ABSTRACT

Thaumastocoris peregrinus (Hemiptera, Thaumastocoridae) is a phytophagous pest of eucalyptus plantations. It was introduced in Brazil in 2008, and expanded rapidly due to its adaptive capacity to different climatic conditions. Eucalyptus has been planted in the Brazilian Amazon since the 1980s, being used in silvopastoral systems and for cellulose production. Since its introduction in the southernmost Brazilian state of Rio Grande do Sul, *T. peregrinus* has expanded its geographical distribution to 117 municipalities in states in the south (Rio Grande do Sul, Santa Catarina and Paraná), southeast (São Paulo, Espírito Santo, Rio de Janeiro and Minas Gerais), mid-west (Mato Grosso do Sul and Goiás) and northeast (Sergipe) of the country. Here we report the first record of *T. peregrinus* in the Brazilian Amazonian state of Pará.

KEYWORDS: insect pest, bronze bug, occurrence, *Eucalyptus*, Brazilian Amazon

Primeiro registro de *Thaumastocoris peregrinus* (Hemiptera, Thaumastocoridae) no estado do Pará, Brasil

RESUMO

Thaumastocoris peregrinus (Hemiptera, Thaumastocoridae) é uma praga fitófaga de plantios de eucalipto introduzida no Brasil em 2008. A espécie expandiu-se rapidamente devido à sua capacidade adaptativa a diferentes condições climáticas. O eucalipto vem se expandindo na Amazônia brasileira desde a década de 1980, sendo usado em sistemas silvipastoris e produção de celulose. Desde a sua introdução inicial no Rio Grande do Sul, *T. peregrinus* expandiu sua distribuição geográfica a 117 municípios nos estados sul (Rio Grande do Sul, Santa Catarina e Paraná), sudeste (São Paulo, Espírito Santo, Rio de Janeiro e Minas Gerais), centro-oeste (Mato Grosso do Sul e Goiás) e nordeste (Sergipe) do país. Aqui relatamos o primeiro registro de *T. peregrinus* no estado do Pará, Brasil.

PALAVRAS-CHAVE: praga agrícola, percevejo-bronzeado, ocorrência, *Eucalyptus*, Amazônia

Thaumastocoris peregrinus Carpintero & Dellapé (Hemiptera, Thaumastocoridae) is a phytophagous pest in both immature and adult stages that occurs in eucalyptus plantations (Carpintero and Dellapé 2006). Attacked trees present symptoms such as drying and color change of the leaves, that change from their natural silvery color to brown-reddish. It is from this leaf color of infested trees, that the insect derives its common name, bronze bug (Jacobs and Nesser 2005; Wilcken *et al.* 2010). Intense *T. peregrinus* infestations cause partial or total defoliation that results in the reduction of the trees photosynthetic area (Penteado *et al.* 2014) and the consequent decrease in its productivity (Lunz and Azevedo 2016), eventually leading to the death of the tree.

Thaumastocoris peregrinus feeds on eucalyptus by making small incisions on the leaves (Lorenzetti *et al.* 2015; Cipriani *et al.* 2015). The adult insect is 3-4 mm long with a brown

flattened body that varies according to the development phase (Jacobs and Nesser 2005; Lorenzetti *et al.* 2015; Lunz and Azevedo 2016). Females of *T. peregrinus* lay an average of 60 black eggs on eucalyptus leaves. The development involves five nymph instars (Jacobs and Nesser 2005) and an approximate 60-day life cycle that can vary with climate conditions (Penteado *et al.* 2014). Generations overlap along the year, so that great numbers of nymphs and adults can occur simultaneously (Noack and Rose 2007).

Originated from Australia, *T. peregrinus* was first recorded in South America in November 2005, in the north of Buenos Aires, Argentina (Noack and Coviella 2006), and later in Uruguay, in January 2008 (Martínez and Bianchi 2010). In Brazil, the species was first recorded in early 2008, in the municipality of São Francisco de Assis, in the southern state

CITE AS: Saliba, I.L.; Lunz, A.M.; Batista, T.F.; Schwartz, G. 2019. First record of *Thaumastocoris peregrinus* (Hemiptera, Thaumastocoridae) in Pará state, Brazil. *Acta Amazonica* 49: 179-182.

of Rio Grande do Sul (Table 1), in hybrid clones of *Eucalyptus urograndis* and *E. urophylla* (Wilcken *et al.* 2010).

The insect rapidly dispersed over eucalyptus plantations throughout Brazil (Figure 1) due to its adaptive capacity, since it can survive under different climate conditions (Pereira *et al.* 2013). Other favorable aspects for the rapid dispersion of *T. peregrinus* were the transport of infested vegetal material of eucalyptus across producing regions (Wilcken *et al.* 2010) and fragile phytosanitary barriers among producing states (Lunz and Azevedo 2016).

