established in 2014 along a gradient of varying residual basal area in a high graded North-Patagonian forest on Chiloé Island, we aim to evaluate the early performance of natural regeneration and restoration cluster underplantings after the removal of the *C. quila* understory. After 4 years, seedlings of *Nothofagus nitida* seedlings had 74% survival, and a mean height growth of 14.7 cm/year. The mean height growth of *N. nitida* seedlings was positively correlated with the percentage of photosynthetic photon flux density (PPFD), and negatively correlated with the residual basal area of the degraded forest ($p < 0.01$). On the other hand, all tree species present in undisturbed conditions (15 tree species) were regenerating in the experiment with a mean density of 9.7 plants/m². The highest density of natural regeneration was in areas with 60-70 m²/ha of residual basal area and between 30- 80% of PPFD. Our results show that natural regeneration from residual trees can assist the recovery of degraded North-Patagonian forests in Chiloé Island following the removal of the *C. quila* understory. Supplementary planting of valuable pioneer tree species that tolerate shade may assist the natural recovery, especially in areas with lower nurse canopy.

DI1d: EMPLOYING PLANTATIONS TO RESTORE NATIVE FORESTS USING SUCCESSIONAL FOREST MANAGEMENT SYSTEMS

Restoring native temperate forests from *Pinus radiata* plantations in Chile: effects of different harvesting treatments and environmental conditions on regeneration success

Klaus Kremer¹, Jürgen Bauhus¹

¹University of Freiburg, Freiburg im Breisgau, Germany (klaus.kremer@waldbau.uni-freiburg.de; juergen.bauhus@waldbau.uni-freiburg.de)

Over the last decades, an important expansion of commercial tree plantations took place in south-central Chile, in some cases at the expense of native vegetation. This has significant consequences on biodiversity and ecosystem services, which cannot be provided to the same extent by plantations as by native ecosystems. In response to requirements of FSC certification, forestry companies are beginning to restore the native ecosystems replaced by exotic tree plantations after 1994. Owing to the lack of knowledge for this process, we have conducted two studies in *P. radiata* plantations. The first study aims at determining the effect of different harvesting treatments (clear-cut, strip felling and control) on the early establishment of natural and artificial regeneration of native tree species. Preliminary results show that strip felling provides the best performance of artificially established seedlings of six species of different shade tolerance. The intermediate cover achieved might provide shelter against extreme conditions, while allowing enough sunlight to reach the forest floor. In our second study we aim at determining the potential for restoration of native forests from natural advance regeneration in *P. radiata* plantations, and to ascertain suitable conditions for its development in the mid-term. We sampled 257 plots in 20-year old plantations of *P. radiata*, along a 432 km latitudinal gradient in the Coastal Range. For each plot we assessed native woody species regeneration, and potential explanatory factors at the site and landscape scale. Results from both studies will provide guidance for the conversion of *P. radiata* plantations to native forests.

Natural forest islands in a matrix of forestry plantations: a refuge of biodiversity and an opportunity for restoration

Rodrigo Vargas-Gaete¹, Paola Arroyo-Vargas², Carla Manríquez¹

¹Laboratorio de Biometría, Depto de Cs. Forestales Universidad de La Frontera, Temuco, Chile; ²Department of Geography, Portland State University, Portland, OR, USA (rodrigo.vargas@ufrontera.cl; paola.arroyovargas@pdx.edu; c.manriquez03@gmail.com)

Most forest plantations are managed as monocultures of fast-growing species, covering large areas. In Chile, forest plantations of exotic species currently cover >3 million ha, principally with *Pinus radiata*. In the coastal mountain range of Chile (35-38° S), plantation establishment has generated areas in which natural forests have become “islands” of biodiversity, surrounded by an “ocean” of plantations. An understanding of how remnant natural patches contribute to biodiversity retention is needed. Natural forest patches retain native plant species inside the patches but also can influence nearby areas into the plantation matrix. This proposal aims at determining attributes of natural forest patches surrounded by plantations, that contribute to retaining plant biodiversity within adjacent plantations. Using as study area ~250,000 ha in the coastal range of Southcentral Chile (°38 S), we (a) quantified the frequency by size, shape, and isolation of natural forest islands found. Afterward, we selected 18 *Nothofagus forest* patches, considering a range of sizes for fieldwork, sampling vegetation, site, structure, and other variables. We (b) analyzed natural forest attributes that influenced plant species richness, and (c) we assessed site attributes that promote the establishment of native species on its understory. *Nothofagus* dominated patches vary in size (0.5 to > 200 ha), but most presented < 8 ha. Plant diversity underneath plantations was primarily explained by plantation attributes, and tree regeneration in the understory of pine plantations was influenced by the distance to natural patches. We discuss current knowledge on fragmented ecosystems and the opportunity that remnant forest patches can offer for the restoration and/or conversion of forestry plantations.

Using *Acacia auriculiformis* plantations as a pathway to restore naturally regenerating forest in the Western Ghats, India: a case study and a call for future investigations

Benjamin Caldwell¹, Sanjai Mohan²

¹FAO, Rome, Italy; ²Indian Forest Service, Bengaluru, India (benjamin.caldwell@fao.org; kt090@ifs.nic.in)

Restoration of degraded forest is a critical path to mitigate climate change and improve rural livelihoods. There are millions of hectares pledged for restoration worldwide, but pathways to achieve those pledges are still emerging. Restoration in highly modified or degraded sites is expensive and problematic; plantations can be one solution: a profitable plantation is established and then maintained for one or two rotations. The plantation is then used as a nurse crop for shade-tolerant indigenous species. Here we present such a case from India. Running along most of India's western coast, the Western Ghats are one of the world's eight hottest biodiversity hotspots. However, their forests are degraded from centuries of timber logging, fuelwood extraction, and conversion for coffee plantations. In response to this, India's Forest Departments began restoration of forestlands converted to agriculture and then abandoned. In many cases, the residual lateritic soils were so degraded and recalcitrant that only *Acacia auriculiformis* showed the capacity to successfully occupy the site. They also planted indigenous tree species under the acacia in a nurse crop trial. Supported by the USAID funded Forest-PLUS project and the Karnataka Forest Department, we determined which species had been most successful in this trial. In adjacent forest, basal area and tree species data from natural forest was also used to construct models that describe structure and composition to guide management targets within degraded indigenous forest. Together, such tools provide means for forest managers to cost-effectively restore indigenous Indian forests at a landscape level.

Regeneration of *Acacia auriculiformis* A. Cunn. ex Benth. plantation in Mt. Makiling Forest Reserve, Philippines: implications to restoration ecology

Marilyn Combalicer¹, Jonathan Hernandez¹, Jessa Ata¹

¹Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines Los Baños, Los Baños, Philippines (mscombalicer@up.edu.ph; johernandez2@up.edu.ph; jpata@up.edu.ph)

There have been a number of debates on the use of exotic species plantations especially for restoration in the Philippines, mainly due to some ecological concerns (e.g. loss of genetic variation). Hence, the potential of *Acacia auriculiformis* A. Cunn. ex Benth., an exotic species, for restoration of a degraded land in Mt. Makiling Forest Reserve (MMFR), Philippines was examined. The composition and structural changes of the grassland under *A. auriculiformis* plantation over a 20-year and 28-year old study periods were analyzed. Results suggest a general trend of changes in *A. auriculiformis* plantation which was once a grassland dominated by *Imperata cylindrica* and *Saccharum officinarum*. Both stems (ha⁻¹) and basal area (m² ha⁻¹) increased significantly in 2010-2018. Increase in the

dominance of native overstory trees coupled with a decrease in the dominance of exotic species was also observed. Lastly, results revealed an increase in species richness and species diversity with the presence of more native trees naturally occurring in MMFR (e.g., *Pterocymbium tinctorium* and *Celtis luzonica*). These are all attributed to ecological processes, including improved soil fertility and microclimate, disturbance, soil seed banks, seed flow of adjacent forests, seed dispersal, and mortality rate along with the N-fixing ability of *A. auriculiformis*. This study, therefore, provides insights that *A. auriculiformis* plantation is potential for restoration of degraded lands in the Philippines. However, this may require in-depth ecological knowledge, silvicultural management practices, and continuous field-based monitoring studies to enhance understanding of the management aspect of a restored landscape.

Floristic composition and diversity in a 50-year old *Terminalia ivorensis* (A. Chev) plantation in Sakponba Forest Reserve, Nigeria

Ekeoba Matthew Isikhuemen¹

¹University of Benin, Benin City, Nigeria (ekeoba.isikhuemen@uniben.edu)

The paper evaluates composition, diversity and evenness of trees/shrubs in a 20 ha Black afara (*Terminalia ivorensis* A. Chev.) plantation established in Sakponba Forest Reserve, Nigeria in 1967. In 2016, all trees/shrubs ≥ 19 diameter at breast height (dbh) were enumerated. Height was measured using a Range Finder while girth was measured at breast height (1.3m) with Girthing tape. Data were analysed using biodiversity and Important Value (IV) indices. Overall, 2131 trees/shrubs distributed among 87 species, 80 genera and 36 families were recorded. *T. ivorensis* accounted for 7% of total trees (>19cm dbh) recorded at the site. Species rank abundance curve and IVI revealed that *Funtumia elastica* (Preuss) Stapf. was the most abundant and important species followed by *T. ivorensis*. The three most important families (based on IVI ranking) were Apocynaceae, Rubiaceae and Mimosodidae. Of the total stems (>60cm dbh) recorded among 87 species, *T. ivorensis* accounted for 76%; it also had the largest number of trees (75%) that grew >30m height. The result of Shannon-Wiener's index was relatively high (3.2) while Shannon Wiener's and Pielou's evenness indices were 0.81 and 0.82 respectively. The study revealed that all the *T. ivorensis* trees (tropical rainforest pioneer) were matured and tending toward the degrading stage of tree growth cycle. Following the outcome of this study, wherein 86 naturally introduced species were enumerated at the study site, it is safe to conclude that the single species plantation established 50 years ago with Black afara has ultimately metamorphosed into a heterogeneous forest.

On the competition for light and nutrients in mixed plantations of *Eucalyptus* and a high diversity of native tree species

Nino Amazonas¹, David Forrester², Carina Silva¹, Danilo Almeida¹, Rafael Oliveira³, Ricardo Rodrigues⁴, Pedro Brancalion¹

¹University of São Paulo, "Luiz de Queiroz" College of Agriculture, Forest Sciences Department, Tropical Silviculture Laboratory, Piracicaba, Brazil; ²Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, Switzerland; ³University of Campinas, Institute of Biology, Department of Botany, Campinas, Brazil; ⁴University of São Paulo, "Luiz de Queiroz" College of Agriculture, Biology Department, Forest Ecology and Restoration Laboratory, Piracicaba, Brazil (namazonas@gmail.com; david.forrester@wsl.ch; carina.camargosilva@gmail.com; daniloflorestas@gmail.com; rafaelosliv@gmail.com; rrrresalq@usp.br; pedrob@usp.br)

Mixed plantations composed of *Eucalyptus* intercropped with a high diversity of native trees are a promising option for combining wood production with biodiversity recovery in forest landscape restoration. Together with ecological advantages, mixtures provide economic benefit during the first years of forest restoration. We investigated facilitation by N-fixing native trees and competition for light and nutrients in three experimental sites in the Atlantic Forest of Brazil. We compared (1) monoculture plantations of *Eucalyptus*, (2) mixed restoration plantations (10 pioneer species and 30 non-pioneer species), and (3) mixed plantations with the same 30 non-pioneer species intercropped with *Eucalyptus*. We compared Intercepted Photosynthetically Active Radiation (IPAR) to investigate competition for light and leaf and wood nutrient concentrations to assess competition for nutrients and between *Eucalyptus* and native species. We also performed a tree-level analysis using neighborhood indices to investigate the facilitation effect mediated by N-fixing native trees on the growth of *Eucalyptus* in mixtures. Contrary to our expectations, we found IPAR was higher in native tree plots, while the lower IPAR in *Eucalyptus* monoculture or mixed plots did not differ. So, native non-pioneers faced stronger competition for light from native pioneers than from *Eucalyptus*. Also, we found no differences in nutrient concentration in leaves and wood when we compared our treatments. Moreover, native N-fixers did not enhance the growth of *Eucalyptus*. Under the traditional silvicultural treatment, the growth differences were not explained by competition for light or nutrients.

Nurse trees as a forest restoration tool for creating mixed, productive and native plantations

Magnus Löf¹

¹Swedish University of Agricultural Sciences, Alnarp, Sweden (magnus.lof@slu.se)

Two-storied mixed plantations can be designed to meet social, economic and environmental objectives during forest reforestation and restoration. In addition, the rapid re-establishment of forests for afforestation or following large disturbances is being seen as one option to increase the contribution of forests to climate change mitigation. The temporary inclusion of pioneer trees as nurse crops can facilitate the establishment of native tree species and may also improve biodiversity, productivity and soil fertility. However, there is little practical experience with the method. This study, from southern Scandinavia, reports how fast-growing nurse trees influence the ecological growing conditions, survival and growth in native target tree species, and in addition report results from different studies around the world concerning the influence of nurse tree species on the growth and performance of target tree species. Transgressive overyielding has been observed in several studies that measured productivity in North America, Scandinavia and elsewhere. Long-term experiments using nurse trees and both native and exotic shade tolerant target tree species are presently being established in southern Scandinavia. Even if productivity is increased, the more complex forests structures may be an obstacle for cost-effective management. However, for restoration practitioners, using nurse trees for rapidly building a new forest structure and simultaneously increase productivity, might be a cost-effective strategy for forest restoration.

On the Restoration of Korean Fir (*Abies koreana*) Forests: the survival rates of reintroduced seedlings on in situ and ex situ

Jaehoon Kim¹, Byoungki Choi¹, Kukman Song¹

¹Warm Temperate and Subtropical Forest Research Center, National Institute of Forest Science, Seoqwipo, Republic of Korea (jkim1922@korea.kr; vegetation01@korea.kr; kukman@korea.kr)

This study was carried out to verify the possibility of restoration of Korean fir forest by the reintroduction of sapling at in situ and ex situ; 460 of seedlings were planted in its natural habitat in 2017 and 2³00 of grafted saplings were planted out of its natural habitat in 2018. The survival rate has been monitored. The relative survival rate gradually decreased from 82.2% in August 2017, 87.6% in October 2017, 84.0% in May 2018, and 75.2% in September 2018. The tendency for the death rate was increased especially during the transition from summer to autumn respectively. The relative survival rate of two areas (relatively

open area and understorey area) was stable over time. The seasonal variation of the survival rate was considered to be a sensitive factor for summer climate change compared to winter season. Especially, long term drought in summer and typhoons accompanied by heavy rainfall tended to increase mortality rate in all types of restoration sites. The survival rate of saplings planted out of its natural habitat was 88.9%. Especially in summer 2018 when summer drought and typhoon damage occurred, the survival rate was relatively high, and it was confirmed that it could be used for restoration of damages. Since the research monitoring period has not been long enough, complex interpretation of various factors for restoration is difficult. We will continue to monitor the survival rate of re-introduced seedlings and the possibility of restoration for the actual application

D1e: FOREST LANDSCAPE RESTORATION FOR CLIMATE CHANGE MITIGATION AND ADAPTATION: INTEGRATING RESEARCH INTO POLICY

African forest landscape restoration initiative: progress and challenges in implementation

Joseph Cobbinah¹, Ernest Foli¹

¹CSIR-Forestry Research Institute of Ghana, Kumasi, Ghana (joe.cobbinah@ymail.com; efoli@hotmail.com)

African development is driven largely by natural resources. Unfortunately these resources are declining in quantity and quality. Only 20 percent of tropical Africa forests remains from previous high of 50 percent. FAO forest resources assessment estimated annual loss of 2.8 million hectares between 2010 and 2015. The continued over-exploitation of forest resources coupled with poor public service resource management systems have led to forest degradation. There is therefore the urgent need to reverse the progressive decline of forest assets which is impacting negatively on the social, economic and environmental well-being of the African populace. The AFR 100 was launched in 2015 to bring 100 million hectares of degraded lands in Africa to restoration. As of mid-September 2018, 27 countries had made restoration commitments totaling 96.4 million hectares. The initiative has potential not only for reversing the decline in forest assets but also enhancing carbon stocks and removal of GHG and resilience to forest and communities to climate variability and change. The paper will present country by country commitment, up to date progress in the implementation of commitment, and country specific challenges to guide planning and share knowledge and experiences in forest landscape interventions.

Improving rural livelihoods and contributing to climate change mitigation and adaptation through reforestation: examples from Ghana

Reginald Tang Guuroh^{1,2}, Ernest G. Foli¹, Daniel A. Ofori¹

¹Council for Scientific and Industrial Research, Forestry Research Institute of Ghana, Kumasi, Ghana; ²University of Cologne, Range Ecology and Range Management Group, Botanical Institute, Cologne, Germany (rguuroh@gmail.com; efoli@hotmail.com; dofori12@gmail.com)

Improving forest cover and avoiding deforestation are useful pathways for climate change mitigation and adaptation. Thus, the restoration of degraded lands is of major significance, and underpins African countries' commitment to restore 100 million hectares of degraded lands under the AFR100 initiative. We present examples of forest restoration efforts from the dry semi-deciduous and moist semi-deciduous zones of Ghana to share knowledge and experiences across the continent on successful restoration efforts that do not only have potential of climate change mitigation and adaptation but that also contribute to food security and livelihood improvement. The examples are drawn from two case studies involving public-private partnerships in forest landscape restoration. So far, approximately 3,205 hectares of plantation have been established under partnership between the Forestry Commission and Timber Industry, while under the Forest Investment Programme 24,925 hectares of native species have been established, involving about 159 forest fringe communities. These projects have provided direct jobs to over 1,000 local people and serve as regular source of income for livelihood support. Several tons of various staple food crops such as maize, plantain, beans are also produced yearly by farmers who have been given the opportunity to integrate food crops into these plantations. These outcomes provide evidence that there are possibilities for government agencies and the private sector to effectively collaborate with rural communities in a participatory manner to bring about successful interventions and that restoration initiatives could be planned to provide multiple benefits.

A decade of adaptation to climate change in Southern and Eastern Africa, opportunities and challenges

Felix Kalaba¹

¹School of Natural Resources, Copperbelt University, P.O Box 21692, Kitwe, Zambia (kanungwe@gmail.com)

Development efforts targeted on poverty reduction, food security and sustainable environmental management are being threatened by climate change in sub-Saharan Africa. This is particularly true for southern and eastern Africa, which has seen an increase in incidences of negative environmental hazards such as extreme temperatures, droughts, and floods. The negative impacts of climate change in this region have increased in the past decades thus negatively affecting rural households who are highly dependent on forest and agriculture. Future climate change forecasts suggests that sub-Sahara Africa will continue to face negative impacts of climate change, and hence the need to develop national level adaptive strategies to help improve the adaptive capacity people especially in rural households. This paper explores current adaptation strategies, options and challenges to climate change in southern and Eastern Africa drawing on evidence from the United Nation's Framework Convention on Climate change (UNFCCC)'s National Adaptation Plans of Action (NAPAs). A content analysis of nine (9) NAPAs from southern and eastern African countries (Angola, Democratic Republic of Congo, Lesotho, Madagascar, Malawi, Mozambique, Tanzania, Uganda and Zambia) was conducted to understand national adaptation strategies proposed in different countries to adapt to climate change. Additionally, opportunities and challenges of implementation of adaptation strategies are discussed drawing on evidence from adaptation research conducted in southern and eastern Africa over the last decade.

Managing the carbon dynamics of afro-montane forests in northern Ethiopia

Hubert Hasenauer¹, Beyene Belay Alem², Elisabeth Pötzelsberger¹, Douglas L. Godbold¹

¹University of Natural Resources and Life Sciences, Vienna, Austria; ²Amhara Agricultural Research Institute, Bahir Dar, Ethiopia (hubert.hasenauer@boku.ac.at; beyene.belay@yahoo.com; elisabeth.potzelsberger@boku.ac.at; douglas.godbold@boku.ac.at)

The Ethiopian government is working on restoring degraded areas and set the forest sector as one pillar in the country's green economy strategy. The aim was to (i) identify potentially suitable reforestation areas in Amhara region, and (ii) predict the carbon sequestration potential and forest management impacts. We collected forest and soil data in four study areas located across the region and use a ecosystem model to predict the net primary productivity (NPP). Potentially

suitable reforestation areas in the Amhara region were identified based on land use suitability, potential vegetation/elevation belt and aridity index. The carbon sequestration potential of identified area was predicted using the ecosystem model under different forest management scenarios: (i) unmanaged (ii) light thinning (thinning 1, 5%, 20yr intervals) and (iii) heavy thinning (thinning 2, 10%, 20yr intervals) and with different rotation periods (10, 30, 50 years). The inventory results of soil carbon ranged from 61 to 206 t C ha⁻¹, whereas the aboveground carbon ranged from 13 to 60 t C ha⁻¹. About 3.4 Mha (Mha = Million hectare) of land, including bare land (0.7 Mha), grass land (1.2 Mha) and shrub land (1.5 Mha) is suitable for reforestation in the Amhara region. Following the Normal Forest idea, and assuming that all identified areas are reforested in a 50 year rotation period, net carbon sequestration (soil and aboveground) could be up to 178 Tg C (Teragram =1012 gram) in unmanaged, 168 Tg C in light thinned and 159 Tg C in heavy thinned forests.

Science-based continental and regional policy interventions will help to sustain productivity of African forests under changing climatic conditions and contain devastation by invasive insect tree pests and diseases

Mercy Gichora¹, Harrison Kojwang², Paul Bosu³, Alemu Gezahgne⁴, Mohamed Lahbib Ben Jamaa⁵

¹Kenya Forestry Research Institute, Nairobi, Kenya; ²Hakon Consultants, Windhoek, Namibia; ³Forestry Research Institute of Ghana, Kumasi, Ghana;

⁴Ethiopian Environment and Forest Research Institute, Addis Ababa, Ethiopia; ⁵National Research Institute for Rural Engineering, Water and Forestry (INRREF), University of Carthage, INRREF, Tunis, Tunisia (mewagi05@yahoo.com; hokojwang@gmail.com; paul_bosu@yahoo.com; alemu.gezahgne@gmail.com; benjamaaml@gmail.com)

One of Africa's aspirations is to participate in global efforts for climate change mitigation that support and broaden the policy space for sustainable development on the continent. Africa also wishes to continue to speak with one voice and unity of purpose in advancing its position and interests on climate change. By 2063, Africa's unique natural endowments, its environment and ecosystems, including its wildlife and wild lands will hopefully still be healthy, valued and protected, with climate resilient economies and communities. Natural forests are one such terrestrial ecosystem which on the contrary is rapidly diminishing as a result of land use conversions to meet diverse needs of an increasing human population. In its place, there has been wide promotion of exotic plantation forestry both on public and private land. The health status of the different forest types is examined closely in this study of forest pests and diseases in Africa. Based on case studies and literature review, plantation forests are found to be particularly vulnerable to biological invasions. The greatest concern remains the fragmented efforts by individual countries in tackling biological invasions by exotic species. Cross-boundary efforts are recommended in managing the spread of pest and disease infestations. African countries therefore require continental and regional policies to keep forests free of pests and diseases. Such policies will not only support sustainable forest management and climate change mitigation but also reverse forest degradation while catering for consumptive and non-consumptive needs of the continent.

Phytoremediation using trees: a case study of native species in Zambia

Emma Sandell Festin¹, Carl Salk¹, Muluaem Tigabu¹, Stephen Syampungani², Henrik Bohlenius¹, Per-Christer Odén¹

¹Southern Swedish Forest Research Centre, Alnarp, Sweden; ²School of Natural Resources, Department of Plant and Environmental Sciences, Kitwe, Zambia (emma.sandell@slu.se; carl.salk@slu.se; muluaem.tigabu@slu.se; ssyampungani@yahoo.com; henrik.bohlenius@slu.se; per.christer.oden@slu.se)

Extensive areas around the world have soils polluted with heavy metals due to human activities and are in need of restoration. Tailing dams are sources of toxic dust particularly hazardous to human health through accumulation in the food chain. Natural regeneration or active restoration of vegetation is difficult due to soils' homogenous grain size, lack of nutrients and elevated levels of heavy metals. Phytostabilization is a new and cost-effective method using plants to stabilize or remove heavy metals from the soil. In this study, we conducted a greenhouse trial of five selected tree species commonly found in the natural forest ecosystem and on tailing dams in the Copperbelt region, Zambia: *Albizia amara*, *Brachystegia bohemii*, *Cassia abbreviata*, *Combretum collinum* and *Senna singuena*. They were raised from seeds and after four weeks, polluted with different concentrations of copper chloride to mimic the growing conditions on a tailing dam. The seedlings grew for 6 months and were then harvested to analyse the uptake of Cu in roots and above ground biomass. None of the tested species were accumulators as they all regulated their uptake. Based on a previous field trial, several of the species were found on both tailing dams and in the natural forest regulate their Cu uptake, making them into facultative metalophytes, or possibly even excluders. Restoration of degraded lands would be aided by field trials targeting species with these traits to identify suitable plants to accelerate the revegetation process.

Effect of enclosures age on restoration of degraded woodlands surrounding Kakuma refugee camp, Turkana County, Kenya

John Kigomo¹, Stephen Ndung'u¹, Eliud Macharia¹

¹Kenya Forestry Research Institute, NAIROBI, Kenya (kiggs2012@gmail.com; stephenmn06@gmail.com; eliud_waweru@yahoo.com)

The settlement of refugees from 1990s mainly in Kakuma and Dadaab in Kenya have degraded woodlands resource base due to high demand of wood products. Various government agencies and development partners in collaboration with local communities have been undertaking rehabilitation of degraded woodlands surrounding Kakuma refugee camp using enclosures. Despite all these efforts there is scanty information on the recruitment and succession process of vegetation within the intervention areas. Enclosures aged between 6 to 12 years were selected to determine the effects of enclosures age on natural regeneration in terms of structural characteristics, composition and diversity. Vegetation data was collected through laying systematic nested plots along diagonally established transect within the selected enclosures. The occurrence of woody vegetation increased progressively from 29 % to 36%. The mean height, diameter at 30 cm above ground, crown diameter and species diversity were significant different at different ages of enclosures (p<0.05). The herbaceous species occurrences were higher in early years (33%) then decreased to 29% but increased to 37% when the enclosures were 12 years. The mean cover and species diversity were not significantly different along enclosure ages (p>0.05). However, relative occurrences were significantly different along the enclosure ages (p<0.05). The study has demonstrated the impact of long term enclosures in recruitment of important trees and grass species. The increasing recruitment of woody vegetation and alternating occurrence of herbaceous species indicates the enclosures are yet to reach species climax levels. This study recommends continued protection and monitoring to achieve the goals of enclosures.

Integrating bioenergy and food production on degraded landscapes in Indonesia for improved socio-economic and environmental outcomes

Syed Rahman¹, Himlal Baral¹

¹Center for International Forestry Research (CIFOR), Bogor, Indonesia (sumonsociology@yahoo.com; h.baral@cgiar.org)

Growing bioenergy crops is a promising solution to meet the need for energy security, income security and land restoration. This paper assesses the socio-economic and environmental benefits of agroforestry systems based on nyamplung (*Calophyllum inophyllum* L.) in the Wonogiri district of Central Java, Indonesia. Data was collected through field observations and focus group discussions (FGD) involving 20 farmers who intercrop nyamplung with maize, paddy and peanuts, and utilize the species in honey production. Calculating each crop's net present value (NPV) demonstrates that when grown as monocultures, staple crops paddy and peanuts lead to negative profitability, while maize generates only a marginal profit; yet honey production utilizing nyamplung produces a NPV nearly 300 times greater than maize. However, when utilizing nyamplung, honey is also the commodity most sensitive to decreases in production, followed by nyamplung-peanut and nyamplung-paddy combinations. While decreases in production have little effect on the NPVs of paddy, peanuts and maize, these annual crops can only be cultivated for a maximum of six years within the nyamplung's 35-year cycle, due to canopy closure after this time. Nyamplung-based agroforestry systems can provide economic, social and environmental gains on different scales. However, when considering the high profit potential of nyamplung combined with honey production, further research is needed to improve and develop bee husbandry practices so this becomes a viable option for local farmers.

Study on the performance of forest tending subsidies in China

Yukun Cao¹, Hongge Zhu¹, Xiangyue Liu¹, Tianbo Wu¹, Weiwei Jia¹, Dan Zhou¹

¹Northeast Forestry University, Harbin, China (cyklk@163.com; honggebill@163.com; 1335759586@qq.com; 136433355@qq.com; jiaaw2002@163.com; 1328262702@qq.com)

In order to protect natural forest resources, the Chinese Government has spent a lot of money on forest tending subsidies for the state-owned forests in Heilongjiang Province. In methodology, data collected by the sampling techniques from forest tending subsidy areas, and site inspections carried out at the various forest nurseries located at key state-owned forest region in the Heilongjiang province. Considering the aspects of ecology, economy and society, we used the methods of qualitative and quantitative analysis, which has calculated and compared the effects between the increment of ecological value and the amount of investments, and put forward relevant policies and suggestions. Conclusions: (1) From the ecological, social and economic perspectives, the paper analyzed the positive impact on the implementation of forest tending subsidy policy on the key state-owned forest regions in Heilongjiang province; (2) The degree of forest-laborers' participation in forest tending needs to be improved, but they are satisfied with the policy of forest tending subsidies; (3) The values of carbon fixation and oxygen release have increased, and the economic value of biodiversity assessed as 66.158 billion yuan, that is 152 times higher than investment of the same period.

Diameter distribution of indigenous trees as possible criterion for indicating stable adapted species in semi-arid rangelands

Edward Mengich¹, Joseph Macharia², Ralph Mitloehner³, Daniel Too⁴, Gabriel Muturi⁵

¹Kenya Forestry Research Institute, Rift Valley Eco-region Research Programme, Londiani, Kenya; ²Department of Botany, Egerton University, Njoro, Kenya;

³Institute of Silviculture, Georg-August University, Goettingen, Germany; ⁴Department of Natural Resources, Egerton University, Njoro, Kenya; ⁵Kenya

Forestry Research Institute Headquarters, Nairobi, Kenya (emengich3@hotmail.com; jmmacharia@egerto.ac.ke; rmitloe@gwdg.de; dktoo@egerton.ac.ke; gabrielmukuria2012@gmail.com)

Declining woody vegetation and climate change are major drawbacks to livelihoods in semi-arid rangelands. Efforts to reverse their impacts through tree planting have been slow due to poor selection criteria for adapted species. This study assessed diameter distributions of indigenous trees as possible criteria for indicating adapted species in these areas. Study sites were identified at Nthangu, Kathonzweni and Kibwezi forests of Makueni County, Kenya using existing vegetation, agro-climatic maps and Landsat Images. The sites have mean annual rainfalls of 974 mm, 700 mm and 616 mm, respectively, and moisture indices of 49%, 35% and 32%. Data were collected by establishing 2500 m² sample plots and assessing tree diameters at breast height (DBH) and DBH distributions. Shapiro-Wilk test was applied on species that occurred in two of the sites to determine normality of their DBH distributions. T-tests were conducted to determine if mean DBHs differed significantly. Statistically significant differences were declared at p<0.05. Mean DBH was higher at both Kibwezi (7.6 cm) and Kathonzweni (6.4 cm) than at Nthangu (4.6 cm). Most ecologically important trees were characterized by high populations of juvenile individuals and near-perfect inverted J-shaped distributions. This indicated regenerating, sustainable and stable populations that were adapted to respective sites. Indigenous trees adapted to Nthangu were *Searsia* spp., *A. hockii* and *Diospyros mespiliformis*. At Kathonzweni, they were *C. collinum*, *C. apiculatum* and *A. tortilis*. At Kibwezi, they were *A. tortilis*, *A. mellifera* and *C. africana*. These were candidates for enrichment planting to rapidly rehabilitate degraded sections of these sites.

D1f: AGROFORESTRY FOR ECOSYSTEM SERVICES

Assessment of indicators of ecosystem services across a gradient of land uses in Southern Brazil

Lucilia Maria Parron¹, Junior Ruiz Garcia², Nerilde Favaretto², Claudia Maria Branco de Freitas Maia¹, George Gardner Brown¹, Denise Jeton Cardoso¹, Vanderley Porfirio-da-Silva¹

¹Embrapa Florestas, Colombo, Brazil; ²Universidade Federal do Paraná, Curitiba, Brazil (lucilia.parron@embrapa.br; jrgarcia1989@gmail.com; nfavaretto@gmail.com; claudia.maia@embrapa.br; george.brown@embrapa.br; denise.cardoso@embrapa.br; vanderley.porfirio@embrapa.br)

Ecosystem services (ES) are the benefits people obtain from ecosystems. The conversion of forests to production systems can have large effects on ES delivery. The aim was to assess how agricultural systems can be managed to maximize the supporting, regulating and provision of ES across of land uses and soil management in *Campos Gerais*, Southern Brazil. We used a set of indicators to assess the strength of ES delivery: soil organic carbon (SOC) and nitrogen (SON) stocks, nitrous oxide emissions and methane oxidation, aboveground carbon stocks, nitrate, ammonium and phosphorus leaching, water infiltration and drainage, diversity of soil fauna, grain, pastures and timber yields. We compared ES from the Native Forest (NF), Eucalyptus Plantation (EP) and systems which employed no-tillage soil management: No-Tillage (NT), Crop-Livestock only (CL) and Agroforestry Crop-Livestock-Tree (CLT). Among the land uses, NF presented greater complexity and the delivery of ES. EP was the second at SOC stocks, water infiltration and soil fauna richness. CLT and CL provided more ES than NT. Shadow of the trees in CLT promotes the well-being to the livestock, however it difficults the recovery of the damages caused by grazing and trampling.

Trees in CLT reduce soil erosion, increase soil quality and C sequestration. Agricultural residues provide biomass for land recovery in NT, CL and CLT, but they do not improve the stability of aggregates and the retention of water into soil. CLT as part of multifunctional landscape can be a viable agroforestry land use option that, in addition to providing food security, it offers a number of ES.

