ABSTRACT

The concentration and reconstitution processes of grape juices can result in losing compounds associated with beverage quality. In this context, three tanks containing 50,000 L of grape juice were individually concentrated up to 68 °Brix using a triple vacuum concentrator. The concentrated juice was reconstituted up to the original °Brix of the whole juice (18.4). Phenolic compounds, sugars and organic acids were quantified by high-performance-liquid-chromatography. “Foxy” aromatic compounds were also quantified by gas-chromatography/mass-spectrometry. The concentration and reconstitution process resulted in significant losses (Tukey test, $p < 0.01$) of *trans*-caftaric acid, decreasing from 397.08 to 159.14 mg/L, chlorogenic-acid from 34.97 to 8.44 mg/L, aromatic furaneol compound from 9.06 to 1.93 mg/L, as well as total losses for gallic-acid, caffeic-acid, *p*-coumaric-acid, syringic-acid, hesperidin, pelargonidin-3-glucoside and epicatechin compounds. The concentration and reconstitution of grape juice preserved the antioxidant capacity and most of the quantified compounds, with the reconstituted juice having good nutritional quality.

1. Introduction

Grape juice consumption has mainly grown in the whole form and also reconstituted from concentrated juice. Factors such as characteristic flavor, aroma, color and refreshment have contributed to its sensory acceptance (Campos et al., 2016; Granato, de Magalhães Carrapeiro, Fogliano, & van Ruth, 2016; Rojo et al., 2019). Another characteristic that has popularized grape juice is the ‘in vitro’ and ‘in vivo’ functional properties associated to the health of grape juice consumers, which is mainly related to phenolic compounds (Corredor et al., 2016; Granato et al., 2016; Toaldo, Cruz, Silva, & Bordignon-Luiz, 2016; Toscano et al., 2017; Dutra, Rodrigues, Oliveira, Pereira, & dos Santos Lima, 2018).

According to Brazilian legislation, concentrated grape juice is a product submitted to physical processes to remove water, increasing the soluble solids content present in the respective whole juice by at least 50%. Reconstituted grape juice is the product obtained by diluting

concentrated or dehydrated juice up to the original concentration of the fresh juice using the °Brix as a parameter for reconstitution (Brazil, 2018).

Grape juices are complex matrices mainly consisting of water and several metabolites, with an emphasis on sugars, organic acids, minerals, phenolic and aromatic compounds (Capanoglu, Vos, Hall, Boyacioglu, & Beekwilder, 2013; Lima et al., 2014; Dutra et al., 2018a, 2018b; Coelho et al., 2018; Guler, Tokusolgu, & Artik, 2018; Li, Wei, Wang, Zhou, & Wang, 2019).

The main Brazilian region which produces and exports grape juice is Rio Grande do Sul State in the southern region of the country. This state produced 140 million liters of whole juice and 117 million liters of concentrated juice in 2018 (Mello, 2019). The São Francisco Valley (SFV) in the Northeast of Brazil has invested heavily in grape juice production since 2012, where the main commercial juices are made by mixing the following Brazilian grapes: Isabel Precoce (*Vitis labrusca*) and the BRS Violeta, BRS Cora, BRS Magna, and more recently BRS

Carmen hybrids (Lima, M.d.S., Silani, I. S. V., Toaldo, I. M., Correa, L. C., Biasoto, A. C. T., Pereira, G. E., Ninow, J. L., Bordignon-Luiz, M. T., 2014; Dutra et al., 2018a; Padilha, dos Santos Lima, Toaldo, Pereira, & Bordignon-Luiz, 2019). According to data collected from the producing companies in the SFV in 2019, 15 million liters of whole juice and 10 million liters for concentrated juices were prepared.

Previous studies have characterized SFV whole grape juices as high quality beverages with a high concentration of phenolic compounds, high 'in vitro' antioxidant capacity and sugars concentration, and normal acidity; presenting the oligosaccharide kestose prebiotic in its composition. The main 'foxy' aromatic compound present in SFV grape juices is Furanol which is associated with the aromatic typicality of the juices of this region, but it is also possible to find lower amounts of methyl anthranilate and 2-aminoacetophenone. The juices can be produced in the SFV region throughout the year due to the climatic conditions of the region which enables staggered production of grapes, which in turn enables placing fresh products in the market in all periods of the year (Lima et al., 2014; Dutra et al., 2018b; Coelho et al., 2018; Padilha et al., 2019).

Several factors influence the chemical composition of juices, including processing techniques (Granato et al., 2016). Previous studies which quantified phenolic compounds and antioxidant capacity in grape juices during the processing steps highlighted a decrease in antioxidant capacity and the levels of some flavanols, phenolic acids and anthocyanins (Capanoglu et al., 2013; Guler et al., 2018). However, no other key quality components were evaluated in these previous studies such as aromas, organic acids or sugars in concentrated juices, nor the quality of reconstituted juices. In this context, the objective of the present study was to evaluate the influence of the concentration and reconstitution process on the phenolic compound, sugar and organic acid profiles by high performance liquid chromatography (HPLC), "foxy" aromatic compounds by gas chromatography/mass spectrometry (GC-MS), and the 'in vitro' antioxidant capacity of grape juices produced in the SFV region in Northeast Brazil.

