Chapter 1
The Use of Analytical Chemistry to Understand the Biomass

Silvio Vaz Jr.

Abstract Modern chemistry plays a strong economic role in industrial activities based on biomass, with an increasing trend of the importance of its application from the deployment of biorefineries and the principles of green chemistry, which make use of the potential of biomass with decreasing impact negative environmental. In this context, analytical chemistry can contribute significantly to the supply chains of biomass, be it plant or animal origin; however, with the first offering the greatest challenges and the greatest opportunity for technical and scientific advances, given its diversified chemical constitution. This chapter presents a general outlook about the application of analytical chemistry to understand the biomass composition and to promote its usages.

Keywords Biomass constitution · Chemical analysis · Instrumental analysis

1.1 Introduction

The use of biomass by man goes back to the principles of humanity, where it was used as a heat source, food, fiber and various items such as weapons. With the development of societies were in great demand and uncontrolled use of this natural resource, which led to massive deforestation of native forests in almost every continent of the globe, whether in greater or lesser extent. On the other hand, agriculture also developed leading to an increase in production and productivity of crops, especially for human and animal consumption.

From the mid-twentieth century, there was a "boom" of consumer society based on petroleum derivatives, which is a non-renewable source and highly polluting raw materials; this might be noticed by the large amount of produced plastic products.

https://doi.org/10.1007/978-3-031-89138-0_1

However, the same society began to notice that oil is a finite source with serious problems observed in several producing countries, such as political and social instability, wars and environmental disasters.

Modern chemistry plays a strong economic role in industrial activities based on biomass, with an increasing trend of the importance of its application from the deployment of biorefineries and the principles of green chemistry, which make use of the potential of biomass with decreasing impact negative environmental. In this context, analytical chemistry can contribute significantly to the supply chains of biomass, be it plant or animal origin, however, with the first offering the greatest challenges and the greatest opportunity for technical and scientific advances, given its diversified chemical constitution. It is worth to mention that the chemical analysis is used to examine the composition, for the characterization of physical and chemical properties and for determining the concentration of chemical species of interest. Figure 1.1 shows, in a simplified way, components of an economic chain from biomass and the application of analytical techniques.

This chapter presents a general outlook about the application of analytical chemistry to understand the biomass composition and to promote its usages.

1.2 Plant Biomass Diversity and Composition

According to data from UN FAO, the global biomass production for food and agroindustrial usages, as primary crop production, reaches 9.5 billion tons, with a huge contribution to the bioeconomy; it comprises cereals, sugar crops, vegetables, oil crops, fruit, roots and tubers and other (Food and Agricultural Organization of the United Nations 2023). The high heterogeneity and a consequent large chemical complexity of plant biomass become the raw material for various ending products such as energy, food, chemicals, pharmaceuticals and materials. We can highlight four types of plant biomass of great economic interest, and to which we turn our attention: oil, saccharides (or sugary), starch and lignocellulosic. Soybean (*Glycine max*) and palm oil (*Elaeis guinensis*) are examples of oil plants species; the sugarcane (*Saccharum* spp.) and sorghum (*Sorghum bicolor* (L.) Moench) are biomass saccharides; maize (*Zea mays*) is a starchy biomass; bagasse, straw and wood biomass are lignocellulosic biomass. Each has its structural features and its chemical characteristics, which are directly related to analytical technology and the best technical approach to be applied during chemical analysis (Vaz Jr. 2014, 2015). Figures 1.2, 1.3, 1.4, 1.5, 1.6 and 1.7 show the chemical structure of components of these biomass types, and Tables 1.1, 1.2, 1.3 and 1.4 show their wt./wt. ratios.