Changes in ecosystem carbon stocks from the conversion of disturbed forest to oil palm plantation in the Peruvian Amazon

Natalia Málaga Durán^{1,2}, Hergoualc'h Kristell¹

¹CIFOR, Lima, Peru; ²TU Dresden, Dresden, Germany (natalia.malaga.duran@gmail.com; k.hergoualc'h@cgiar.org)

Land use, land use change and forestry in Peru is the main contributing sector to national GHG emissions (51%). While Peru has pledged to reduce GHG emissions, oil palm plantations are currently under expansion in the Amazon at the risk of forest conversion. The study aimed to characterize the structure and composition of remnant disturbed forests adjacent to oil palm plantations in the Peruvian Amazon, to determine the carbon stock change from such transition. The research was based on full inventories performed in four disturbed forest and six oil palm stands. The latter ones using a space-for-time substitution approach (stand ages 1,4,7,15,23, 28) to assess the carbon stock change over a rotation period. All carbon pools were measured and compared over the land use transition. Previous forest practices linked to logging activities showed a negative effect in composition and structural parameters of the forest, e.g. the mean basal area was 22 (SE 1.4) m² ha⁻¹. Overall, converting disturbed forests to oil palm plantations resulted in a carbon debt scenario; the carbon stock changed from 140.7 (SE 5.8) Mg C ha⁻¹ in forests to a time-averaged carbon stock of 74.3 (SE 2.2) Mg C ha⁻¹ in oil palm plantations. Above ground carbon was the main contributing pool; followed by soil organic carbon and necromass. This research contributes to the sustainable management of forest landscapes under a climate smart strategy, as it concludes, in terms of carbon footprint, that disturbed forests should be excluded from the conversion to oil palm production.

Collective construction of multifunctional landscapes / Construção coletiva de paisagens multifuncionais

Na escala da paisagem, a agrobiodiversidade é responsável por inúmeros serviços ecossistêmicos como a qualidade da água, a polinização e o controle de pragas. A intensificação ecológica consiste em manter a produção agrícola, conservando a agrobiodiversidade, usufruindo dos serviços ecossistêmicos. O processo de condução da investigação está amparado em métodos participativos de pesquisa, iniciados há 10 anos na Bacia Hidrográfica do rio Guapi-Macacu (Rio de Janeiro), junto ao assentamento São José da Boa Morte. Os resultados representam um importante conhecimento sobre espécies arbóreas e práticas de manejo adaptativo, voltados a: 1. Projetar e testar sistemas agrícolas resilientes baseados na biodiversidade local; 2. Aumentar a segurança alimentar, resgatando cardápios tradicionais baseados em recursos locais; 3. Estudar os serviços ambientais de intensificação ecológica avaliando o papel do elemento arbóreo para a presença de agentes de controle biológico e polinizadores (abelhas, vespas e aves). Os resultados deste trabalho representam uma importante contribuição no processo de adequação dos sistemas produtivos as mudanças climáticas e conservação da biodiversidade, principalmente no sentido de tornar a biodiversidade um recurso concreto do ponto de vista da unidade produtiva e para a soberania alimentar das famílias agricultoras, além de permitir aos produtores maior autonomia na seleção de tecnologias que melhor atendam às necessidades locais, a fim de colaborar com o processo de recuperação da resiliência de paisagens degradadas.

Ungulates affect ecosystem functioning and mediate biodiversity and ecosystem services in Mediterranean oak woodlands

Miguel Nuno Bugalho¹, Xavier Lecomte², Maria Conceição Caldeira²

¹Centre for Applied Ecology, School of Agriculture, University of Lisbon, Lisbon, Portugal; ²Forest Research Centre, School of Agriculture, University of Lisbon, Lisbon, Portugal (migbugalho@isa.ulisboa.pt; xlecomte@isa.ulisboa.pt; mcaldeira@isa.ulisboa.pt)

Ungulate herbivores are rapidly expanding across their geographical areas of distribution. By consuming vegetation, ungulate herbivores reduce plant biomass, change plant species composition and may negatively affect regeneration of tree species. Through effects on vegetation, therefore, ungulate herbivores affect ecosystem functioning and mediate trade-offs between biodiversity and ecosystem services. Here, we describe a long-term (over 14 years) browsing and grazing exclusion experiment to assess how a wild ungulate (red deer *Cervus elaphus* and fallow deer *Dama dama*) population affected trade-offs among plant diversity, ecosystem functioning and ecosystem services of a Mediterranean oak woodland of Southern Portugal. Deer halted shrub encroachment into the ecosystem and, through reduction of the competitive shrub cover, increased the diversity of the grassland understory. Through changes in plant species composition deer also led to increased soil moisture and temperature which accelerated rates of litter decomposition and nutrient cycling. Additionally, by reducing shrub cover, deer decreased the aboveground vegetation carbon stocks but also the probability of severe wildfires. This may ultimately enhance adult oak survival and indirectly benefit long-term ecosystem carbon storage. Biodiversity and ecosystem services trade-offs need to be considered when considering ecosystem management, including decisions related with ungulate ecology and management.

Forest gardens increase the resilience of farming enterprises

Kamal Melvani^{1,2}

¹Neo Synthesis Research Centre, Polgasowita, Sri Lanka; ²Charles Darwin University, Darwin, Australia (neosynth@sltnet.lk)

Traditional farming enterprises challenged by increased climate variability stay resilient because they are tree-dominated, and farmers have acquired skills in adaptive land management from ancestors or local experience. Although farming enterprises are well studied, land management practices and landscape patterns underlying their adaptive capacity are less explored. Using mixed methods, this study investigated 85 farming enterprises across nine locations of Sri Lanka's Intermediate zone to understand which land use contributes to their adaptive capacity and best fulfills household needs. Farming enterprises incorporate On- and Off-farm components. On-farm comprises land uses including forest gardens (FGs), paddy, cash crops, swidden plots, plantations and livestock. Off-farm mainly involves employment. Locations were investigated by their socioeconomic determinants, water availability and rainfall variability, and land uses characterised and compared by area, age, tenure, agrobiodiversity and utility benefits. Results revealed that most farmers were female and had primary

education. Off-farm engagement was minimal. Farming enterprises were predominantly rainfed and farmers' perceptions of rainfall variability substantiated by meteorological data. Interannual and seasonal rainfall variability prevailed in the reference and preceding years. Forest gardens were the oldest land use, had the greatest area, highest plant and crop species richness, crop diversity, numbers of primary and secondary crops, and products. They provided several benefits to households and their tree-dominance ensured strong adaptive capacity. However, farmers adopted multiple land uses with diverse landscape designs because this offered greater opportunities, buffered risk and fostered resilient farming enterprises. Policy-makers must engage farmers when planning for resilient farming enterprises in a changing climate.

Horizontal distribution of the soybean yield in integrated crop-livestock-forest system in the north of Mato Grosso, Brazil

Maurel Behling¹, Géssica de Carvalho², Andre Luiz de Souza², Diego Camargo³, Jonas Fallgatter³

¹Embrapa Agrossilvipastoril, Sinop, Brasil; ²Mestrado em Agronomia, PPGA, Universidade Federal do Mato Grosso/Sinop-MT, Sinop, Brasil; ³Universidade Federal de Mato Grosso, Sinop, Brasil (maurel.behling@embrapa.br; gessikaengflorestal@gmail.com; andre_itauba@hotmail.com; camargo.die@gmail.com; j.fallgatter@hotmail.com)

The integrated crop-livestock-forest system can enhance the overall production, especially of soybeans, and economics of farming in regions characterized by warm climate. The aim of this study was to evaluate whether strip of trees in the integrated crop-livestock-forest systems (ICLF) change the horizontal distribution of the soybean yield and reduces the production by area four years after the establishment of eucalyptus, in the north region of Mato Grosso State, Brazil. The experiment was conducted at Sinop/MT, evaluating the following treatments: 1) crop with soybean during the main season and maize intercropped with *Brachiaria brizantha* during the second season and 2) Crop-livestock-forest system with triple rows (3.5 m x 3.0 m) of eucalyptus, spacing of 30 m and east-west orientation, annually cultivated with soybean crop (main season) and maize intercropped with *B. brizantha* (second season). The experimental design was in randomized blocks with four replicates. In the production systems with trees, evaluations were carried out in four equidistant transects, at 3, 6, 10 and 15 m from the rows on the northern and southern sides. Significant differences were verified in the agronomic characteristics of soybean, difference in productivity was verified comparing the exclusive and integrated systems. The tree component affect the soybean yield by area in the fourth year of the system implementation. The interference of eucalyptus reduced the soybean grain yield by 20.0% and the effect was stronger close to the tree rows.

DIG: CLOSE-TO-NATURE SILVICULTURE: FOR PEOPLE, PRODUCTS AND NATURAL PROCESSES

Legacies of previous disturbances structure contemporary forests

John Stanturf¹, Kalev Jogiste¹, Lee Frelich², Marek Metslaid¹, Ahto Kangur¹, Palle Madsen³

¹Estonian University of Life Sciences, Tartu, Estonia; ²University of Minnesota, St. Paul, USA; ³InNovaSilva, Vejle, Denmark (drdirt48@gmail.com; kalev.jogiste@emu.ee; freli001@umn.edu; marek.metslaid@emu.ee; ahto.kangur@emu.ee; pallemadsen47@gmail.com)

Alternative forest management approaches seek to emulate natural disturbance regimes and produce more diverse forest structure and composition with lesser emphasis on traditional timber objectives. These alternative management paradigms, including continuous cover forestry, biodiversity restoration, and close-to-nature forestry, all emphasize "natural" conditions, including natural disturbance regimes. Although they may differ in their approach to managing complexity and defining what is "natural", they all recognize that ecosystems are dynamic and that persistent effects of previous disturbances play a significant role in structuring ecosystems. Ecosystem legacies, remnants of previous conditions persisting after disturbances, collectively comprise ecosystem memory. Ecosystem memory in turn contributes to resilience and possibilities of ecosystem reorganization following further disturbance. Overlapping legacy concepts (disturbance, biological, soil, land-use, and silvicultural) are subsumed in the new terms "material legacy" (individuals or matter, e.g., survivors, coarse woody debris, nutrients left after disturbance) and "information legacy" (adaptations to historical disturbance regimes). The resulting six legacy types (above- and belowground, biotic and abiotic material legacies and above- and belowground information legacies) are influenced by differential patterns of editing and conditioning by "legacy syndromes" that result from natural or human-manipulated disturbance regimes. These legacy syndromes in turn influence forest response to management actions and constrain resilience, leading to a mosaic of natural, manipulated, and artificial (novel) ecosystems across the landscape. The condition of forest ecosystems depends on the temporal and spatial pattern of natural and anthropogenic disturbances and the legacies that are produced and persist.

Close to nature forest management for multiple purposes: an option for China

Shuirong Wu¹, Heinrich Spiecker²

¹Chinese Academy of Forestry, Beijing, China; ²University of Freiburg, Freiburg, Germany (shuirongwu@126.com; instww@iww.uni-freiburg.de)

The ecological, economic and social benefits of forestry are of high importance worldwide. After a heavy decline in forest area up to the 1950s, the Chinese government has implemented ambitious afforestation plans, initially mainly to counteract environmental consequences of deforestation like floods and landslides. During the last four decades, China's forest area increased from 12% to 22%. In response to climate change, China planned to increase another 40 million ha by 2020 and 4.5 billion m³ more by 2030 from the 2005 level. However, many of the Chinese forests are of low vitality and low productivity. On the other hand, China's fast growing economy requires additional resources especially renewable resources such as wood. Furthermore, forest environmental services are gaining more and more importance. The huge demand on timber and the increase in protected forest area at the same time result in a severe shortage of wood. Highly productive and healthy forests are needed which provide not only wood and non-wood forest products but also urgently needed ecosystem services. A strategic transition in China's forest management is needed, with a shifting emphasis from area expansion to stand productivity and quality enhancement, from overwhelming timber production to multipurpose management for various forest goods and services, and from monoculture plantations to biodiversity rich mixed forests. Based on an overall view of the challenges of China's forests and the alternative management options, this paper presents case studies and suggestions on close to nature forest management for China.

Introducing complexity through silviculture: transforming plantations one step at a time

Robert Schneider¹, Luc Sirois, Laurie Dupont-Leduc¹, Emmanuel Duchateau¹, Tony Franceschini¹

¹Université du Québec à Rimouski, Rimouski, Canada (robert_schneider@uqar.ca; luc_sirois@uqar.ca; laurie.dupont-leduc@uqar.ca; emmanuel.duchateau.1@ulaval.ca; tony.franceschini@uqar.ca)

The province of Quebec, in Eastern Canada, has implemented ecosystem-based forest management practices that obliges managers to emulate natural stands in managed forests. These guidelines must also be applied to intensively managed plantations. New silvicultural practices such as thinning by elite tree release have been proposed to achieve both wood production and ecological services goals. Early results from silvicultural trials have shown that differences in wood production between elite tree, thinning from below and control plots are very small at the stand level. Trees released by elite tree thinning have however higher increment rates as the competition is less important. Even though there are differential tree growth rates, combined with different harvesting patterns, the changes in stand structure remain very small. Using simulation results, thinning patterns alone do not greatly influence stand structure. The use of gaps must also be considered in order to significantly change the spatial structure of the stands. Gaps, however, come at a cost, whereby stand production is decreased proportionally to the size of the gaps. Prior to deciding which path to follow, more information is needed on the stand structure of old, unmanaged stands. An ongoing study of old, unmanaged stands will enable managers to set their ecological goals. Simulation tools can then be used for a first estimate of stand productivity trajectories.

A retention forestry experiment in a planted conifer forest in Hokkaido, Japan: initial responses of understory plants to harvesting

Nobuhiro Akashi¹, Yasuyuki Ohno¹, Noritoshi Nitta¹

¹Hokkaido Research Organization, Forestry Research Institute, Hokkaido, Japan (akashi-nobuhiro@hro.or.jp; ohno-yasuyuki@hro.or.jp; nitta-noritoshi@hro.or.jp)

The montane region of Hokkaido, northern Japan, was once dominated by mixed deciduous broadleaf and evergreen conifer forests. Timber has been harvested selectively since the 19th century, although natural regeneration was often difficult because dwarf bamboo (*Sasa* spp.) prevented seedling establishment. During the late 20th century, *Abies sachalinensis*, a native conifer species, and *Larix kaempferi*, an introduced conifer species, were planted after massive clear-cutting. Most timber is now produced from planted forests. Recently, maintaining biodiversity has become a requirement in planted forests. In this context, the Retention Experiment for Plantation Forestry in Sorachi, Hokkaido (REFRESH) was launched in 2013, with an *A. sachalinensis* forest plantation. We surveyed understory plants at REFRESH before and after harvesting to evaluate the effectiveness of retention forestry. In dispersed retention sites, naturally regenerated broadleaf trees were retained. Each aggregated retention site included a 0.36-ha intact patch. The understories of broadleaf stands were commonly covered with *Sasa* spp., and species richness was low. In contrast, closed conifer canopies eliminated *Sasa* and provided varying habitats for understory plants, depending on disturbance by forestry operations. After harvesting, both clear-cut and dispersed retention sites were dominated by disturbance-dependent herbaceous species. Species composition was not altered within retention patches at aggregated retention sites; however, most of the trees retained in one of three retention patches had become windfall within a few years of harvesting. Therefore, planted *A. sachalinensis* forests with retained broadleaf trees may provide various habitats for native plant species, although intact patches are necessary to maintain understory plants

Rodent-mediated seed dispersal of *Juglans mandshurica* regulated by gap size and position in larch plantations: implication for converting pure larch plantations into mixed larch-broadleaf forests

Qiaoling Yan¹, Jing Wang¹, Jiaojun Zhu¹, Jinxin Zhang¹

¹CAS Key Laboratory of Forest Ecology and Management, Qingyuan Forest CERN, Institute of Applied Ecology, Chinese Academy of Sciences, Shenyang, China (qlyan@iae.ac.cn; yanqiaoling1978@126.com; jiaojunzhu@iae.ac.cn; zhangjinxin@iae.ac.cn)

Larch (*Larix* spp.) is extensively planted after clear-cut of secondary forests in Northeast China to satisfy enormous timber demands. However, some serious problems in larch plantations (LPs) (e.g., soil fertility decline, acidification of surface runoff) become prominent due to mono-species composition. Converting pure LPs into mixed larch-walnut forests would solve these issues. Rodent-mediated seed dispersal of walnut (*Juglans mandshurica*) determines the regeneration success (or not) and is closely related with stand structure. Forest gap is an uneven thinning by changing stand structure in plantation management, and rodent-mediated seed dispersal of photophilous walnut may be changed with two key characteristics of gaps (i.e., gap size and within-gap position). The field trial was carried by releasing tagged seeds of walnut in artificial gaps of LPs with two sizes and at four positions of gap edges during two continuous years. Our results showed that gap size significantly affected the seed removal rates, i.e., the rate in medium gaps (2.05 grains/day) was faster than in small gaps (1.81 grains/day). The interannual variation of seed production changed the rodents behavior and seed dispersal process, and caused faster removal rate (2.86 grains/day) with numerous dispersal quantity (43.27%) and shorter dispersal distance (7.84 m) in the non-mast year (2015). Besides, 7.00% of *J. mandshurica* seeds was cached in the canopy gaps by rodents. It can be concluded that creating gaps with bigger size in LPs is a feasible practice of converting LPs into mixed larch-broadleaf forests by promoting the rodent-mediated seed dispersal of walnut.

The need for new approaches to managing native forests in central-Southern Chile: a proposal from forest degradation / Necesidad de nuevos enfoques para el manejo de bosques nativos del centro-sur de Chile: una propuesta a partir de la degradación forestal

Bastienne Schlegel¹, Christian Little¹, Gerardo Vergara¹, Carlos Bahamondez¹

¹Instituto Forestal (INFOR), Valdivia, Chile (bschlegel@infor.cl; clittle@infor.cl; gvergara@infor.cl; cbahamon@infor.cl)

Los bosques templados del centro sur de Chile han sido clasificados como de importancia mundial dado su estado de conservación y endemismo; y valorados positivamente por rol en la regulación de funciones ecológicas y oferta de bienes y servicios. Sin embargo, la historia de uso de estos bosques, asociada a procesos de deforestación y degradación, han cambiado el paradigma respecto a su destino, observándose estrategias divergentes -públicas y privadas- para su conservación y manejo en el mediano y largo plazo. La presencia de bosques en sitios de buena calidad, como aquellos dominados por especies del género *Nothofagus*, permite proyectar algunas estrategias de manejo como sistemas productivos multifuncionales que cumplen un importante rol social, como por ejemplo la producción de madera. Sin embargo, cabe preguntarse si los actuales métodos de corta y regeneración permitidos por el Estado para obtener productos del bosque, son los más adecuados para cumplir con este objetivo y asegurar la sostenibilidad de las intervenciones. A través de un enfoque metodológico basado en una definición clara del concepto degradación forestal y una evaluación de los resultados de planes de manejo forestal, discutiremos si los actuales tratamientos silviculturales aplicados en bosques nativos son los más efectivos para asegurar el proceso de regeneración. Concluiremos respecto a la necesidad de modificar las alternativas de manejo silvícolas basadas en el entendimiento de la dinámica forestal, el control de las amenazas que afectan la composición y estructura de los bosques, y las múltiples funciones que éstos proveen para el bienestar social.

Biodiversity benefits with uneven-aged silviculture

Joakim Hjältén¹, Klara Joelsson¹, Therese Löfroth¹, Jean-Michel Roberge¹, Timothy Work², Heloise Gibb³

¹Department of Wildlife, Fish and Environmental Studies, Swedish University of Agricultural Sciences, Umeå, Sweden; ²Département des sciences biologiques, Université du Québec à Montréal, Québec, Canada; ³Department of Zoology, La Trobe University, Melbourne, Australia (joakim.hjalten@slu.se; klara.joelsson@sodra.com; therese.lofroth@slu.se; jean-michel.roberge@skogsstyrelsen.se; work.timothy@uqam.ca; h.gibb@latrobe.edu.au)

Large scale use of even-aged silviculture (clear-cutting) commencing in the mid-20th century has had negative impacts on forest biodiversity. As a consequence, uneven-aged silviculture, involving selective removal of some older trees in a stand which mimics natural small scale stand dynamics and thus potentially benefit species associated with old forests, is currently being considered to help meet the ecological and social criteria required for sustainable forest management. We used a large-scale chronosequence study spanning 50 years to study beetle diversity in uneven-aged silviculture compared with both short-term impacts and the longer-term legacy of even-aged silviculture. We compared: (1) even-aged recently clear-felled stand, (2) even-aged recently thinned stand, (3) uneven-aged stands subjected to selective felling with (4) uneven-aged reference stands to assess how abundance, species richness and composition of beetles were affected by even-aged and uneven-aged management. Both even-aged silviculture treatments (clear-felling and thinning) had different beetle composition compared to the reference stands, indicating that assemblages had yet to recover even 50 years into the rotation. However, beetle composition did not differ between uneven-aged managed and thinned stands. The result supports our prediction that uneven-aged silviculture better maintains beetles assemblages associated with semi-natural mature forest than even-aged silviculture. The greater temporal continuity in selectively felled stands could benefit species dependent of mature or old growth forest since some of the needed habitat qualities are continuously available. Uneven-aged silviculture could therefore serve as an important tool for landscape planning to benefit biodiversity and thus help fulfil environmental commitments.

Microsite availability and planted black spruce growth responses to disturbance by mechanical site preparation in Canadian paludified forests

Mohammed Henneb^{1,2}, Osvaldo Valeria^{1,2}, Nelson Thiffault³, Nicole Fenton^{1,2}, Yves Bergeron^{1,2}

¹Université du Québec en Abitibi-Témiscamingue, Rouyn-Noranda, Canada; ²Institut de Recherche sur les Forêts (IRF), Rouyn-Noranda, Canada; ³The Canadian Forest Service (CFS), Québec, Canada (mohammed.henneb@uqat.ca; osvaldo.valeria@uqat.ca; nelson.thiffault@canada.ca; nicole.fenton@uqat.ca; yves.bergeron@uqat.ca)

Eastern Canadian boreal ecosystems dominated by black spruce (*Picea mariana* (Mill.) B.S.P.) have a high potential for fibre production. Some sites are, however, characterized by a low productivity due to paludification; a natural process by which organic layer thickness (OLT) increases on clay soils over time. Paludification leads to a decline in growth and regeneration due to the poor quality of microsites, which offer low nutrient availability and low temperatures. Little information is available on the potential of silviculture to restore productivity of paludified sites. In this context, our objectives were to 1) evaluate the effects of disturbances generated by three silvicultural treatments (partial harvest, disk trenching scarification and plowing) on the availability of microsites and their impacts on planted black spruce seedlings growth; and 2) determine treatment effects on *Sphagnum* and ericaceous shrub recovery and growth. Our results show that microsites availability and short-term seedlings growth were influenced by post-harvest OLT and silvicultural treatments. Plowing was most effective in low-moderate paludified areas (post-harvest OLT ≤ 45 cm), whereas scarification performed best in highly paludified areas (post-harvest OLT > 45 cm). Seedlings growth was also influenced by planting quality and microtopography. *Sphagnum* and ericaceous shrub recovery varied according to treatments. Our results will provide a better understanding of the conditions for successful regeneration establishment in paludified forests, hence supporting the restoration of site productivity.

D1p: DISTURBANCE, ECOSYSTEM MEMORY, RISK AND FOREST MANAGEMENT IN A CHANGING SOCIO-ECOLOGICAL ENVIRONMENT'

Lifecycle management techniques for large timber of *Larix principis-rupprechtii* Mayr plantations

Xianzhao Liu¹, Xuanrui Huang², Zhidong Zhang², Wenbin Han³, Ruidong Gao³

¹Institute of Forest Resource Information Techniques, Chinese Academy of Forestry, Beijing, China; ²College of Forestry, Agricultural University of Hebei, Baoding, China; ³Guancen mountain State-owned Forest Administration, Shanxi Province, Ningwu, China (lxz9179@163.com; hxr1962@163.com; 877703546@qq.com; 596080552@qq.com; 497386874@qq.com)

Larix principis-rupprechtii Mayr, a fast-growing planted tree, is one of the main tree species for timber supply in China. As a native species, *Larix principis-rupprechtii* Mayr has been widely planted in north of China due to its high quality timber (i.e., straight shape, and decay resistant wood). However, the high-quality large-size timbers of *Larix principis-rupprechtii* Mayr are still rare and demanded for industry development. Reviewing the theories of multi-function forestry and close-to-natural forestry, we proposed a technical system of lifecycle silviculture, including: (1) theory and principle of large timber management; (2) indexes system of management technology; (3) management planning and operation designing; (4) silvicultural systems; (5) standardization of operation measures. The proposed technique system generally formed from theory, index, technologies, processes, and measures to the demonstration case of integrated large timber management technology system, will be helpful for large size timber supply of *Larix principis-rupprechtii* Mayr.

Rare, endemic and endangered tree species in secondary forest fragment in the Atlantic Forest, Brazil

Jônio P. Caliman¹, Maria G. F. Reis¹, Geraldo G. Reis¹, Filipe V. P. Cacau¹, Thales G. V. Martins¹, Lydiane L. S. Bastos¹

¹Universidade Federal de Viçosa, Departamento de Engenharia Florestal, Viçosa, MG, Brasil (jpcaliman@gmail.com; mgfreis@ufv.br; greisufv@gmail.com; filipecacau@gmail.com; thales.eng.florestal@gmail.com; lbastos@ufv.br)

The Atlantic Forest, in Brazil, a world biodiversity hotspot, was highly degraded and, nowadays the remaining fragments are mostly of medium and small size. Many tree species from this biome are considered rare, endemic and, or at risk of extinction. A floristic study of natural regeneration (greater than 10 cm height and smaller than 5 cm diameter) and adult trees (greater than 5 cm diameter) was undertaken in ten sites in a secondary forest fragment. It was sampled 5,601 individuals of 51 families, 128 genus and 226 species. There were 26 rare species (with only one individual in the inventory) being one endemic (*Gutteria australis*) and one at risk of extinction (*Melanoxylon brauna*). Half of the rare species was sampled only as adult trees. Eight species are endemic of this biome, being four sampled at both natural regeneration and adult trees. From six species that are in the list of species at risk of extinction, three (*Dalbergia nigra*,

Euterpe edulis and *Ocotea odorifera*) were sampled in more than 50% of the sites studied in this fragment. Knowing the ecology of these species helps planning actions related to conservation of specific forest fragments and, or their inclusion in degraded land recovery projects (Supported by CNPq, FAPEMIG, CAPES and UFV).

Multivariate analysis use in the evaluation of mosaics of forest vegetation relating to soil attributes and edge effect

Maria Teresa Vilela Abdo¹, Sergio Valiengo Valeri², Antonio Sergio Ferraudo², João de Sousa Neto³, Maria Beatriz Bernardes Soares¹, Guilherme Xavier Lucio dos Santos³, Matheus Siqueira Oliveira⁴, Paulo Sergio Cordeiro Junior³, Bruna Aparecida Bettini⁵, Monica Helena Martins¹
¹APTA, Pindorama, Brasil; ²Universidade Estadual Paulista "Júlio de Mesquita Filho", Jaboticabal, Brasil; ³UNIRP, São José do Rio Preto, Brazil; ⁴UNIFEB, Barretos, Brazil; ⁵Universidade Federal de São Carlos, Araras, Brasil (mvilela@terra.com.br; sergio.valeri1@gmail.com; fsajago@gmail.com; neto_sousa14@hotmail.com; beatriz@apta.sp.gov.br; guilhermexaviersantos@hotmail.com; matheus_oliv@hotmail.com; paulo-gege@hotmail.com; bruna_bettini@hotmail.com; mo-martins@hotmail.com)

Atlantic forest biome in Brazil has high biodiversity that is threatened due to fragmentation and its remnants retain important residual flora that should be preserved. Studies of environmental conditions that influence species occurrence in those areas are very important to preserve them. This study characterized remnants vegetation in the Biological Reserve, Pindorama-SP, Brazil, classified as seasonal semideciduous forest sampled, using soil attributes and vegetation data. Soil attributes altitude, basal area, height and number of trees with diameter at breast height (DBH) = 5 cm and distance from remnant edge were evaluated. The hierarchical clustering, based on parameter evaluated separated groups of plots according to similarity. Soil attributes and distance from the edge influenced endemic trees and non-arboreal vegetation showing that preservation of native vegetation should consider these species relationships. Plots with higher clay percentage, higher fertility and closer to remnants edge had higher infestation of non-arboreal plants as bamboo, lianas and different grasses species and had lower species diversity, basal area and height of tree species. Multivariate analysis techniques can be very helpful to explain vegetation mosaics and species interactions in surveys for forest evaluations.

Post-fire regeneration of an Andean subparamo, in Colombia

Korina Ocampo-Zuleta¹, Angela Parrado-Rosselli²
¹Bogotá Botanical Garden, Bogotá, Colombia; ²Universidad Distrital Francisco José de Caldas, Bogotá, Colombia (korinaocampozuleta@gmail.com; aparrador@udistrital.edu.co)

The effect of fire in burned ecosystems depends on the dominance of characteristic traits that allow plants to recruit new individuals. Regenerative characteristics such as resprouting and wind-dispersal are considered fire-adaptive traits as they allow the rapid establishment of individuals to post-fire conditions. Recently, the Andean subparamo in Colombia has experienced severe forest fires, but little is known on its ability to recover or not after a fire. Therefore, we examined whether plant regeneration after a subparamo fire in 2016 was associated to fire tolerance traits such as resprouting, dispersal mode and fruit type. We sampled, every four months, from 1 to 3 years after the fire, all recruits found in 24 5x5m plots. New individuals were classified as resprouts or seedlings. Among seedlings we characterized the dispersal mode and the fruit type. Results showed that trees comprised 55% of the taxa. More tree (100%) than herb (92%) taxa resprouted. Although seed was not the main regeneration mechanism (72%), seedling abundance increased with time. The number of seedlings emerged from wind dispersed seeds was higher than other dispersal modes; however, seedlings emerged from zoochory seeds increased with time. Achenes and capsules, with woody and coriaceous pericarps, were the most important fruit types. We discuss that although the Andean subparamo is not a fire-prone ecosystem, it has fire-adaptive traits such as resprouting and wind dispersal, which should be considered in restoration programs. We also, highlight the importance of animal (mainly birds) dispersal for the arrival of new propagules after a fire.

Charcoal hearth soils: a tremendous environmental and cultural heritage.

Giovanni Mastrodonardo¹, Valentina Pescini², Elisa Carrari³, Giacomo Certini¹
¹Università di Firenze, Firenze, Italy; ²Università di Genova, Genova, Italy; ³CNR-IPSP, Sesto Fiorentino, Italy (giovanni.mastrodonardo@gmail.com; valpes87@gmail.com; elisa.carrari@ipsp.cnr.it; giacomo.certini@unifi.it)

Charcoal making is one of the oldest forms of forest exploitation. For this purpose, firewood domes were built in the forests in appositely shaped emplacements, then left to burn for days under controlled semi-anoxic conditions. Lots people were involved over time, directly or indirectly, in this activity, which has left a trace in the collective memory and has shaped a variety of landscapes. The legacy of such an activity is a plethora of abandoned charcoal hearths, where soil shows a thick, black, charcoal-rich top layer, which often overlies a complex sequence of pedogenic horizons that reveals successive land uses and/or climatic phases. Charcoal hearth sites can be considered as ecological micro-islands, being often characterized by a peculiar understory and by lack of tree regeneration. A multidisciplinary study of relict hearth soils may allow reconstructing past forests composition and exploitation, as well as the ecological and socio-cultural history of the region. Charcoal hearth soils are also impressive carbon reservoirs, particularly appreciable in terms of contrast to climate change, as much of the carbon present in them is charcoal, which is a form of carbon with extremely long residence times in soil. This contribution deals with some studies we carried out in Tuscany (Italy), which demonstrate the high potential of charcoal hearth soils for storing carbon and revealing the evolution of the landscape over time, including its anthropic component. Forest management should also be aimed at preserving charcoal hearth soils, with their important environmental and historical significance.

Predicting diameter at breast height from diameter at ground level in a mixed ombrophile forest: a tool for forestry expertise / Predição do diâmetro à altura do peito a partir do diâmetro à altura do toco em Floresta Ombrófila Mista: uma ferramenta para peritagem florestal

Mauricio Gorenstein¹, Veridiana Weber¹, Elisabete Vuaden¹, Álvaro Boson Castro Faria¹, José Agostinho Rosa Júnior¹
¹Universidade Tecnológica Federal do Paraná, Dois Vizinhos, Brasil (mauriciorg@utfpr.edu.br; veridianapadoin@utfpr.edu.br; elisabetev@utfpr.edu.br; alvarob@utfpr.edu.br; juniormetall.79@gmail.com)

A área basal e a distribuição diamétrica são importantes indicadores da estrutura florestal. Esses atributos têm forte relação com a idade, valor ecológico e econômico da floresta. Equações preditoras do diâmetro a altura do peito (dap) a partir do diâmetro a altura do toco (dat) são necessárias para o cálculo da área basal e consequente valoração florestal. Em trabalhos de peritagem florestal a determinação do estágio sucessional de povoamentos cortados somente é possível através da aplicação dessas equações. O ajuste da equação linear em dados de diferentes povoamentos de Floresta Ombrófila Mista mostrou que o uso do fator

de conversão de 0,8 é uma alternativa prática e genérica para a obtenção do dap a partir do dat para as florestas com maior presença de *Araucaria angustifolia* em sua composição. Nas florestas com maior quantidade de angiospermas o melhor ajuste foi com o modelo linear simples completo $\text{dap} = 3,7842 + 0,7661 \text{ dat}$.

Is the seed rain sufficient to passive restoration areas?