In the southeastern region of the state of Pará, in the eastern Brazilian Amazon, soil and climatic conditions are favorable to the development of eucalyptus plantations (Filgueiras *et al.* 2011). Today, Pará is the 10th Brazilian state in area planted with eucalyptus, with almost 134,000 ha, being mainly used to supply the energy and cellulose markets (IBA 2017). Reports on the occurrence of new dangerous biotic agents in these plantations are scarce, which is likely due to the lack of periodic monitoring by plantation owners.

Here we provide information on the occurrence of *T. peregrinus* in eucalyptus plantations from Pará state, extending the geographic distribution of this pest in Brazil. Sampling was carried out in 2015 and 2016, in areas of commercial plantations of *Eucalyptus* spp. in southeastern Pará, in the municipalities of Paragominas ($03^{\circ}20'07.08''S$, $47^{\circ}11'21.54''W$), Ulianópolis ($03^{\circ}58'26.50''S$, $47^{\circ}33'01.96''W$), Dom Eliseu ($04^{\circ}30'02.73''S$, $47^{\circ}49'31.50''W$) and Rondon do Pará ($04^{\circ}36'32.91''S$, $47^{\circ}57'18.51''W$) (Figure 1). The climate type is Aw, according to the Köppen classification. Yellow sticky traps (ISCA Technologies, Brazil) were used in 32 georeferenced points. Traps were placed in the interior of the plantations, at least 100 m from the border. Each trap was located between two trees at 1.60 m from the soil. Traps were replaced monthly. Retrieved traps were analyzed at an entomology laboratory at Universidade Federal Rural da Amazônia, in Belém (Pará state, Brazil) under a stereoscopic microscope QM Q7714Z. Specimens of *T. peregrinus* were identified through the use of taxonomic keys by