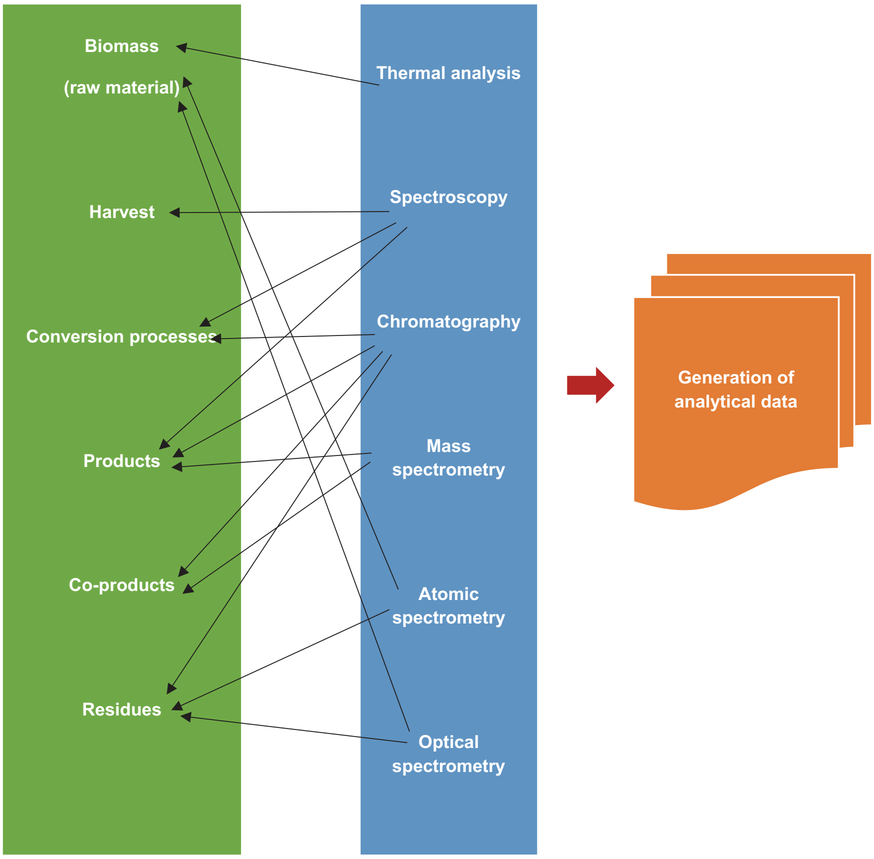

Fig. 1.1 Flowchart of the relationship between components of a biomass chain and chemical analyses to generate analytical data. This relationship is a proposal of use and other combinations can be established according to physicochemical properties, economic aspects and equipment availability

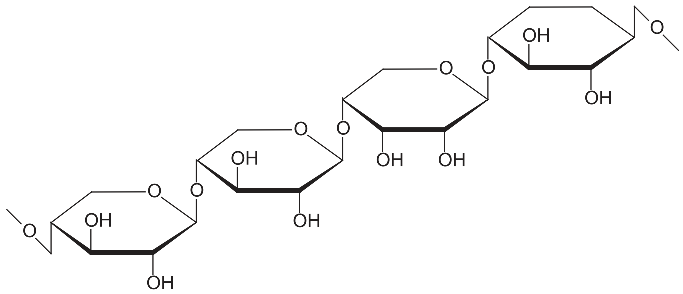

Fig. 1.7 Chemical structure of hemicellulose; the oligomeric units composed of D-glucose and pentoses (mainly D-xylose) are linked by means of a 1,4-β-D bond

Table 1.1 Chemical composition of oils extracted from oleaginous biomass (Gunstone 2004)

Plant	% wt./wt. palmitic acid	% wt./wt. stearic acid	% wt./wt. oleic acid	% wt./wt. linoleic acid	% wt./wt. triacylglycerols
Palm oil	44	4	39	10	3
Soybean	11	4	23	8	1

Table 1.2 Chemical composition of broth extracted from sugarcane (Faria et al. 2011) and sweet sorghum (Mamma et al. 1995)

Plant	% wt./wt. sucrose	% wt./wt. glucose	% wt./wt. organic acid
Sugarcane	85.3	–	24
Sweet sorghum	14.8	1.5	–

Table 1.3 Chemical composition of corn grain flour (Sandhu et al. 2007), cassava (Charles et al. 2005) and potato (Liu et al. 2007)

Plant	% wt./wt. starch	% wt./wt. protein	% wt./wt. fiber	% wt./wt. others
Corn (flour from grain)	90.1	6.5	0.52	1.99 (lipid)
Cassava (pulp)	83.8	1.5	2.5	0.2 (lipid)
Potato (pulp)	71.5	8.6	5.4	–

Table 1.4 Chemical composition of cellulosic biomasses (Vassilev et al. 2012)

Biomass	% wt./wt. cellulose	% wt./wt. hemicellulose	% wt./wt. lignin
Barley straw	48.6	29.7	21.7
Corn cobs	48.1	37.2	14.7
Grasses	34.2	44.7	21.1
Sugarcane bagasse	42.7	33.1	24.2
Rice husks	43.8	31.6	24.6
Wheat straw	44.5	33.2	22.3
Eucalyptus	52.7	15.4	31.9

1.3 Chemical Analysis and Its Application in Biomass Study

Chemical analysis, in a general way, can be considered as the use of concepts of analytical chemistry and their technical and analytical methods in research and actual troubleshooting of varying complexity in different scientific and technological fields. Chemical analysis can generate information both qualitative and quantitative. Techniques and analytical methods provide support for the implementation of regulatory legislation and market environment, such as carbon credit market in order to ensure the quality of raw materials and yields of manufacturing processes while also allowing the development of new products and materials that add value to biomass. Chemical analysis plays an important role in the exploitation of biomass and is supporting technologies for all processing stages of production chains, such as sugarcane, soybean, corn, forestry, pulp and paper, agribusiness waste, among others.