Camila Rocha Pergentino da Silva¹, Leonardo Augusto Martins¹, Rita Camila Nobre Sampaio¹, Vera Lex Engel¹

¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Faculdade de Ciências Agronômicas, Botucatu, Brasil (camilapergentino@hotmail.com; leonardomartins@gmail.co; ritacamilasampaio@gmail.com; vera.lex@unesp.br)

Passive restoration has been used as a strategy for the restoration of ecological corridors of native vegetation in forest plantations. Ecological filters restrict the dispersal, formation and maturation of a natural community and knowing them allows them to be manipulated to reassemble the desired native community. The objective was to test the hypothesis that the passive restoration of ecological corridors can be limited by the low arrival of propagules through the seed rain. The study consisted of three ecological corridors ranging from 1 to 2.6 km in length. In each one, 36 plots of 400m² were drawn, at distances varying from 24 to 790 m from the edge of the nearest fragment. In each plot were installed four circular collectors of 0.25 m², totaling 144. The collection was performed monthly, during 12 months. Most of the seed rain species were autochthonous (from trees already established in the corridors themselves). The abundance and richness of seed rain of the tree species decreased significantly with the increase of the distance of the fragment, showing the existence of a dispersion filter for these species in these corridors. Although the propagules arrive in significant quantities in the areas, the passive restoration does not occur properly, due to the large amount of grasses present in the corridors and the presence of the dispersion filter in the places near the fragments of the surroundings. The addition of aloctones propagules should increase the permeability of this filter, however, this would only work if there were control of the amount of grasses.

Forest degradation and effect on water resources in Aravali Mountains of Haryana, India

Subhash Chander¹, Jagdish Chander²

¹Haryana Forest Development Corporation, Gurugram, Indi; ²Haryana State Biodiversity Board, Panchkula, India (syadavhfs02@gmail.com; jagdish.chander@hotmail.com)

Aravalis are the oldest mountain chain in the world. The range of these mountains falls under arid and semi-arid regions of India in the states of Gujrat, Rajasthan, Haryana ending in national capital Delhi. The best forests of these mountains comprise of *Annogeissus pendula* and its associates. But now most of the forests have been invaded by *Procopis juliflora*. Fuelwood collection, grazing and invasion by *Procopis juliflora* are major causes of forest do. Lots of regular water streams and falls used to be there in Aravalis of Haryana State. But due to degradation of forests, the water in most of the streams have dried and others the discharge has come at a point of extinction of these water streams or falls. An analysis of these water resources of Haryana Aravalis will be presented.

DIQ: AGROFORESTRY FOR ECOSYSTEM SERVICES

Estimating carbon storage by tree in an integrated agriculture production system in a protected area in the Brazilian subtropic / Estimativa de sequestro de carbono por árvores em um sistema integrado de produção agropecuária em área de proteção ambiental no subtropical brasileiro

Silvano Kruchelski¹, Vanderley Porfirio-da-Silva², Thales Baggio Portugal¹, Gilmar Paulinho Triches³, Anibal de Moraes¹

¹Universidade Federal do Paraná, Curitiba, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Instituto Federal de Santa Catarina, Rio do Sul, Brasil (silvanokr65@gmail.com; vanderley.porfirio@embrapa.br; baggio.thales@gmail.com; gilmartriches@gmail.com; anibaldemoraes@gmail.com)

Florestas e árvores sequestram carbono e são componente chave em relação às mudanças climáticas, em termos de mitigação e resiliência. O setor de Agricultura, Silvicultura e Uso da Terra é responsável por quase 25% emissões antropogênicas de gases de efeito estufa, principalmente pelo desmatamento, manejo de gado, solo e nutrientes. Foi conduzido um experimento na Estação Experimental da Universidade Federal do Paraná (Pinhais, PR), com árvores de *Eucalyptus benthamii*, plantadas em 2013 no espaçamento de 14 X 2m (357 árvores/ha) integradas com pecuária (PF) e com lavoura-pecuária (LPF). As desramas foram feitas aos 21 e 33 meses; aos 44 meses fez-se o desbaste, diminuindo a densidade para 156 e 147 árvores/ha, respectivamente para PF e LPF. Aos 56 meses de idade as árvores apresentavam volume individual médio de 0,30 m³ para PF e 0,34 m³ para LPF, fixando 0,31 tCO₂ e 0,34 tCO₂, respectivamente. Com base no fator de emissão de metano entérico de 56 kg/animal/ano, parametrizado pelo IPCC para bovinos de corte, foi estimada a mitigação realizada pelas árvores, são necessárias pelo menos 4 árvores para mitigar a emissão de um bovino de 450 kg (UA). Cada hectare dos sistemas estudados pode mitigar a emissão de metano de pelo menos 36 UAs. No ciclo de 2017/18, os sistemas PF e LPF suportaram carga animal de 1,7 UA/ha e 1,4 UA/ha, com emissão estimada em 2,2 tCO₂/ha e 1,9 tCO₂/ha, contra o sequestro médio anual nas árvores de 7,9 tCO₂/ha e 8,6 tCO₂/ha, respectivamente.

Agroforestry-based application of microbial inoculant for sustainable upland forest farms in the Philippines

Nelson M. Pampolina¹, Julieta A Anarna², Mercedes U. Garcia¹

¹Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines Los Banos, Laguna, Philippines; ²BIOTECH, University of the Philippines Los Banos, Laguna, Philippines (nmpampolina@up.edu.ph; j_anarna@yahoo.com; mugarcia@up.edu.ph)

Ecological balance is necessary for productive agroforestry system where beneficial microbes can function in improving growth, biomass, harvest, and carbon sequestration. This paper demonstrated the importance of indigenous microbial inoculation through community-based approach in nursery and agroforest production to reduce usage of chemical fertilizer while enhancing growth and simultaneously improve livelihood potentials in uplands near mountainous ecosystem in Southern Luzon, Philippines. Local isolates of beneficial bacteria and endomycorrhizal fungi were obtained from rhizosphere of nine agroforest crops (*Mormodica charantia*, *Solanum melongena*, *Cucurbita maxima*, *Abelmoschus esculentus*, *Capsicum baccatum*, *Vigna unguiculate*, *Solanum lycopersicum*) that were traditionally raised as ingredient for nutritious native dish planted with *Theobroma cacao* and *Coffea arabica*. These high value crops are commercially known around the urbanized region where woody perennials were maintained as forest cover to favor soil, microclimate, and carbon sequestration. Microbial isolates were described, purified, mass-produced with *Centrosema pubescens* and *Leucaena leucoccephalla* as hosts, and tested in nursery and field growth performance following standard procedures. Effects of inoculant were significant ($p < 0.05$) in improving parameters (eg. height, diameter, biomass, yield) of selected crops. Combining inoculant with farmers practice increased crop production by about half and prolong generally lifespan

of crops. Use of inoculant can improve agroforest farmer's income by 30-40%, reduce chemical application by half of their consumption, ensure local food security, and encourage soil biodiversification. Further verification trials in other climatic, edaphic, and socio economic conditions across the region are important to appreciate values of soil inoculant for sustainable upland forest farming in the Philippines.

A systematic map of agroforestry research focusing on ecosystem services in the Asia-Pacific Region

Seongmin Shin¹, Khaing Thanda Soe², Haeun Lee¹, Tae Hoon Kim¹, Seongeun Lee¹, Mi Sun Park¹

¹Seoul National University, Pyeongchang, Republic of Korea; ²Seoul National University, Seoul, Republic of Korea (seongmin@snu.ac.kr; haingthandaso@gmail.com; haeunl630@snu.ac.kr; switch-thkim@snu.ac.kr; lse1229@snu.ac.kr; mpark@snu.ac.kr)

Agroforestry is an intensive land management system through integration of trees into crop and animal farming. Agroforestry provides diverse ecosystem services by bridging the gap among agriculture, forestry and husbandry. In particular, agroforestry is a significant approach for improving environmental, economic and social benefits in the Asia-Pacific region. This research aims to examine the research trend of agroforestry focusing on ecosystem services in the Asia-Pacific region. Systematic mapping methodology was applied to this research. Analysis units are academic articles related to agroforestry practices in the Asia-Pacific region. The articles published within almost 50 years (1970-2018) were collected through the international specialized academic database, SCOPUS. The selected articles include various types of agroforestry including silvorable/agrosilviculture, silvopasture, forest farming and so on. Three types of ecosystem services captured in agroforestry were coded and mapped; 1) provisioning services, 2) regulating and supporting services, and 3) cultural services. Consequently, the results indicate the research focuses of agroforestry and their changes in the Asia-Pacific region. In particular, the ecosystem service related result implies social, environmental and economic approach to agroforestry. Therefore, this study helps us understand dominant research on ecosystem services of agroforestry in the Asia-Pacific Region and supports design of future research of agroforestry by presenting the historical changes and the current status of agroforestry research.

Adaptation measures for minimizing the impacts of disturbances in protective forests: projects “RockTheAlps” and “GreenRisk4ALPs”

Jurij Beguš¹, Andrej Breznikar¹, Andreja Nève Repe¹, Aleš Poljanec¹

¹Slovenia Forest Service, Ljubljana, Slovenia (jurij.begus@zgs.si; andrej.breznikar@zgs.si; andreja.repe@zgs.si; ales.poljanec@zgs.si)

Ecosystem management of protection forests aims at maintaining forests near a state at which their protection function is secured. Due to climate changes, the uncertainty about forest management in mountainous areas has increased in the last decades. The magnitude, frequency and type of natural disturbances have changed resulting in more frequent and higher damages of forest stands. Additionally forests are threatened by the rapid spread of invasive alien species and other harmful organisms. In natural hazard management and disaster risk reduction, forests are increasingly considered equal to technical or civil engineering measures. Thus, the role of forests in protection against erosion, floods, snow and earth avalanches, torrents and falling rocks is considered irreplaceable in the light of changing environment. In the frame of two Alpine Space Programme projects, the RockTheAlps and GreenRisk4ALPs, current forest management practices were analysed and adoption measures to decrease risks in forest management were discussed. Quick sanitation measures in damaged forests including timely detection and removal of weakened trees are necessary to prevent the gradation of harmful organisms. In addition, adequate silviculture measures are relevant to increase stability and vitality of forest stands. Key measures include small-scale regeneration, regulation of tree species composition in line with changing site conditions, gradual and early regeneration of potentially threatened forests and prevention and limitation of the spread of invasive alien species. The results of both projects will be presented and future challenges in preventing forest damage due to extreme weather events will be further discussed.

The future of adoption of agro ecology farming system in Uganda: apportunities and challenges

Bosco Bua¹

¹Kyambogo University, Kampala, Uganda (bbua@kyu.ac.ug)

Agroecology is an approach whereby agriculture is practiced bearing in mind the role of the surrounding environment. Agroecology emerged as alternative farming system due to the realization of the devastating effects of the continuous and indiscriminate use of agrochemicals such as pesticides and fertilisers to enhance agricultural production. However, it soon became evident that some of the chemicals have long lasting residual and debilitating effects on the environment as well as toxicity to humans and animals. In Uganda, the adoption of agroecology is manifested in many ways including the use of agroforestry, the formulation and adoption of a policy on organic agriculture, the development and running of academic course/programmes at universities and other higher institution of learning. In the fact, though relatively new, a number of individuals have been trained at bachelors, masters and also PhDs. Additionally, a number of trainer of trainers have been trained in different aspects of agroecology. Therefore, at the national level the government is very supportive on the implementation of pro-agroecology related practices that are user- friendly and environmentally sensitive. However, the targeted beneficiary especially the farmers and other stakeholders are the major challenge. This paper therefore discusses the opportunities and challenges in adoption adopting agroecology as an alternative farming system in Uganda.

Integrated crop-livestock-forest systems for neutralizing greenhouse gases / Sistema integração lavoura-pecuária-floresta para neutralização de gases de Efeito Estufa (GEE)

Karina Pulrolnik¹, Kleberson de Souza¹, Roberto Guimarães-Júnior¹, Robélio Marchão¹, Lourival Vilela¹, Arminda Carvalho¹, Sebastião Moraes Neto¹

¹Embrapa Cerrados, Brasília, Brazil (karina.pulrolnik@embrapa.br; kleberson.souza@embrapa.br; roberto.guimaraes-junior@embrapa.br; robelio.marchão@embrapa.br; lourival.vilela@embrapa.br; arminda.carvalho@embrapa.br; sebastião.moraes@embrapa.br)

A integração lavoura-pecuária-floresta – ILPF, é um sistema de produção propício para alcançar produtividade satisfatória e mitigar os gases de efeito estufa da atividade pecuária, proporcionando ainda balanço positivo de carbono, conciliando produtividade e sustentabilidade. O objetivo deste trabalho é demonstrar o potencial do sistema ILPF como estratégia para a compensação das emissões de gases de Efeito Estufa (GEE). O estudo foi realizado no campo experimental da Embrapa Cerrados (Planaltina-DF) em um experimento com ILPF implantado no ano de 2009. Para as medições de balanço de carbono foram avaliados o tratamento sem árvores (sistema integração lavoura-pecuária – ILP) e o tratamento com fila dupla de árvores de eucalipto espaçadas 22 m entre os renques (ILPF), totalizando 417 árvores por hectare. No sistema ILPF implantado na Embrapa Cerrados, uma única árvore foi capaz de acumular, em média, 30,2 kg de C.ano-1 (considerando 45% de C da massa seca de biomassa aérea da planta). Isto equivale ao sequestro 110,5 kg de CO₂eq.ano-1 da atmosfera por cada árvore inserida no sistema. Dados ainda preliminares demonstram que uma população de 417 árvores/ha em 15% da área total de produção em um sistema de

ILPF seria suficiente para neutralizar todas as emissões de GEEs oriundas dos animais em recria (CH_4) e da pastagem (N_2O), deixando ainda um saldo positivo de carbono. Assim, pode-se afirmar que a introdução do componente florestal no sistema ILPF é uma opção viável para estocar o CO_2 atmosférico na forma de madeira.

Influence of shading on the growth of a native shrub species, *Cestrum intermedium* Sendtn (Solanaceae), and its implications for forest restoration projects / Influência do sombreamento sobre o crescimento de uma espécie arbustiva nativa, o *Cestrum intermedium* Sendtn (Solanaceae), e suas implicações em plantios de restauração florestal

Gabriela Sanches Dolenc¹, Susane Rasesa², Girlei Costa da Cunha³, Eduardo Gusson³, Frederico Miranda³, Flávio Bertin Gandara Mendes²

¹Klabin SA, Brazil; ² Escola Superior de Agricultura “Luiz de Queiroz”, Universidade de São Paulo, Piracicaba, Brazil; ³Biodendro, Piracicaba, Brazil (gabrielasdolenc@gmail.com; susane.rasesa@gmail.com; girlei.cunha@gmail.com; eduardogusson@gmail.com; fredtsmiranda@gmail.com; fgandara@usp.br)

O trabalho, que faz parte da temática de introdução de espécies não-arbóreas do projeto de P&D “Metodologia para a formação de microclima favorável ao estabelecimento de biodiversidade no entorno de reservatórios hidroelétricos” financiado pela AES Tiête, teve como objetivo estudar a adaptação às diferentes condições de luz de uma espécie arbustiva nativa, o *Cestrum intermedium* Sendtn (Solanaceae), a fim de avaliar sua plasticidade ecológica e sua implicação de cultivo com base em seu papel funcional na dinâmica de regeneração de florestas. O estudo consistiu em três experimentos – teste de germinação no Laboratório de Ecologia Vegetal Aplicada e Agroecologia, semeadura em tubete no viveiro do Departamento de Ciências Florestais e implantação em campo na Estação Experimental da Genética da ESALQ/USP. Os resultados obtidos apontam o potencial da espécie para enriquecimento de biodiversidade em projetos de restauração. Mesmo que seu desenvolvimento tenha sido lento em ambiente sombreado durante o período avaliado, sua taxa de sobrevivência foi satisfatória. Em ambiente a pleno sol, o resultado foi ainda mais interessante, indicando seu potencial para ser utilizada na fase inicial dos projetos de restauração. O arbusto, que teve rápida resposta fenológica em campo quando recebendo radiação solar direta, terá papel fundamental de atração de fauna nos primeiros anos do projeto, o que favorecerá a dispersão de sementes. Além disso, seu desenvolvimento em altura e diâmetro de copa poderá oferecer melhoria da condição microclimática do solo, facilitando o estabelecimento de regenerantes, controlando a mato competição e protegendo as mudas arbóreas de pequeno porte.

D1r: AGROFORESTRY FOR ECOSYSTEM SERVICES

Remediating degraded areas at the Pirapitinga Ecological Station / Recuperação de áreas degradadas na Estação Ecológica de Pirapitinga

Suzi Theodoro¹, Fernanda Medeiros², Marco Ianniruberto¹

¹Universidade de Brasília, Brasília, Brazil; ²Universidade Federal de Viçosa, Viçosa, Brazil (suzitheodoro@unb.br; fafeh2802@gmail.com; ianniruberto@unb.br)

A pesquisa foi desenvolvida na Estação Ecológica de Pirapitinga, localizada no reservatório de Três Marias/MG. O principal objetivo da pesquisa foi a recuperação de uma área degradada. Foram utilizados os princípios da rochagem e dos sistemas agroflorestais. O delineamento da área contou com sete tratamentos e três repetições, que resultaram em 21 blocos (Controle; Composto Orgânico; Sedimento; Remineralizador; Sedimento + Remineralizador; Sedimento + Composto Orgânico e Sedimento + Remineralizador + Composto Orgânico). Cada bloco teve uma área de 4m². A proporção de remineralizador e de sedimento utilizada foi de 5ton/ha e de composto orgânico de 10ton/ha. As sementes de hortaliças, leguminosas, agrícolas e florestais nativas do Cerrado (Cedro, Jatobá, Copaíba, Gonçalves Alves, Mutamba e Baru) tiveram a mesma distribuição espacial. Foram semeadas três sementes de cada espécie florestal. Após sete anos de pesquisa averiguou-se que todas as espécies se beneficiaram de diferentes maneiras dos insumos minerais/orgânicos e da forma de manejo. Ocorreu a redução da toxidez de Al³⁺ no solo que ampliou as possibilidades de desenvolvimento das plantas. A presença de matéria orgânica foi positiva para a produção das hortaliças e das espécies agrícolas, bem como para proteger o solo. A espécie florestal que apresentou a melhor taxa de germinação foi o Gonçalves Alves e a Mutamba foi a espécie com maior crescimento (12m). Os blocos com Sedimento+Rocha tiveram as maiores taxas de sobrevivência. Após sete anos, os resultados mostram que a remineralização do solo somado a cobertura vegetal são ferramentas que revertem os processos de erosão e degradação.

COPABASE: Cooperativism and agro-extractivism allied with sustainability and preservation of the Cerrado Biome / COPABASE: cooperativismo e agroextrativismo aliados a sustentabilidade e preservação do Bioma Cerrado

Flavio Macedo¹, Livia Amorim¹

¹Secretaria de Educação do DF, Brasília, Brasil (flavioxavierxe10@gmail.com; liviaamorimdosreis@gmail.com)

O presente artigo tem por objetivo analisar a exploração de frutos do Cerrado na região noroeste de Minas Gerais, utilizando como base os conceitos do cooperativismo e agroextrativismo. É fundamental para a preservação do Cerrado a aplicação de novos modelos econômicos e políticos que possam incorporar estratégias de uso do bioma a partir do conhecimento científico, de projetos de educação e sensibilização junto à população, da garantia de proteção formal eficaz de espécies e ecossistemas e do reconhecimento dos recursos naturais e serviços ambientais do bioma. As cooperativas vêm a cada dia aumentando sua área de atuação, evidenciando a importância de se olhar para os recursos disponíveis em cada local - recursos naturais, frutos do cerrado, práticas de cultivo, incentivando a preservação e ampliando o estímulo às novas gerações de buscar o mínimo impacto ao meio ambiente. A Copabase tem como finalidade fortalecer, beneficiar e comercializar com sustentabilidade produtos da agricultura familiar e do extrativismo de frutos do Cerrado no vale do Rio Uruçua. Fundada a partir da necessidade de organização de famílias de alguns municípios do noroeste de Minas Gerais para exploração dos frutos do Cerrado, a cooperativa se dedica à agricultura familiar e à Economia Solidária desenvolvendo também ações socioeducativas no âmbito do agroextrativismo, agroecologia e cooperativismo, educação de jovens e adultos, preservação ambiental, segurança alimentar e boas práticas de fabricação de alimentos. Devido a sua atuação, a Copabase é de extrema importância para o cooperativismo e preservação do Bioma Cerrado no noroeste de Minas Gerais.

Accumulated leaf litter in an integrated silvopasture system with eucalyptus clones in the Northwest region of Goiás, Brazil / Serapilheira acumulada em sistema silvopastoril com clones de eucalipto na região Noroeste do Estado de Goiás

Francine Neves Calil¹, Jorge Luis Sousa Ferreira¹

¹Universidade Federal de Goiás, Goiânia, Brazil (fncalil@gmail.com; jorgeluisferreira89@hotmail.com)

A produção de serapilheira e a devolução de nutrientes em ecossistemas florestais, e constituem a via mais importante do ciclo biogeoquímico de nutrientes (fluxo no sistema solo-planta-solo). O objetivo deste estudo foi analisar a serapilheira acumulada em três clones de eucalipto em sistema silvopastoril (SSP) no município de Nova Crixás – GO. Os três clones implantados são: AEC 2034 (*E. camaldulensis* x *E. grandis*) x *E. urophylla*, AEC 2111 (*E. camaldulensis* x *E.*

grandis) x *E. urophylla* e AEC 0043 (*C. citriodora* x *C. torelliana*). Foram plantados em arranjo formados por renques de quatro linhas, distanciadas de 3 m e de 2,5 m entre plantas na linha e entre renques de 34 m. No momento de coleta as árvores apresentavam 2,5 anos. Para a coleta de serapilheira foi utilizado um gabarito de 0,0625 m², onde foram coletadas 10 amostras aleatórias em cada área. O material foi levado ao laboratório, colocado para secagem e após obter peso constante, foi pesado. Foi feita uma extrapolação dos valores para kg ha⁻¹ e feita uma média para a produção de serapilheira produzida por cada clone. O clone AEC 0043 apresentou 9.425,76 kg ha⁻¹, que foi o clone com maior produtividade. Os clones AEC 2034 e AEC 2111 apresentaram, respectivamente, 8.446,40 kg ha⁻¹ e 4.576,48 kg ha⁻¹.

Management systems for Yerba Mate (*Ilex paraguariensis* St. Hilaire) in Comandante Andresito, Misiones: soil and tree community characteristics / Sistemas de manejo de Yerba Mate (*Ilex paraguariensis* St. Hilaire) en Comandante Andresito, Misiones: caracterización de suelo y comunidad arbórea

Rocio Bermudez Pose¹, Alejandra Gil², Ivan Crespo³

¹Fundación Agroecológica Iguazú, Comandante Andresito, Argentina; ²Facultad de Agronomía de la Universidad de Buenos Aires, Buenos Aires, Argentina;

³Universidade Federal do Paraná, Curitiba, Brasil (rocio@guayaki.com; agil@agro.uba.ar; ivancrespo@ufpr.br)

La yerba mate, especie nativa de la Selva Misionera, se encuentra adaptada a ambientes parcialmente sombreados. No obstante, en Misiones se implanta en áreas abiertas previamente desmontadas. Los antecedentes indican que su cultivo bajo manejo convencional, va perdiendo productividad a lo largo de su ciclo de vida asociado principalmente a la degradación del suelo. Esto se relaciona con características climáticas y topográficas regionales y un manejo agrícola inapropiado. Se caracterizaron los aspectos físicoquímicos del suelo y, a su vez, la composición arbórea del estrato medio y alto, en yerbales bajo un gradiente de diferentes manejos productivos: monocultivo, yerbal convencional regenerado, yerbal bajo monte y selva, en Comandante Andresito, Misiones. A través de un análisis multivariado de las variables físicoquímicas del suelo, se ha observado un contraste entre los manejos de selva y agroforestería con respecto al manejo convencional. La MO y el Ca presentaron una tendencia decreciente en el monocultivo vs selva y agroforestería a diferencia del P. La infiltración mostró la misma tendencia, presentando menor tasa en el sistema convencional, comparado a los otros manejos. La caracterización arbórea de los distintos sistemas, permitió identificar tres comunidades asociadas a cada uno de ellos, presentando el sitio agroforestal una mayor riqueza. Este trabajo nos permite aproximar que el cultivo de yerba mate en agroforestería posibilita una mayor diversidad arbórea y mayor conservación relativa (y reestablecimiento inclusive) de ciertos atributos físicoquímicos del suelo respecto al manejo convencional. Esta información ha de ser complementada en futuros estudios que incluyan otras variables del sistema.

Analysis of ecosystem services through non-timber forest products (NTFPs) provided by the Baban Rafi Forest in Niger

Moussa Massaoudou¹, Rabiou Habou², Tougiani Abasse³

¹National Institute for Agricultural Research, Maradi, Niger; ²Université de Diffa, Diffa, Niger; ³National Institute for Agricultural Research of Niger (INRAN), Niamey, Niger (moussaoudou13@gmail.com; rabiouhabougarba@yahoo.fr; abasse.tougiani@gmail.com)

In the Sahelian, forest and agroforestry ecosystems constitute the main source of income and food supplement for the populations, especially in the rural part where the socio-economic life is inseparable from the exploitation of products they offer. The Baban Rafi Forest is one of the forests where local communities reconciled exploitation with conservation through interventions of national planning policies and strategies. The objective of this study is to identify and analyze the indicators of use and pressure related to the exploitation of Non-Timber Forest Products of this forest. Ethnobotanical and forest inventory surveys were conducted in the peripheral villages of the forest. The analysis of the results made it possible to identify 70 ligneous species belonging to 55 genera and 28 families; used either in food, in fodder or in the traditional pharmacopoeia. The structural and regenerative analysis of six priority woody species for the populations, showed a regressive dynamic which would be due to a strong anthropic pressure, linked to the demographic growth in the zone. Domestication of these priority species would help conserve them and sustainably meet the needs of these local communities.

An integrated agroforestry system for small rural producers using clones of eucalyptus, angico, and aroeira intercropped with cowpeas in the region of Itaparica, Pernambuco, Brazil / Sistema agrossilvicultural para pequenos produtores rurais, com clones de eucaliptos, angico e aroeira consorciados com feijão-caupi, na região de Itaparica, Pernambuco, Brasil

José Antonio Aleixo da Silva¹, Rinaldo Luiz Caraciolo Ferreira¹, Francisco Tiberio Alencar Moreira¹, Marília Regina Costa Castro²

¹Universidade Federal Rural de Pernambuco, Departamento de Ciência Florestal, Recife, Brasil; ²Instituto Federal de Educação Ciência e Tecnologia, Recife, Brasil (jaaleixo@uol.com.br; rinaldo.ferreira@ufrpe.br; tiberioflorestal@gmail.com; mariliarcastro@uol.com.br)

O objetivo desta pesquisa foi avaliar o crescimento e retorno econômico de dois clones de eucaliptos e duas essências nativas: angico e aroeira, em um sistema agrossilvicultural com feijão-caupi, usando três fontes de nutrientes: resíduos de tanques de piscicultura e sedimento de lago e controle, em três espaçamentos, em um experimento no Instituto Agrônomo de Pernambuco na região de Itaparica, semiárido pernambucano. Foram instaladas 144 parcelas, nos espaçamentos 3mx2m e 4mx2m em monocultivo e 4mx2m em consórcio, distribuídas aleatoriamente com quatro repetições. O feijão-caupi foi semeado no espaçamento 0,80mx0,30m, plantando na área útil de cada parcela do sistema agrossilvicultural. O delineamento estatístico foi o multivariado de medidas repetidas. Para a análise econômica do sistema agroflorestal e dos monocultivos foram considerados os custos e as receitas com a produção do feijão-caupi ao longo do período de avaliação, três anos. As fontes de nutrientes, resíduos dos tanques de piscicultura e sedimentos do lago de Itaparica, contribuíram significativamente no crescimento em alturas das culturas florestais e do feijão-caupi, tornando-se alternativas para serem usados como biofertilizantes em plantios florestais e agrícolas na região de Itaparica. As maiores médias em altura do foram do clone MA-2001, no espaçamento 3mx2m. Os consórcios com as espécies nativas apresentaram os melhores resultados na produtividade do feijão-caupi que por sua vez obteve maior produtividade em relação ao sistema agrossilvicultural quando plantado em monocultivo. Na análise econômica das essências florestais, a venda de lenha e estacas proporcionou as maiores receitas, quando comparado com a venda de apenas lenha.

Tree diversity and use in agricultural and livestock landscapes in the Colombian Caribbean región

Milton Rivera Rojas¹, Sonia Camargo Roa², Jaime Andres Arias Rojas¹, Darwin Fabian Lombo¹, Jose Edwin Mojica¹

¹Agrosavia, Agustín Codazzi Cesar, Colombia; ²ICA, Santa Marta, Colombia (mrivera@agrosavia.co; soniacatalinacamargo@gmail.com; jarias@agrosavia.co; dlombo@agrosavia.co; jmojica@agrosavia.co)

Bs-T is one of the most intervened ecosystems due to the increase of extensive livestock and agriculture. Livestock is used to occupy the territory based on integration of invasive plants, mainly grasses. Because of the lack of documentation about the uses of the tree species in Colombia, farmers, guided by organizations, have been working on sustainable livestock, promoting the incorporation of native trees into the production systems. Due to the lack of information on the uses of the native trees in the Caribbean Region, a non-probabilistic sampling was used to obtain primary information, which was focused on three consultation groups. The “Expert” group, consisting of professionals, scientists, among others, who after being surveyed, referred to the second group called “knowledgeable”, consisting of technical assistants and some professionals. The last group, “producers”, was named after the “knowledgeable”, consisting of farmers. Moreover, tree species, their uses and used parts of the plant, were variables included in the above survey. The information was tabulated, getting the descriptive statistical analysis and recognizing diversity into the landscapes of the region; 294 tree species were reported which belong to 53 families. According to the species uses, 18 categories were reported; within construction (152), fence posts (132), firewood (110), among others. Furthermore, the main environmental values that were mentioned are; water protection (72), soil protection (85), thermal comfort on livestock (79) and fauna feeding (150). Finally, medicinal uses (143), cultural symbols (28), ornamental uses (71) and domestic uses (107) were the main uses mentioned in sociocultural perspectives.

Willows beyond wetlands: uses of *Salix* L. species for ecosystem services

Julia Kuzovkina¹

¹University of Connecticut, Storrs, USA (jkuzovkina@uconn.edu)

Species of *Salix* characterized by ecological resilience are predisposed for use in conservation and environmental projects in many climatic zones. The economic importance of *Salix* is increasing and emerging in a wide array of practical applications to restore ecosystems and to provide various ecosystem services. These uses include bioengineering, phytoremediation, and biomass production for fuel and lumber. Willow plantation systems offer promise for carbon sequestration, water quality improvement, soil enrichment, biodiversity conservation, and production of specialty products for crafts. Most recently, the importance of *Salix* to support a broad range of wildlife became important. It was reported that willow stands support a high density of breeding bird communities and willow thickets provide stopover sites for about sixty bird species, the highest number for all studied habitats. Numerous invertebrate herbivores from aphids to caterpillars feed upon willows, which support a large food-web of higher trophic level organisms. There is evidence for a rich insect fauna (up to 450 species) associated with willows. *Salix* is listed as number two on a list of host plants after oaks supporting 456 Lepidoptera species. Willows are becoming very important for sustaining fruit and berry pollinating insects as they are the earliest nectar and pollen sources for bees. They provide for a diverse pollinator group and ensure full pollination services to the surrounding plant communities – an important service considering the problem related to the bee colony collapse in North America. Current investigation generates specific knowledge about the overall insect values of various species of *Salix*.

D2a: APPLIED GENETICS FOR FOREST MANAGEMENT AND CONSERVATION

Identifying the United States tree species and populations most vulnerable to genetic degradation

Kevin Potter¹, Maria Escanferla², Barbara Crane³, Robert Jetton⁴, John Hastings⁵, William Hargrove⁶, Gary Man⁷

¹Department of Forestry, North Carolina State University, Research Triangle Park, NC, USA; ²Department of Forestry, North Carolina State University, Raleigh, NC, USA; ³Southern Region, National Forest System, USDA Forest Service, Atlanta, GA, USA; ⁴Camcore, North Carolina State University, Raleigh, NC, USA; ⁵USDA Animal and Plant Health Inspection Service (APHIS), Raleigh, NC, USA; ⁶Southern Research Station, USDA Forest Service, Asheville, NC, USA; ⁷Forest Health Protection, USDA Forest Service, Washington, DC, USA (kpotta@ncsu.edu; mescanf@ncsu.edu; barbaracrane@fs.fed.us; rmjetton@ncsu.edu; hastings.john.m@gmail.com; whargrove@fs.fed.us; gman@fs.fed.us)

A variety of threats, most importantly insect and disease infestation and climate change, will increase the likelihood that forest tree species could experience species-level genetic degradation or population-level extirpation during the next century. Scientists and managers from throughout the U.S. Forest Service therefore developed a framework for forest tree and population conservation priority-setting assessments. This Project CAPTURE (Conservation Assessment and Prioritization of Forest Trees Under Risk of Extirpation) framework is data-driven and guided by expert opinion, and allows for the quantitative grouping of species into vulnerability classes that may require different management and conservation strategies. We have applied this framework twice to categorize and prioritize North American tree species for gene conservation, monitoring, management and restoration: once for insect and disease threats (419 tree species) and once for climate change exposure (339 species). These categorizations are based on risk factors relating to each species' (1) exposure to the threats, (2) sensitivity to the threats, and (3) capacity to adapt to the threats. We used K-means clustering to group species into classes based on these vulnerability dimensions. The most vulnerable classes encompass the species that will require immediate conservation intervention. Other groups of species will require different management approaches. We have further assessed populations within highly vulnerable species to prioritize them for *ex situ* seed collection. These assessment tools are flexible and designed for repeated application with the availability of new information. They also are valuable for determining which species and populations to target for pro-active gene conservation and management actions.