2. Material and methods

2.1. External standards and chemicals

External standards for aromatic compounds and oligosaccharides: 2-octanone, methyl anthranilate, 2-aminoacetophenone, 4-hydroxy-2,5-dimethyl-3 (2H) -furanone, 1-kestose, nystose and raffinose were purchased from Sigma-Aldrich (St. Louis, MO, USA). Tartaric, malic, citric, succinic and formic acids were obtained from Química Vetec (Rio de Janeiro, RJ, Brazil). TPTZ (2,3,5-Triphenyltetrazolium chloride), Trolox (6-hydroxy-2,5,7,8-tetramethylchromate-2-carboxylic acid), 2,2-diphenyl-1-picrylhydrazil (DPPH), 2,2-azino-bis (3-ethylbenzothiazoline-6-sulfonic acid) (ABTS), and the external standards of the phenolics: gallic acid, p-coumaric acid, chlorogenic acid, syringic acid, *trans*-caffeic acid, caffeic acid, hesperidin, naringenin, procyanidin B1, catechin, epicatechin and procyanidin B2, cyanidin-3,5-diglucoside, malvidin-3,5-diglucoside, and pelargonidin-3,5-diglucoside were purchased from Sigma-Aldrich (St. Louis, MO, USA). Acetonitrile, methanol, potassium persulfate and ethyl alcohol were obtained from Merck (Darmstadt, HE, Germany). The ultrapure water was obtained using a Marte Científica purification system (São Paulo, SP, Brazil). Procyanidin A2, epigallocatechin gallate, epicatechin gallate, kaempferol 3-glucoside, quercetin 3-rutinoside (rutin), quercetin 3-glucoside, myricetin, peonidin-3-glucoside, petunidin-3-glucoside, delphinidin-3-glucoside, delphinidin-3-glucoside, malvidin-3-glucoside, cyanidin-3-glucoside, pelargonidin-3-glucoside came from Extrasynthese (Genay, France). *cis*-Resveratrol and *trans*-resveratrol were obtained from Cayman Chemical Company (Ann Arbor, MI, USA).

2.2. Grape juice processing and sampling

The present study was carried out in the industrial grape juice production line of the Queiroz Galvão Alimentos S/A company, Timbaúba Farm, Petrolina, PE, Brazil. Batches of 50,000 L of whole grape juice were processed on three consecutive days (3 repetitions) with a blend of the following grapes: Isabel Precoce – 50%, BRS Magna – 40% and BRS Carmem – 10%. The grapes were destemmed and crushed, heated to 55 °C, added with pectinase and remained in maceration for 60 min. (depectinization). Pressing was performed and the drained juice was centrifuged, pasteurized at 85 °C for 3 min and then submitted to cold stabilization (tartaric stabilization) at a temperature of 2 °C for 7 days. After tartaric stabilization, the juice was drained, reheated to 25 °C and pumped into vacuum concentrating tanks, where samples named 'whole juice' were collected. The whole juice was filled in 300 mL glass bottles, pasteurized at 85 °C for 3 min and kept refrigerated (5 ± 1) until the analyzes were performed.

The respective whole juices were concentrated in a continuous set of three vacuum evaporating tanks (triple effect) of descending films at a temperature of 50 °C and pressure ≥ 600 mm Hg until reaching 68 °Brix for three consecutive days (3 repetitions). Concentrated juice samples (68 °Brix) were collected in 300 mL colorless glass bottles and kept in the refrigerator (5 ± 1) until the analyzes were performed.

The reconstituted juices were obtained by diluting concentrated juices until achieving soluble solids content of 18.4 °Brix using distilled water. After the reconstitution, the juices were filled in 300 mL colorless glass bottles, pasteurized at 85 °C for 3 min., cooled and kept in a refrigerator (5 ± 1) until the analyzes were performed.

All juice elaboration processes were carried out in August 2019 and all chemical analyzes were performed in September 2019. The treatments were named whole grape juice (WGJ), concentrated grape juice (CGJ) and reconstituted grape juice (RGJ), manufactured in industrial conditions and processed in three independent batches (3 repetitions).

2.3. Quality analysis – classic parameters and color

The pH was measured in a PHS-3B digital bench potentiometer (Tecnal, Brazil), soluble solids (SS) in °Brix, analyzed using a HI 96.801 digital refractometer (Hanna, United States), titratable acidity (AT) by titrimetry, and color and hue (tone) intensity by the absorbances 420, 520 and 620 nm in a UV 2000A UV-Visible spectrophotometer (Instrutherm, Brazil) using glass cuvettes with 0.2 cm of optical path, all following the methodology described by the International Organization of Grape and Wine - OIV (2011).

2.4. In vitro antioxidant capacity by spectrophotometry

The in vitro antioxidant capacity was evaluated using the Ferric reducing antioxidant power (FRAP) (Rufino et al., 2006), Hydrogen peroxide scavenging activity (H_2O_2) (Ruch, Cheng, & Klaunig, 1989), and free radical scavenging by DPPH (1,1-diphenyl-2-picrylhydrazyl) and ABTS 2,2-azino-bis-(3-ethylbenzothiazoline-6-sulfonic acid) techniques following the methodologies described by Kim, Guo, and Packer (2002) and Re et al. (1999), respectively. Analytical standard Trolox was used to construct the calibration curves except for the FRAP method, in which ferrous sulphate was used. The results were expressed as Trolox equivalents per liter of grape juice ($mmol TE L^{-1}$) and $mmol of Fe^{2+}$ per liter of grape juice ($mmol Fe^{2+} L^{-1}$).