In the study of biomass and its transformation, or conversion processes, the application of chemical analysis can take place as follows:

- Determining the chemical constitution of various biomass (raw materials), products, by-products, co-products and wastes.
- Monitoring of chemical, biochemical and thermochemical conversion processes.
- Observation of physical and chemical properties and characteristics of biomass and their molecular constituents.

Nowadays, there are several possible methodological approaches, as well as a large number of analytical techniques available and chemical analysis can be applied to all operations in a biomass chain, from hence its importance for monitoring and quality control of raw materials, products, processes and waste.

The analytical techniques used in the quantification of analytes—the species of interest for the analysis—are divided into two classes: classical techniques based on mass, volume, charge and mol measurement, which provide absolute values; and instrumental techniques based on relative values, expressed as mg L^{-1}, mg kg^{-1}, $\mu g\ m^{-3}$ and so on.

Until the early twentieth century, chemists employed the separation of analytes by techniques such as extraction, precipitation or distillation. For qualitative analysis, these separated analytes were treated with appropriate reagents to produce compounds that could be identified by properties such as solubility, color, melting and boiling points. The quantitative analysis was done using simple techniques with good accuracy, which are used to this day, as the volumetry (volume measurement) and gravimetry (mass measurement)—these are typical examples of classical techniques.

Since then, different aspects of the observed classical techniques began to be investigated and several experiments have been carried out aiming now measure analytes from some particular physicochemical property, usually associated to phenomena as the absorption and emission of radiation, which are the beginning of instrumental techniques, such as atomic spectrometry and molecular spectroscopy. These findings stimulated the development of a wide variety of instruments that are used in this technical class. The techniques are generally faster than the classical and are used in the determination of low concentrations of analyte, such as trace concentrations of ng L^{-1} values or below it.

The following equations express the foundations of these two sets of techniques.

$$A_{S(c)} = kn_{A(c)} \tag{1.1}$$

$$A_{S(i)} = kC_{A(i)}. \tag{1.2}$$

Equation 1.1 applies to classical techniques, where $A_{S(c)}$ is the measured signal—or the response—of the analyte, k is the proportionality constant to be standardized and $n_{A(c)}$ is the number of moles, charge or mass obtained from the measuring. On the other hand, Eq. 1.2 applies to instrumental techniques, where the measured signal $A_{S(i)}$ is also the response of the analyte, k is the proportionality constant to be standardized again and $C_{A(i)}$ is the relative concentration of the analyte measurement. However, some spectroscopic and microscopic techniques covered in this book do not necessarily obey these two concepts, mainly to report the structural characteristics of the sample.

Table 1.5 lists certain physical properties operated by analytical techniques and promotes the measured response.

Table 1.5 Physical properties used in analytical techniques most commonly used in chemical analysis of biomass (modified from Skoog et al. 2014)

Properties	Instrumental technique
Absorption of radiation	Spectrophotometry and photometry (ultraviolet and visible) Atomic spectrometry Infrared spectroscopy (near, medium and far) Nuclear magnetic resonance (solid and liquid states)
Electric current	Voltammetry (cyclic, square wave, anodic, cathodic, polarography)
Diffraction of radiation	X-ray diffraction
Emission of radiation	Emission spectroscopy (X-ray, ultraviolet and visible) Optical emission spectrometry Fluorescence (X-ray, ultraviolet and visible)
Mass	Gravimetry
Electrical potential	Potentiometry
Thermal properties	Gravimetric and volumetric Calorimetry Thermal analysis
Ratio mass/charge	Mass spectrometry
Refraction of radiation	Refractometry and interferometry
Electric resistance	Conductometry

The instrumental techniques measure a physical phenomenon resulting from a molecular or atomic property that is qualitatively or quantitatively related to the analyte, i.e., the physical phenomenon will produce a signal that is directly correlated to the presence or concentration of analyte in the sample. Table 1.6 shows some examples related to the use of instrumental techniques for the analysis of biomass and its products, and Table 1.7 shows analytical techniques widely used in analyses of chemical composition of raw materials.