The geographic origin of old Italian cypresses in North Italy revealed by nuclear SSR markers

Nicola La Porta^{1,2}, Paolo Baldi¹

¹IASMA Research and Innovation Centre, Fondazione Edmund Mach, Via Edmund Mach 1, 38010 San Michele all'Adige (Trento), Italy; ²EFI Project Centre on Mountain Forests (MOUNTFOR), Via Edmund Mach 1, 38010 San Michele all'Adige (Trento), Italy (nicola.laporta@fmach.it; paolo.baldi@fmach.it)

The Italian cypress (*Cupressus sempervirens* L.) has an important role in the characterization of Mediterranean landscape mainly for its aesthetic and ornamental function and also because it is an excellent pioneer specie for reforestation and for timber production. Since antiquity cypress has been cultivated far beyond its natural geographic range for religious and aesthetic reason. At present its geographic distribution is characterized by disjoint populations or single plants. In this study genetic variability of 600 old cypress trees belonging to 26 populations from different part of North and Central Italy and one population from Turkey has been studied using SSR markers. Nine polymorphic SSR primers couples producing a total of 104 alleles. Turkey showed 15 private alleles. The number of observed alleles in all the populations per locus varied from 8 to 22. Values of Nei's gene diversity and Shannon information index suggesting that

populations are characterized by low genetic variability probably due to the strong anthropic pressure that this species has undergone. AMOVA revealed a very strong differentiation between Turkey and all Italian populations and a good significant differentiation among Italian groups. UPGMA dendrogram shows two main clusters, one with all the North-Eastern Italian populations and the second one with Tuscans and North-Western Italian populations. The only exception is the population from Bozen. These results suggest that the artificial transfer of cypress reproductive materials highlighting the human-mediated manipulation of cypress populations in Italy and the political and commercial barriers that were present before the first world war.

Forest genetic monitoring: preliminary results of a microsatellite-based genetic study of *Fagus orientalis* (Lipsky) from Iran and *Fagus sylvatica* (L.) from Germany and Ukraine

Barbara Fussi¹, Darius Kavaliauskas¹, Saboura Rahanjam², Nataliya Hrunyk³, Yurii Yusypovych³, Vasyl Lavnyy³, Khosro Sagheb-Talebi⁴

Natural disturbances and human activities effects diversity of forests on various levels: genetic, species and ecosystems. High genetic diversity of forest trees ensures that forests can grow, adapt and evolve under environmental change, but they may face threats when such change occurs faster than the species' adaptive and evolutionary mechanisms can handle. Therefore it is necessary to implement a forest genetic monitoring (FGM) system which could to assess a forest population's capacity to survive, reproduce, and persist under rapid environmental changes on a long-term scale. Consequently two FGM plots in Germany; one in Ukraine for European beech and one in Iran for Oriental beech were established based on Konnerth et al. (2011) FGM plot design. Through an intensive selection procedure in each FGM plot we sampled 250 adult trees (DBH > 15 cm) and leaves from 200 saplings in four natural regeneration subplots (50 individuals in each). Subsequent genetic analyses were based on 16 nuclear microsatellite markers. Data regarding genetic variation and genetic differentiation among four FGM plots and among adult trees and natural regeneration within the plots will be presented. First results indicate that genetic diversity was distributed evenly from adults to natural regeneration. Genetic diversity within the Iranian Oriental beech population is slightly higher than in a Central European beech populations. Continuation of FGM in future will allow us to draw conclusions about the population's evolutionary potential through comparison to the now assessed baseline data.

Application of molecular genetics in certification of forest reproductive material: testing the origin and genetic diversity of European beech (*Fagus sylvatica* L.) seed collected by commercial nurseries in Slovenia

Marko Bajc¹, Barbara Štupar¹, Nataša Šibanc¹, Hojka Kraigher¹, Marjana Westergren¹
 Slovenian Forestry Institute, Department of Forest Physiology and Genetics, Ljubljana, Slovenia (marko.bajc@gozdis.si; barbara.stupar@gozdis.si; natasa.sibanc@gozdis.si; hojka.kraigher@gozdis.si; marjana.westergren@gozdis.si)

Long-term success of afforestation and reforestation, especially in changing environment, depends on the origin of forest reproductive material (FRM) and its genetic variation. Paper control of FRM origin is embedded in European legislation, while use of molecular tools for verification of FRM origin and its genetic variation are not obligatory. Nevertheless, such tools may be used to improve control over the origin and genetic quality of FRM, consequently contributing to more resilient forests in the future. European beech seed collected by commercial nurseries from seven forest seed stands (FSS) were submitted for certification to Slovenian Forestry Institute (SFI) in 2016 and 2018 in accordance with the Forest reproductive material act. Verification of origin and testing of genetic diversity of the individual tree seed samples and seed lots were based on the analysis of 16 nuclear microsatellite markers. Seed origin was verified through comparison against reference samples collected by SFI from the specified FSS. Tests revealed that two seed lots from 2016 did not originate from the specified FSS, in addition to exhibiting very low levels of genetic diversity. Consequently, they were not approved for use in Slovenian forests. Significantly lower levels of genetic diversity were associated with seed samples collected from too few seed trees, highlighting the importance of collecting FRM from a sufficient number of trees – a minimum of 25 trees, at least two adult tree heights apart from one another, as required by Decree on approval issued by SFI, to maintain the genetic diversity observed in natural stands.

Interim genetic monitoring application in the presence of incidental data: theory and application

Filippos Aravanopoulos¹, Nickos Tourvas¹, Ermioni Malliarou¹, Evangelia Avramidou¹, Anna-Maria Farsakoglou¹, Paraskevi Alizoti¹, Evangelos Barbas¹, Ioannis Ganopoulos¹, Fotios Kiourtsis², Barbara Fussi³, Hojka Kraigher⁴

Species demography and genetic diversity are affected by climatic oscillations and anthropogenically induced stresses. Their potential for future rapid adaptation is questioned, given the pace of environmental change. Quantifying temporal alterations (at ≥ 10 year intervals for genetic markers) in genetic structure and diversity (forest genetic monitoring, FGM), brings prognosis before irreparable harm befalls. As the first evaluation will only create baseline data, true comprehensive FGM will materialize at the second assessment several years later. FGM may circumvent this problem by incorporating incidental comparative data from earlier studies or from younger cohorts at the baseline study, by examining: information capacity (IC) of the marker system (depending on locus numbers, polymorphism level, gene action mode), and direction of differences in allelic richness and evenness. This approach is applied in a Mt. Olympus FGM population of Greek hybrid fir using 11 f-nSSRs in two cohorts (250 adults, 200 juvenile plants). Comparisons between this and a previous study, and between cohorts showed: (a) present IC is high indicating a better representation of the underlying genome variation, (b) genetic diversity (nA, nE, LGP, I, HE) is significantly higher in the present study, (c) genetic diversity is higher in the mature cohort as seen in other studies, but differences in some metrics are not statistically significant. Conclusions: no indication for adverse effects; a gene conservation unit can be established; the interim FGM assessment proved a valuable tool for evaluating conservation potential in the absence of more complete temporal-scale data. This work is funded by project EC-LIFE13 ENV/SI/000148.

Development of a system for forest genetic monitoring through the implementation project LIFE GENMON

Hojka Kraigher¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia (hojka.kraigher@gozdis.si)

Forest genetic monitoring (FGM) gives the possibility to detect changes in the adaptability of forest genetic resources (FGR) to the changing environments before any visual signs can be observed. The European Forest Genetic Resources programme (EUFORGEN) has been promoting conservation of FGR since its establishment in 1994, and almost as long FGM has been discussed by the FAO group on FGR. However the first implementation project to support its development in Europe with special emphasis on South-Eastern Europe, is the LIFE project LIFE GENMON, followed by several research projects within the European Horizon scheme. With the session "Applied genetics for forest management and conservation" we are contributing to the long-term goals of sustaining forests threatened by the range of impacts due to the fast climate change, as well as support a better definition and control of sustainable forest management practices through implementation of FGM. For this, not only the sampling design, and definition of indicators and verifiers of genetic diversity changes in time need to be defined per species, but also silvicultural guidelines, the FGM Manual and Decision support tool, as well as regulative background need to be prepared and accepted at the national, regional and continental scale, and general support for forestry raised. The presentation contributes to the aims and means of the project LIFE GENMON (LIFE13 ENV/SI/000148) LIFE For European Forest Genetic Monitoring System which is in line with goals of EUFORGEN (European Programme for Forest Genetic Resources).

Alternative sampling design for forest genetic monitoring

Natalija Dovč¹, Rok Damjanic¹, Marjana Westergren¹, Marko Bajc¹, Domen Finžgar¹, Darius Kavaliauskas², Dalibor Ballian³, Barbara Fussi², Filippos A. Aravanopoulos⁴, Hojka Kraigher¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Bavarian Office for Forest Seeding and Planting, Teisendorf, Germany; ³Faculty of Forestry, University of Sarajevo, Sarajevo, Bosnia and Herzegovina; ⁴Aristotle University of Thessaloniki, University Campus, Thessaloniki, Greece (natalija.dovc@gozdis.si; rok.damjanic@gozdis.si; marjana.westergren@gozdis.si; marko.bajc@gozdis.si; d.finžgar@sms.ed.ac.uk; darius.kavaliauskas@asp.bayern.de; ballian.dalibor9@gmail.com; barbara.fussi@asp.bayern.de; aravanop@for.auth.gr; hojka.kraigher@gozdis.si)

The existing sampling design for forest genetic monitoring (FGM), used in the LIFE GENMON project, is based on "The German concept". According to this concept, the experimental plot should have a total area of 4 hectares with intensive section of 100 x 100 m surrounded by extensive section with dimensions of 200 x 200 m. Within the intensive section 250 adult trees are to be randomly selected. If the tree density is too low in the intensive section, the remaining trees are to be included in the extensive section. During the first assessment of the beech monitoring plot questions about the appropriateness of the above described design arose. It is difficult to claim that a plot, established in accordance with the above-mentioned requirements, is representative of the beech stand within which it is located. In order to assess genetic diversity and its changes over time as objectively as possible, we have designed an alternative sampling design that meets the demands of replications, independence, randomness and interspersed to the greatest extent possible, making the sample representative of the studied population. The alternative sampling design consists of 5 plots, randomly distributed within the entire stand (100 ha). Within each plot 50 adult trees and 40 natural regeneration trees are randomly selected. A comparison between two sampling designs will show whether there are differences in the genetic diversity assessment and the direction in which a sampling design for FGM should develop to give the most relevant results with manageable amount of effort.

Phenology of European beech (*Fagus sylvatica* L.) as part of forest genetic monitoring in Slovenia

Rok Damjanic¹, Marjana Westergren¹, Domen Finžgar¹, Natalija Dovč¹, Melita Hrenko¹, Barbara Fussi², Filippos A. Aravanopoulos³, Hojka Kraigher¹

¹Slovenian Forestry Institute, Ljubljana, Slovenia; ²Bavarian Office for Forest Seeding and Planting, Ljubljana, Slovenia; ³Aristotle University of Thessaloniki, Thessaloniki, Greece (rok.damjanic@gozdis.si; marjana.westergren@gozdis.si; d.finžgar@sms.ed.ac.uk; natalija.dovc@gozdis.si; melita.hrenko@gozdis.si; barbara.fussi@asp.bayern.de; aravanop@for.auth.gr; hojka.kraigher@gozdis.si)

Phenology is a highly important adaptive trait, which determines the growing season and the reproductive period of plants. Climate change, the associated increased temperature and late spring frost damage are the main reasons why phenology is changing over the years. From 2016 we are monitoring the spring and autumn phenology of European beech (*Fagus sylvatica* L.), one of ecologically and economically most important broadleaves in Europe. In the beginning 40 trees were monitored for bud break, leaf senescence, flowering and fructification. The number of trees was extended to 250 in the last 2 years. Each tree on the plot was georeferenced and its crown projection was measured. The presented data shows the comparison of phenology between trees and tree groups. Data analysis and representation of phenology was also performed in the spatial dimension, representing trees in different phenological stages with their tree crowns on a spatial plot. In this way we can easily observe spatial patterns of trees and/or recognize single trees which have different phenology than others. The presentation contributes to the aims and means of the project LIFE GENMON (LIFE13 ENV/SI/000148) LIFE For European Forest Genetic Monitoring System, cofinanced by the Ministry for the environment and spatial planning RS, and in Slovenia by the Ministry for agriculture, forestry and food and the Slovenian Forestry Institute.

Variation in genetic diversity of European beech (*Fagus sylvatica* L.) seed from different reproductive year (2006 vs 2016) and its importance for forest genetic monitoring

Darius Kavaliauskas¹, Barbara Fussi²

¹Bavarian Office for Forest Seeding and Planting, Teisendorf, Germany (darius.kavaliauskas@asp.bayern.de); ²barbara.fussi@asp.bayern.de

Regular reproductive cycles and seed formation in forest trees ensure that the population is able to survive and reproduce. Over the last few decades, forests have been facing many threats and pressures, especially those related to climate change and human impact. As a result of changing environment frequency of reproductive years become more irregular and the amount of reproducing trees and viable seeds can decrease drastically in different populations. Furthermore, natural regeneration can be influenced by annual variation in flowering abundance as well as flowering synchronization, which typically have a genetic and an environmental component, affecting the genetic composition of the seed crop and the subsequent natural regeneration in a forest stand. To fully understand how these threats affect genetic diversity forest genetic monitoring (FGM) should be used as an early warning system. For this aim an FGM plot for European beech in south of Germany was established in 2006. Seeds from 20 single trees at different reproductive years (2006 / 2016) were collected and genotyped based on 16 nuclear microsatellite loci (in total 800 seeds). Based on gained data the questions we are trying to answer are: (i) Are there significant changes in genetic diversity parameters of seeds over years? (ii) Are there significant changes in the mating system over years? First results indicate that there are no significant changes in genetic diversity measures of seeds from different reproductive year. Further results regarding FGM mating system parameters based on seeds genetic variation from different reproductive year are presented.

Use of microsatellite markers for clonal identification in European larch seed orchard

Pavlna Máchová¹, Helena Cvrčková¹, Olga Trčková¹

¹Forestry and Game Management Institute, Czech Republic Jiloviště (machova@vulhm.cz; cvrkova@vulhm.cz; trckova@vulhm.cz)

The Simple Sequence Repeats (SSR) method of DNA analyses was used to clonal identification in a model European larch (*Larix decidua* Mill.) seed orchard. Total genomic DNA was extracted by DNA Plant Mini Kit (QIAGEN) from needles taken from 170 sampled trees of seed orchard. Samples were screened using selected 13 polymorphic nuclear microsatellite markers. Measuring the size of amplification products was carried out using the genetic analyser Applied Biosystems 3500. The obtained data were analysed using the statistical programs CERVUS, GenAIEx 6.503 and Micro-Checker. There were detected 133 different alleles at 13 loci in the 170 European larch tree individuals from seed orchard. The most polymorphic in our set of samples was locus bcLK211. By applying the 13 suitable markers to the 42 clones from model seed orchard we obtained multilocus genotypes (MLG). Clone affiliation declared by its owner was confirmed in 71 % of sampled trees, but on the basis of obtained genotypes, it is possible to assign 98 % of sampled tree to clones from seed orchards. The obtained results illustrate the utility of the microsatellite loci for assessing spatial patterns of genetic diversity and for individual identification. This work was supported by the Ministry of Agriculture of the Czech Republic, institutional support MZE-RO0118.

Evaluation of the genetic diversity of selected Czech Norway spruce stands

Helena Cvrčková¹, Pavlna Máchová¹, Olga Trčková¹

¹Forestry and Game management Research Institute, Czech Republic Jiloviště (cvrkova@vulhm.cz; machova@vulhm.cz; trckova@vulhm.cz)

The genetic structure of selected Norway spruce stands from the Jeseníky Mts., Orlické hory Mts., and Krušné hory Mts. (Czech Republic) was studied to verify the genetic quality. The genetic variability of tree populations ensures the stability and sustainability of forest ecosystems. DNA polymorphism at twelve nuclear microsatellites of fourteen Norway spruce stands was investigated. The level of genetic diversity within 14 investigated Czech Norway spruce stands was relatively high. Mean values for number of different alleles ranged from 12.25 (stand SM J51) to 15.92 (stand SM T1). The values of observed heterozygosity (Ho) ranged from 0.65 to 0.81, and expected heterozygosity (He) from 0.81 to 0.86. Pairwise population FST values ranging from 0.007 to 0.030 indicated low genetic differentiation between units, and values of Nei's genetic distance among Norway spruce units ranged from 0.083 to 0.313. The structuring of investigated Norway spruce stands was also confirmed by different ratios of genetic profiles according to the Bayesian clustering method results. Closer genetic similarity was seen in the stands from the gene conservation unit in the Orlické hory than in other studied stands. The most genetically different stand was from the Krušné hory. Knowledge based on DNA analyses regarding the variability of genetic resources will contribute to the quality of the reproduction material and to creation of an optimal species composition in forests. This work was supported by the projects of the Ministry of Agriculture of the Czech Republic - institutional support MZE-RO0118 and no. NAZV QK1810129

Genetic structure of *Bertholletia excelsa* throughout the Brazilian Amazon region / Estrutura genética de *Bertholletia excelsa* ao longo da Amazônia brasileira

A *Bertholletia excelsa* Bonpl. (Lecythidaceae) é uma espécie arbórea endêmica das matas de terra firme e com ampla distribuição ao longo de toda a Floresta Amazônica. De grande relevância econômica devido à extração das sementes realizada por populações locais, está entre os produtos mais exportados da Amazônia. Atualmente, faz parte da lista oficial das espécies em extinção, sendo classificada como vulnerável. Tendo em vista este contexto torna-se de suma importância o estabelecimento de estratégias para definição de áreas prioritárias para a conservação da espécie. Uma dessas ferramentas é a caracterização da diversidade e estrutura genética em populações naturais. Esse trabalho amostrou árvores em 22 populações naturais da *B. excelsa* ao longo da Amazônia brasileira, totalizando 140 amostras em todos os estados da região Norte. Foram construídas bibliotecas genômicas NextRAD, e o sequenciamento resultou na identificação de ~30.000 locos SNPs (*Single Nucleotide Polymorphism*). Com os genótipos SNPs foram estimados parâmetros de diversidade e estrutura genética. Observamos níveis elevados de diversidade genética e identificamos regiões da Amazônia brasileira com diversidade genética única. São apresentados resultados das estatísticas F de Wright, bem como a correlação entre distâncias genéticas e geográficas. Utilizamos o método Bayesiano de agrupamento implementado no pacote *geneland* para visualizar a estruturação genética na paisagem, que usamos para discutir propostas de áreas prioritárias para conservação. Apoio financeiro: Embrapa (Processo SEG: 02.13.05.017.00.00).

Lack of interaction between provenances and habitats of scots pine (*Pinus sylvestris* L.) in two experimental plots in Bosnia and Herzegovina

Mirzeta Memišević Hodžić¹, Dalibor Ballian^{1,2}, Hojka Kraigher²

¹University of Sarajevo, Sarajevo, Bosnia and Herzegovina; ²Slovenian Forest Institute, Ljubljana, Slovenia (mirzeta.mh@sfsa.unsa.ba; balliandalibor9@gmail.com; hojka.kraigher@gozdis.si)

The research studies interactions between provenances of Scots pine in two test planes (Romanija Glasinac, 1000 m and Gostović Zavidovići, 480 m above sea level) of different ecologic conditions in Bosnia and Herzegovina. The test includes 11 provenances with 10 families in each, and in five repetitions. All interactions are calculated on the basis of value of diameter at breast height and height of plants that are 21 years old. Šipovo was the best provenance in Glasinac plane, with average breast-height diameter amounting to 14.04 cm and 8.82 m height, while Olovo showed lowest results – 11.99 cm and 7.72 m. In Gostović plane, Bosanski Petrovac had the biggest average breast-height diameter – 12.28 cm while maximum height was recorded in Rogatica provenance – 10.96 m. Smallest average breast-height diameter (9.74 cm) and minimum height was recorded in Doboj seed orchard provenance. Variance analysis showed statistically significant differences between provenances in terms of diameter at breast height and height values. The obtained values of coefficient have shown that there

is no interaction between provenances and habitats in any provenance located in the observed planes. The reason for lack of interaction lies within the species biology. It is a pioneering species with fast flow of genes. This is the reason for weak differentiation of provenances in Bosnia and Herzegovina which is seen in relatively small areas of Central Dinarides. Considering the lack of interaction, best provenances in each plane indicate that they should be used in the given ecological conditions.

D2b: CONSERVATION, DOMESTICATION AND BREEDING OF NATIVE SPECIES

Tree for the future program: prototyping conservation of threatened trees in the Philippines

Pastor Jr. Malabrigo^{1,2}, Ronino Gibe², Allan Barcena², Jimson Solatre², Ernesto Jr. De Guzman²

¹Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines Los Baños, Los Baños, Philippines;

²Energy Development Corporation, Pasig, Philippines (plmalabrigo@up.edu.ph; gibe.rc@energy.com.ph; barcena.av@energy.com.ph; solatre.js@energy.com.ph; ernestoboydg@yahoo.com)

Philippine biodiversity is highly considered the most threatened in the planet being the 2nd biodiversity hottest spot and the 4th most endangered forest ecosystems with only 7% of the original forest cover remaining. Same with deforestation, Philippines has a very long history of reforestation. Unfortunately, until very recently, more than 90% of the reforestation projects used exotic species. With the increasing number of tree species being included in the Philippine Red List for Plants, the Energy Development Corporation (EDC) initiated a corporate social responsibility program called Tree for the Future (TFTF). Its main objective is to mainstream planting of threatened trees and bring the species back to abundance. TFTF follows four key steps in trying to prevent the extinction of Philippine threatened trees namely: 1) species rescue and protection; 2) mass propagation; 3) establishment of future mother trees; and 4) advocacy and awareness campaign. Since 2008, EDC has been exploring almost every island of the Philippines to document remaining natural populations of the most threatened native trees. With coordination and partnership with concerned agencies, propagules were collected and mass propagated through vegetative material recovery (VMR) facility. Its clonal facility has developed propagation protocols for 20 threatened species. Propagules produced from the VMR were donated and planted to schools and parks. To date, EDC has planted around 8,000 threatened trees in 164 partner schools all over 16 regions of the country with 90% survival rate. To promote awareness and better appreciation, EDC chronicles its learning experiences through books and media publications.

Participative tree domestication as a strategy for use and conservation of high-value native forest species in Uruguay

Zohra Bennadji¹, Marcelo Alfonso¹, Stefani Mello¹, Pablo Nuñez¹

¹INIA Uruguay, Tacuarembó, Uruguay (zbennadji@inia.org.uy; malfonso@inia.org.uy; smello@inia.org.uy; pnunez@inia.org.uy)

As a traditional livestock country, Uruguay is still an emergent forestry country despite the commercial plantations boom of the nineties, based on exotic fast growing species. There is a scarce experience on the conservation, domestication and breeding of native forest species in the country and this situation has a negative impact on the establishment of agroforestry systems and on the implementation of native forests conservation and restoration actions. The purpose of this work is to present the knowledge generated in participative tree domestication of high-value native forest species in Uruguay as a strategy for shortening the way and opening opportunities for: (i) the improved seed and seedling production, (ii) the forest species diversification, (iii) the small scale forestry establishment, (iv) the use/incorporation of high-value native forest trees in livestock and agriculture activities and (v) the awareness on climate change impacts and its relationship with deforestation-afforestation, land use and land restoration.

NZ Kauri: an iconic ancient species in crisis from kauri dieback

Rosie Bradshaw¹, Yanan Guo¹, Pierre-Yves Dupont², Carl Mesarich¹, Joe Win³, Preeti Panda⁴, Nari Williams⁴, Rebecca McDougall⁴

¹BioProtection Research Centre, Massey University, Palmerston North, New Zealand; ²Institute of Environmental Science and Research Limited, Christchurch, New Zealand; ³The Sainsbury Laboratory, Norwich, United Kingdom; ⁴Scion, NZ Forest Research Institute, Rotorua, New Zealand (r.e.bradshaw@massey.ac.nz; y.guo.1@massey.ac.nz; pierre.dupont@esr.cri.nz; c.mesarich@massey.ac.nz; joe.win@sainsbury-laboratory.ac.uk; preeti.panda@scionresearch.com; nari.williams@scionresearch.com; rebecca.mcdougall@scionresearch.com)

In New Zealand, 99% of the ancient, iconic and culturally significant native kauri (*Agathis australis*) were destroyed by early settlers seeking a living in the new land. Now the species is close to crisis point due to an epidemic of kauri dieback, caused by the root-infecting oomycete pathogen, *Phytophthora agathidicida*. No-one has yet managed to eradicate a *Phytophthora* pathogen from a forest, so current methods to manage this disease have included considerable efforts to prevent its spread into uninfected forests. Some success in slowing the progression of the disease has been made by injecting phosphite into infected trees and a citizen science project has helped to expand the number of trees that could be treated in this way. Further hope for the future lies in screening kauri for resistance or tolerance to the disease and a screening programme in progress at Scion (NZ) suggests that dieback tolerance may be present in kauri populations. Work on the genomics of kauri itself is subject to cultural restrictions. However, insights into the genome of the pathogen, and the use of alternative plants for initial screening, have enabled identification of pathogen effector proteins that may help cause disease or elicit host defence. We hope to screen these effector proteins in kauri tissue to determine if they show the same functions in the natural host. Ultimately, we aim to identify host targets that interact with the effector proteins to help determine the genetic basis of susceptibility and resistance in kauri.

Genetic variation, trade-offs and association genetics for growth, bud burst and pathogen susceptibility in maritime pine

Agathe Hurel¹, Marina De Miguel², Cyril Dutech¹, Marie-Laure Desprez-Loustau¹, Christophe Plomion¹, Isabel Rodríguez-Quilón³, Agathe Cyrille¹, Thomas Guzman¹, Ricardo Alia³, Santiago C. González-Martínez¹, Katharina B. Budde¹

¹BioGeCo, INRA - Université de Bordeaux, Cestas, France; ²BioGeCo, INRA - Université de Bordeaux, Cestas, France; ³Department of Forest Ecology and Genetics, Forest Research Centre, INIA, Madrid, Spain (agathe.hurel@inra.fr; marina-amapola.de-miguel-vega@inra.fr; christian-cyril.dutech@inra.fr; marie-laure.desprez-loustau@inra.fr; christophe.plomion@inra.fr; irodriguezquilon@gmail.com; agathe.cyrille@gmail.com; thomas.guzman@etu.u-bordeaux.fr; alia@inia.fr; santiago.gonzalez-martinez@inra.fr; katharina.budde@inra.fr)

Forest ecosystems are increasingly challenged by extreme events, e.g. pest and pathogen outbreaks, which cause severe ecological and economical losses. A key to preserve forest ecosystems is the understanding of the genetic basis of adaptive traits in forest trees. Maritime pine, a conifer widely distributed in southwestern Europe and North Africa, grows under contrasted environmental conditions promoting local adaptation. Adaptive phenotypes, such as height, bud

burst, and presence/absence of nests of pine processionary moth were assessed in a clonal common garden, that comprises trees from range-wide populations. Additionally, we implemented experimental approaches to assess susceptibility to the pathogens *Diplodia sapinea* and *Armillaria ostoyae* by excised shoot inoculations. The presence/absence of nests of pine processionary was not heritable, whereas heritability for height (0.156) and bud burst (0.241) was moderate. Heritability for susceptibility to pathogens was lower, 0.096 for *D. sapinea* and 0.021 for *A. ostoyae*, but still significant. Genetic correlations between traits revealed a trade-off in pathogen susceptibility between *D. sapinea* and *A. ostoyae* necrosis length. Pathogen susceptibility was also genetically correlated with tree height, positively for *D. sapinea* and negatively for *A. ostoyae*. Trees from the southern populations tended to be smaller and showed lower susceptibility to *D. sapinea* but higher to *A. ostoyae* while the opposite was found for northern Atlantic populations. Genotype-phenotype associations using 4,227 genome-wide SNPs revealed several loci significantly associated to each trait. While current breeding programs of maritime pine mainly focus on growth traits, this study provided important results to develop strategies that consider forest resilience to pathogen outbreaks.

Methodology for environmental and genetic characterization of Araucaria populations for conservation and sustainable use of genetic resources / Metodologia orientada à caracterização ambiental e genética de populações de araucária para conservação e uso sustentável dos recursos genéticos

Marcos Silveira Wrege¹, Valderês Aparecida Sousa¹, Ananda Virginia de Aguiar¹, Márcia Toffani Simão Soares¹, Elenice Fritzsos¹, Itamar Antonio Bognola¹, João Bosco Gomes¹, Leticia Penno de Sousa², Cristiane Vieira Helm, Patrícia Póvoa de Mattos¹ 

¹Embrapa Florestas, Colombo, Brasil, ²Embrapa Clima Temperado, Pelotas Brasil (marcos.wrege@embrapa.br; valderes.sousa@embrapa.br; ananda.aguiar@embrapa.br; marcia.toffani@embrapa.br; elenice.fritzsos@embrapa.br; itamar.bognola@embrapa.br; joao.bv.gomes@embrapa.br; leticia.penno@embrapa.br; cristiane.helm@embrapa.br; patricia.mattos@embrapa.br)

Araucaria angustifolia (Bertol.) O. Kuntze. está presente no bioma Mata Atlântica, predominantemente na Floresta Ombrófila Mista e se encontra na lista vermelha das espécies criticamente em perigo de extinção da IUCN, sendo vulnerável em função das mudanças climáticas. O acordo firmado pelo Brasil em 2015 na COP21 enfatiza a necessidade de “incrementar a capacidade nacional em conservação e uso sustentável da biodiversidade”. Com base nesta demanda, desenvolvemos uma metodologia orientada à caracterização ambiental e genética de populações de *A. angustifolia*, como subsídio à sua conservação e uso sustentável. O método consiste em 5 etapas: 1) definição de margens de ocorrência e seleção de regiões prioritárias para amostragens; 2) amostragens para genotipagem e dendrocronologia; 3) amostragens de solos; 4) estudo do clima e 5) identificação de nichos ecológicos das populações. Ao agregar abordagem multidisciplinar, foi possível propor novos métodos de coleta de material genético e de análise das condições pedoclimáticas, aumentando a eficácia, acurácia e segurança no processo de geração de informações referentes ao comportamento da espécie. Os resultados preliminares indicam que a maior parte das populações de *A. angustifolia* ocorre em regiões com características ambientalmente parecidas e que uma pequena parte ocorre em situações diferentes. Neste último caso, as populações devem ser priorizadas para coleta de germoplasma e é onde devem ser priorizados testes experimentais, uma vez que a chance de encontrar indivíduos mais adaptados às regiões típicas de ocorrência é maior. A metodologia desenvolvida é passível de aplicação a outras espécies florestais nativas semelhantes, com pequenas adaptações.

Geographic structuring of the genetic variability of *Ilex paraguariensis* St. Hil. in Uruguay / Estructuración geográfica de la variabilidad genética de *Ilex paraguariensis* St. Hil. en el Uruguay

Pablo Hernández¹, Alexandra Gottlieb², Arley Camargo³, Magdalena Vaio⁴, Pablo Speranza¹

¹Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay; ²Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales – Ciudad Universitaria, Pabellón II, 4to piso, Departamento de Ecología, Genética y Evolución, Lab; 62, C1428EHA, Buenos Aires, Argentina; ³Centro Universitario de Rivera, Universidad de la República, Rivera, Uruguay; ⁴Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay (pablohernandez27@gmail.com; alexandragottlieb@gmail.com; arley.camargo@gmail.com; magdalenavaio@gmail.com; pablosperanza@gmail.com)

Ilex paraguariensis St. Hil. es una planta subtropical perteneciente a la familia Aquifoliaceae, posee follaje siempre verde, porte arborescente y es longeva. Su distribución natural abarca los territorios de Brasil, Argentina, Paraguay y Uruguay. Es una especie de gran interés socio-cultural y comercial porque con sus hojas se elabora la yerba, principal ingrediente de la bebida del “Mate” o “Tereré”. En Uruguay las poblaciones naturales de *I. paraguariensis* representan el límite sur de la distribución de la especie, localizándose en áreas de refugio o “Hot Spots” ubicadas en el norte y este del país. Se tiene escasa información sobre las poblaciones uruguayas, pero se cree que pueden aportar variantes de interés para el mejoramiento y conservación de la especie. Este trabajo se dispone probar que se detecta estructuración geográfica de la variabilidad haplotípica de *I. paraguariensis* en el territorio uruguayo y que la diversidad entre dichas poblaciones es mayor que la encontrada en el resto de su distribución. Para probar esta hipótesis se obtuvo el ADN de 273 individuos georreferenciados, distribuidos a lo largo de 17 sitios de colecta en bosques relictuales y se analizó la información conjunta obtenida de la amplificación del ADN con 30 marcadores microsatélites cloroplásticos. Las poblaciones uruguayas aparecen altamente estructuradas y diferenciadas de las muestras de Paraguay, Argentina y Brasil. Se observa una diferenciación genética clara y ausencia de flujo de semillas entre poblaciones, con importantes implicancias para la conservación y exploración del germoplasma.