The FRAP reagent was prepared in 300 $mmol L^{-1}$ acetate buffer (pH 3.6), 10 $mmol L^{-1}$ TPTZ (2,4,6-tris(2-pyridyl)-s-triazine) in a 40 $mmol L^{-1}$ HCl and 20 $mmol FeCl_3$ solution. The grape juice (90 μL) and 270 μL of ultrapure water were mixed with 2.7 mL of FRAP reagent. They were subsequently mixed in a tube and incubated for 30 min in a thermodigester block (Bioplus IT-2002, Barueri, SP, Brazil). The absorbance was measured at 595 nm.

H_2O_2 method: a hydrogen peroxide solution (4 mmol) was prepared

in phosphate buffer (pH 7.4). The juice samples (0.4 mL) were mixed with hydrogen peroxide solution (0.6 mL) with the final volume adjusted to 3 mL using the phosphate buffer. The absorbances were spectrophotometrically determined at 230 nm after 10 min. Phosphate buffer was used as the blank sample.

The ABTS^{•+} radical was formed by the reaction of the 7 mmol ABTS solution with 140 mmol potassium persulfate incubated at 25 °C without light incidence for 16 h. The radical was diluted in ethanol to the absorbance of 0.70 ± 0.05 at 734 nm. Next, a 300 μ L aliquot of the sample was transferred to 2700 μ L of the radical and the readings were carried out 6 min after adding the sample in a dark environment.

A DPPH solution (1 mmol L⁻¹) was prepared in absolute ethanol and diluted to an absorbance of 0.900 ± 0.050 (100 μ mol L⁻¹). The antioxidant capacity of the samples was assessed through the decay rate in absorbance at 517 nm. The absorbance of free radical solution was determined before and after adding juice samples. The absorbance was measured at time $t = 30$ min after adding the grape juice. All absorbance readings were performed using a UV-Vis 2000A spectrophotometer (Instrutherm, Brazil).

2.5. Determination of phenolic compounds, organic acids, sugars and oligosaccharides by HPLC

All analyses by high performance liquid chromatography (HPLC) were performed using an Agilent 1260 Infinity LC chromatography system (Agilent Technologies, Santa Clara – USA) coupled to a refractive index detector (RID) (model G1362A) and a diode array detector (DAD) (model G1315D). The data were processed using OpenLAB CDS ChemStation Edition software (Agilent Technologies, Santa Clara – USA).

The individual phenolic profile was determined in HPLC/DAD according to the method validated by Padilha et al. (2017) with adaptations by Dutra et al. (2018). The column used was Zorbax Eclipse Plus RP-C18 (100 \times 4.6 mm, 3.5 μ m) with a Zorbax C18 (12.6 \times 4.6 mm, 5 μ m) (Zorbax, USA) pre-column. The oven temperature was maintained at 35 °C and the injection volume was 20 μ L of the sample, previously diluted in phase A and filtered through a 0.45 μ m membrane (MillexMillipore, Barueri, SP, Brazil). The solvent flow was 0.8 mL min⁻¹. The gradient used in the separation was 0–5 min: 5% B; 5–14 min: 23% B; 14–30 min: 50% B; 30–33 min: 80% B, in which solvent A is a phosphoric acid solution (pH 2.0) and solvent B is methanol acidified with H₃PO₄ 0.5%. Compound detection occurred by comparison with the external standards. All quantified phenolics showed calibration curves with $R^2 > 0.998$. The detection and quantification limits (LOD & LOQ, respectively) for all analyzed compounds were LOD < 0.17 mg L⁻¹ and LOQ < 1.41 mg L⁻¹. The spectral purity of the peaks was assessed by the threshold test (purity factor > 990) in order to ensure that there was no coelution in the quantified peaks, following the methodology of Padilha et al. (2017). The chromatogram obtained from the mixture of the phenolic compounds external standards is shown in Fig. Supplementary figure 1 in the supplementary material.

Sugar and organic acids were simultaneously determined in HPLC-DAD/RID using the methodology validated by Coelho et al. (2018). An Agilent Hi-Plex H ion exchange column (300 \times 7.7 mm) with internal particles of 8.0 μ m was used and protected by a PL Hi-Plex H pre-column (5 \times 3 mm) (Agilent Technologies, Santa Clara, CA, USA). The column oven temperature was maintained at 70 °C. The sample volume injected was 10 μ L and the solvent flow was 0.6 mL min⁻¹. The mobile phase was a 4 mmol L⁻¹ H₂SO₄ solution. The grape juice was previously diluted in ultrapure water, filtered through a 0.45 μ m nylon membrane (MillexMillipore, Barueri, SP, Brazil) and injected. Organic acids were detected in a DAD (210 nm), and sugars using a RID. All quantified sugars and acids showed calibration curves with $R^2 > 0.997$. The limits of detection and quantification for all evaluated compounds were LOD < 0.044 g L⁻¹ and LOQ < 0.151 g L⁻¹, respectively.