In general, the application of an analytical method for biomass products must follow the steps presented in Fig. 1.8. Any failure or absence of the sequence compromises the reliability of obtained results.

1.4 Sustainability and Economic Aspects of Analytical Chemistry

Based on the understanding that we should reduce or eliminate negative environmental impacts of processes and products, combined with a social and economic improvement—i.e., ensure the sustainability of an entire production chain—began to consider biomass as a potential source of raw material for energy, chemicals, food, pharmaceuticals, materials, among others. On the other hand, analytical chemistry has the commitment to become also sustainable in its application; for instance, by means the use of green chemistry principles and strategies (De la Guardia and Garrigues 2011).

To establish a sustainable method with positive impacts on the environment, society and economy, we can apply some of the 12 principles of green chemistry (Anastas and Warner 1998):

- Prevent the generation of waste instead of treating them.
- All reagents should be consumed for the formation of products; there should be an atom economy.
- The use of solvents, separation agents, etc., should be unnecessary if possible and innocuous when done.
- Reduce or avoid the formation of derivatives, since this involves the use of additional reagents, which can generate more waste.
- Develop analytical methodologies that can be used for real-time monitoring and control prior to the formation of toxic compounds, in order to contribute to the prevention of pollution.

Furthermore, the analysis of biomass should be, per se, based on the principles of green chemistry, since the first use of context is reflected in the sustainability of raw materials.

Finally, the choice of an analytical technique or an analytical method should be taken into account the following technical and economic aspects:

Table 1.6 Some examples of analytical techniques and their uses in chemical analyses of biomass (modified from Vaz Jr. 2014)

Technique	Principle of measurement	Example of use	Advantages	Disadvantages
Differential scanning calorimetry	Enthalpy changes	Determination of combustion properties of biomass (exothermic or endothermic)	Small quantity of samples; high sensitive; determines physicochemical changes in materials impossible to determine by other technique	–
Capillary electrophoresis	Migration of ions or charged particles	High efficiency separation for polar compounds from biomass degradation	High separation efficiency	Limitation for non-polar compounds
Mass spectrometry	Molecular fragmentation	Structural identification and quantification of several organic compounds based on m/z ratio	Identification and resolution of complex molecular structures	Necessity of separation techniques, such as chromatography, for a better resolution
X-ray fluorescence spectroscopy	Emission of characteristic X-rays	Multielement quantification in solid and liquid samples from biomass residues	Easy to handle; non-destructive	Chemical composition and morphology of the sample can affect the result
Infrared spectroscopy (near and medium)	Vibrational energy absorption	Structural identification of organic compounds and lignocellulosic components	Easy to handle, mainly for near infrared	Low resolution for compounds with same functional groups (sum of bands); however, the application of chemometrics can help to overcome this limitation
X-ray diffractometry	Intensity of X-rays diffracted	Determination of crystallinity and chemical composition of cellulose	Important physical information for natural fibers and polymers usages	Long acquisition time (hour or day) for process control

(continued)

Table 1.6 (continued)

Technique	Principle of measurement	Example of use	Advantages	Disadvantages
Scanning electron microscopy	Surface scanning with a primary electron beam	Surface and structural analysis of materials (e.g., catalysts)	Important physical information for natural fiber and polymers usages	Long acquisition time (hour or day) for process control
Nuclear magnetic resonance (e.g., ^{13}C in solid state)	Transition of nuclear spin inside atomic nuclei; interactions between nuclei-nuclei and nuclei-surround electrons	Structural identification of organic compounds from biomass processing (e.g., lignocellulosic and oleaginous)	Resolution of complex molecular structures	Long acquisition time (hour or day) for process control, except under a high concentration of the analyte (e.g., fatty acids)
Voltammetry (e.g., cyclic and square wave)	Changes in current as a function of potential	Chemical speciation and quantification of metals and non-metals (e.g., catalysts for glycerin use), or verification of glucose or starchy oxidation processes	Rapid response	Search for the better electrolyte or voltammetric technique can expend time

- The analyte of interest and its physicochemical characteristics (solubility, pKa, speciation, etc.)—a technical factor that can reduce or increase costs and the final price.
- The analytical matrix to which the analyte is sorbed (water, air, soil, sludge, biological fluid, plant, industrial waste, etc.) and physical state (solid, liquid or gaseous)—a technical factor that can reduce or increase costs and the final price.
- The need to obtain results in the short, medium or long period of time—a market factor that can reduce or increase the final price.
- Existence of analytical method developed and/or validated that meets the limits of detection or quantification required by law for the analyte—less effort, faster and cost reduction.
- Impact generated by the analytical result (e.g., release of a batch of product or monitoring of effluent)—as a market factor, it will reduce or increase the final price.
- The technique robustness, low standard deviation of the results, regardless of condition—they are parameters of quality control to be taken in account.
- Destructive or non-destructive technique—it will reduce costs.