Estimating realized gene flow patterns in the Kenyan population of *Acacia senegal* (syn. *Senegalia senegal*): an empirical comparison of SNP and microsatellite variations

Stephen F. Omondi¹, Damase Khasa²

¹Kenya Forestry Research Institute, Nairobi, Kenya; ²Laval University, Quebec, Canada (stephen.f.omondi@gmail.com; damase.khasa@ibis.ulaval.ca)

Despite the importance of seed and pollen dispersal for survival of tree species across landscapes, data on gene dispersal on important tropical dryland species that are undergoing various population dynamics remain scarce. Understanding the patterns of gene dispersal in these ecosystems is important for conservation and tree improvement purposes. We investigated pollen and seed mediated gene flow in disturbed and undisturbed populations of *S. senegal* based on microsatellite and genotyping-by-sequencing (GBS) multilocus genotypes of seedlings and adult trees. We performed parentage assignments using likelihood and seedling neighborhood approaches. We also undertook spatial genetic structure (SGS) analyses for the two growth stages. The SNPs showed higher resolution power and assignment rates than microsatellites, however, a combination of the two marker types provided a robust parentage assignments. We found occurrence of high frequency of long-distance pollination events in disturbed than undisturbed population, however, localized seed dispersal were evident in both populations. Parentage analysis showed high amounts of pollen (40 %) and seed (20 %) immigration in both populations. Significant positive spatial genetic structure was found for the adult cohorts in undisturbed population for distance classes 25 and 50 m, indicating short distance of historical seed dispersal. Our results suggest long distance gene flow within the species and recommend conservation of remnant and isolated populations and/or individual

trees to promote genetic connectivity among populations. Seed collection for tree improvement or conservation should observe a minimum distance of 60 m to avoid sampling of closely related individuals.

Efficiency of artificial neural networks to predict genetic values and genetic gains in *Bactris gasipaes*

Gustavo Rodrigues¹, Antonio Nascim Kalil Filho², Wanderley Santos³, Karina Martins¹, Ananda Virginia de Aguiar²

¹Universidade Federal de São Carlos, Sorocaba, Brasil; ²Embrapa Florestas, Colombo, Brasil; ³Universidade Estadual Paulista “Julio de Mesquita Filho”, Ilha Solteira, Brasil (henriquesr.gustavo@gmail.com; antonio.kalil@embrapa.br; wanderley.dossantos@hotmail.com; karimartins@yahoo.com; ananda.aguiar@embrapa.br)

Bactris gasipaes, popularly known in Brazil as pupunha, is a palm species native to tropical America. The heart-of-palm and the fruits are edible and commercially harvested from plantations. Brazil is the main producer in the world, but the domestic market consumes almost the entire annual production. Strategies to maximize their productivity through breeding are therefore necessary. In this study we propose the use of Artificial Neural Networks (ANN) with Multilayer Perceptron method to predict genetic gains and values and capture genotype information that are not contemplated in conventional stochastic procedures. The germplasm used in this study is composed by progeny tests from open-pollinated seeds. Those tests were established in Paraná, Amazonas and Roraima states, in complete block design with one plant per linear plot, in 2 x 1m spacing. The phenotypic traits were height, diameter and heart-of-palm production. We used ANN to predict genetic values and rank genotypes for selection. In ANNs, we used as input of the network the individual breeding and genotypic values. The data was randomly divided into training (80%) and extrapolation (20%) data. The best ANN architecture was three hidden layers with 14-5-5 neurons, and showed a root mean square error (RMSE) of 0.3999, a mean absolute error (MAE) of 0.3898 and coefficient of determination (R^2) of 0.9596 with the residual graph showing no bias. The performance of ANN showed superiority than multiple regression models in predict genetic gains and genetic values.

D2c: CONSERVATION, SUSTAINABLE MANAGEMENT AND DEVELOPMENT OF FOREST GENETIC RESOURCES ACROSS THEIR RANGES: REGIONAL RESEARCH AND COLLABORATION

Assessing the value, performance and potential implementation of assisted migration across Canada's forests

Guillaume Peterson St-Laurent¹, Shannon Hagerman¹, Robert Kozak¹

¹Faculty of Forestry, University of British Columbia, Vancouver, Canada (peterson.guil@gmail.com; shannon.hagerman@ubc.ca; rob.kozak@ubc.ca)

Proponents of assisted migration—the intentional movement of tree species (either within or outside of native range) to more suitable areas based on climatic projections and genetically-informed seed selection—see this novel forest management strategy as a means to enhance forest resilience in an era of global climate change. Others express caution or outright objection, pointing to the potential risks associated with assisted migration, such as the introduction of invasive species or pests/diseases and planted tree species failing to establish. This study used a cross-Canada survey to quantify the judgements of forestry and conservation specialists about the possible implementation of five climate-adaptive reforestation options representing a continuum from business-as-usual to technologically intensive interventions in Canada's forests, and including assisted migration within and outside of native range. Results from the survey highlight the diversity of professional judgements on the relative importance of forest management objectives in the context of climate change and the likely performance of reforestation options in Canada's forests. The study also explores the influence of four key factors—economic, governance, scientific knowledge and social licence—on the implementation of assisted migration strategies in Canada's forests and assesses the anticipated risks and benefits of such actions. Finally, the analysis outlines positive and negative attitudes regarding assisted migration strategies as a means of adapting to climate change within the practitioners' community.

Predicting the potential habitation and threats of a near threaten and cross-border rosewood species (*Dalbergia cultrata*)

Ping Huang¹, Yu Liu¹, Wenyun Yang², Yichen Zong¹, Yongqi Zheng¹

¹State Key Laboratory of Tree Genetics and Breeding; Laboratory of Forest Silviculture and Tree Cultivation; Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China; ²Research Institute of Resources Insects, the Chinese Academy of Forestry, Kunming, China (huangping@caf.ac.cn; nefuly@126.com; yangwenyun1@163.com; zongyc@caf.ac.cn; zhengyq@caf.ac.cn)

Dalbergia cultrata is a rosewood species and widely distribute in a tropical and subtropical zone in Indo-China peninsula, and the south of China. In recent decades, its nature population has been shrinking seriously due to anthropogenic activities or other threats. Understanding the habitat requirements of this species, evaluating habitat quality, and predicting its potential habitat are also essential to conserve the target species. Hence, the following work had been carried out: (1) the preliminary survey of natural population of *D. cultrata* was investigated; (2) based on the public and realistic occurrences including China and neighboring countries, the potential habitat and its requirements of were predicted. (3) habitat suitability of *D. cultrata* for double CO₂ level scenario were calculated. The results showed that (1) natural populations distributed in tropical zone in the south of China is sporadic, small and young. Their habitation is fragmented by criss-crossed road and rubber plantation, which may increased difficulties of natural regeneration and gene flow. (2) distribution of *D. cultrata* is mainly influenced by the isothermality, annual range of temperature, and precipitation of wettest and warmest quarter, which suggested it is sensitive to climate change. (3) Habitat suitability will be reduced in for double CO₂ level scenario. Therefore, making a priority to conserve the natural resource of *D. cultrata* is imperative and significant in response to threats. However, *D. cultrata* is cross-border and vulnerable species, we also appeal and desire to seek further cooperation with resource-owner countries on the conseravtion and sustainable use of *D. cultrata*.

Conservation approaches for forest genetic resources of the Indian Himalayan Region

Manisha Thapliyal¹, Pravin Rawat¹, Amit Simalti¹, Neha Pant¹

¹Forest Research Institute, Dehradun, India (manishathapliyal98@gmail.com; pravinrawat15@gmail.com; amit.simalti90@gmail.com; neha.pant55555@gmail.com)

The Himalayas well known for complex and diversified biological and physical attributes, are spread over the north-western and north-eastern states of India. Due to richness and uniqueness of biodiversity elements, the region has been recognized as one of the 35 global biodiversity hotspots. However, increased use of its forest resources and shrinking forest land base threaten the sustainability of forest genetic resources and highlight the importance of conservation

and sustainable management of these resources both *in situ* as well as *ex-situ*. We have undertaken a research programme on conservation of Forest Genetic Resources (FGRs) with special focus on the exploration and conservation of FGRs of North-West Himalayas. The major activities under the programme are documentation, characterization, seed and Germplasm Storage of FGRs. The population of the prioritized species (including rare, endangered, threatened and vulnerable) are being explored, populations geo-tagged, phenological observations and species associations recorded. Their seeds are collected, processed, tested for physical and physiological quality and desiccated to safe moisture levels for storage. The seed storage physiology of important Himalayan species like Birch, *Carpinus*, *Fraxinus*, pines, spruce, fir, oaks, rhododendrons, walnut, *Corylus jacquemontii*, high-altitude medicinal plants, etc. is being studied for chalking out a long-term *ex situ* conservation programme. The orthodox seeds are processed for conservation after slow desiccation to lowest safe moisture levels. Desiccated seeds are then vacuum sealed in triple-layered aluminium bags and stored in Seed bank at -180C. Thus, *ex situ* conservation becomes the focal point of gene conservation programme of FGRs of Indian Himalayan Region.

Morphological differences in *Pinus strobiformis* across latitudinal and elevational gradients

Alejandro Leal-Saenz¹, Kristen Waring², Samuel Cushman³, Andrew Eckert⁴, Lluvia Flores-Renteria⁵, Mitra Menon⁴, Christian Wehenkel⁶

¹Universidad Juárez del Estado de Durango, Durango, Mexico; ²School of Forestry, Northern Arizona University, Flagstaff, USA; ³USDA Forest Service, Flagstaff, USA; ⁴Department of Biology, Virginia Commonwealth University, Richmond, USA; ⁵Department of Biology, San Diego State University, San Diego, USA; ⁶Instituto de Silvicultura e Industria de la Madera, Universidad Juárez del Estado de Durango, Durango, Mexico (aleals@ujed.mx; kristen.waring@nau.edu; sam.cushman@gmail.com; aeckert2@vcu.edu; lfloresrenteria@sdsu.edu; menonm2@vcu.edu; wehenkel@ujed.mx)

The variation in morphological tree traits may occur in response to environmental conditions and other factors, including evolutionary adaptation. Evaluating the variability in tree morphology is therefore critical for testing ecological and evolutionary models that predict the functional or adaptive nature of phenotypic plasticity. However, quantifying morphological variation within a widespread tree species such as *Pinus strobiformis* (SWWP) across a large spatial scale is preferable in order to identify the relative importance of different environmental and genetic factors in relation to variations in intraspecific morphological traits. SWWP is the most widely distributed white pine in Mexico. This species is a key component of mixed conifer forests in the region in both north-western Mexico and south-western USA and highly susceptible to the invasive tree disease, white pine blister rust, caused by the fungus *Cronartium ribicola*. The dual threats of this non-native fungal pathogen and a warmer, drier projected future climate have created an uncertain future for SWWP. The objectives of the present study were a) to model and map the spatial distribution of cone and seed morphological traits of SWWP and b) to estimate the relative importance of different environmental and genetic factors on these morphological traits. We found that both genetic and environmental factors influenced the morphological traits but influential factors varied by trait. The variation results from both the ability of genotypes to produce morphological phenotypes and regional selection. Morphological phenotypes may arise as a response to environment conditions.

Conservation and sustainable use of oak Forest Genetic Resources in Romania

Ecaterina Nicoleta Apostol¹, Marius Budeanu¹, Flaviu Popescu¹, Ovidiu Badea¹, Dragos Postolache¹, Ioana Plesca, Constantin Nechita¹, Cristian Sidor¹, Stefan Leca¹

¹National Institute for Research and Development in Forestry (INCDS), Marin Drăcea, 077190, Romania (cathyches@yahoo.com; budeanumarius@yahoo.com; flaviu.popescu@icashd.ro; obadea@icas.ro; dragospostolache@yahoo.com; ioana0407@yahoo.com; nechitadendro@gmail.com; cristi.sidor@yahoo.com; stefan.leca@icas.ro)

Our research aimed to show the influence of climate change on Forest Genetic Resources (FGR) consisting of thermophilic and xerophyte, or relatively thermophilic and mezoxerophyte oak taxa. Changes that can occur in the phenology of biological processes, considered as the most sensitive and prominent responses to global climate change were investigated. Five native species *Quercus pedunculiflora* K. Koch, *Q. robur* L., *Q. petraea* (Matt.) Liebl., *Q. pubescens* Willd., *Q. virgiliana* Ten. were evaluated in Romania. Phenological observations were made in the entire crown at a two-four days interval; in addition, wood microcores were collected weekly in order to study the xylogenesis phenology. The findings of the survey show that there is a significant correlation ($r=0.8$, $p < 0.05$) between leaves unfolding and environmental factors (average daily temperatures). A weakly positive correlation between the time of bud burst and cambium activity ($r=0.36$, $p=0.172$) was registered. The presence of the representative taxa specimens in all three phenological categories: precocious, intermediate and tardy shows a high level of the variability and adaptability of the natural regenerated population. As expected, the tardy specimens, who have a share of 6% of all analyzed trees, can avoid the late frost (especially in the flowering period) and the early spring defoliators. The identified adapted phenotype are recommended as forest reproductive base material for the corresponding provenance region and for the *ex situ* conservation of the specie.

Germination of various dryland tree species important to the Turkana Community in Kenya

Acacia tortilis, *Acacia senegal*, *Acacia oerfota*, *Terminalia brownii* and other tree species are important tree species in several parts of the world more so in African pastoral lands. The trees occur naturally in mostly the arid and semi-arid regions of Africa from north to southern parts. The trees apart from providing ecosystem services have various parts including; leaves, pods, gum exudates, and barks have several uses ranging from food, fodder, medicines and commercial use. The major challenge is the lack of successive young generations of trees in these pastoralism areas due to the land tenure system and existing browsing by livestock; there is thus need to know how these germinate to act as a source of knowledge guiding afforestation of rangelands and improve the availability of seed. The aim of this paper is to show how these trees germinate in a controlled arid environment and the growth characteristics of the seedlings in order to predict the early growth of above-ground biomass. The methods begin with selective collection of seeds from wild sources in various areas of Turkana County, Kenya. Subsequent seed pre-treatments, sowing and measurement of growth data to show the tree seed performance under certain controlled conditions and how growth is influenced under the specific controlled conditions under review in relation to its naturally occurring environments. The key observations were there wasn't uniform germination with some new pre-treatments showing better performance, though once germinated various height to Root Collar Diameter equations were compared and showed areas to improve.

Applications of genomic data in European conifers

Sanna Olsson¹, Francesca Bagnoli², Guàrdia Giovanni³, Caroline Scotti-Saintagne³, Ricardo Alía⁴, Bruno Fady³, Santiago C. González-Martínez^{4,5,6}, Maria Mayol⁶, Giovanni G. Vendramin², Delphine Grivet^{1,4}

Genomic and transcriptomic datasets offer ample possibilities to increase Forest Genetic Resources by providing relevant markers such as SSR, SNPs, exon capture and single-copy genes. Developing these “omic” resources in conifers is challenging due to their large genome size, long repetitive segments as well as gene and genome duplications, which has limited available reference genomes. However, during the last decades more markers have been made available, with their use depending on the objectives of the studies. At the interspecific level, single-copy genes from nuclear, chloroplast or mitochondrial genomes are a preferred source to be used in studies focusing on phylogeny, biogeography, demographic history and adaptation. At intra-specific level, SSR and SNP markers are useful for a wide range of applications ranging from breeding, genetic conservation and wood trade control to association studies. In this presentation, examples of uses, applications and limitations of various molecular markers will be given for conifers. In particular, markers and results based on the transcriptomes of English yew (*Taxus baccata*), Aleppo and Brutia pines (*Pinus halepensis-brutia* species complex) as well as European black pine (*Pinus nigra*) will be presented.

Implications for the conservation, genetic diversity, and population structure of rosewood (*Aniba rosaedora* Ducke) in the Peruvian Amazon region using ISSR markers / Implicaciones para la conservación, diversidad genética y estructura poblacional de *Aniba rosaedora* Ducke “palo de rosa” en la Amazonia Peruana empleando marcadores ISSR

Stalin Juan Vasquez Guizado¹, Juan Carlos Castro Gomez¹, Muhammad Azhar Nadeem², Fawad Ali³, Tedi Pacheco Gómez⁴, Jhon Antoni Vargas Santillan¹, Esperanza Torres Canales⁴, Gyuhwa Chung⁵, Faheem Shehzad Baloch²

¹Centro de Investigaciones de Recursos Naturales de la Amazonia de la Universidad Nacional de la Amazonia Peruana, Iquitos, Peru; ²Universidad Bolu Abant Izzet Baysal, Bolu, Turkey; ³Universidad Quaid-I-Azam, Islamabad, Pakistan; ⁴Universidad Nacional de la Amazonia Peruana, Iquitos, Peru; ⁵Universidad Nacional de Chonnam, Chonnam, Democratic People's Republic of Korea (stalinvg2388@gmail.com; juanccgomez@yahoo.es; azharjoiya22@gmail.com; fawadali365@gmail.com; tepago@gmail.com; biovargas17@gmail.com; torrescanales2@gmail.com; chung@chonnam.ac.kr; balochfaheem13@gmail.com)

Aniba rosaedora Ducke “palo de rosa” es un árbol forestal en peligro de extinción en la Amazonía, contiene un compuesto aromático de alto valor económico “Linalool” utilizado en la industria de la perfumería. Los bosques naturales de palo de rosa se han agotado considerablemente debido a la sobreexplotación y el uso excesivo de la industria cosmética. Para evaluar la diversidad genética de esta especie se colectaron 90 genotipos provenientes de 8 poblaciones. A partir de ello, se amplificaron 11 marcadores ISSR, obteniendo 375 (99,2 %) bandas polimórficas y un PIC promedio de 0,774. El promedio del número efectivo de alelos (Ne), la diversidad genética de Nei (He) y el índice informativo de Shannon (I) fue 1,485, 0,294 y 0,453 respectivamente. El resultado del AMOVA, reveló una alta variación genética dentro de las poblaciones (88%) y baja entre las poblaciones (12%). La estructura genética, el Neighbor Joining y el análisis principal de coordenadas, agruparon los 90 genotipos de *Aniba rosaedora* Ducke en tres grupos (A, B y C). Se calcularon diversos parámetros de diversidad a nivel interpoblacional que reveló una mayor diversidad genética en el grupo A debido al mayor flujo de genes. El análisis Neighbor Joining unió los grupos A y B, mientras que el grupo C se encontró bastante divergente. Se concluye que las poblaciones de palo de rosa con mayor diversidad genética, deben tener prioridad para la conservación *in situ* y, mientras tanto, deben realizarse esfuerzos serios para recolectar más poblaciones de palo de rosa para la conservación *ex situ*.

D2d: GENETICS, MANAGEMENT AND CONSERVATION OF CERRADO FOREST SPECIES: THEIR CHALLENGES AND ACHIEVEMENTS.

Genetic selection of regenerants of *Astronium fraxinifolium* Schott in a natural population in South Mato Grosso Cerrado degraded area

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil (marcelo.alcantara@unesp.br; maiaracornacini@gmail.com; dgzaruma@gmail.com; josecambuim@yahoo.com.br; rickom.is@gmail.com; pattyfalves@gmail.com; mario.moraes@unesp.br; cl.marino@unesp.br)

The environmental impact caused by large enterprises and construction sites are a challenge for modern society where recovering diversity and plant cover becomes essential. For this, studies with native tree populations are of great importance. In this sense, the objective of this study was to select patterns of *Astronium fraxinifolium* Schott, regenerators of a Cerrado degraded area with high genetic value (BLUP), aiming to provide subsidies for the study of the specie, reforestation and conservation. Within a parcel of degraded area previously demarcated of approximately 170ha, located at the Teaching, Research and Extension Farm - FEPE of the São Paulo State University - UNESP, the population was mapped and divided into a grid of 10 rows by 10 columns. A total of 338 adult specimens were randomly selected and measurements were made of the Diameter at breast height (DAP) and Height. Selections of the genotypes were obtained using the BLUP procedure from the SELEGEM REML / BLUP Software with the supply of known heritability and phenotypic variance values from a progeny test of *A. fraxinifolium* near the site. We selected the 50 best individuals for both characters. The results obtained show a selection gain of 48.59% for DAP and 34.30% for Height. These data show the potential of this regenerating natural population for a possible seed breeding or breeding program, providing possible progenies with superior genetic quality for the recovery of degraded areas, reforestation, conservation or timber production.

Unmanaged tree gene banks may hinder full-potential phenotypic traits expression in *Myracrodruon urundeuva* Fr. Allemão (Anacardiaceae), a highly endangered Cerrado timber species but yet showing genetic variability.

Luciane Sato^{1,2}, José Cambuim¹, Daniele Zulian¹, Francieli Saul¹, Lara Riva¹, José Oliveira-Júnior³, João Antônio Andrade¹, Damase Khasa², Miguel Freitas^{4,1}, Mário Moraes¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil; ²Université Laval, Québec, Canada; ³FAIT, Itapeva, Brazil; ⁴Instituto Florestal de São Paulo, São Paulo, Brasil (luciane_sato@yahoo.com.br; josecambuim@yahoo.com.br; danizullian@gmail.com; francieli_eng.ambiental@yahoo.com.br; lara-comar@hotmail.com; jose089797@hotmail.com; joao.ac.andrade@unesp.br; damase.khasa@ibis.ulaval.ca; miguellmfreitas@yahoo.com.br; mario.moraes@unesp.br)

Ex situ conservation in gene banks is an important strategy to safeguard endangered plant species avoiding the narrowing of species genetic base. The South American native timber species *Myracrodruon urundeuva* has experienced rampant exploitation and destruction. Its gene bank (BAG-A) was set up in 1987 in West Central Brazil and currently has 20 preserved Brazilian populations from distinct biomes in different common garden experiments. This study aimed at assessing genetic variability of two *ex situ* conserved *M. urundeuva* Cerrado populations -25 local (S) and 25 non local (A)- based on their progenies (6 replications, 25 families/experiment, 8 plants/plot). Variance components and genetic parameters were estimated using mixed linear models based on height (h), diameter at breast height (DBH) and mean crown diameter (MCD). Deviance analyses were conducted to verify significance of predicted models. Differences in progenies' traits were neither explained by genotypes (χ^2 values for DF = 1; α = 1%: (A) h = 0.2, DBH = 0.42, MCD = 0.37; (S) h = 2.31, DBH = 3.25, MCD = 2.92) nor by origin (χ^2 values for DF = 1; α = 1%: h = 0.3, DBH = 1.90, MCD = 0.00). Significance was found for all traits for block effects (χ^2 values for DF = 1; α = 1%: (A) h = 236.54, DBH = 152.28, MCD = 150.11; (S) h = 186.82, DBH = 93.91, MCD = 113.54). Results suggest genetic variability may reveal higher in BAG-A if specific management is established to counteract environmental effects

Flowering in test of provenance and progenies of *Astronium fraxinifolium* Schott (Anacardiaceae) in three reproductive events

Maiara Ribeiro Cornacini¹, Marcelo Augusto Mendes Alcantara¹, Janaina Rodrigues da Silva², Aparecida Juliana Martins Corrêa³, José Cambuim², Ricardo de Oliveira Manoel¹, Patricia Ferreira Alves², Ananda Virginia de Aguiar⁴, Mário Luiz Teixeira de Moraes², Celso Luis Marino¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil; ³Universidade Federal de São Carlos, Sorocaba, Brasil; ⁴Embrapa Florestas, Colombo, Brasil (maiara.cornacini@gmail.com; marcelo.alcantara@unesp.br; janainars_t@hotmail.com; jumartinscorrea@gmail.com; josecambuim@yahoo.com.br; rickom.is@gmail.com; pattyfalves@gmail.com; ananda.aguiar@embrapa.br; mario.moraes@unesp.br; cl.marino@unesp.br)

The unbalanced sex ratio in dioecious species implies the unequal contribution of the number of gametes, thus reducing the effective population size. In this sense, we did the sexual identification of individuals of *Astronium fraxinifolium*, a timber specie belonging to Anacardiaceae family, dioecious, and that naturally inhabits the Cerrado. The individuals are located in a provenance and progeny test at the UNESP's farm, in Selvíria – MS, Brazil, installed in 1996 in a randomized complete block design with 30 families from Mato Grosso do Sul (MS) and 30 from São Paulo (SP), 5 replicates and 10 plants per plot, spaced 3 m × 1.5 m, alternating with *Jacaranda cuspidifolia*. The sexual identification of the trees occurred in 2014, 2017 and 2018 based on the visualization of the male and female flowers, we observed at 130, 186 and 335 trees from SP and 194, 331 and 542 trees from MS respectively. In all the events the provenance of MS had a higher flowering percentage (16%, 28% and 47%) than SP (11%, 17% and 31%). The sex ratio was biased for the male flowers: 2.34, 2.0 and 1.14 for MS and 2.78, 1.69 and 1.39 for SP. We observed a flowering increase and a tendency to a balance between the sex ratio. This could occur for some reasons: by the natural decrease of *J. cuspidifolia* in the test, by a later maturation of some individuals or by the age of individuals, so further investigations are necessary to better understand the species reproductive biology.

Genetic variation in and between progenies of *Myracrodruon urundeuva* in anthropized areas / Comportamento da variação genética entre e dentro de procedências e progênes de *Myracrodruon urundeuva* em áreas antropizadas

Lara Comar Riva¹, Francieli Alves Caldeira Saul¹, Luciane Missae Sato¹, José Cambuim¹, Marcela Aparecida de Moraes², Mario Luiz Teixeira de Moraes¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil; ²Universidade de São Paulo, Ribeirão Preto, Brasil; ¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil (lara-comar@hotmail.com; francieli_eng.ambiental@yahoo.com.br; luciane_sato@yahoo.com.br; josecambuim@yahoo.com.br; marcela.apmoraes@gmail.com; mario.moraes@unesp.br)

A *M. urundeuva* é uma espécie arbórea endêmica da América do Sul, conhecida pela madeira. O objetivo desse estudo foi avaliar o comportamento e a variação genética para a forma do fuste em um teste de procedências (Bauru/SP e Selvíria/MS) e progênes aos 31 anos de idade. O experimento foi instalado na Fazenda de Ensino, Pesquisa e Extensão, da FEIS/UNESP, Selvíria-MS, utilizando o delineamento experimental de blocos casualizados, com 28 progênes de cada procedência, 3 repetições e 10 plantas por parcela. As estimativas dos parâmetros genéticos foram obtidas a partir do procedimento REML/BLUP, SELEGEN. A forma do fuste não apresentou diferenças significativas entre procedências e progênes, apenas nas parcelas, sugerindo a influência ambiental no experimento. Isto se confirma com os baixos valores de herdabilidade (menor que 0,1), mostrando pouco controle genético, e os altos valores do coeficiente experimental e coeficiente de determinação dos efeitos de parcelas (acima de 10%). Já o coeficiente de variação genética foi maior na procedência de Selvíria (5,26%) do que em Bauru (1,60%). A arquitetura das plantas não foi influenciada pelas procedências, mostrando que a maioria das plantas teve a tendência de bifurcação acima de 1,30 m com diâmetro igual ao fuste principal e tortuosidade acentuada abaixo do DAP. Em razão dos baixos valores obtidos nas herdabilidades a próxima geração de melhoramento deve apresentar baixos incrementos médios para a forma do fuste, devido este caráter apresentar baixo controle genético, porém, apresentará níveis apropriados de variabilidade genética, justificando a sua conservação *ex situ*.

Micro propagation of *Nothapodytes nimmoniana* Graham through adventitious mode of regeneration

P. V. Somashekar¹, K. C. Nitesh¹, Malllesh Lingachar¹, K. T. Chandrashekar¹

¹Sandalwood Society of India, Bangalore, India (drsomashekarpv@gmail.com; niteshosmane@gmail.com; malllesh@itrads.com; ktchandrashekar2@gmail.com)

Nothapodytes nimmoniana or *Nothapodytes foetida* Syn. *Mappia foetida* belonging to Icacinaceae family is an endangered tree species of Western Ghats of India. It is an excellent source of quinoline alkaloids, Camptothecin (CPT) and 9-methoxy camptothecin (9-OMeCPT) used clinically as anticancer agents for the treatment of solid tumors. Over exploitation for raw material of CPT from *N. nimmoniana* and habitat destruction has led to population decline by 50-80% in the last decade. Development of *in vitro* propagation and conservation techniques are highly desirable as there is no reported cultivation or conservation protocols of this species. In this study rapid *in vitro* cloning of *N. nimmoniana* through adventitious mode of regeneration was tried. MS medium supplemented

with additives and various PGRs were tried to optimize the protocol for multiple shoot induction and multiplication. *In vitro* germinated seedlings were used as a source of explant such as leaf, nodal, intermodal, root, cotyledon and hypocotyls. Only leaf segments and hypocotyls induced multiple shoots. Among the various cytokinins and its concentrations tested, MS agar gelled medium supplemented with additives. Hypocotyl as an explant showed base swelling in the medium containing additives + BAP 1.0mg/l and BAP 5.0 mg/l without shoots at initial stage, where as medium with additives + BAP 2.5mg/l showed single shoot of 1.5cm in length with dwarf leaf and well developed roots. Sub culturing of shoots was found essential for further shoot multiplication on fresh medium within 3 weeks interval.

Genetic variation for morphological traits of *Handroanthus impetiginosus* in active germplasm bank

Camila Amaro dos Santos¹, Maiara Ribeiro Cornacini¹, Marcelo Augusto Mendes Alcantara¹, Marcos Vinicius e Silva Bottaro¹, Ana Carla Farias Pardo¹, Darlin Gonzalez Zaruma¹, Bruno César Rossini¹, José Cambuim², Alexandre Marques da Silva², Mário Luiz Teixeira de Moraes³, Celso Luis Marino¹
¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil (camilaamaro912@gmail.com; maiara.cornacini@gmail.com; marcelo.alcantara@unesp.br; m.franceis@hotmail.com; ana_carlafp@hotmail.com; dgzaruma@gmail.com; bruno.rossini@unesp.br; josecambuim@yahoo.com.br; alexandre.marques@unesp.br; mario.moraes@unesp.br; cl.marino@unesp.br)

Handroanthus impetiginosus (ipê roxo) has great economic and ecological importance. Due to the quality of wood, it's one of the most hunted species in Brazil and the second most expensive wood. Thus, the work estimated the genetic variation of a population of *H. impetiginosus* located in the Active Germplasm Bank (BAG), at the city of Rosana - SP. The BAG was introduced in the year 2000 and has 32 species with 30 families, three replicates and plots with eight plants in linear form, at spacing of 1.5 m × 3.0 m. Survival, diameter at breast height (DAP) and height were measured at 17 years old. Estimates of variance components and genetic parameters were obtained using the genetic-statistical software SELEGEN-REML / BLUP. We observed a good adaptation of the population to the place with survival above 75%. The DAP mean was 9.34 cm and height was 7.78 m. The coefficient of genetic variation for DAP was 9.83% and for height of 2.69%. Among the traits the DAP was considered as a candidate to guide the selection of individuals in future strategies for seed collection or thinning, as we verified intermediary values of coefficient of relative variation (0.26) and accuracy (0.43). The effective population size was 101.2 which provides for the conservation of alleles with frequency ≥ 6%. Therefore, the results indicate that there is genetic variability and the population may be used as a basis for future programs of breeding and conservation for the specie.

Genetic conservation of *Hymenaea stigonocarpa* Mart ex Hayne in the Bolsão region of Mato Grosso do Sul, Brazil / Conservação genética de *Hymenaea stigonocarpa* Mart ex Hayne na região do Bolsão Sul-Mato-Grossense

Darlin Gonzalez Zaruma¹, Fernando Brandão de Andrade², Murilo da Serra Silva³, José Cambuim⁴, Silvelise Pupin⁴, Marcela Aparecida de Moraes⁵, Mario Luiz Teixeira de Moraes⁴

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil; ²Companhia Energética de São paulo, CESP, Presidente Epitácio, Brasil; ³Instituto Federal, Marabá, Brasil; ⁴Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil; ⁵Universidade de São Paulo, Ribeirão Preto, Brasil (dgzaruma@gmail.com; fernando.brandao@cesp.com.br; mserrasilva@yahoo.com.br; josecambuim@yahoo.com.br; silvelise.pupin@gmail.com; ma_apmoraes@yahoo.com.br; teixeira@agr.feis.unesp.br)

O aumento dos remanescentes causados pela fragmentação do bioma Cerrado está acarretando o isolamento das populações arbóreas e diminuição do fluxo gênico entre elas. Nesse contexto o conhecimento sobre os parâmetros genéticos relacionados aos caracteres silviculturais contribui para a melhor escolha de estratégias de conservação *in situ* e *ex situ*. *Hymenaea stigonocarpa* é uma espécie restrita à Caatinga e ao Cerrado da região central e sudoeste do Brasil, de importância ecológica, econômica, social e cultural. O objetivo do presente estudo foi avaliar a variação genética para caracteres de crescimento de *H. stigonocarpa*, em um teste de progênies instalado em Selvíria-MS (*ex situ*) em junho de 2013, a partir de 41 árvores matrizes de uma população da Reserva Particular do Patrimônio Natural em Brasilândia-MS (*in situ*). O delineamento experimental foi de blocos casualizados, com uma planta por parcela, 20 repetições, no espaçamento de 3,0 × 1,5m. Foram obtidos dados de altura (ALT), diâmetro à altura do peito (DAP) e sobrevivência (SOB) aos 4 anos de idade. O valor médio para ALT, DAP e SOB foi de 2,6 m, 3,3 cm e 74,7%, respectivamente, que indicam boa adaptação da espécie ao local. O coeficiente de variação genética () para os caracteres ALT e DAP foi de 42,8 e 27,2%, respectivamente e a herdabilidade individual (), para esses dois caracteres, variou de 0,46 a 0,32, respectivamente. Desse modo, as progênies apresentam bom desempenho e variação genética proporcional a população de referência (Brasilândia), o que permite que o teste de progênies possa ser utilizado em programas de conservação.