The prebiotic oligosaccharides 1-kestose, nystose and raffinose in HPLC/RID followed the method validated by Lima (2019). The grape juice samples were filtered through a 0.45 μ m nylon membrane and the volume of 20 μ L was injected. The separation took place on a Synergi™ Hydro-RP C18 column with polar endcapping (150 \times 4.6 mm, 4 μ m) (Phenomenex, Torrance, CA, USA) at 35 °C. The solvent flow used was 0.7 mL. The gradient used was 0–8 min: 100% A; 8–9 min: 80% B; 9–12 min: 80% B; 12–13 min: 100% A; 13–20 min: 100% A (flowrate of 1.5 mL min⁻¹); in which solvent A was ultrapure water and solvent B was acetonitrile. The detection of oligosaccharides occurred in the RID. The detection and quantification limits for all analyzed compounds were LOD < 0.042 g L⁻¹ and LOQ < 0.109 g L⁻¹, respectively. All quantified sugars and acids showed calibration curves with $R^2 > 0.998$.

Chromatograms representing the analysis of phenolic compounds, sugars, organic acids, and oligosaccharides in the whole juice are shown in Figs. Supplementary figure 2, 3 and 4, respectively.

2.6. Determining the “Foxy” aromatic compounds by GC–MS

Determination of the “Foxy” aromatic compounds Methyl anthranilate (MA), Furaneol and 2-Aminoacetophenone (2-AAP) were performed following the method validated by Dutra et al. (2018b). The aromatic compounds were extracted using the liquid–liquid method (LLE) with ethyl acetate as the organic phase. Three grams of anhydrous sodium sulfate and 1 mL of the internal standard (2-octanone at 44.8 mg L⁻¹) were added to 50 mL of grape juice. Three successive vortex extractions were performed with 8, 2 and 2 mL of ethyl acetate, respectively, during 5 min. The organic phases of the three extractions were mixed and centrifuged at 3000 turns for a period of 2 min. The supernatant was filtered through a 0.22 μ m porosity Nylon membrane (Millex Millipore, Barueri, SP, Brazil).

The analyzes were performed using an Agilent Technologies model 7820A gas-chromatograph system (GC) coupled to an Agilent Technologies model 5977E MSD selective mass detector (MS) using split mode with a 30:1 ratio and 15 mL/min flow division at 200 °C. A CP-WAX 52 CB capillary column (30 m \times 0.25 mm \times 0.25 μ m) (Varian, Lake Forest, CA, USA) with a flow rate of 0.5 mL/min was used. The oven temperature was 60 °C (1 min), heating at 10 °C/min. up to 200 °C (5 min.) and maximum oven temperature of 220 °C. The temperature was maintained at 200 °C and the mobile phase was Helium gas with a purity of 5.0. The analysis was carried out in SIM mode, in which the specific ions sought for furaneol were (m/z) 43, 57 and 128; 2-AAP (m/z) 92, 120, 135, 136; and MA (m/z) 92, 119 and 151. Next, 1 μ L of the sample was injected and the identification was compared with the retention time of external standards and confirmation by specific ions. Data acquisition and processing was performed using Mass Hunter Agilent Technologies™ Software (Santa Clara, CA, USA). A typical chromatogram for the analysis of aromatic compounds in whole grape juice is shown in the Fig. Supplementary figure 5.

2.7. Statistical analysis

The results obtained were submitted to variance analysis (one-way ANOVA) and compared by the Tukey test at 1% of error probability. Principal component analysis (PCA) was also performed using the SPSS Version 20.0 statistical package for Windows (SPSS, Chicago, USA).

3. Results and discussion

3.1. Basic quality analysis, sugars, organic acids and oligosaccharides

The results obtained for basic quality analyzes are shown in Table 1. The average pH values were 3.01, 3.06 and 3.36 in concentrated (CGJ), reconstituted (RGJ) and whole (WGJ) grape juices, respectively. The concentration process resulted in an increase in the soluble solids

Table 1
Classic analysis, sugar and organic acids from whole, concentrated and reconstituted grape juices.

Classic analysis	Grape juices		
	Whole	Concentrated	Reconstituted
pH	3.36 ± 0.11 ^a	3.01 ± 0.10 ^b	3.06 ± 0.01 ^b

The results are expressed as mean ± standard deviation (n = 3). Means followed by the same letter in lines are not different among themselves by the Tukey's test at 1% of error probability. ND = not detected.

content (°Brix) from 18.4 to 67.6 °Brix during the whole juice concentration, with the cited results being in accordance to Brazilian legislation, which establishes a minimum of 14° Brix for whole grape juice, and a minimum increase of 50% in the soluble solids content in the respective concentrated juice (Brazil, 2018). The titratable acidity values were 0.76% in whole juice, 0.69% in reconstituted and 2.82% in concentrated juice. There was no significant difference between WGJ and RGJ juices regarding °Brix, titratable acidity and color according to the Tukey test at 1% of error probability. These results are in accordance with those described by other authors for commercial grape juices from the SFV (Coelho et al., 2018; Lima, 2015; Padilha et al., 2017). The main differences observed in °Brix, titratable acidity and color were for the CGJ, which was already expected due to the water removal in the concentration process, increasing the content of soluble solids such as sugars, organic acids and other compounds related to color (Aguar, Miranda, Gomes, Santos, & de Freitas, 2012). These results demonstrate that the reconstituted juice did not differ significantly from the whole juice in basic physico-chemical characteristics, and that the concentration process preserved the color of the juice after reconstitution.