Table 1.7 Examples of analytical techniques widely used in analyses of chemical composition of raw materials from biomass (modified from Vaz Jr. 2014)

Raw material	Parameter	Analytical technique	Advantages	Disadvantages
Sugarcane for ethanol production	Content of sugars	HPLC-refractive index detector	Methods established	Long acquisition time for chromatographic run (approximately 30 min)
Vegetable oils for biodiesel production	Content of fatty acids and esters	GC-flame ionization detector	Methods established	Necessity of organic solvent to extract the analyte
Bioenergy crops	Energetic characteristics	Near infrared spectroscopy	Rapid response and easy to handle	Low band resolution, which can be improved by chemometrics application
Residues for gasification	Energy content	Differential scanning calorimetry	Rapid response and easy to handle	–

- Satisfactory analytical response—off course without the correct response the result will not able.
- Cost per analysis—it is limiting, but not fundamental.

More detailed information about the choice of the technique and/or method can be obtained in the *Ewing's Analytical Instrumentation Handbook* (Grinberg and Rodriguez 2018) and in the book *Applications of Analytical Chemistry in Industry* (Vaz Jr. 2023).

It is always important to consider the toxicological and occupational aspects when applying analytical procedures, since chemicals usually offer a potential risk to those who handle them. Therefore, the laboratory team must be aware of implementing safety procedures and, above all, take care to follow them.

1.5 Conclusions

Chemical analysis of biomass is an important branch of analytical chemistry because it can provide information about the constitution of raw materials, products, by-products and co-products, residues, etc. Analytical techniques can be applied on a whole biomass chain to solve many technical and scientific problems related to—but not only—best uses for a biomass, improvement of conversion processes, increase in the quality of products and control of residues.

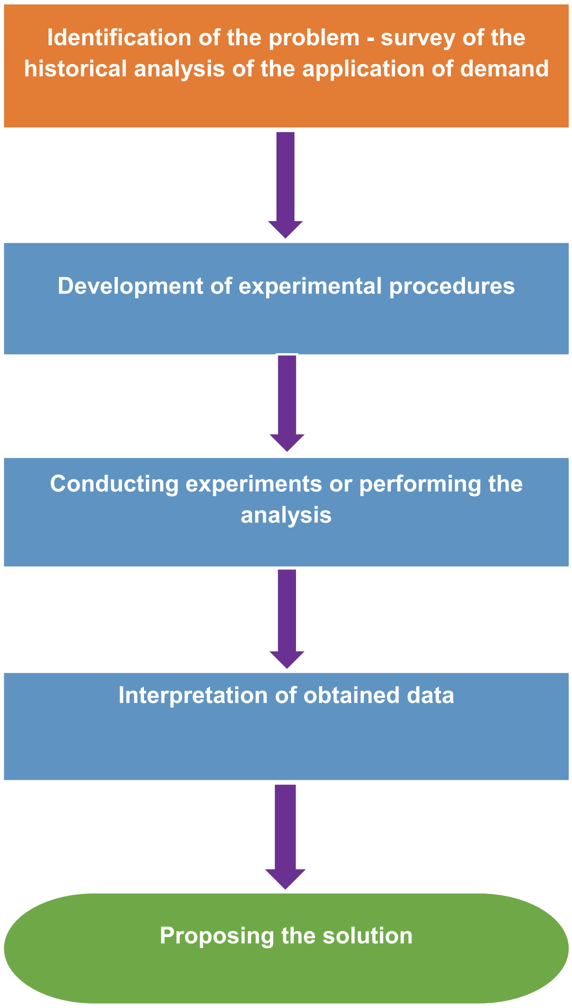

Fig. 1.8 Flowchart describing the steps for the application of an analytical method for biomass

The plant biomass is a very complex analytical matrix and it needs cutting edge techniques to understand its composition and properties, what can be replicated for its products obtained from conversion processes. Furthermore, to explore all the possibilities offered by techniques and methods is desirable to procedure the sustainable and economic evaluation.