Genetic variation for growth traits in progenies of *Myracrodruon urundeuva* in Selvíria, Brazil / Variação genética para caracteres de crescimento em progênies de *Myracrodruon urundeuva* em Selvíria, Brasil

Francieli Alves Caldeira Saul¹, Daniele Fernanda Zulian¹, José Cambuim¹, Alexandre Marques da Silva¹, Maiara Ribeiro Cornacini², Regivan Antônio de Saul¹, Mario Luiz Teixeira de Moraes¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Botucatu, Brasil (francieli_eng.ambiental@yahoo.com.br; danielezullian@gmail.com; josecambuim@yahoo.com.br; alexandre.marques@unesp.br; maiara.cornacini@gmail.com; regivanantonio@zipmail.com.br; mario.moraes@unesp.br)

A *Myracrodruon urundeuva* possui ampla distribuição no Brasil, pertence à família Anacardiaceae. Atualmente a espécie encontra-se em extinção, sendo fundamental estratégias que assegurem sua conservação genética. Verificou-se a variação genética em um teste de progênies de *M. urundeuva*. O teste foi instalado em outubro de 2017 na região de Selvíria-MS. O delineamento experimental utilizado foi o de blocos casualizados: uma planta por parcela, 48 repetições, no espaçamento de 8,0 m x 4,0 m x 1,0 m, consorciada com três espécies. Foram utilizadas 45 progênies, procedentes de árvores matrizes da região de Iturama-MG. Aos 12 meses de idade foram obtidos dados de altura (ALT), diâmetro à 30 cm do solo (D30) e sobrevivência (SOB). As estimativas de componentes de variância e parâmetros genéticos foram obtidas pelo método da máxima verossimilhança restrita e melhor predição linear não viciada (REML/BLUP). A SOB foi alta (>87,0 %), a média de ALT e D30 foi de 95 cm e 9,3 mm, respectivamente, apresentando boa adaptação inicial, contribuindo com a conservação da espécie. Foram obtidas diferenças significativas entre progênies a 1% de significância, para todos os caracteres analisados. Para o caráter ALT, o coeficiente de herdabilidade em nível de média de progênies, acurácia e coeficiente de variação genética em nível de progênies foram de 0,62; 0,78 e 10,2%. Para o D30, os valores foram de 0,57; 0,76 e 8,0%. A variação genética detectada para os caracteres ALT e D30 é um indicativo de que essa população possa ser utilizada em programas de conservação e melhoramento genético.

Sex ratio of a base population of *Myracrodruon urundeuva* in Selvíria, Mato Grosso do Sul, Brazil / Proporção sexual de uma população base de *Myracrodruon urundeuva* em Selvíria, MS

Daniele Fernanda Zulian¹, Francieli Alves Caldeira Saul¹, José Oliveira Júnior², Luciane Missae Sato³, José Cambuim¹, Lorena Frigini Moro Capo¹, Mario Luiz Teixeira de Moraes¹, Ananda Virginia de Aguiar⁴

¹Faculdade de Engenharia de Ilha Solteira, Unesp, Ilha Solteira, Brazil; ²Faculdade de Ciências Sociais e Agrárias de Itapeva, Itapeva, Brazil; ³Faculdade de Ciências Sociais e Agrárias de Itapeva, Ilha Solteira, Brazil; ⁴Embrapa Florestas, Colombo, Brazil (danizullian@gmail.com; francieli_eng.ambiental@yahoo.com.br; ze0897@gmail.com; luciane_sato@yahoo.com.br; josecambuim@yahoo.com.br; lorenafmc@gmail.com; mario.moraes@unesp.br; ananda.aguiar@embrapa.br)

Nativa da América do Sul, a *M. urundeuva* ocorre em diferentes formações florestais. A espécie apresenta uma madeira de alto valor econômico, e devido à exploração predatória de sua madeira foi incluída na lista oficial do IBAMA como espécie ameaçada de extinção. É uma espécie dioica, e os povoamentos florestais exibem desvios da expectativa de equilíbrio de 1:1 da razão sexual. Assim, a proporção sexual dos indivíduos em uma população base de *M. urundeuva* aos 31 anos de idade foi estimada. O teste foi instalado em dezembro de 1987 na Fazenda de Ensino, Pesquisa e Extensão (FEPE/Unesp), em Selvíria – MS. O povoamento é composto por 28 árvores matrizes de duas populações, Bauru - SP e Selvíria – MS. O sistema de plantio foi aleatório, no espaçamento 3 X 3 m, com um total de 1.662 indivíduos. Em agosto de 2018, foi realizada a sexagem (macho e fêmea) dos indivíduos em floração. A porcentagem de florescimento foi de 89,3 % (1.210 indivíduos). Isso indica uma boa adaptação da espécie ao local de plantio, e que as condições ambientais foram favoráveis para este evento reprodutivo. A razão sexual entre plantas femininas e masculinas foi de 0,55 (1,2 ♀:1♂). A população base de *M. urundeuva* aos 31 anos apresenta uma proporção sexual próxima ao encontrado na natureza (1 ♀:1♂). Esse resultado contribuirá de maneira positiva para o sucesso reprodutivo da espécie, e consequentemente para sua conservação e melhoramento genético, principalmente, se no manejo do povoamento esta razão sexual for mantida aos longos dos anos.

Genetic correlations and groupings in progenies of *Myracrodruon urundeuva* / Correlações genéticas e agrupamentos em progênies de *Myracrodruon urundeuva*

Francieli Alves Caldeira Saul¹, Daniele Fernanda Zulian¹, Luciane Missae Sato¹, Lara Comar Riva¹, José Cambuim¹, Alexandre Marques da Silva¹, Mario Luiz Teixeira de Moraes¹

¹Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil (francieli_eng.ambiental@yahoo.com.br; danielezullian@gmail.com; luciane_sato@yahoo.com.br; lara-comar@hotmail.com; josecambuim@yahoo.com.br; alexandre.marques@unesp.br; mario.moraes@unesp.br)

Myracrodruon urundeuva possui alto valor econômico pela excelente qualidade da madeira, estudos de correlações entre caracteres de importância econômica têm sido uma ferramenta fundamental para trabalhos de conservação e melhoramento genético. O trabalho verificou a correlação genética entre caracteres de crescimento e aplicou-se um teste de agrupamento em um teste de progênies de polinização aberta de *M. urundeuva*. O teste foi instalado na Fazenda de Ensino, Pesquisa e Extensão (FEPE/Unesp), em Selvíria-MS, em outubro de 2017. O delineamento experimental foi o de blocos casualizados: 45 tratamentos (progênies), uma planta por parcela e 48 repetições, no espaçamento de 8,0 m x 4,0 m x 1,0 m, consorciada com três espécies. As sementes das árvores matrizes foram coletadas na região de Iturama-MG. Aos 12 meses de idade foram obtidos dados de altura (ALT), diâmetro à 30 cm do solo (D30). As correlações genéticas entre os caracteres e análise de agrupamento pelo método de otimização de Tocher foram realizadas a partir do procedimento REML/BLUP. A estimativa do coeficiente de correlação genética entre os caracteres ALT e D30 foi alta (89,4%). Isso sugere que a possibilidade de seleção em um caráter e a obtenção de ganhos indiretos em outro é relativamente alta. O agrupamento de Tocher com base na distância de Mahalanobis, possibilitou a formação de sete grupos distintos, com concentração de aproximadamente 66,66% das progênies no primeiro grupo. Indivíduos mais contrastantes e produtivos obtidos a partir do agrupamento de Tocher serão selecionados para cruzamentos, contribuindo para o melhoramento genético da espécie.

Diversity of flora composition in a restored area of Cerrado / Diversidade da composição florística de uma área restaurada no Cerrado

Francieudes Pereira do Nascimento¹, Sybelle Barreira¹

¹Universidade Federal de Goiás, Goiânia, Brazil (framurilo@gmail.com; sybelle.barreira@gmail.com)

Nas últimas décadas, o Cerrado perdeu mais de 50% da vegetação original pela expansão da agricultura e pecuária. A flora dos remanescentes encontra-se bastante ameaçada, com o desaparecimento de espécies nativas endêmicas ao longo do tempo. Diversos fatores atuam na mudança da composição florística e na densidade populacional destes fragmentos, como aqueles ligados as taxas de ingresso, de recrutamento, de mortalidade e crescimento, bem como aqueles relacionados às perturbações que podem ocorrer na comunidade vegetal, como os incêndios. Diante disso, o objetivo deste trabalho foi avaliar as alterações na diversidade florística, com base nos levantamentos passados e atuais, com isso, podendo se fazer uma inferência sobre a efetividade da restauração. Foram identificados e mensurados todos os indivíduos lenhosos com DAP maior que 15 cm e coletado a altura. A composição, riqueza e diversidade de espécies lenhosas foram comparadas entre os anos de avaliação, a partir do cálculo do índice de diversidade Shanon, já para avaliar a abundância relativa das espécies, foi calculado Equabilidade de Pielou e por fim, foi usado índice de dominância de Simpson, já que este dá maior peso às espécies comuns. Não houve variação e, para diversidade o resultado encontrado foi de 10,392, portanto, tal resultado indica que não houve aumento na diversidade de espécies em relação ao senso anterior, porém ainda há diversidade de espécies na área. Sendo assim, foi possível verificar ao longo do tempo que não houve o aparecimento de novas espécies. Contudo, medidas são necessárias para que se garanta o equilíbrio dinâmico.

D2f: INTEGRATING TREE RESISTANCE DEVELOPMENT WITH DEEPER UNDERSTANDING OF LOCAL AND LONG-DISTANCE MOVEMENT OF PEST POPULATIONS TO IMPROVE MANAGEMENT OF INVASIVE PESTS

Integration of rapid phenotyping technologies into management of invasive alien forest pathogens and insect pests: realistic approach or false hope?

Pierluigi (Enrico) Bonello¹

¹The Ohio State University, Columbus, OH, USA (bonello.2@osu.edu)

The classic conceptual triangle that models the main, necessary factors contributing to plant disease or insect outbreaks includes a susceptible host, a virulent or aggressive pathogen/pest, and a conducive environment. If even just one of the three factors is missing, then disease or insect outbreak will not occur. This model functions very well in agriculture, where the three factors are often controllable in one way or another. The same cannot be said for forests, where the environment is hardly modifiable (except for silvicultural adjustments in some specific cases) and where pathogen inoculum load/insect populations are almost never controllable. This situation suggests that very often the only leverage we have is on the host side of the equation, i.e. host resistance. Yet, the vast majority of current approaches to dealing with invasive, endemic or alien forest pathogens and insects is to tackle pathogen/insect populations, sometimes silviculture, and very rarely, and often only as a last resort, host resistance. This approach, however, belies a poor understanding of how far the science of tree resistance selection and development has progressed in the last 10-15 years. Therefore, I propose that host resistance should be a first response to dealing with invasive forest pathogens and insects, supported by several studies demonstrating that resistance phenotyping can be quickly accomplished using chemometrics. These tools present very promising opportunities to incorporate host resistance up front in a holistic and arguably much more effective future approach to disease and insect pest management in forest environments.

Prospects of gene manipulation and genome editing for understanding tree defense mechanisms

Chung-Jui Tsai¹, Maria Ortega¹, Chhana Ullah², W. Patrick Bewg¹, Scott Harding¹

¹University of Georgia, Athens, USA; ²Max Planck Institute for Chemical Ecology, Jena, Germany (cjtsai@uga.edu; ortega77@uga.edu; cullah@jce.mpg.de; bewg@uga.edu; sharding@uga.edu)

Trees in natural and managed forests face constant threats of insects and pathogens, made worse by introduced pests and increasing frequency and severity of abiotic stress due to climate change. Understanding the mechanisms of tree-pest interactions and defense strategies can inform pest management practices, and shed light on breeding for resilient trees by conventional, molecular or biotechnological means. This presentation will highlight the utility of gene manipulation and genome editing in *Populus* for investigating biotic and abiotic stress responses, with case studies of chemical as well as physical defense traits. The defense hormone salicylic acid has a well-established role in disease resistance of herbaceous annuals against biotrophs; however, a similar role in trees remains equivocal. *Populus* differs from *Arabidopsis* in many aspects of salicylic acid biosynthesis, signaling and homeostasis, and in growth-defense tradeoffs. Specifically, elevated salicylic acid in transgenic poplar, but not *Arabidopsis*, activates biosynthesis of condensed tannins—flavonoid end products that possess antimicrobial activities against several fungal pathogens. Identification of tree-specific mechanisms like this can offer more relevant gene targets for molecular breeding or transgenic improvement. With the advent of CRISPR genome editing technology, it is now possible to obtain null mutants in long-lived trees with unprecedented precision and efficiency. We show that knockout of three trichome-regulating MYB genes in poplar resulted in glabrous mutants with altered photosynthetic properties, metabolite profiles and biotic and abiotic stress responses. These plants facilitate dissection of the roles trichomes play in physical and chemical defenses.

Global movement of *Eucalyptus* pathogens successfully managed by species selection or resistance breeding

Treena Burgess¹, Michael J. Wingfield²

¹Murdoch University, Perth, Australia; ²University of Pretoria, Pretoria, South Africa (tburgess@murdoch.edu.au; mike.wingfield@fabi.up.ac.za)

Eucalypts constitute the largest component of global hardwood plantations, contributing substantially to the economies of many countries. But they are increasingly plagued by pathogens, all of which are inconsequential in the native forests. Eucalypts provide a particularly interesting model to study tree diseases because plantations have been established in countries where these trees are non-native but also in Australia where they are commonly established adjacent to native eucalypt forests. These situations present opportunities for pathogen movement between the two systems. Of the many eucalypt diseases found in plantations globally, the leaf diseases caused by pathogens in the Teratosphaeriaceae have resulted in the most serious damage. Our research groups have conducted several population genetic studies showing how these pathogens have been distributed globally with gemplasm. For the most part, the resulting diseases have been successfully managed through the deployment of resistant clones. However, when a new pathogen emerges such as in the case of *Teratosphaeria pseudo-eucalypti*, a considerable period of time is needed to develop disease-resistant planting stock. The selection for, as well as the durability of, this resistance is dependent upon the genetic diversity of the pathogen. It is consequently essential to ensure vigilant biosecurity is established and/or maintained to prevent introductions of pathogens to new areas. It is equally important to prevent the introduction of new genotypes of pathogens that have already become established as invasive aliens as these can contribute to the rapid breakdown of resistance in planting stock.

The population structure and genetic diversity of the pine needle pathogen, *Dothistroma pini* in Europe

Ariska van der Nest¹, Michael J. Wingfield¹, Vimbai I Siziba¹, Petra Vesela², Irene Barnes¹

¹Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, South Africa; ²Department of Forest Protection and Wildlife Management, Mendel University, Czech Republic Brno (ariska.vandernest@fabi.up.ac.za; mike.wingfield@fabi.up.ac.za; vi.siziba@gmail.com; petra.vesela@mendelu.cz; irene.barnes@fabi.up.ac.za)

Dothistroma needle blight is an important disease of *Pinus* species that is caused by two different pathogens, *Dothistroma pini* and *D. septosporum*. *Dothistroma pini* is known only from the northeastern USA and Europe. There is a distinct lack of knowledge regarding the population structure and diversity of this pathogen or its origin. Recently, sixteen microsatellite markers were developed for *D. pini*. This provided an opportunity to investigate the population diversity and structure and to determine its mode of reproduction for populations that have been collected in twelve countries on eight different hosts in Europe over a period of twelve years. In total, 285 isolates from Belgium, Czech Republic, France, Hungary, Romania, Russia, Serbia, Slovakia, Slovenia, Spain, Switzerland

and Ukraine were screened with microsatellite markers and species-specific mating type markers. A total of 120 unique multilocus haplotypes were identified. AMOVA results suggests that the population structure is not influenced by host distribution. Populations from Mykolaiv Oblast and Hola Prystan in Ukraine displayed the highest level of genetic diversity followed by populations from Russia, Spain and La Bouyale in France. Both mating types were detected in most populations but not those from Russia, Slovenia and a population from Mykolaiv Oblast in Ukraine. Evidence for sexual recombination, was however, only supported in the population from Spain. The observed population structure and several shared haplotypes between non-bordering countries in Europe suggests a human influence on the dispersal of the pathogen on the continent.

Perspectives of biotic and abiotic molecular studies to improve teak tree

Helaine Carrer¹, Perla Oliveira¹, Fernando Hurtado¹, Esteban Galeano²

¹Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo, Piracicaba, Brasil; ²University of Alberta, Edmonton, Canada (hecarrer@usp.br; perla.oliveira@usp.br; fermathur1992@usp.br; galeanog@ualberta.ca)

Teak tree (*Tectona grandis*L.f.) is a tropical hardwood tree species, belongs to Lamiaceae family and it is native to South and Southeast Asia. Teak has been introduced in several tropical countries in Latin America during the last 50 years. This tree has a high value in the timber trade for manufacturing of woody products due to its extraordinary qualities of color, density and durability. Despite the importance of this species, genetic and molecular studies available are limited. Water deficit and diseases as rust and teak canker are the main challenges for the improvement of teak productivity. Molecular studies of transcriptomic profiling and gene expression are essential to improve knowledge of genes related to water deficit tolerance and disease resistance. In this respect, using RNA-seq, it was performed a total of 462,260 transcripts from different organs such as seedlings, leaves, flowers, root, stem and branch. All of them were phylogenetically grouped with several gymnosperms and flowering plants. In this presentation, teak molecular genetic improvement, marker-assisted selection and plant transformation research will be presented.

Insights from population genetics and genomics for the management of the invasive pest *Sirex noctilio*

Bernard Slippers¹

¹Forestry and Agricultural Biotechnology Institute, University of Pretoria, 0002, South Africa (bernard.slippers@fabi.up.ac.za)

The Sirex woodwasp, *Sirex noctilio*, is a serious invasive forest pest around the world. Information from population genetics studies over the last two decades and the emerging information from genomics studies are transforming the understanding of the biology of this pest and its invasion, including options for management. When it was first introduced, population genetics revealed the extensive distribution of clonal lineages of the mutualistic fungus, *Amylostereum areolatum*, associated with the wasp. These lineages were sometimes distributed across continents, highlighting the routes of spread of the wasp. Subsequent studies have revealed multiple sources of introduction in most environments, with complexity increasing over time. This is in contrast to the reduced diversity in biocontrol agents in these same environments, bar some notable exceptions in presumably native and some non-native environments. The patterns in the diversity in populations of the wasp, fungus and biocontrol agents and their interactions have also been shown to have relevance to the management of the wasp. Recent genomics studies are now unlocking insights into reproductive and physiological mechanisms that influence the interactions amongst these symbionts, including previously unknown symbionts. This information is also making it possible to explore the role of gene editing, such as through CRISPR, for the management of the wasp in invasive populations.

D2p: CONSERVATION, DOMESTICATION AND BREEDING OF NATIVE SPECIES

Mating patterns of *Virola surinamensis* trees reveal Amazonian estuary populations might be under risk

Taruhim Miranda Cardoso Quadros¹, Fátima Conceição Marquez Piña-Rodrigues², Laura Luciana de Melo Moreira Silva³, Ivonir Piotrowski², Miguel Luiz Menezes Freitas⁴, Karina Martins⁵

¹Universidade Estadual de Santa Cruz, Centro de Biotecnologia e Genética, Ilhéus, Brazil; ²Universidade Federal de São Carlos, Departamento de Ciências Ambientais, Sorocaba, Brazil; ³Universidade Federal de São Carlos, Sorocaba, Brazil; ⁴Instituto Florestal de São Paulo, Setor de Melhoramento Florestal e Genética da Conservação, São Paulo, Brazil; ⁵Universidade Federal de São Carlos, Departamento de Biologia, Sorocaba, Brazil (talumcq@hotmail.com; fpina@ufscar.br; laurasilva_@live.com; ivonir@ufscar.br; miguellmfreitas@yahoo.com.br; kmartins@ufscar.br)

Virola surinamensis is an Amazonian tree species commonly found in floodplain areas. The species' high economic value arises from its several commercial uses, varying from seed oil for cosmetics destinations to woody products. Consequently, *virola*'s natural populations in Brazil have been intensively exploited, leading the species to a status of endangered. Although characterized as dioecious, a high level of homozygosity was found in Eastern Amazon remaining adult populations, possibly as a result of extensive logging. In order to understand the high level of inbreeding, this study aimed to evaluate seeds sampled in eleven *V. surinamensis* seed trees in remaining populations located in two areas (Cotijuba and Cameté) in Pará state, Brazil. Offspring from eleven maternal trees (12 to 20 seeds per tree) were sampled in seed traps and genotyped for seven microsatellite loci. Inbreeding coefficients corrected for null alleles were very high, $FIS = 0.233$ in Cameté and $FIS = 0.244$ in Cotijuba. This result may reflect the impact of drastic reduction in population sizes, in which few remnant trees effectively mate. The average coancestry coefficient within fruit traps was 0.047 (0.024 - 0.079 range) in Cameté and 0.086 in Cotijuba (0.025 - 0.159 range). Significant spatial genetic structure was detected, with low relatedness occurring in seed trees with distances smaller than 23m in Cotijuba and 47m in Cameté ($\rho_{ij} = 0.093$ and 0.052, respectively). Overall, our results suggest that non-random mating pattern might be due to the small number of mating adults, precluding long term persistence of these populations. Funding: TMCQ scholarship by São Paulo Research Foundation (FAPESP 2016/19618-2)

Environmental and genetic characterization of maté (*Ilex paraguariensis*) for conservation and sustainable use of genetic resources / Proposta para caracterização ambiental e genética de erva-mate com vistas à conservação e uso sustentável dos recursos genéticos

Marcos Silveira Wrege¹, Valderês Aparecida de Sousa¹, Márcia Toffani Simão Soares¹, Elenice Fritzsos¹, Ananda Virginia de Aguiar¹, Itamar Antonio Bognola¹, João Bosco Gomes¹, Leticia Penno de Sousa², Cristiane Vieira Helm¹, Patricia Póvoa de Mattos¹

¹Embrapa Florestas, Colombo, Brasil; ²Embrapa Clima Temperado, Pelotas, Brasil (marcos.wrege@embrapa.br; valderes.sousa@embrapa.br; marcia.toffani@embrapa.br; elenice.fritzsos@embrapa.br; ananda.aguiar@embrapa.br; itamar.bognola@embrapa.br; joao.bv.gomes@embrapa.br; leticia.penno@embrapa.br; cristiane.helm@embrapa.br; patricia.mattos@embrapa.br)

Ilex paraguariensis St-Hil. está predominantemente no bioma Mata Atlântica, na Floresta Ombrófila Mista, sendo vulnerável às mudanças climáticas. O acordo firmado pelo Brasil na COP21 enfatiza a necessidade de 'incrementar a capacidade nacional em conservação e uso sustentável da biodiversidade'. Com base nesta demanda, desenvolvemos uma metodologia orientada à caracterização ambiental e genética de populações de *I. paraguariensis*, como subsídio à conservação e uso sustentável. A proposta visa determinar como os fatores ambientais e genéticos influenciam nas zonas de ocorrência das populações e de que forma as mudanças climáticas influenciarão no seu deslocamento, em sua base genética e adaptação na região de ocorrência, nos bancos de germoplasma e nos plantios. O trabalho envolveu o seguinte passo-a-passo: 1) definição das margens de ocorrência e seleção de regiões prioritárias para amostragens; 2) caracterização genética das populações; 3) caracterização das propriedades físico-químicas do solo; 4) determinação dos compostos fitoquímicos e 6) identificação dos nichos ecológicos das populações. Ao agregar multidisciplinariedade na definição de zonas, parâmetros e novos métodos de amostragens de material genético, incrementou-se a a eficácia, acurácia e segurança no processo de geração de informações quanto ao comportamento da espécie. Os resultados indicam que a maior parte das populações de *I. paraguariensis* ocorre em regiões com características parecidas; uma minoria ocorre em situações distintas, as quais devem ter prioridade para coleta de germoplasma e testes experimentais, pois a chance de encontrar indivíduos melhor adaptados às regiões típicas é maior. A metodologia desenvolvida é passível de aplicação a espécies semelhantes, com pequenas adaptações.

Genetic material production unit for *Pinus cembroides* Zucc / Unidad Productora de Germoplasma Forestal de *Pinus cembroides* Zucc

Juan Carlos Cuevas Cruz¹

¹Universidad Autónoma Chapingo, Texcoco, Estado de México, Mexico (jcuevas_chapingo@hotmail.com)

Los bosques de *Pinus cembroides* Zucc. son característicos de las zonas áridas del norte y centro de México, es la principal especie de pinos piñoneros del país, crece sobre laderas de montaña en suelos delgados y pedregosos; por su amplia adaptabilidad y resistencia a condiciones extremas ha sido utilizada para proyectos de reforestación y restauración ecológica. Con el propósito de conservar y producir germoplasma de procedencia y calidad fenotípica conocida de *Pinus cembroides*, en el 2018 se estableció y procedió a la certificación de una Unidad Productora de Germoplasma Forestal (UPGF), Fuente Identificada-Rodal-Semillero de ocho hectáreas, ubicada en los Bienes Comunales de Sombrerete, Municipio de Cadereyta, Querétaro, México. Mediante ésta estrategia de conservación se busca beneficiar a 224 comuneros y a sus familias, dedicados a la recolección y venta de piñón. El total de individuos de la UPGF es de 2880; 94 árboles fueron seleccionados como fenotípicamente superiores, considerando sus características de altura total, diámetro normal, volumen, diámetro de copa, rectitud de fuste y conformación de copa. Se encontró una amplia variación fenotípica, con un coeficiente de variación mayor a 30 % para cuatro de las seis características consideradas, con excepción de la altura total y rectitud de fuste, siendo el coeficiente de variación de 24 y 25 %, respectivamente. Se obtuvo un diferencial de selección de 2.0 m en altura, 5.4 cm en diámetro normal y 0.104 m³ en volumen, de tal manera que se pueden obtener ganancias en las características de crecimiento con la selección de los árboles.

Biometry of fruits and seeds from Brazil nut trees selected for genetic improvement in Rondônia, Brazil / Biometria de frutos e sementes de castanheiras selecionadas para o melhoramento genético, em Rondônia

Danielli Carvalho dos Santos¹, Hebson Carvalho do Nascimento², Lúcia Helena de Oliveira Wadt³

¹Faculdade de Rondônia, Porto Velho, Brazil; ²Embrapa Rondônia, Porto Velho, Brazil (engf.danielli@gmail.com; hebson.nascimento@embrapa.br; lucia.wadt@embrapa.br)

Estudar a variabilidade genética na produção da castanheira é importante para seleção de genótipos de alta qualidade e também para estratégias de conservação. A biometria dos frutos e sementes possibilita quantificar a variabilidade genética dentro e entre populações além de analisar os caracteres morfológicos da planta. O presente trabalho apresenta dados biométricos de frutos e sementes de *Bertholletia excelsa* coletados em Costa Marques (10 genótipos) e Guajará-Mirim (11 genótipos), RO. Dados de massa fresca (MFF), espessura da casca (EC), diâmetro do fruto (DF), altura do fruto (AF) foram anotados para cada fruto (5 por genótipo). De cada fruto foram amostradas 10 sementes e avaliados o número de sementes por fruto (NSF), altura da semente (AS), largura mediana (LMS) e espessura mediana (EMS). No geral os frutos e sementes de Costa Marques foram maiores e mais pesados que os de Guajará-Mirim, mas como representam uma mesma região do Estado de Rondônia, serão apresentadas as médias gerais. O peso fresco médio dos frutos foi 463,3 gr variando de 129,4 a 857,2 gr. A espessura média da casca do fruto foi 16,11 mm, com mínimo de 6,23 mm e máximo de 10,75 mm. O número médio de sementes por fruto foi 16,5, variando de 5 a 24. O comprimento médio das sementes foi de 4,22 cm, com mínimo de 2,03 cm (Guajará-Mirim) e máximo de 5,78 cm (Costa Marques). No geral, as sementes de ambos locais foram semelhantes em termos de tamanho médio, mas com alta variação entre genótipos.

Assessing an improved population of açai palms established on dry land in Amapá, Brazil / Avaliação de uma população melhorada de açazeiros estabelecida em terra firme no Amapá

Larissa Favacho¹, Rayane Rios², Silas Mochiutti³

¹Universidade do Estado do Amapá, Macapá, Brasil; ²Universidade Federal do Amapá, Macapá, Brasil; ³Embrapa Amapá, Macapá, Brasil (l_favacho@hotmail.com; rayanerios7@gmail.com; silas.mochiutti@embrapa.br)

O açazeiro (*Euterpe oleracea* Mart.) é a espécie de maior ocorrência nas florestas inundáveis da Amazônia Oriental. A polpa do fruto desta palmeira vem ganhando mercado, propiciando o seu cultivo em áreas de terra firme pela utilização de técnicas de fertilização e irrigação. A disponibilidade de sementes melhoradas para plantios comerciais é somente da cultivar BRS-Pará. Neste estudo, avaliou-se as características das plantas e dos frutos de um plantio de açazeiro com seis anos de idade, estabelecido com sementes oriundas da segunda geração de melhoramento da BRS-Pará. A população avaliada apresentou média de 5,50m de altura, 10,7cm de DAP e 57,2cm comprimento de cinco entrenós, indicando que as plantas apresentaram baixa estatura e boa estrutura,

oferecendo facilidade de colheita dos cachos. Cerca de 83% dos açazeiros apresentaram perfilhamento e 100% das plantas encontravam-se produzindo frutos, sendo que 67% destas plantas possuíam duas ou mais estipes produzindo. A emissão de espigas foi de 1,38 planta/mês e a produção de frutos de 1,15 cachos/planta/mês. O mês com maior produção de frutos foi janeiro (1,44 cachos/planta) e o menor foi abril (1,04 cachos/planta). O peso médio de cacho foi de 2,51kg. Os frutos apresentaram 12,1mm de diâmetro longitudinal e 14,0mm de transversal, com peso de 1,57g por fruto. O rendimento de polpa dos frutos foi de 25,9%, bem superior ao obtido pela BRS-Pará. A segunda geração de seleção apresentou características desejáveis superiores aos da BRS-Pará, indicando a possibilidade de lançamento de uma nova cultivar de açazeiros para produção de frutos.

Genetic diversity and structure of *Anadenanthera* spp. populations in tropical dry forests using microsatellite markers / *Diversidade genética e estrutura de populações de Anadenanthera spp. em florestas secas tropicais usando marcadores microssatélites*

Fabricio Francisco Santos da Silva¹, Lucia Helena Piedade Kiill², Tatiana Ayako Taura², Claudinéia Regina Pelacani¹, Barbara França Dantas², Carlos Antônio Fernandes Santos²

¹Universidade Estadual de Feira de Santana, Feira de Santana, Brazil; ²Embrapa Semiárido, Petrolina, Brazil (fabriciofrancisco2006@gmail.com; lucia.kiill@embrapa.br; tatiana.taura@embrapa.br; claudineiapelacani@gmail.com; barbara.dantas@embrapa.br; carlos-fernandes.santos@embrapa.br)

Anadenanthera colubrina e *Anadenanthera peregrina* são árvores de ampla distribuição em florestas secas tropicais. Ferramentas que auxiliem no estudo de espécies florestais são importantes para conservação dos recursos genéticos deste grupo. Buscamos responder duas questões: (1) quais os níveis de variabilidade genética e estrutura de populações em *Anadenanthera* spp.? (2) o uso de microssatélites pode auxiliar na identificação taxonômica deste grupo? A extração de DNA de folhas foi realizada pelo método 2X CTAB, e os produtos da PCR foram separados em géis de poliacrilamida a 6%. O dendrograma UPGMA foi gerado usando o índice de Jaccard, com base na distância genética em 39 alelos de nove loci. A análise da variância molecular foi realizada usando a decomposição total entre e dentro de populações de *Anadenanthera* spp. O fluxo gênico (Nm) foi estimado pelo número de migrantes, com base no parâmetro Φ_{ST} . O tamanho dos alelos variou de 175 pb a 794 pb. A média da frequência alélica, Conteúdo de Informação de Polimorfismo (PIC) e heterozigosidade foram de 0,58, 0,52 e 0,45, respectivamente, demonstrando uma alta capacidade de detecção de variabilidade genética. O coeficiente de similaridade variou entre 20 e 80%, com valor cofenético de 0,81. Os dois agrupamentos bayesianos dividem-se em *A. colubrina* e *A. peregrina*. A variabilidade genética entre as populações é alta, $\Phi_{ST} = 0,217$ ($P < 0,001$), restringindo o Nm para um migrante por geração (0,9). O uso destes marcadores possibilita o estudo de genética de populações, bem como auxilia na identificação taxonômica de *Anadenanthera* Speg.

Effect of self-fertilization on heritability estimates in *Bactris gasipaes* Kunth

Dayane Tomigian¹, Gustavo Henrique Sousa Rodrigues², Ananda Virginia de Aguiar³, Valderes Aparecida de Sousa³, Antonio Nascim Kalil Filho¹

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal de São Carlos, Sorocaba, Brasil (dayane.tomigian@gmail.com; henriquesr.gustavo@gmail.com; ananda.aguiar@embrapa.br; valderes.sousa@embrapa.br; antonio.kalil@embrapa.br)

The pupunha (*Bactris gasipaes*) is distinguished by production of two food products: the palm-heart and the fruit. It is a monoicous species. While the species is allogamous, self-pollination may occur in the same inflorescence; between inflorescences of the same stipe and between inflorescences in different stipes in the same grouping. Self-pollination and inbreeding reduce heterozygosity and genetic variability. As a consequence, populations will tend to be more homogeneous genetically. The endogamy is cumulative over the generations due to the crosses between relatives. The objective of this work was to determine the effects of self-fertilization rates on *B. gasipaes* progenies. The phenotypic traits evaluated were productions of palm heart in 108 progenies of half siblings located in the Brazilian states of Paraná, Amazonas and Roraima. The experimental and statistical designs were completely randomized blocks with one plant per linear plot, in 2x1 meters. Six different self-fertilization rates were used: 0, 0,05, 0,10, 0,15, 0,20 and 0,25 to estimate the heritability. The self-fertilization rates were estimated for production traits using Selegen REML-BLUP software considering six different rates: 0%, 5%, 10%, 15%, 20% and 25%. The self-pollination negatively affected the heritability of palm-heart production trait. The heritability showed a drop in value from 3,15% to 1,33% in Roraima, 6,62% to 0,98% in Amazonas, and didn't show different values to Paraná.