The final soluble solids content (°Brix) and color maintainance in concentrated juices mainly depends on the production technique and process conditions such as temperature and pressure applied to the vacuum concentrators; however, it is recommended to achieve °Brix ≥ 65, (usually 68 °Brix) to guarantee the microbiological stability of the product during storage at room temperature (Capanoglu et al., 2013; Gollück, Souza, & Tavares, 2008; Guler et al., 2018). In addition to the classic technique of concentrating juices by heating combined with the use of vacuum, other techniques of removing water without using heating such as reverse osmosis membranes, osmotic evaporation and cricoconcentration have also been used. However, 65 °Brix is not always reached for preservation at room temperature (Aguar et al., 2012; Aider & Halleux, 2008; Couto, Cabral, Da Mata, Deliza, & Freitas, 2011; Gunathilake, Yu, & Rupasinghe, 2014).

The averages of total quantified sugars were 156.2 g L⁻¹, 159 g L⁻¹ and 635.9 g kg⁻¹ in RGJ, WGJ and CGJ samples, respectively (Table 1). The main sugars present in the evaluated samples were glucose and

fructose, with values of 80.5 and 78.4 g L⁻¹ (WGJ), and 79.8 and 76 g L⁻¹ (RGJ), respectively. The glucose and fructose levels increased to 316.8 and 317 g kg⁻¹ from the concentration process in the CGJ sample, respectively. Maltose was also present in smaller amounts. There was no significant difference between the glucose and fructose levels in the WGJ and RCJ juices, but these results were already expected since these monosaccharides do not suffer degradation in the concentration process temperature (50 °C). Maltose presented a significant loss from WGJ juice to RCJ, which may suggest an eventual hydrolysis of this disaccharide. The glucose, fructose and maltose values are in accordance with those obtained in other studies on the composition of whole grape juices from the SFV (Coelho et al., 2018; Padilha et al., 2019).

The quantified amount of organic acids was 8.14 g L⁻¹ in WGJ juice, 6.20 g L⁻¹ in RGJ juice and 29.70 g kg⁻¹ in CGJ juice (Table 1). These results are similar to those presented in other studies with whole grape juice from the SFV region (Coelho et al., 2018; Lima et al., 2014). The main acids present in the juices were tartaric and malic in values of 3.61 and 3.81 g L⁻¹, respectively, in WGJ juice. The Tukey test (p < 0.01) showed a significant difference between the WGJ and RGJ juices only for tartaric acid, where the values were 3.61 and 0.43 g L⁻¹ respectively, resulting in a decrease of 88.1% for the mean value. The amounts of citric, succinic and formic acids did not significantly differ when comparing WGJ and RGJ juices.

The decrease in the tartaric acid content in WGJ juice for RGJ may be associated with insolubilization of tartaric acid in the form of potassium bitartrate crystals during the concentration process (Li et al., 2019). Sugars and organic acids are related to the taste balance of grape juices (Coelho et al., 2018), and there was generally no significant difference in the studied juices regarding these substances when comparing whole and reconstituted juice, except for tartaric acid which decreased.

Regarding prebiotic oligosaccharides, raffinose and nystose were not detected, but 1-kestose was present in values of 0.062 g L⁻¹, 0.184 g kg⁻¹ and 0.044 g L⁻¹ in the WGJ, CGJ and RGJ samples, respectively (Table 1). According to the Tukey test (p < 0.01), there was no significant difference in the 1-kestose contents between the WGJ and RGJ juices, which shows that the concentration process could preserve

this important prebiotic. In a study performed by Lima, M.d.S., Nunes, P.C., Silva, B.L.A., Padilha, C.V.S., Bonfim, T. H. F., Stamford, T.L.M., Vasconcelos, M.A.S., Aquino, J.S. (2019), 1-kestose was reported in

commercial grape juices from the SFV, where it was observed that this prebiotic oligosaccharide (even in small amounts) together with phenolic compounds in the grape may have a possible synergistic effect for consumers regarding their intestinal health.

3.2. Profile of phenolic compounds and 'in vitro' antioxidant capacity

The phenolic composition of the studied juices is shown in Table 2. A total of 29 phenolic compounds were quantified by HPLC, with 7 flavanols, 4 flavonols, 8 anthocyanins, 2 stilbenes, 2 flavanones and 6 phenolic acids.

3.2.1. Flavanols and flavonols

Within the flavanols in the evaluated juice samples presented in Table 2, the highest amounts were observed for procyanidin B2, catechin and procyanidin B1, whose values in the whole juice (WGJ) were 28.03, 27.78 and 12.17 mg L⁻¹ respectively. The concentration process increased the content of these flavanols, in which the values of procyanidin B1, catechin and procyanidin B2 in the CGJ juice were 107.9, 104.7 and 30.75 mg kg⁻¹, respectively. No significant differences for catechin, procyanidin B2 and procyanidin A2 were observed between the WGJ and RGJ juices according to the Tukey test (p < 0.01). Significant differences were only observed for the procyanidin B1 compound, with lower values observed in the RGJ sample (6.4 mg L⁻¹). The epicatechin, epicatechin gallate and epigallocatechin gallate flavanoids were only present in the whole juice, being lost in the concentration process.