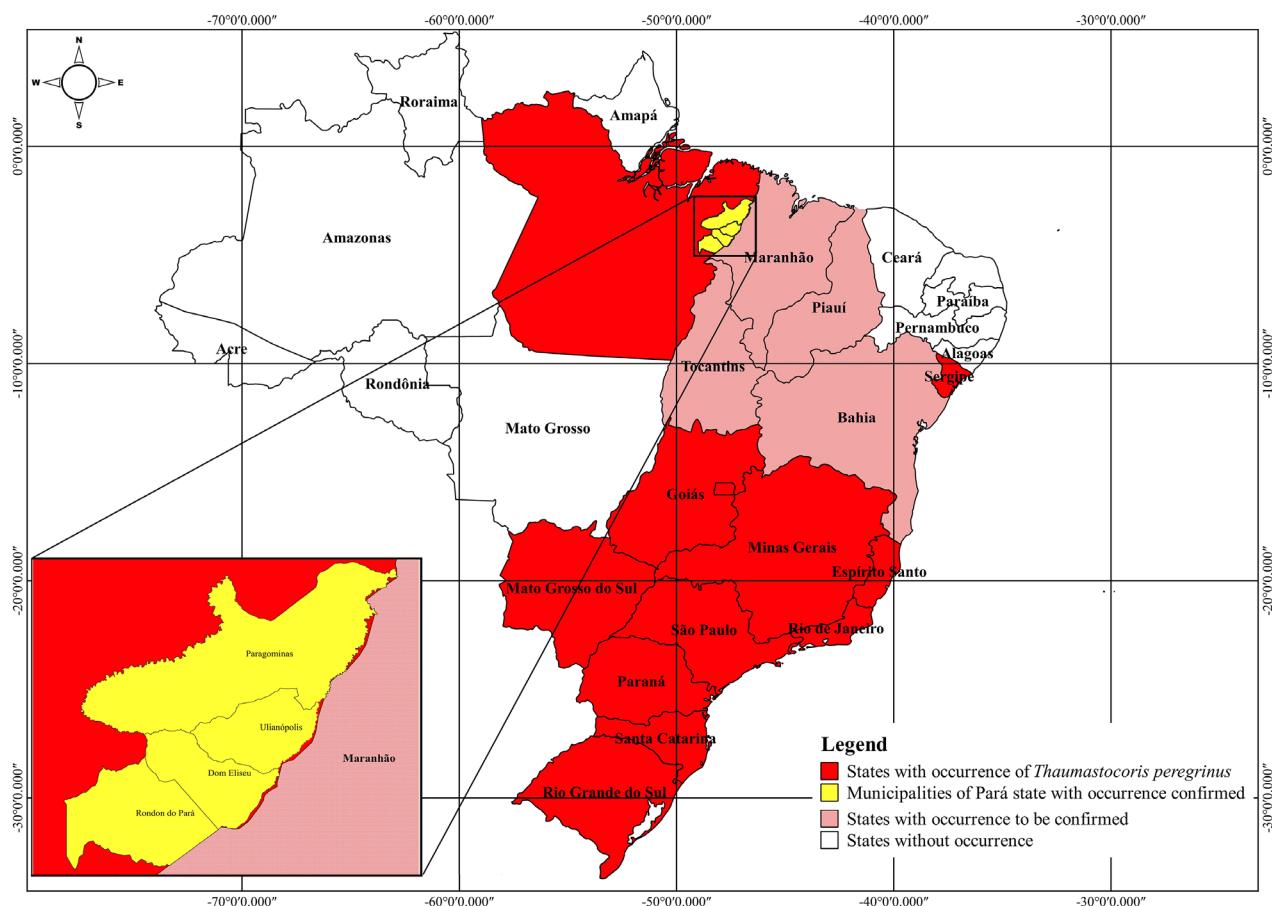

Figure 1. Distribution of the bronze bug, *Thaumastocoris peregrinus* in Brazil, showing in red the states with confirmed occurrences. The first record was in the southern state of Rio Grande do Sul in 2008 (see Table 1 for first records in other states). The municipalities in Pará state where the species was first recorded (this study) are indicated in yellow. States in which the species has been reported, but no voucher-based records exist to date, are indicated in pink. This figure is in color in the electronic version

Table 1. Chronological evolution of first records of the bronze bug, *Thaumastocoris peregrinus* in different Brazilian states. The first record in Brazil was in Rio Grande do Sul state in January 2008.

Date of first record	Number of municipalities	State	Source

2015	4	Pará	This study

Carpintero and Dellapé (2006) and Wilcken *et al.* (2010). Voucher specimens of the collections were deposited in the entomological collection of Embrapa Amazônia Oriental in Belém, Pará, Brazil, under number 2444. Quantitative data of these samplings will be analyzed elsewhere.

A total of 1,358 individuals were collected, 438 (32.2%) in 2015 and 920 (67.8%) in 2016, in all four municipalities sampled. *Thaumastocoris peregrinus* occurred in clones of *E. camaldulensis*, *E. urophylla*, *E. grandis*, and in hybrid clones of *E. camaldulensis*. Nymphs and eggs were also observed in neighbor trees around the traps, but these trees showed no sign of serious damage.

Many eucalyptus species are attacked by *T. peregrinus*, especially *E. camaldulensis* and the hybrid *E. urograndis* (Queiroz 2009). Moreover, *E. camaldulensis* is considered as the most susceptible eucalyptus species to insect pests (Wilcken 2008). *Thaumastocoris peregrinus* also attacks *E. tereticornis* and the hybrid of *E. camaldulensis* x *E. grandis* (Jacobs and Nesser 2005). *Eucalyptus urophylla* and *E. grandis* were also very susceptible to *T. peregrinus* attacks (Soliman *et al.* 2012).

Increases in plantation areas normally result in increases in insect species that adapt themselves to the crops (Costa and Araldi 2014). Exotic insect pests in forest plantations can be a threat to forest productivity due to the economic losses coming from plantation damages caused by these insects (Garlet *et al.* 2016). There is scarce information regarding the efficient management of *T. peregrinus*.

Probably the *T. peregrinus* invasion in Pará started from eucalyptus plantations in the neighboring state of Maranhão, where the presence of *T. peregrinus* has been reported in

newsfeeds (SAGRIMA 2014), although no voucher-based record exists yet of the occurrence of the species in this state. Eucalyptus has been cultivated in Pará for more than 30 years without adequate insect pest monitoring by plantation owners. Based on the pest's first records in the mid-western state of Goiás (Table 1) it is reasonable to estimate that *T. peregrinus* is in Pará since 2013. Furthermore, *T. peregrinus* can also be present in eucalyptus plantations in Bahia, Piauí, Maranhão and Tocantins (Figure 1), although there are no scientific records of its occurrence published for these states.

Our findings highlight the importance of using periodic and systematic monitoring methods to determine pest infestation levels and population dynamics in eucalyptus commercial plantations, and which eucalyptus species are more susceptible to pests. Systematic studies also help to identify possible native natural enemies of pest species that could favor the use of ecological pest management.

Since its first occurrence, and including the records we present in here, *T. peregrinus* has now been recorded in 117 Brazilian municipalities, and in 11 federal states (Table 1)

ACKNOWLEDGMENTS

We are grateful to Conselho Nacional de Desenvolvimento Científico e Tecnológico – CNPq (project # 474457/2013-3 CNPq/Universal call for proposals nr. 14, Faixa B), and to Empresa Brasileira de Pesquisa Agropecuária – Embrapa (project # 02.12.01.028.00.00 Embrapa/Macropograma 2) for funding, which made this work possible.