Genetic divergence in *Bactris gasipaes* progenies

Dayane Tomigian¹, Gustavo Henrique Sousa Rodrigues², Ananda Virginia de Aguiar¹, Valderes Aparecida de Sousa¹, Antonio Nascim Kalil Filho¹

¹Embrapa Florestas, Colombo, Brasil; ²Universidade Federal de São Carlos, Sorocaba, Brasil (dayane.tomigian@gmail.com; henriquesr.gustavo@gmail.com; ananda.aguiar@embrapa.br; valderes.sousa@embrapa.br; antonio.kalil@embrapa.br)

Pupunha (*Bactris gasipaes*) is a species with a large socioeconomic importance. This species is cultivated for two products widely used in culinary activities; more specifically, the palm-heart and its fruit. However, the majority of its production is destined for domestic consumption. As a result, it becomes necessary to implement breeding tools to increase its productivity. Controlled crosses between more productive and genetically divergent genotypes are very important procedures used to improve the production. The purpose of this work was to verify which progeny were the most genetically divergent in three progeny tests, and the phenotype traits most related to the production of palm-heart. The tests were implanted in Paraná, Amazonas and Roraima states, composed of a total 103 different progenies in a randomized complete block design with one plant per linear plot in a spacing 2 x 1 meters. The traits height, diameter and different palm heart production (as basal, apical and total) were measured. For the genetic divergence the Mahalanobis distance and the Tocher grouping were applied using the software Selegen REML/BLUP. Genetic correlations among the traits were also estimated. Positive and significant genetic correlations were verified between palm-heart production traits. Progenies were clustered in 11, 8, and 6 different groups for the progeny's tests in Parana, Amazonas, and Roraima. Progenies from divergent groups will be used for controlled crosses.

D2q: CONSERVATION, DOMESTICATION AND BREEDING OF NATIVE SPECIES

Genetic diversity of *Azelia africana* Sm. (African mahogany) from southwestern Nigeria

Adejoke Akinyele¹, Steele Katherine A.², Mark Quinton-Tulloch²

¹Department of Forest Production and Products, University of Ibadan, Ibadan, Nigeria; ²School of Environment, Natural Resources and Geography, Bangor University, Bangor, United Kingdom (akinyelejo@yahoo.co.uk; k.a.steele@bangor.ac.uk; m.quinton-tulloch@bangor.ac.uk)

Uncovering the genetic variation of different populations of *Azelia africana* as well as their variability and/ relatedness at the inter- and intra-population levels is important for conserving the genetic diversity and managing the existing population of this species. In this experiment, we extracted DNA samples from young

healthy leaves collected from a total of 50 seedlings of *A. africana* from three naturally growing populations in Southwestern Nigeria. The extracted DNA were tested using different microsatellite markers. The amplified products were visualized in a 3% super fine resolution agarose gel and photographed for further analysis. The microsatellite markers were applied on duplicate samples from each individual tested, and only the clear, unambiguous and reproducible bands amplified in both cases were considered for scoring the data to get a binary data matrix. The number of polymorphic and monomorphic amplification products was determined for each primer and all the individuals. Cluster analysis was used to generate a Principal component analysis (PCA) and dendrogram showing relatedness/diversity in the samples using R studio. A total of 28 potential microsatellite loci were tested for amplification and polymorphism, and 8 successfully amplified. Result obtained was used to compare the efficiency of primers and to estimate the overall utility of each marker system. Level of similarity among individuals was established as a percentage of polymorphic bands. The 8 microsatellite loci can be used for further genetic studies of *A. africana*, to determine its conservation status.

Variation in early characters for genetic improvement of *Virola surinamensis* (Rol. Rottb ex.) Warb. (Myristicaceae), a multipurpose tree species of Amazonian floodplains

Aparecida Juliana Martins Corrêa¹, Fatima Conceição Márquez Piña-Rodrigues¹, Karina Martins¹, Mario Luiz Teixeira de Moraes², Miguel Luiz Menezes Freitas³

¹Universidade Federal de São Carlos, Sorocaba, Brasil; ²Universidade Estadual Paulista “Júlio de Mesquita Filho”, Ilha Solteira, Brasil; ³Instituto Florestal, São Paulo, Brasil (jumartinscorrea@gmail.com; fpina@ufscar.br; kmartins@ufscar.br; mario.moraes@unesp.br; miguelmfreitas@yahoo.com.br)

Classified as endangered due to its intense logging, *Virola surinamensis* has high silvicultural commercial value due to its diversity of products (bark, fruit, seeds, wood, etc.). The use of phenotypic characters for early selection is an important improvement tool, due to the ease of obtaining data to be evaluated. Seeds and seedlings of 95 mother-trees were sampled throughout Brazilian Amazon. We measured length (L, mm) and width (W, mm) of seeds; diameter of neck height (DNH, mm), total height (HT, cm), epicotyl height (EHT, cm) and hypocotyl height (HHT) from seedlings at six months aged. We used the completely randomized design in “y = u + g + e” model, by maximum likelihood restricted and selection for best unbiased linear prediction methods (REML/BLUP), in a joint analysis for the characters evaluated. The likelihood ratio test (LRT, α (1%) = 6.63) showed that the analyzed characters can be used for the selection, since they present high variation among the matrices, either for seeds (LRTL = 1988.57; LRTW = 1615.28) and for seedlings (LRHT = 1050.37, LRDNH = 162.67, LRTEHT = 1341.49, LRTHHT = 1037.04). Early vegetative traits in this case will not only help to anticipate the selection processes of the best genetic material before going to the field, but also to anticipate stages of cycle production and reduce implementation costs in long term.

Flowering and fruiting patterns, seed characteristics and germination of indigenous forest trees in Mount Makiling Forest Reserve, Philippines: implications to sustainable germplasm conservation

Lerma Maldia¹, Dianne Joy Aguilon¹, Jessa Ata¹, Marilyn Combalicer¹, Reynaldo Lorida², Amelita Luna³, Marilyn Quimado¹, Crusty Tinio¹

¹Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines Los Baños, Laguna, Philippines;

²University of the Philippines Land Grant Management Office, University of the Philippines Los Baños, Laguna, Philippines; ³Office of the Coordinator for Research, Extension, and Linkages, College of Forestry and Natural Resources, University of the Philippines Los Baños, Laguna, Philippines (lsmaldia@up.edu.ph; ddaguilon@up.edu.ph; jpata@up.edu.ph; mscombalicer@up.edu.ph; relorida@up.edu.ph; acluna@up.edu.ph; marilyn.quimado@gmail.com; cetinio@up.edu.ph)

Genetic resources of a country are important assets. Their conservation must be established and is fundamental to the sustainable and productive management of the forest ecosystem in which they occur. This presentation summarizes our recent three-year observation on flowering and fruiting patterns, seed calendar, seed characteristics, including dormancy and germination, seed technology and other activities on germplasm conservation of indigenous forest trees in Mount Makiling Forest Reserve in Luzon, Philippines. MMFR is a protected and key biodiversity area, with an extremely high biodiversity conservation priority, and one of the country's key ecotourism sites. The number of candidate mother trees varied widely across target species. Of 29 species, with a total of 312 candidate mother trees selected and geo-tagged, 17 species showed widely varied phenological patterns across mother trees within and among species. There are general trends observed for flowering and fruiting, to wit: synchronous flowering and fruiting among mother trees within species at defined periods annually; asynchronous flowering among mother trees within species or at irregular intervals within species during the observation period, and the rest have not flowered within the period. This resulted to varied periodicity and intensity of seed fall within and among species. Significant number of species had short seed dormancy and produced less fruits, making seed availability for seed technology and seedling production activities for *in situ* and *ex situ* conservation a crucial concern. Flowering, fruiting and seed fall patterns, dormancy, and other seed characteristics, therefore, should be well-understood in order to achieve sustainable germplasm conservation.

Application of artificial neural networks for ecological niches modelling in *Araucaria angustifolia* and *Ilex paraguariensis*

Gustavo Rodrigues¹, Ananda Virginia de Aguiar², Marcos Silveira Wrege², Marcia Toffani Simão Soares², Valderês Aparecida de Sousa², Elenice Fritzsos², Karina Martins¹

¹Universidade Federal de São Carlos, Sorocaba, Brasil; ²Embrapa Florestas, Curitiba, Brasil Curitiba, Brazil

(henriquesr.gustavo@gmail.com; ananda.aguiar@embrapa.br; marcos.wrege@embrapa.br; marcia.toffani@embrapa.br; valderes.sousa@embrapa.br; elenice.fritzsos@embrapa.br; karimartins@yahoo.com)

Nowadays, discussions about the conservation of natural populations around the world is focused on the risks of global climate change. In trees, adaptive selection processes occur slower than the actual pace of climatic changes. So cold-adapted species such as *Araucaria angustifolia* and *Ilex paraguariensis* may suffer a range reduction and even extinction of entire populations in some regions. In the context of the adaptation of climate change, an interesting strategy regarding breeding and genetic conservation programs is developing to select genotypes potentially able to cope with future climate change. Ecological Niche Modelling (ENM) methods are helpful to identify geographic regions where species grow better. Artificial Neural Network is an ENM method that results in niche models with high accuracy and efficiency. This study used the Artificial Neural Network to model regions where *A. angustifolia* and *I. paraguariensis* might grow better, considering the present and future climate scenarios. Two phenotypic variables (total height and diameter at breast height) measured in trees from six natural locations and several climate and edaphic data were used for the ANNs. These were constructed using the technique Multilayer Perceptron, in software R, where the number of neurons and layers were tested. We presented the best ANN architecture for each species, based on different accuracy metrics, and discuss differences between current and future range based on ANNs models. We, then, will discuss how these results would be applied in specific conservation and breeding strategies.

Fingerprinting of sengon (*Falcataria moluccana* (Miq.)) accessions resistant to boktor pest and gall rust disease using microsatellite markers

Ulfah J Siregar^{1,2}, Dewi Rahmayanti², Apriliya Damayanti¹

¹Bogor Agricultural University, Bogor, Indonesia; ²SEAMEO BIOTROP, Bogor, Indonesia (siregaruj@gmail.com; dewi@biotrop.org; ⁴⁰⁷april@gmail.com)

Sengon (*Falcataria moluccana* Miq.) is multipurpose fast growing tree species, which is widely planted in community forest. Sengon is an alternative resource for biomass energy and it can be used for wood-pellet. However, sengon has treats to the disease is caused by a fungi called *Uromygladium falcatarium* and stem borer called boktor (*Xystrocera festiva*). This research was aimed to provide genetic information of resistant and susceptible to gall rust disease as well as stem borer to obtain SSR markers which are able to differentiate the accessions. Sengon DNA was extracted using Dneasy plant mini kit from QIAGEN. The result showed that eight SSR markers (Pafa02, Pafa03, Pafa04, Pafa05, Pafa06, Pafa07, Pafa08 and Pafa10) could amplify most of the sengon accessions used in this study. However, only four primer pairs (Pafa06, Pafa07, Pafa08 and Pafa10) were able to produce polymorphic fragments on stem borer of sengon accessions. The population of sengon susceptible and resistant to gall rust disease from Sukabumi and Kediri has a high genetic diversity (He) value ranging from 0.431 to 0.518. Sengon resistant to stem borer has the highest He (0.650) than susceptible population (He = 0.623). Sengon accessions of gall rust disease has genetic distance of 0.267 to 0.495 and sengon accessions of stem borer resistant was closely related to susceptible population with 0.160 genetic distance.

Developing procedures for bamboo hybridization: Learning from the synchronous flowering of six bamboo species in Kerala, India

Vidya R Sankar¹, Muralidharan E M¹

¹Kerala Forest Research institute, Thrissur, India (vidyacheruvallil@gmail.com; emmurali@kfri.org)

The fortuitous synchronous flowering of six species of bamboo in the KFRI Bambusetum at Thrissur, India and vicinity during 2014 to 2017 offered the rare window of opportunity to study the phenomenon and exploit the benefits of hybridization. Clumps of *Dendrocalamus asper*, *D. giganteus*, *Pseudoxytenanthera stocksii*, *D. strictus* and *Ochlandra travancorica* in the bambusetum and a natural population of *Bambusa bambos* flowered during the same time in the district. Floral biological features of the species such as anther dehiscence, pollen production, pollen viability and pollen germination were compared. Pollen viability varied from 35 % in *P. stocksii* to 83% in *D. giganteus* and germination from 22% in *P. stocksii* to 78% in *D. asper*. Hybridization was attempted through reciprocal crosses between the different species. Attempts to improve the anther dehiscence was carried out employing direct sunlight, silica gel, calcium chloride etc. Hurdles in cross pollination were overcome using procedures like use of germination media on the stigma, cut-style pollination, *in ovulo* fertilization and *in vitro* culture excised pistils and *in vitro* pollination/fertilization in *D. asper*, *D. giganteus* and *P. stocksii*. Surface sterilization procedures without compromising the viability of the pollen and ovules were developed. Pollen stored in organic solvents survived upto 280 days at 4°C. The precise nutritional and environmental conditions essential to maintain the female receptivity and seed set, time of excising the ovule was determined. Valuable information on pollen storage and *in vitro* conditions conducive to carrying out hybridization was generated that can facilitate future hybridization efforts.

Phylogeography of *Tamarix austromongolica* inferred from the *trnQ-rpS16* and ITS sequence variation

Wen Yuexian¹, Gan Honghao¹, Shi Shengqing¹, Chu Jianmin¹

¹Research Institute of Forestry, Chinese Academy of Forestry, Beijing, China (wenyuexian123@163.com; ganhonghao@163.com; shi.shengqing@caf.ac.cn; cjmcaf@163.com)

In order to explore the geographical structure and migration of the lineages among the populations of *Tamarix austromongolica* in the Yellow River Basin, China. The samples from seventeen *T. austromongolica* populations were analyzed by one pair of chloroplast genes (*trnQ-rpS16*) and one pair of nuclear gene ITS sequences in this paper. Four chloroplast haplotypes and 32 nuclear haplotypes were detected. AMOVA analysis showed that the genetic variation of tamarix populations mainly occurred in the population, the genetic differentiation coefficient Nst (0.154) was less than Gst (0.191), and there was no obvious genealogical geographic structure among the populations. The results of neutrality test showed that Tajima's D and Fu's Fs were both significantly negative. Combining with the mismatch distribution analysis, it showed that *T. austromongolica* population experienced rapid expansion. The haplotype distribution and network structure showed that the population near Jishishan County and Yongjing County in Gansu Province are oldest. Then the differentiated haplotypes are relatively old, which started from Taiji Town (TJ) in Yongjing County and down to Dongying City (DY) in Shandong Province. The unique haplotypes R10, R11 and R12 of Qinghai Province are differentiated by R1. The group distance is relatively long and relatively young. It is speculated that the *T. austromongolica* population migrated from the upstream to the downstream. Finally, the upstream source of the Yellow River was lengthened, and the group of *T. austromongolica* migrated to Qinghai Province, which is consistent with the formation direction of the Yellow River.

D2r: CONSERVATION, SUSTAINABLE MANAGEMENT AND DEVELOPMENT OF FOREST GENETIC RESOURCES ACROSS THEIR RANGES: REGIONAL RESEARCH AND COLLABORATION

Floristic biodiversity in Meghalaya: an indo-burma hotspot area of India

Sangeeta Gupta¹

¹Forest Research Institute, Dehradun, India (sangeeta.fri@gmail.com)

Meghalaya, meaning the abode of clouds is one of the states of India that falls under the Indo-Burma hotspot. The total forest area of the State is 15584 sq km which is about 69% of the geographical area of the state. However, only 1027.20 sq km is under the control of State Forest Department, which constitutes only 4.58 % of the total geographical area of the State and 6.56 % of the total forest area of the State. Rest of the area is community owned and is under control and management of the Autonomous District Councils. About 5.06 % of the State's Geographical Area is covered by the protected area network in Meghalaya that includes 2 national Parks, 4 wildlife Sanctuaries and 1 Biosphere Reserve, playing an important role in in-situ conservation of Biodiversity. There are 79 sacred forests covering approximately 90 sq km. For a state of 22,429 sqkm it may appear that Meghalaya flora is well protected but looking at the extent of floristic diversity still more needs to be done. A study was carried out to estimate the floristic biodiversity of Meghalaya and the results showed an estimated figure of about 60-80% flora being different at an interval of every 30 km distance. Comparison of floristic of three areas viz. Jowai (altitude 100-1800 m), Nongpoh (160-1300 m) and Balphakram (50-1026 m) were made. The presentation shall focus upon further areas that need to be covered under protected area network based on the floral diversity.

Genetic Diversity of *Casuarina equisetifolia*

Pan Hu¹, Chonglu Zhong¹, Yong Zhang¹, Khongsak Pinyopusarerk²

¹Research Institute of Tropical Forestry, Chinese Academy of Forestry, Guangzhou, China; ²CSIRO National Research Collections Australia, Canberra, Australia (hupan622@139.com; zclritf@126.com; seamanzhy@163.com; khongsak.pinyopusarerk@csiro.au)

Casuarina equisetifolia natural distributed in Australia, Thailand, Malaysia, Indonesia, the Philippines, Melanesia, Polynesia and Guam, etc. The EST-SSR markers were used to determine the genetic diversity and population structure among the 29 typical natural and introduced populations. Based on 13 pairs of EST-SSR primers with amplified stability, clear band and higher polymorphism were obtained and used. The 308 alleles can be identified from the 13 SSR loci, average alleles number per loci was 23.69, range of alleles number was from 11 to 48. Range of effective alleles number, Shannon's index, observed heterozygosity and effective heterozygosity were 1.533-7.029, 0.691-2.139, 0.270-0.655 and 0.393-0.858, respectively. According Shannon's index, the order of genetic diversity level from high to low of the 5 regions was: African introduced (AF)>Asia natural (AN)>Oceania natural (OP)>Central American introduced (CI)>Asia introduced (AI); the order of genetic diversity level of the 29 populations was given. The serious inbreeding between populations was occurred during the whole distribution. The 70.12% of total variance was from the individuals within populations. The order of variance was: AN (81.15%) > AI (74.58%)>CI (72.29%)>AF (68.43%)>OP (61.45%). Though variation from populations accounted for only 25.42 % to 38.49% of the total variation, given the serious inbreeding that identified in the population, population selection should also attach great importance in future. Based on UPGMA dendrogram of the 29 populations proved that introduced populations of China should be from Asia natural populations, while introduced populations of Kenya, and India and Veitnam might from Oceania natural populations.

Population structure and regeneration status of *Prunus africana* (Hook.f.) Kalkm. after selective and clear felling in Kibale National Park, Uganda

Arthur Arnold Owiny^{1,2}

¹Uganda Christian University, Mukono, Uganda; ²Makerere University Biological Field Station, Kampala, Uganda (owinyiarnth@yahoo.com)

Prunus africana is a globally threatened indigenous medicinal tree species, and food for many primates. Its population has declined in Sub-Saharan Africa due to unsustainable harvest and poor protection. In this study, we determined the population density, population structure and regeneration status of *P. africana* in the former clear felled, selectively logged, and primary forests of Kibale National Park, and assessed the effects of dense cover of *A. pubescens* on its regeneration. Trees were measured from 180 randomly established plots. The densities of *P. africana* seedlings and saplings differed significantly among the three forests while that of poles and mature trees did not. The density of seedlings was significantly higher in the selectively logged than in primary forests. The density of saplings was higher in clear felled than in selectively logged forests. Tree density was not negatively affected by *A. pubescens* cover. Clear felled areas had a more stable population structure with better regeneration, while selectively logged and primary forests had unstable population structures with poor recruitment potential. Our results show that *P. africana* regenerates more in intensively disturbed forest areas than less disturbed or primary forests, highlighting the importance of regenerating forests in the conservation of *P. africana*.

High-throughput development of SSR markers in diverse *Liriodendron chinense* germplasm

Bin Li¹, Ping Huang¹, Yongqi Zheng¹

¹Chinese Academy of Forestry, Beijing, China (libin1200@163.com; pippin09@163.com; zyg8565@126.com)

Liriodendron chinense, ranges widely in subtropical China and northern Vietnam, however, inhabits several small isolated populations and is now an endangered species due to its limited seed production. The objective of this study was to develop a set of SSR markers useful for genetic studies in *L. chinense* and their characterization in diverse germplasm. We developed novel SSR markers for *L. chinense* from randomly sequenced regions of the genome using next-generation sequencing. In total, 6,147 SSR markers were isolated from 2.84 GB genomic sequences. The most common of SSR motifs were dinucleotide (70.09%), followed by trinucleotide motifs (23.10%). The motif AG/TC (33.51%) was the most abundant, followed by TC/AG (25.53%). A set of 13 SSR primer combinations were tested for amplification and their ability to detect polymorphisms in a set of 109 *L. chinense* individuals, representing distinct varieties or germplasm. The number of alleles per locus ranged from 8 to 28 with an average of 21 alleles. The expected heterozygosity (HE) varied from 0.19 to 0.93 and observed heterozygosity (HO) ranged from 0.11 to 0.79. The SSR markers characterized and tested in this study provide a valuable tool to detect polymorphisms in *L. chinense* for future genetic studies and breeding programs.

Grafting selected Brazil nut (*Bertholletia excelsa*) genotypes in Acre, Brazil: sprout survival and vigor / Enxertia de genótipos de castanheira selecionados no Estado do Acre: pegamento e vigor dos brotos

Joana Keila da Silva Gomes¹, Fernanda Lopes da Fonseca², Manoel Freire Correia², José Ricardo de Oliveira Duarte³, Joziane Silva Evangelista³, Lúcia Helena de Oliveira Wadt⁴

¹Faculdade de Ciências Humanas, Exatas e Letras de Rondônia, Porto Velho, Brasil; ²Embrapa Acre, Rio Branco, Brasil; ³Universidade Federal do Acre, Rio Branco, Brasil; ⁴Embrapa Rondônia, Porto Velho, Brasil (keylasg@hotmail.com; fernanda.fonseca@embrapa.br; manael.correia@embrapa.br; jose-ricardo.duarte@embrapa.br; joziane.gestorambiental@gmail.com; lucia.wadt@embrapa.br)

O manejo da castanheira-da-amazônia, atividade reconhecida como alternativa para a conservação da Amazônia, tem suas limitações quanto a produtividade, logística e acesso aos castanhais nativos. Isso justifica investimentos para seleção e disponibilização de material genético de alta qualidade. A Embrapa iniciou, em 2013, um programa de melhoramento genético com materiais do AC, RR e AP. No Acre foram selecionados 20 genótipos, nos Seringais Filipinas e Cachoeira, os quais foram caracterizados e enxertados em pomar clonal. Este trabalho apresenta o pegamento dos enxertos aos 180 dias, além do vigor das brotações aos 470 dias. Genótipos do Filipinas tiveram melhor pegamento (87,5%) que os do Cachoeira (67%). Os genótipos C204, F217 e F391 foram os melhores, com destaque para o F391 que apresentou melhor desenvolvimento dos brotos. Considerando que o enxertador e a forma de conservação das hastes foram semelhantes, as diferenças observadas podem estar associadas à época de coleta das hastes, uma vez que no Cachoeira foi final de outubro e no Filipinas início de novembro. Além disso, dos 11 brotos classificados como vigorosos, 10 foram do Filipinas. Diferenças genéticas também podem explicar as variações observadas, embora a incompatibilidade entre enxerto e porta-enxerto seja um aspecto que ainda precisa ser estudado.

Analyzing the biodiversity of wild fauna in the Galilea forest for conservation in the Cordillera Oriental in Tolima, Colombia / Análisis de la biodiversidad de la fauna silvestre del bosque de Galilea para su conservación en la cordillera Oriental del Tolima (Colombia)

Miguel Ángel Quimbayo Cardona¹, Hugo Loaiza¹, Linda Mosquera¹, Luis Alfredo Lozano Botache¹, Uriel Pérez Gómez¹, Consuelo Carvajal²
¹Universidad del Tolima, Ibagué, Colombia; ²CORTOLIMA, Ibagué, Colombia (miguelq@ut.edu.co; hnloaizah@ut.edu.co h, lcelestemosquera@ut.edu.co; llozano@ut.edu.co; uperez@ut.edu.co; consuelo.carvajal@cortolima.gov.co)

El bosque de Galilea, localizado sobre la margen occidental de la cordillera Oriental en el departamento del Tolima (Colombia) tiene un área de 33.000 ha entre los 1.200 y 2.800 m, con temperaturas entre 12° y 24° C. Es un ecosistema estratégico por la producción de agua que alimenta el embalse del río Prado que provee energía a la región. Presenta bosques primarios y fragmentos generados por actividades antrópicas. En el marco de los estudios para la declaratoria como área protegida durante el año 2018 se realizaron caracterizaciones fauna silvestre en las localidades Río Naranjo (1.600 m) y Campo Hermoso (1.900 m). Se realizaron búsquedas intensivas, observaciones directas, capturas y grabaciones de cantos. Se han registrado 29 especies de herpetos (24 anfibios y 5 reptiles), 225 de aves y 34 de mamíferos. Herpetofauna: una especie endémica, una especie casi endémica, dos especies en CR, una especie en VU y una especie en NT a nivel internacional. Avifauna: una especie en Apéndice I CITES, 44 especies en Apéndice II CITES, dos especies endémicas, 17 especies casi endémicas y cuatro especies en VU a nivel nacional. Mamíferos: una especie en Apéndice I CITES, tres especies en Apéndice II CITES, dos especies en VU a nivel nacional, una especie en VU y una especie en NT a nivel internacional. Se tienen nuevos registros de distribución de dos especies de aves y una especie de anfibio para esta área. Se están evaluando cuatro especímenes de anfibios que podrían ser especies nuevas para la ciencia.

Ex situ conservation of European beech (*Fagus sylvatica* L.) in Romania

Ecaterina Nicoleta Apostol¹, Marius Budeanu¹, Marin Tudoroiu¹, Cristiana Georgeta Ciuvat¹, Robert Ivan¹, Stefan Leca, Albert Ciceu¹
¹National Institute for Research and Development in Forestry (INCD) Marin Drăcea, 077190, Romania (cathyches@yahoo.com; budeanumarius@yahoo.com; borys19@gmail.com; cristiana_pif@yahoo.com; ivan_robert89@yahoo.com; stefan.leca@icas.ro; albert.ciceu@yahoo.ro)

With large distribution range, European beech (*Fagus sylvatica*) is one of the most ecological and economical important tree species in Europe. In the context of climate change, the European Programme for the Conservation of Forest Genetic Resources (EUFORGEN) has a special network for broadleaf species, including beech, which is considered important for its adaptability, plasticity and wood production. In Romania is considered one of the most important species for conservation of local genofond, seed source, protection area, as well as for wood production; 60 European beech natural populations, mapped as base material for production of forest reproductive material, were sampled in representative of the full range of the species in the country. Qualitative and quantitative characters for trunk and stem for 30 trees per population were described in order to evaluate inter- and intrapopulation phenotypic variability. The results show that the trees in the studied populations have superior phenotypic, both in quantitative and qualitative traits. In order to conserve Romanian beech genetic diversity, seeds from 15 Forest Genetic Resources were collected and used to install provenance trials.

Production and growth of key species seedlings of the Atlantic Forest in danger of extinction in response to mycorrhizal fungus

Rozimar De Pereira¹, Erick Johnson Cruz¹, Anna Fridha Ott¹, Luana Souza Cruz¹
¹Universidade Federal do Recôncavo da Bahia, Cruz das Almas, Brazil (rozimarc@gmail.com; erickjohnson1492@gmail.com; annafridha@gmail.com; luuanacruz@gmail.com)

The type of substrate used in seedling production has a significant effect in the quality and growth characteristics of a plant. This work reports on a greenhouse experiment designed to assess the development of seedlings of *Paubrasiliana echinata*, *Dalbergia nigra*, *Astronium fraxinifolium*, and *Schinopsis brasiliensis* inoculated with the following arbuscular mycorrhizal fungi (AMF): *Glomus clarum* Becker and Gerdemann, and *Gigaspora margarita*. A completely randomized factorial design was set up with 3 treatments and 25 replicates. The inoculation of AMFs was made while transplanting the seedlings to plastic sacks containing 10 g of inoculate. The morphometric parameters evaluated were: height, H; diameter, D; Relation H/D; weight of the fresh and the dry matter of the aerial and root parts, and leaf area. The results showed that the most effective method for dormancy breaking of *P. brasiliana*, *D. nigra* seeds was the immersion in a 70% H₂SO₄ solution for 5 min, whereas for *A. fraxinifolium* and *S. brasiliensis* the best efficiency were attained through immersion in water at ambient temperature for 48 h and mechanical scarification, respectively. The control treatment for *S. brasiliensis* resulted in higher seedlings with smaller diameters as compared to those obtained using AMFs. The most efficient fungus for height and diameter growth rates of *S. brasiliensis* was *G. margarita*. The best response for *D. nigra* seedlings was also obtained with the inoculation of *G. margarita*, which showed the highest observed maximum height and diameter of the forest species studied in this work.

D4a: CLOUD COMPUTING AND REMOTE SENSING TO UNDERSTAND 30-YEAR DYNAMICS OF BRAZILIAN FORESTS

Introduction to MapBiomass session: cloud computing and remote sensing to understand 30-year dynamics of Brazilian forest

Tasso Azevedo¹
¹MapBiomass, São Paulo, Brazil (tasso.azevedo@gmail.com)

There are a number of mapping and monitoring initiatives for forest cover, but there is still a lack of understanding of the dynamics, factors, and pressures that impact forests over time in the landscape. The MapBiomass project is a large-scale, rapid and collaborative initiative to monitor the dynamics of land cover and land use, and thus contributes to understanding processes that affect forest conservation. The project started in Brazil three years ago, providing free annual land cover and land use maps in the country from 1985 to 2017 on an interactive platform (www.mapbiomas.org), and recently with local institutions, it was expanded in the entire Amazon Basin (<http://amazonia.mapbiomas.org>) and Chaco region (<http://chaco.mapbiomas.org>), besides the possibility of expansion to other countries and regions.

Evaluation of land use and land cover patterns in the Caatinga Biome from a 30-year time perspective (1987 - 2017)

Khalil Ali Ganem¹, Washington Franca Rocha², Rodrigo Vasconcelos², Soltan Duverger³, Diego Pereira Costa²

¹Universidade de Brasília, Brasília, Brasil; ²Universidade Estadual de Feira de Santana, Feira de Santana, Brasil; ³Universidade Federal da Bahia, Salvador, Brasil (khalilganem@hotmail.com; wrocha@uefs.br; rrvuefsppgm@gmail.com; solkan1201@gmail.com; costapdiego@gmail.com)

The Brazilian Annual Land Use and Land Cover Mapping project – MapBiomias – has been globally outstanding for producing, within the framework of the Google Earth Engine platform, a robust and open access database on land use and land cover of the six Brazilian biomes, with a spatio-temporal approach. This mapping has used machine learning algorithms and cloud computing in a highly functional environment with great computational capacity, where results have been applied to study current and relevant environmental topics, such as deforestation, drought, natural disasters, water availability and climate monitoring. In this work, we present a statistical analysis of the land use and land cover patterns of the Caatinga biome for the period 1987 to 2017. To do this, from the access to the MapBiomias' online platform (mapbiomas.org), data on the area of each major class of the legend of the project were collected for the Caatinga, in the given period. The classes are: forest formations, non-forest natural formations, farming, non-vegetated areas and water bodies. These data had their reduction and growth patterns evaluated comparatively with each other and with data from other sources. At the end, there was a decrease of approximately 5.8% (4.84 million hectares) of the class area that corresponds to the forest formations in the biome over the 30 years evaluated. At the same time, data from farming class increased by about 5.4% (4.55 million hectares), which may be a strong evidence that the forests have been removed from the Caatinga in favor of farming expansion.

Mapping the different formations of native vegetation in the Cerrado over the past 30 years / Mapeamento das diferentes formações de vegetação nativa do Cerrado nos últimos 30 anos

Vera Arruda^{1,2}, Camila Balzani¹, Ane Alencar¹, Felipe Lenti¹, Julia Shimbo¹, Carol Nóbrega¹

¹IPAM Amazônia, Brasília, Brasil; ²Universidade de Brasília, Brasília, Brasil (vera.arruda@ipam.org.br; camila.balzani@ipam.org.br; ane@ipam.org.br; felipe.lenti@ipam.org.br; julia.shimbo@ipam.org.br; caroline.correa@ipam.org.br)

O Cerrado é o segundo maior bioma sul-americano e a savana mais rica e ameaçada do mundo. Caracterizado por um mosaico de formações vegetais naturais (florestas, savanas e campos) com influência da sazonalidade climática, a classificação desse bioma por imagens de satélite é de alta complexidade. Neste trabalho, apresentamos uma estratégia de classificação de imagens de satélite para mapear anualmente os três principais tipos de vegetação do Cerrado baseada na computação em nuvem usando a plataforma Google Earth Engine. Utilizando imagens Landsat dos últimos 30 anos, selecionamos pixels sem nuvem dentre as imagens disponíveis e extraímos 46 métricas espectrais que explicam o comportamento do pixel em cada ano de 1985 a 2017. A classificação foi realizada por aprendizado de máquina na forma do algoritmo Random Forest, usando 18.000 amostras sorteadas em cada formação nativa, e aplicação de técnicas de pós-classificação como filtros espacial e temporal. Ao longo de três décadas, a vegetação nativa no Cerrado diminuiu de 136 para 112 Mha (com 55% de áreas naturais remanescentes em 2017). A classe Savana predomina no bioma e apresentou a maior mudança em área, com 15,6 Mha convertidos em agropecuária, enquanto a classe Floresta perdeu 9,3 Mha. Como o Cerrado possui apenas 7,8% de sua cobertura em áreas protegidas, é imprescindível identificar áreas críticas de perda de vegetação nativa como estratégia para deter o desmatamento e garantir a persistência de paisagens naturais representativas em regiões com alta pressão de conversão.