In a study performed by Guler et al. (2018), the composition of phenolic acids and four flavanols in grape juices were analyzed during their processing steps from pressing to concentration at 45 °Brix at an evaporation temperature of 50 °C and 600 mm Hg vacuum. The authors did not observe significant difference for catechin, epicatechin or epigallocatechin between the whole and concentrated grape juice. However, if we consider the amount of water removed during concentration and subsequent reconstitution until the achievement of the °Brix of the whole juice, there was a considerable loss of these flavanols in the concentration process.

Mirycetin was the main compound present regarding flavonols in terms of quantity, with average values of 57.17 mg L⁻¹ in WGJ juice, 279.5 mg kg⁻¹ in CGJ and RGJ 52.6 mg L⁻¹. Quercetin 3-glucoside showed values of 9.24 mg L⁻¹, 19.3 mg kg⁻¹ and 3.96 mg L⁻¹ in WGJ, CGJ and RGJ juices, respectively. Grape juices also presented kaempferol 3-glucoside and rutin in their composition, but in lower amounts. The concentration process did not affect the quantified flavonols as

there was no significant difference between the values found in the WGJ and RGJ samples.

3.2.2. Anthocyanins

Nine anthocyanins were quantified in grape juices and are shown in Table 2, where pelargonidin 3,5-diglucoside was the only one not detected. The main anthocyanins found in whole grape juice with highest amounts were malvidin 3,5-diglucoside (89.7 mg L^{-1}), petunidin 3-glucoside (88.1 mg L^{-1}) and malvidin 3-glucoside (52.5 mg L^{-1}). However, the following compounds were also detected in lower amounts: delphinidin 3-glucoside (11.7 mg L^{-1}), peonidin 3-glucoside (9.33 mg/L), cyanidin 3,5-diglucoside (7.82 mg/L), cyanidin 3-glucoside (5.6 mg L^{-1}) and pelargonidin 3-glucoside (2.23 mg L^{-1}). The concentration process resulted in an increase of amounts of almost all anthocyanins, except for the degraded pelargonidin 3-glucoside. The mean values

obtained for the three main anthocyanins quantified in the concentrated juice were malvidin 3,5-diglucoside (433.3 mg kg^{-1}), petunidin 3-glucoside (346 mg kg^{-1}) and malvidin 3-glucoside (200.7 mg kg^{-1}). There was no significant difference according to the Tukey test between WGJ and RGJ juices regarding the most quantified anthocyanins, showing that the concentration process preserved most of these important pigments which are related to juice color. These results corroborate with the juice color analyzes, in which no significant differences were observed between whole and concentrated juices.

In a study performed by Capanoglu et al. (2013), a large loss in the content of anthocyanins malvidin 3-glucoside, petunidin 3-glucoside, peonidin 3-glucoside, delphinidin 3-glucoside and of the flavonol quercetin 3-rutinoside (rutin) was reported in the conventional process of Nevsehir Patlak grape juice concentration up to 72 °Brix; however, the process conditions such as evaporation temperature, vacuum

pressure and number of tanks were not mentioned.

3.2.3. Stilbenes and flavanones

cis-resveratrol amounts were observed in average values of 8.32 mg L⁻¹ in whole juice, 57.7 mg kg⁻¹ in concentrated juice and 5.63 mg L⁻¹ in reconstituted juice. Furthermore, values of 1.17 mg L⁻¹ in WGJ, 3.5 mg kg⁻¹ in CGJ and 0.73 mg L⁻¹ in RGJ were observed for *trans*-resveratrol (Table 2).

Regarding the stilbenes content, the whole and reconstituted juices did not present significant differences ($p < 0.01$), indicating that

these compounds were not degraded during the conservation process.

For flavanones, naringenin values of 3.53 mg L⁻¹, 5.17 mg kg⁻¹ and 2.01 mg L⁻¹ were found in the WGJ, CGJ and RGJ samples, respectively. Hesperidin was only present in the whole grape juice sample with mean values of 2.63 mg L⁻¹. The WGJ and RGJ juices did not differ significantly in relation to naringenin, indicating that this compound was resistant to the concentration process. Hesperidin was lost in the concentration of grape juice.

3.2.4. Phenolic acids

Among the six quantified phenolic acids presented in Table 2, *trans*-caftaric acid was the main compound present in grape juices, with average values of 397.08 mg L⁻¹ (WGJ), 764.86 mg kg⁻¹ (CGJ) and 159.14 mg L⁻¹ (RGJ). The second main acid observed by amount was chlorogenic acid with values of 34.97 mg L⁻¹ in WGJ, 38.28 mg kg⁻¹ in CGJ and 8.44 mg L⁻¹ in RGJ. A significant decrease of approximately 59.9% for *trans*-caftaric acid and 75.9% for chlorogenic acid in whole juice for reconstituted juice was observed according to the Tukey test.

Gallic, syringic, caffeic and p-coumaric acids were only present in the whole juice samples in values of 11.51, 17.51 and 10.15 mg L⁻¹, respectively, demonstrating that these were degraded during the concentration process. The obtained results suggest that the concentration process considerably decreases the phenolic acid content of grape juices, with this phenolic family being the most susceptible to losses in the concentration process among those evaluated in the present study.

In the work of Guler et al. (2018), a great loss of gallic, caffeic, p-coumaric, vanillic and caftaric acids was also observed in the grape juice concentration process up to 45 °Brix at a temperature of 50 °C in a vacuum of 600 mm Hg, in accordance with the results observed in the present study.