Beyond processing capacity and image availability: the role of training samples in satellite land use classifications

Diego De Abelleira¹, Santiago Banchoff¹, Santiago Verón¹, Hernan Elena², Martín Perez³, Juan José Gaitan¹, Fabiana Arealos⁴, Marcos Rosa⁵, José Volante²

¹INTA, Hurlingham, Argentina; ²INTA, Salta, Argentina; ³INTA, Mendoza, Argentina; ⁴Guyra, Asunción, Paraguay; ⁵Departamento de Geografía - FFLCH, Sao Paulo, Brasil (deabelleira.diego@inta.gov.ar; banchoff.santiago@inta.gov.ar; veron@agro.uba.ar; elena.hernan@inta.gov.ar; perez.martin@inta.gov.ar; gaitan.juan@inta.gov.ar; fabiana@guyra.org.py; mrosa@arcplan.com.br; volante.jose@inta.gov.ar)

The advent of cloud computing platforms like Google Earth Engine and the extensive availability of high resolution images changed the land use - land cover classification paradigm. Within this context, the relative importance of accurate ground truthing has increased compared to processing capacity. We here provide a general guide to sample collection and processing developed in the framework of the Project MapBiomias Chaco to produce annual land cover maps for the Gran Chaco Americano. Our proposal identifies good practices for the generation of high quality samples through visual interpretation of LANDSAT and Google Earth images with the support of MODIS time series. Mapbiomas interpreters consensuated the map legend with class definitions based on FAO LCCS, a common criteria to assign the classes based on visual interpretation and time series visualization, and recommendations to draw polygon samples. These recommendations were related to: spatial distribution of samples, balanced number of samples, scale of viewing, class homogeneity of pixels, temporal stability of classes. The workflow included an iterative process of reviewing of samples by different participants, including the redefinition of recommendations and criteria. In parallel, an outlier filter was applied to samples to avoid training the classifications with noisy pixels values for a same class. Results showed in general that both the redefinition of recommendations and reviewing of samples, as well as the application of outliers filtering have a significant increment in the overall accuracy.

Recent land use and land cover change dynamics in the Chaco Argentino

Santiago Banchoff¹, Diego De Abelleira¹, Santiago Verón¹, Elena Hernán², Martín Perez³, Juan José Gaitan¹, José Volante²

¹INTA, Hurlingham, Argentina; ²INTA, Salta, Argentina; ³INTA, Mendoza, Argentina (banchoff.santiago@inta.gov.ar; deabelleira.diego@inta.gov.ar; veron@agro.uba.ar; elena.hernan@inta.gov.ar; perez.martin@inta.gov.ar; gaitan.juan@inta.gov.ar; volante.jose@inta.gov.ar)

Land transformation is one of the most significant human changes on the Earth's surface processes. Therefore, land use land cover time series are a key input for environmental monitoring, natural resources management, territorial planning enforcement at national scale. We here capitalize from the MapBiomias initiative to characterize land use land cover (LULC) change in the Argentine Chaco between 2010 and 2017. Specifically we sought to a) quantify annual changes in the main LULC classes; b) identify the main LULC transitions and c) relate these transitions to current land use policies. Within the MapBiomias project, Landsat based annual maps depicting natural woody vegetation, natural herbaceous vegetation, dispersed natural vegetation, cropland, pastures, bare areas and water were generated using Random Forest machine learning algorithms trained by samples produced by visual interpretation of high resolution images. Annual overall accuracy ranged from 0,69 to 0,71. Our results show that, between 2010 and 2017, agriculture and pasture lands increased ca. 1.7 Mha while forest and herbaceous vegetation decreased by 0.56 Mha and 0.75 Mha. Transitions from forests to agriculture accounted for 5.77% of the overall deforestation while

86% was associated to pastures and natural herbaceous vegetation. Forest loss occurred primarily (39%) on areas non classified by the territorial planning Law, followed by medium (33%), high (19%) and low (9%) conservation priority classes. These results illustrate the potential contribution of remote sensing to characterize complex human environmental interactions occurring over extended areas and timeframes.

Change in land coverage and use in the Amazon basin, 2000–2017 / Cambio de cobertura y uso del suelo en la Cuenca Amazónica para el periodo 2000 - 2017

Cicero Cardoso^{1,2}, Sandra Rios^{3,2}, Saul Cuellar^{4,2}, Rodrigo Lazo^{5,2}, Andres Llanos^{6,2}, Maria Borja^{7,2}, Antonio Victor^{8,2}

¹ISA, Sao Paulo, Brazil; ²RAISG, Sao Paulo, Brazil; ³IBC, Lima, Peru; ⁴FAN, Santa Cruz, Plurinational State of Bolivia; ⁵PROVITA, Caracas, Venezuela, Republic of Bolivarian; ⁶GAIA, Bogotá, Colombia; ⁷ECOCIENCIA, Quito, Ecuador; ⁸IMAZON, Belem do Para, Brazil (caugusto@socioambiental.org; srios.ibc@gmail.com; scuellar@fan-bo.org; rlazo@provitaonline.org; allanos@gaiamazonas.org; maolgaborja@gmail.com; antoniovictor@amazon.org.br)

La Red Amazónica de Información Socioambiental Georeferenciada (RAISG) -un consorcio de organizaciones de la sociedad civil de los países amazónicos orientado a la sostenibilidad socioambiental de la Amazonía- en un esfuerzo por contribuir en el análisis de los cambios de la cobertura y el uso del suelo en la cuenca Amazónica, viene liderando conjuntamente con la Iniciativa Mapbiomas, la elaboración de estos mapas anuales para el periodo 2000 - 2017. Esta iniciativa ha sido posible gracias a la contribución de cada uno de los miembros de la RAISG, 7 ONGs miembros de la red que representan a 6 de los 9 países de la Cuenca Amazonica, y a la coalición con el equipo de Mapbiomas Brasil. Esta coalición ha permitido robustecer la metodología Mapbiomas Brasil para que la herramienta responda a las características propias del resto de la cuenca, pues la cuenca incluye otros biomas que no están presentes en Brasil como son las áreas andinas de los países de Bolivia, Perú y Ecuador. El interés de la red es producir información y conocimientos capaces de incidir sobre la generación de políticas públicas sostenibles. Dar a conocer los resultados obtenidos en cifras y mapas para todo el ámbito amazónico -partiendo de la premisa que la Cuenca Amazónica debe ser entendida y planificada de manera integral, transfronteriza y holística- contribuirá a mejorar nuestro conocimiento sobre los bosques amazónicos, las dinámicas de uso y demás coberturas vegetales de la cuenca. Asimismo, contribuirá a la planificación y ordenamiento territorial.

Tree species classification with multivariate neural networks and time series of satellite data

André Wästlund¹, Eva Lindberg¹, Johan Holmgren¹, Heather Reese², Håkan Olsson¹

¹Swedish University of Agricultural Sciences, Umeå, Sweden; ²University of Gothenburg, Gothenburg, Sweden (andre.wastlund@slu.se; eva.lindberg@slu.se; johan.holmgren@slu.se; heather.reese@gu.se; hakan.olsson@slu.se)

Accurate information about tree species is of great interest for the forestry sector, as well as for ecological modelling. Medium to fine spatial resolution satellite images can be used to identify tree species, particularly when multi-seasonal data are available. With the current availability of satellite data time-series with high temporal resolution, phenology information expressed as seasonal variations in the signal, can be used to improve tree species mapping. In this study we use a dense time-series of freely available optical satellite data (Sentinel-2) and sample plots from the Swedish National Forest Inventory, to classify tree species all over Sweden. Computing power from the cloud-based Google Earth Engine gives us the possibility to process and analyze time-series data for thousands of images, an analysis that was not possible before. Characteristic patterns in the time-series are used by a Deep-Learning neural network (Convolutional neural network and Long short-term memory are tested) to classify tree species. Preliminary results indicate that dense time-series of freely available satellite data and Deep-Learning neural networks can improve tree species classification.

Mapbiomas Arida: monitoring degradation in the semi-arid and the regeneration in the units of recovery of degraded areas in the Northeast of Brazil

Washington Franca Rocha^{1,2}, Jocimara Souza Britto Lobão¹, Rodrigo Vasconcelos^{1,3,2}, Diego Pereira Costa^{1,2,3}, Deorgia Tayane Souza¹, Marcos Reis Rosa^{4,5}, Frans Germain Corneel Pareyn^{6,7}, Tasso Azevedo⁵

¹Universidade Estadual de Feira de Santana, Feira de Santana, Brazil; ²Mapbiomas, Feira de Santana, Brazil; ³Geodatin – Inteligência em Dados e Geoinformação, Feira de Santana, Brazil; ⁴Universidade de São Paulo, São Paulo, Brazil; ⁵Mapbiomas, São Paulo, Brazil; ⁶APNE - Associação Plantas do Nordeste, Recife, Brazil; ⁷Mapbiomas, Recife, Brasil (wrocha@uefs.br; juci.lobao@uefs.br; rnvuefsppgm@gmail.com; costapdiego@gmail.com; dtmsouza@uefs.br; mrosa@arcrplan.com.br; franspar@rocketmail.com; tasso.azevedo@gmail.com)

The MapBiomas - Arida platform is one of the spin - offs of the Mapbiomas Project (www.mapbiomas.org) and aims to create a system to support managers and the local community so that they can follow the evolution in time of the biophysical processes that trigger the desertification and the actions developed in the Units of Recovery of Degraded Areas - URAD, aiming at the Land Degradation Neutrality - LDN, which is one of the Sustainable Development Objectives - SDO, established by the United Nations - UN. In this platform On this platform are available annual biophysical data from 2000 to 2018 derived from remote sensing products processed from the GEE (Google Earth Engine). These are: Annual Coverage and Land Use Maps; Annual transitional matrix maps; Annual Net Primary Productivity Maps; Annual CO₂-Soil maps and Annual water mirror maps. In addition, it has a Workspace environment, that is, an interactive online environment where managers and specialists can monitor the evolution of the areas imaged by various sensors (Landsat 7 and 8, Modis and Sentinel) in each pixel of the images. Arida also has makes available an App for mobile devices for field data collection and registration of new URADs.

Identifying areas for native vegetation restoration in degraded lands with the help of MapBiomas and GLOBIOM-Brazil

Wanderson Costa¹, Marluce Scarabello¹, Aline Soterroni¹, Fernando Ramos¹

¹Instituto Nacional de Pesquisas Espaciais, São José dos Campos, Brasil (wcosta.comp@gmail.com; mascarabello@gmail.com; alinesoterroni@gmail.com; fernando.ramos@inpe.br)

Created by Greenhouse Gas Emissions Estimation System (SEEG) in 2015, MapBiomas (Brazilian Annual Land Use and Land Cover Mapping Project) is one of the most recent Brazilian initiatives to generate annual land cover/use maps. Its mapping methodology is fully automated and integrated with Google Earth Engine and allows the possibility of comparing historical data since 1985. This mapping methodology facilitates the application of the Brazilian Forest Code, in addition to monitoring protected areas and pointing out opportunities for forest restoration. This study aims at using MapBiomas as the initial land cover/use map of the GLOBIOM-Brazil model. GLOBIOM-Brazil is a global economic partial equilibrium model that simulates, in a spatially explicit way, the competition for land among the main sectors of the land-use economy subjected to technology, resource and policy restrictions. Brazil's new Forest Code, including its debt offset mechanism (CRA), is explicitly included in our scenarios. Potential forest restoration areas are taken from the Rural Environmental

Registry (CAR). Final identification of forest restoration areas also takes into account the opportunity costs, estimated by GLOBIOM-Brazil. Restoration costs take into account the previous use of the land, i.e., if it was cropland, pasture, abandoned land or degraded land. Our results emphasize the use of MapBiomias and GLOBIOM-Brazil as a support in the development of forest restoration policies.

Agricultural losses from biogeophysical climate change in Brazil: A business case for ecosystem protection?

Avery Cohn¹, Sally Thompson²

¹Tufts University, Boston, USA; ²University of California, Berkeley, Berkeley, USA (avery.cohn@tufts.edu; sally.thompson@berkeley.edu)

In the Amazon and Cerrado biomes of Brazil, slowing ecosystem conversion could help to protect valuable ecosystem services, but comes at the cost of foregone revenue from the expansion of agricultural activities. As part of a wider effort to estimate the likelihood that reducing ecosystem conversion will be net beneficial to key agricultural and government actors, we produced spatially explicit, near-term, probabilistic estimates of economic damage to the agricultural economy stemming from ecosystem services lost under ecosystem conversion. Underlying these estimates was an ecological forecasting framework. We assembled the framework using two sets of statistical models, selected for their predictive skill and drawing on remotely sensed and in situ evidence. Agricultural land use and native ecosystem area were extracted from MapBiomias 3.0. The first model set predicted the response of agriculturally relevant rainfall and temperature parameters to regional land use and land cover change. The second set predicted the response of agricultural productivity to changes in the regional climate. Together with idealized land use and land cover scenarios, we linked these models and used them to forecast economic damage to the agricultural sector stemming from ecosystem conversion. The results of the forecast exhibited a high degree of uncertainty, but nevertheless revealed the costs of damage from a considerable area of ecosystem conversion to robustly exceed the opportunity cost of conservation. Partitioning the uncertainty demonstrated several priority areas for improved modeling and data in the agricultural, ecological, and climatological domains.

Understanding the importance of the Cerrado for deforested-driven greenhouse gas (GHG) emissions in Brazil from 1990 to 2017

Felipe Lenti^{1,2}, Júlia Shimbo¹, Vivian Ribeiro¹, Ane Alencar¹, Amintas Brandão Jr.³, Tasso Azevedo⁴

¹Instituto de Pesquisa Ambiental da Amazônia, Brasília, Brasil; ²Universidade de Brasília, Departamento de Ecologia, Brasília, Brasil; ³University of Wisconsin, Nelson Institute, Madison, USA; ⁴Observatório do Clima, São Paulo, Brasil (felipe.lenti@ipam.org.br; julia.shimbo@ipam.org.br; vivian.ribeiro@ipam.org.br; ane@ipam.org.br; brandaojr@gmail.com; tasso.azevedo@gmail.com)

The Cerrado, second largest biome in Brazil, is characterized by a savanna-dominated matrix enfolding forest and grassland patches. Native vegetation was already suppressed in 45% of its 2M km² territory in 2017. Cerrado remnants reserves 9 GtC, but this stock is prone to rapid conversion due to lack of protection and agricultural suitability. Governmental monitoring of GHG emissions associated with Cerrado deforestation covers the period of 1990-2010, leaving an information gap about the role Cerrado plays in the national emission profile in recent years. Here we present trends in land-use change emissions estimates for Cerrado from 1990 to 2017, produced by the SEEG (System for Estimating Greenhouse Gas Emissions) initiative. To estimate deforestation-driven emissions we used country specific emission factors and annual deforestation rates derived from the MapBiomias time-series. Deforestation was defined as pixels that remained in a vegetation class for at least three years and then transitioned to a land-use class, remaining in the later for two years or longer. Emissions from 1990 to 2017 were summed 18% of Brazil land-use change sector (7 GtCO₂e). Cerrado average contribution to the land-use change sector was 22% from 1990-1999, 15% from 2000-2009 and 20% from 2010-2017. The increase in Cerrado contribution in recent years indicates accelerated conversion in Cerrado in relation to other biomes. The Brazilian Forest Code allows for legal suppression of 325.000 km² and an associated emission of 3.2 GtCO₂e. Reducing national land-use change emissions requires urgent efforts by both public and private sectors to halt deforestation in Cerrado.

D4b: TECHNOLOGICAL INNOVATIONS FOR NATIVE FOREST MANAGEMENT IN DIFFERENT BRAZILIAN BIOMES

Forest management 4.0: planning with drones / Manejo Florestal 4.0 - planejamento com aeronaves remotamente pilotadas (RPAs)

Evandro Orfanó Figueiredo¹, Symone M Melo Figueiredo², Marcus V.N. d'Oliveira¹, Erica K.M. Santos²

¹Embrapa Acre, Rio Branco, Brasil; ²Universidade Federal do Acre, Rio Branco, Brasil (evandro.figueiredo@embrapa.br; symone.figueiredo@ufac.br; marcus.oliveira@embrapa.br; ericakerolaine@gmail.com)

A cada dia se fazem mais presente no campo, os processos que envolvem as geotecnologias de precisão, com inclusão de máquinas robotizadas e guiadas por computadores, sensores de presença e GNSS. Importantes aliadas nessa nova era do planejamento florestal de grande teor digital, são as aeronaves remotamente pilotadas (RPAs) ou mais conhecidas como *drones*. O manejo de precisão de florestais tropicais na Amazônia também acompanha a nova geração tecnológica, contemplando para isso: os inventários florestais semiautônomos a partir de RPAs, GNSS pós-processado e uso de algoritmos para segmentação e geolocalização automática de árvores. O objetivo do trabalho foi propor um calendário preliminar de inventário florestal com uso de RPAs (classe III), contemplando as árvores codominantes e dominantes, acima de 50 cm de DAP1,3m. O mapeamento da cobertura florestal a partir de ortofotos de alta resolução (< 7 cm) será uma etapa que deverá preceder a entrada da equipe de inventário em campo. Dessa maneira, a equipe de inventário florestal iniciará seus trabalhos com a geolocalização precisa de todas as árvores dominantes, facilitando significativamente a busca por espécies de interesse. O trabalho foi na reserva florestal da Embrapa Acre, na Amazônia Brasileira, com a RPA DJI P4Pro, por meio de voos semiautônomos. Para segmentação foram testados diversos parâmetros utilizando o algoritmo GEOBIA. O acompanhamento mensal da floresta a partir de ortofotos de alta resolução, possibilita traçar um perfil modal preliminar das fenofases de cada uma das 14 espécies estudadas, demonstrando assim a viabilidade do inventário automatizado com as RPAs. ■

Alternative systems for primary transport of wood planks in low-intensity sustainable forest management / Sistemas alternativos para o transporte primário de pranchas de madeira no manejo florestal sustentável de baixa intensidade

Iran Pires¹, João Melo¹, Ana Carolina Vieira¹, Ana Luiza Violato Espada^{1,2} , Elias Serejo¹

¹Instituto Floresta Tropical, Belém, Brasil; ²University of Florida, Gainesville, USA (iran@ift.org.br; joao@ift.org.br; carolina@ift.org.br; violatoespada@ufl.edu, elias@ift.org.br)

Na Amazônia existem diversas experiências de transporte primário de madeira na modalidade de Plano de Manejo Florestal Sustentável (PMFS) Pleno, com inúmeros arranjos de equipamentos e planejamentos já definidos em função do terreno, equipamentos disponíveis e graus de investimentos. Mas na modalidade

PMFS de baixa intensidade, comumente realizado por comunidades tradicionais, muitas experiências têm baixo investimento tecnológico. Atividades manuais ainda são frequentes, com pouca diversidade de planejamento operacional e excessivo esforço físico. Com a finalidade de testar sistemas alternativos para o transporte primário de pranchas de madeira no manejo florestal de baixa intensidade, o Instituto Floresta Tropical (IFT) realizou testes na Reserva Extrativista Ituxi, Lábrea-AM. A área total da Unidade de Manejo Florestal é de 1.403,53ha. A área destinada para o teste corresponde à 1ª Unidade de Produção Anual, com 136ha. Com a finalidade de melhorar os índices de produtividade e diminuir o esforço humano, foram testados o uso do microtrator e motocicleta para o transporte de pranchas de madeira. O uso desses equipamentos, por serem de pequeno porte e ágeis, é uma boa alternativa de aplicação para o manejo de baixa intensidade, em que a aquisição de tratores convencionais se torna inviável. Microtratores e motocicletas têm como principais características a acessibilidade de preços de aquisição, baixo consumo de combustível e custos reduzidos de manutenção. Também a diminuição do esforço físico para a realização da atividade florestal leva à uma maior motivação dos manejadores, diminuindo a evasão da mão-de-obra durante as operações florestais e aumentando o envolvimento do manejador.

Equipment for drying shell-on Brazil nuts in family extractive operations / Equipamentos para secagem de castanha-da-amazônia com casca em unidades familiares extrativistas

Virgínia Alvares¹, Marcelino Guedes², Fernanda Fonseca¹, Cleisa Cartaxo¹

¹Embrapa Acre, Rio Branco, Brasil; ²Embrapa Amapá, Macapá, Brasil (virginia.alvares@embrapa.br; marcelino.guedes@embrapa.br; fernanda.fonseca@embrapa.br; cleisa.cartaxo@embrapa.br)

Secagem, armazenamento e transporte de castanha-da-amazônia na floresta são etapas críticas da produção. Seu manejo inadequado favorece a contaminação por fungos filamentosos e toxinas de potencial carcinogênico. As tecnologias de manutenção da qualidade e segurança alimentar da castanha devem considerar o custo de adoção e a disponibilidade local de energia, infra-estrutura e mão-obra. Este estudo apresenta resultados da avaliação, em conjunto com produtores extrativistas, dos seguintes equipamentos de secagem de castanha-da-amazônia: 1) secador a ar quente (troca de calor indireto) por convecção natural, instalado na RESEX Chico Mendes (Acre), com capacidade para secagem de 200 a 300 litros de castanha com casca; e 2) paiol solar para secagem e armazenamento, construído em madeira, com câmara de aquecimento coberta com telhas translúcidas, instalado na RESEX Cajari (Amapá), com capacidade para 3000 litros de castanha com casca lavada. O primeiro reduziu o tempo de secagem de 15 dias para 6 horas, controlando fungos filamentosos totais e mantendo os níveis de aflatoxinas abaixo dos limites legais. Como contribuição, os produtores apontaram: necessidade de homogeneização da temperatura no trocador de calor; isolamento térmico da fornalha e redução do fluxo de ar na fornalha. O segundo reduziu o peso inicial em 20% após três dias, fornecendo castanhas limpas e de melhor aparência, atributos desejados pela comunidade por facilitar o transporte e manuseio e, conseqüente, agregar valor. Ajustes nos equipamentos deverão ser realizados para que o produto atinja os padrões de qualidade e segurança normatizados, possibilitando renda às famílias extrativistas e garantindo a sustentabilidade da atividade.

Optimization of trails and adding value to Brazil nut extractivism (Bertholletia excelsa Bonpl.): a case study / Otimização de trilhas e valorização da atividade extrativista da Castanha-da-amazônia (Bertholletia excelsa Bonpl.): um estudo de caso

A coleta da castanha-da-amazônia envolve grande número de pessoas, que tem nesta atividade uma importante complementação da renda familiar. Apesar desta importância, a atividade precisa ser cada vez mais valorizada e valorada. A dinâmica de coleta da castanha envolve um grande esforço laboral, com grandes deslocamentos dentro dos castanhais, afim de se realizar a amontoa e quebra de ouriços, para posterior transporte das castanhas in natura. A otimização do traçado de trilhas visa identificar o melhor percurso, combinando fatores que determinam o grau de dificuldade de se percorrer determinada região e uma maior eficiência de acesso a árvores selecionadas, utilizando variáveis de relevo, hidrografia e localização espacial de castanheiras, integradas por meio de geotecnologias, com enfoque em análise de redes. Um estudo de caso foi realizado em um castanhal de aproximadamente 145 ha, localizado no município de Epitaciolândia, Acre, onde se aplicou a metodologia para acesso a 115 castanheiras produtivas. Na geração de trilhas otimizadas, superfícies de custo (tempo) são obtidas, as quais permitem o cálculo do tempo gasto na atividade de coleta da castanha, incluindo deslocamentos no terreno até as árvores produtivas, amontoa, quebra de ouriços e transporte até o destino final. O tempo total gasto na coleta em 115 castanheiras foi de 33 dias/homem, que convertidos ao valor da diária local, resultou em um custo com mão-de-obra de aproximadamente R\$ 1.650,00. O estudo demonstrou ser possível contribuir para a valorização da etapa de coleta, auxiliando em uma mais justa definição de preços do produto para os agroextrativistas.

Approach to estimating fruit production in native populations of Euterpe precatoria Mart. palms in southwestern Amazonia: experience at the Chico Mendes Extractive Reserve, Acre, Brazil / Abordagem para estimativa a produção de frutos de populações nativas de açai solteiro (Euterpe precatoria Mart.) na Amazônia Sul-ocidental: a experiência da Reserva Extrativista Chico Mendes, Acre

¹Embrapa, Acre, Brasil; ²Universidade Federal de Santa Catarina, Florianópolis, Brasil; ³Embrapa Rondônia, Porto Velho, Brasil (fernanda.fonseca@embrapa.br; cleisa.cartaxo@embrapa.br; lucia.wadt@embrapa.br)

O principal desafio relacionado à qualidade da castanha-da-amazônia é a presença de aflatoxinas, problema que já chegou a afetar severamente o mercado internacional da amêndoa. O uso de boas práticas de manejo (BPM) tem reduzido significativamente esse tipo de contaminação, possibilitando a retomada do mercado. Se por um lado identificam-se aspectos favoráveis à adoção das BPM por produtores extrativistas, como a adequação das práticas à realidade produtiva, a redução da contaminação e o melhor rendimento no processamento nas usinas, por outro, um conjunto de fatores restringem seu uso. Este resumo tem como objetivo discutir os principais desafios identificados para a adoção das BPM em Brasiléia, Acre, município brasileiro localizado na fronteira com o Peru e Bolívia. A pesquisa aborda elementos sobre o processo de transferência de tecnologia, sua apropriação e os fatores que interferem na tomada de decisão do extrativista sobre a adoção das diretrizes técnicas de manejo. O estudo se baseou em observações em campo e narrativas de manejadores de castanha. Com base nas informações levantadas, pode-se afirmar que as BPM para a produção da castanha, foram apropriadas pelos extrativistas na etapa de pré-coleta. Entretanto, nas etapas de coleta e pós-coleta, as BPM apresentaram baixa adoção em virtude de fatores como não diferenciação de preço para o produto manejado; elevada concorrência de compradores na região da tríplice fronteira; baixa capacidade de gestão das associações de produtores para buscar mercados diferenciados; e insuficiente assistência técnica para orientar a adoção das práticas e apoiar o monitoramento da qualidade do produto.

Approach to estimating fruit production in native populations of *Euterpe precatoria* Mart. palms in southwestern Amazonia: experience at the Chico Mendes Extractive Reserve, Acre, Brazil / Abordagem para estimativa a produção de frutos de populações nativas de açaí solteiro (*Euterpe precatoria* Mart.) na Amazônia Sul-ocidental: a experiência da Reserva Extrativista Chico Mendes, Acre

Andrea Alechandre¹, Elaine Lopes¹, Daniel Papa², Dorila Gonzaga²

¹Universidade Federal do Acre, Rio Branco, Brasil; ²Embrapa Acre, Rio Branco, Brasil (andreaalechandre@gmail.com; lopes.elaine7@gmail.com; daniel.papa@embrapa.br; dorila.gonzaga@gmail.com)

Os frutos de açaí são o principal produto do extrativismo vegetal no Brasil, tanto pela quantidade produzida quanto pelo valor obtido. A *Euterpe precatoria* Mart. (açaí solteiro) tem ocorrência na Amazônia Ocidental, respondendo por 26% da produção brasileira de frutos, sendo a *E. oleracea* Mart. (açaí-do-pará) responsável por 3/4 da produção total. Apesar do grande potencial econômico, o açaí solteiro ainda é pouco utilizado economicamente no estado do Acre. O objetivo desse trabalho foi desenvolver e testar uma abordagem para estimar o potencial produtivo do *E. precatoria* em comunidades da Reserva Extrativista Chico Mendes. Para tanto foram seguidas as seguintes etapas: mobilização das lideranças para definição das áreas de levantamento; capacitação de técnicos extrativistas no mapeamento de açazeiros; mapeamento com GPS de navegação; elaboração de mapas a partir de softwares de SIG (TrackMaker, Google Earth Pro e ArcGis); cálculo da estimativa de produção de frutos; validação dos mapas com a comunidade; uso dos mapas para planejamento de coleta e comercialização. A aplicação desta abordagem permitiu: a melhoria da organização comunitária voltada à comercialização de açaí; técnicos extrativistas capacitados em mapeamento; “colocações” (unidade produtiva familiar) com produção de açaí estimada; comprador de matéria-prima compromissado com a aquisição da produção; e o interesse de outros produtores extrativistas em aplicar a metodologia. A maior dificuldade encontrada foi para o deslocamento no período chuvoso devido as más condições de trafegabilidade dos ramais. Esta é uma abordagem aplicável para estimar o estoque da produção de quaisquer produtos florestais não madeireiros manejado por populações tradicionais.

Challenges in adopting good management practices for sustainable extraction of Brazil nuts in Acre, Brazil / Desafios para a adoção das boas práticas de manejo para o extrativismo sustentável da castanha-da-amazônia no Acre

¹Serviço Florestal Brasileiro, Brasília, Brazil (drivejrocha@gmail.com; rejane.mendes@florestal.gov.br; raimundo.deusdara@florestal.gov.br; bernardo.trova@florestal.gov.br; kimberly.castro@giz.de; leandro.biondo@florestal.gov.br; gustavo.oliveira@florestal.gov.br; pedro.salles@florestal.gov.br; carlos.sturm@florestal.gov.br; consultora4.gecaf@florestal.gov.br; gabriela.goncalves@florestal.gov.br; tatiana.calçada@florestal.gov.br; lilianna.mendes@florestal.gov.br)

O Cadastro Ambiental Rural (CAR), instituído pelo Código Florestal Brasileiro (CFB), integra as informações georeferenciadas da vegetação nativa de todos imóveis rurais, e configura-se a principal plataforma digital de planejamento do uso do solo para produção rural sustentável do mundo. As informações autodeclaratórias dos produtores rurais, são armazenadas em um banco de dados geoespacial, integrado e desenvolvido em plataformas livres, para todo o território nacional e composto por diversas regras de negócios baseadas na legislação vigente e estruturadas por requisitos do Serviço Florestal Brasileiro (SFB), gestor nacional do SICAR. A representação espacial dos imóveis rurais a partir do uso de imagens de satélite de alta resolução permite semi-automatização da análise da cobertura de vegetação nativa para diagnosticar o cumprimento da regularidade ambiental dos imóveis rurais, bem como áreas para recomposição da vegetação nativa. Este trabalho descreve, os cinco anos de implantação e dados contextualizados com as informações por bioma, a partir dos remanescentes de vegetação nativa declarados e respectivo detalhamento das informações florestais sob a ótica estratégica de conservação florestal provida pelos imóveis rurais no Brasil. Desde sua implantação, o SICAR recebeu cerca de 5,5 milhões de imóveis rurais, totalizando área de mais de 503,5 milhões de hectares. Nos dados declarados, 40,6% representa a cobertura de vegetação nativa, 27,6 % as áreas de Reserva Legal e 3,9%, as Áreas de Preservação Permanente - APP. Nestes, 79,2% das áreas de Reserva Legal e 59% das APP cobertas de vegetação nativa. Ademais, 58,1% dos imóveis rurais declaram adesão aos Programas de Regularização Ambiental – PRA.

A first Amazon CH₄ budget and its controls based on atmospheric data from vertical profiles measurements

The role of tropical regions in the global CH₄ balance remained uncertain, due these regions have until recently been poorly observed with large-scale integrating in-situ observations. To contribute in understanding the CH₄ balance in tropical regions, we have started a lower-troposphere greenhouse gas-monitoring program over Brazilian Amazon Basin consisting of regular vertical profile greenhouse gas observations at four sites. Samples are collected regularly each 2 weeks, using light aircraft. We will present an analysis of these data and what they tell us about the Amazon CH₄ cycle and its contribution to global CH₄ concentration. We estimate fluxes upwind of the sites from the profile data using a column budgeting approach (Miller et al., 2007). Over the full period (2010-2017) the Amazon Basin was a source of CH₄, but with regional variations. There are comparably high and highly variable emissions from the eastern part of the basin exhibiting strong variability, with particularly high CH₄ fluxes in two different periods of the year (beginning of the wet season and in the dry season). In contrast to this, a clear seasonality was observed at the other three sites, with the largest emissions occurring at the beginning of the wet season (January to March). Emissions from biomass burning contribute with a small part of the total flux at each site. We will finally discuss what is the influence from precipitation and temperature in the Amazon CH₄ emissions. Acknowledgment: FAPESP, NERC, CNPq, MCTI, NOAA, IPEN and INPE.

Understanding the relationships between local deforestation and CO₂ atmospheric measurements in the Brazilian Amazon

Graciela Tejada¹, Luciana Gatti^{1,2}, Luana Basso¹, Henrique L.G. Cassol³, Luciano Marani¹, Caio Correia^{1,2}, Lucas Domingues^{1,2}, Stephane Crispim¹, Raiane Neves¹, Liana O. Anderson⁴, Luiz EOC. Aragão³, Egidio Arai³, Manuel Gloor⁵, John B. Miller⁶, Celso von Randow¹

Amazon forests play a fundamental role in the global carbon balance as a carbon sink, but temperature elevations and frequent extreme events as droughts and floods could make the forests a source of CO₂. Local atmospheric measurements of greenhouse gases are needed to better understand how forest will respond to climate change. The lower-troposphere greenhouse gas (GHG) monitoring program over Brazilian Amazon Basin, has been collecting biweekly GHGs vertical profiles in four sites since 2010. We aim to understand the relationships between local deforestation and CO₂ aircraft measurements in the Brazilian Amazon. We calculated annual deforestation (using the Amazon Deforestation Calculation Program - PRODES), land use and cover change data (using the Brazilian Institute of Geography and Statistics - IBGE) and fire data (using the Fire Monitoring System) in each annual influence area at the four flight measurement sites of the Brazilian Amazon from 2010-2017 (and also in the mean influence area of all years by sites). We found that when we see total deforestation, it has a relationship with global CO₂ emissions in the Brazilian Amazon biome. Fire has a strong relationship in the drought years, mostly in 2012. Looking at each site, we found specific correlations with deforestation, fire and land use. The biggest challenge was to compare spatial analyzes of land use change and fire with punctual data of airplane GHGs measurements. This study will contribute in our understanding of anthropogenic activities over the Amazon forest in a changing climate.