The values obtained for the families of phenolic compounds analyzed in the WGJ, CGJ and RGJ juices generally suggest that the decreasing order of compound loss during juice concentration was: Phenolic acids > flavanols > stilbenes > anthocyanins > flavanones > flavonols.

3.2.5. 'In vitro' antioxidant capacity

According to Granato et al. (2018a), it is necessary to use methods which simulate different action mechanisms in evaluating the bioactivity of food and beverages through in vitro antioxidant capacity such as single electron transfer, transition metal chelating capacity and protein transfer hydrogen atoms, and associate these methods to obtain the profile of bioactive compounds such as phenolic compounds by instrumental techniques.

The antioxidant capacity (AOX) in the present study was measured in grape juices by the free radical scavenging with DPPH and ABTS methods, elimination of the reactive oxygen species by hydrogen peroxide (H₂O₂), and the FRAP iron reducing power method; in addition, 29 antioxidant phenolic compounds were quantified by HPLC. The results for DPPH, ABTS and H₂O₂ methods were expressed as equivalent to millimols of Trolox per liter of juice (mmol TE L⁻¹), and the results for the FRAP method were expressed as equivalent to millimols of iron per liter (mmol Fe²⁺ L⁻¹).

The AOX results are presented in Fig. 1. The mean of the AOX values for the whole grape juice was 21 mmol TE L⁻¹, 28.7 mmol TE L⁻¹ and 122 mmol TE L⁻¹, for the DPPH, ABTS and H₂O₂ methods, respectively, and 71.3 mmol Fe²⁺ L⁻¹ for the FRAP method. Furthermore, the observed means for AOX for the reconstituted juice were 19.7 mmol TE L⁻¹ (DPPH), 26.3 mmol TE L⁻¹ (ABTS), 107.7 mmol TE L⁻¹ (H₂O₂) and 57.7 mmol Fe²⁺ L⁻¹ (FRAP). No significant differences was observed in comparing the IGJ and RGJ juices according to the Tukey test ($p < 0.01$), showing that the concentration process preserved the juice antioxidants after its reconstitution. Concentrated juice presented mean AOX values of 65 mmol TE L⁻¹ (DPPH), 86.7 mmol TE L⁻¹ (ABTS), 446.7 mmol TE L⁻¹ (H₂O₂) and 190.5 mmol Fe²⁺ L⁻¹ (FRAP), demonstrating that the concentration process significantly increased the AOX

of this product.

The results observed for whole and reconstituted grape juices are in accordance with those reported in other studies for SFV whole juices (Lima et al., 2014; Dutra et al., 2018a; Padilha et al., 2017, 2019), with these AOX values being considered high.

In studies carried out by Muselík, García-alonso, Martín-lópez, and Žemli (2007), Tabart, Kevers, Pincemail, Defraigne, and Dommès (2009) and Mudnic et al. (2010), the antioxidant capacity of several individual phenolic compounds were measured by DPPH, ABTS, and FRAP methods, among others. It was observed that almost all flavanols, flavonols, anthocyanins, flavanones and phenolic acids characterized in the present study showed antioxidant capacity in the DPPH, ABTS and FRAP systems. Based on this, the maintenance of most phenolic compounds in grape juice during concentration explains the maintenance of AOX in RGJ juices when compared to the WGJ juice.

Capanoglu et al. (2013) evaluated losses of phenolic compounds with an emphasis on anthocyanins, and antioxidant capacity by the DPPH, ABTS, FRAP and CUPRAC methods during the production stages of concentrated grape juice. When comparing the whole juice with the concentrate, a sharp decrease in AOX activity was observed followed by a reduction in phenolic contents, which demonstrates the effective contribution of phenolics in the AOX of grape juices.

3.3. Aromatic “Foxy” compounds

The results obtained for the quantified aromatic compounds are shown in Fig. 2. The “Foxy” Furanol and 2-aminoacetophenone aromas were detected in all evaluated juices. Methyl anthranilate was not detected.

The average values of furaneol observed in the studied grape juices were 9.06, 6.39 and 1.93 mg/L for the whole, concentrated and reconstituted juices, respectively. 2-Aminoacetophenone was observed in amounts of 0.16, 0.61 and 0.20 mg/L in the WGJ, CGJ and RGJ samples, respectively. There was a significant decrease in furaneol content during the concentration process in which the values dropped from 9.06 mg/L in the WGJ to 1.93 in the RGJ, resulting in a decrease of 78.7% for this compound. The 2-aminoacetophenone remained stable in the concentration process, while the WGJ and RGJ juices did not differ significantly.

According to Dutra et al. (2018b), furaneol is an aromatic compound related to the typical juices from the SFV region, and its sensory perception threshold is 300 $\mu\text{g L}^{-1}$, being associated with strawberry, pineapple and mango (Dutra et al., 2018b). 2-aminoacetophenone is a molecule formed by oxidative degradation of indolylacetic acid (IAA), a phytohormone which naturally occurs in grapes, and has a sensory perception threshold of 2 $\mu\text{g L}^{-1}$; being described as a fruity and sweet aroma (Hoenicke, Borchert, & Grüning, K., Simat, T., 2002). Commercial SFV whole juices and samples of Brazilian commercial nectars (beverages obtained by reconstituting concentrated juices) were characterized in the study by Dutra et al. (2018b), in which the furaneol levels ranged from 0.45 to 2.08 mg L^{-1} (sugar added juices) and 0.15–7.83 mg L^{-1} (whole juices), depending on the grape variety used in the juice formulation.

Aguiar et al. (2012) pointed out that the aroma loss during conventional concentration is due to the high temperatures used. The same authors also reported a significant loss of volatile compounds associated with the aroma during the concentrating process of apple juices by reverse osmosis (25 °C to 28 °Brix) and osmotic evaporation (30 °C to 51 °Brix) at low temperatures. These data suggest that there will always be aromatic compound losses in any water removing process in juices, either by thermal degradation, water vapor drag, volatilization, or solubilization in mechanically removed water, to a greater or lesser extent.

Even with the furaneol loss during the concentration process (50 °C, vacuum > 680 mm Hg, up to 68 °Brix) in the present study, the amount of this aromatic compound in RGJ juice was still six times

greater than its threshold for sensory perception.

The results obtained in this study demonstrate that the concentration process resulted in a decrease of aroma compound content in the evaluated grape juices, but maintained a sufficient quantity of ‘foxy’ aromatic compounds to be sensorially detected.

3.4. Principal component analysis

A chemometric analysis was carried out using a principal component analysis (PCA) in order to evaluate the impact of processes on organic acids, sugars, phenolic compounds, flavors and antioxidant capacity of grape juices in an integrated manner. Principal components 1 and 2, PC1 and PC2 respectively, explained 98.1% of the experiment variance. PC1 explained 73.3% of the variance and PC2 24.8%, as can be seen in Fig. 3. Aiming at robustness in the interpretation, we only considered separations with an analysis factor (component loadings) of ≥ 0.70 in $\text{PC} > 0$, and ≤ -0.70 at $\text{PC} < 0$, according to the results shown in Table 3.

With a higher percentage of explained variance, $\text{PC1} > 0$ separated CGJ due to higher values of sugars, organic acids, oligosaccharide 1-kestose, 2-Aminoacetophenone, antioxidant capacity (DPPH, ABTS, FRAP and H_2O_2), stilbenes, anthocyanins and flavonols, catechin and procyanidins. These results demonstrate that the water reduction in the concentration process considerably increased the amount of all these metabolites and antioxidants in the CGJ.

PC2 clearly separated the samples from WGJ and RGJ, where $\text{PC2} > 0$ grouped the WGJ due to the higher values of phenolic acids, and the flavanols epicatechin, epigallocatechin and epigallocatechin gallate, pelargonidin 3-glucoside, hesperidin, furaneol and tartaric acid. This arrangement demonstrated that these were the main compounds with reduction during juice concentration. $\text{PC2} < 0$ grouped the RGJ due to the lower values of the compounds grouped with the WGJ.

The principal component analysis clearly showed the effect of the concentration and reconstitution processes of grape juice when compared to the whole juice, in which the main phenolic compounds lost were phenolic acids, some flavanols, hesperidin and pelargonidin 3-glucoside. Other compounds lost in the concentration/reconstitution of juices were the aromatic compound furaneol and tartaric acid. However, the reconstituted juice generally preserved the catechin and procyanidins flavanols, flavonols, anthocyanins, antioxidant capacity, the aromatic compound 2-Aminoacetophenone, prebitico1-kestose, sugars and organic acids.

PCA proved to be a powerful technique for interpreting the phenomena involved in the grape juice processes, in accordance with the Tukey test results of the present study. Other studies which also applied the PCA chemometric technique in interpreting the influence of processes on the quality of grape juice also showed agreement with multiple comparison tests such as Tukey, and also highlighted the power of PCA in interpreting the process phenomena (Granato, Koot, Schnitzler, & van Ruth, 2015; Lima, M.d.S., Dutra, M.C.P., Toaldo, I.M., Corrêa, L.C., Pereira, G.E., De Oliveira, D., Bordignon-Luiz, M.T., Ninow, J.L., 2015; Coelho et al., 2018; Granato et al., 2018b; Silva et al., 2019; Padilha et al., 2019).

4. Conclusion

The grape juice concentration and reconstitution processes did not affect the basic analytical characteristics such as °Brix, titratable acidity and color in comparison with the whole juice. However, the concentration and reconstitution process resulted in partial losses of caffeic-acid (59.9%), chlorogenic-acid (75.9%), aromatic compound furaneol (78.7%) and tartaric-acid (88.1%) compounds, and total losses (100%) for gallic-acid, caffeic-acid, *p*-coumaric-acid, syringic-acid, hesperidin, pelargonidin-3-glucoside and epicatechins. Despite the losses in the furaneol aromatic compound, its concentration in the reconstituted juice was still 6 times greater than its sensory perception

threshold, showing that this “Foxy” aroma could still be sensorially detected. The concentration and reconstitution of the grape juice preserved the antioxidant capacity and most of the quantified compounds. The concentration process of whole grape juice in the present study preserved most of the plant metabolites of interest in the sensory quality and bioactive compounds of grape juices. The reconstituted juice was considered to be of good nutritional quality and demonstrates the great potential for high quality concentrated juices in the São Francisco Valley in northeastern Brazil.
